Remark 5.2. The only case where we can prove the existence of eigenvalues for large values of λ is in (1.2). Also, in this case, we can obtain a concentration result near the origin. At this point, we do not know whether the solutions given by Theorems 3.5 and 3.6 coincide for $\lambda \in (0, \lambda_0)$.

Remark 5.3. We observe that in (1.3), there is a concentration of the spectrum in the near proximity of the origin. At this point, the order relation between the parameters $\lambda_1(\Delta)$ and λ^* is not known. Furthermore, the multiplicity of eigenvalues in the interval $(0, \lambda_1(\Delta)) \cap (0, \lambda^*)$ is also unknown, as we lack information on whether the solutions given by Theorems 3.7 and 3.8 coincide.

Remark 5.4. Since we only have some information on the qualitative behavior for large values of the parameter λ in (1.2) (we refer here to Theorem 3.6), a more challenging question is to develop an exhaustive analysis for all $\lambda > 0$ in the other two cases.

Remark 5.5. A promising direction for future research emerges when the reaction function is defined as $f(x,z) = |u|^{p^*(x)-1} + \varepsilon$. This formulation enables an investigation into the interplay between the growth behavior of the potential function ϕ and the critical growth behavior of the reaction function f. For related results in this direction, we refer to [10,16].

Communicated by Michal Fečkan

Abstract. This article investigates a stochastic fast-slow fishery economic model with Allee effect. The fast-slow dynamic behavior of the deterministic system is discussed by using the theory of singular perturbation. Research shows that singular Hopf bifurcations will occur under the influence of strong Allee effect, while the dynamic behavior of the system will be more complex under the influence of weak Allee effect, resulting in relaxation oscillations. For the stochastic system, the existence of stationary distribution is discussed for both stochastic fast-slow system and system with time scale parameter as ordinary parameter. Then, the stochastic bifurcation behavior of the system is discussed, and it is found that stochastic-P bifurcation and stochastic-D bifurcation will occur. Finally, the correctness of the conclusion is verified through numerical simulation.

Keywords: fast-slow system, canard circle, relaxation oscillation, ergodic stationary distribution, stochastic bifurcation.

1 Introduction

The bioeconomic model of fishery resources is based on the dynamic model of fishery populations, combined with ecological, economic and social factors, to study the relationship between the quantity of fishery resources and human activities. The fishing industry has high social significance, as it directly affects the livelihoods and food supply of fishermen. In order to ensure the stable growth of human needs, it is necessary to study the stability of the dynamic model of fishing resources [20, 34].

In the fishery economy, the human capture operations are a key link and the main way to obtain fishery resources, driving the development of the fishery economy. In recent years, many scholars have incorporated capture as a parameter into biological models, studied bioeconomic models described by differential algebraic equations, and generated interesting and rich dynamic behaviors [2, 15, 25]. Clark [7] incorporated dynamic capture into the model,

✉Corresponding author. Email: zhangyue@mail.neu.edu.cn

believing that capture would be affected by total revenue and total cost, and treating it as a fixed parameter is unrealistic. Therefore, it is necessary to introduce capture as a variable into the bioeconomic system.

The Allee effect is an important dynamic phenomenon in ecosystems [18], which suggests that when a population is too sparse or too dense, it can inhibit population growth, meaning that each population has its own optimal density for survival. With the deepening of research on population dynamics, scholars have gradually introduced the classification of strong and weak Allee effects in order to more accurately describe the performance of populations under different degrees of low density. For species with strong Allee effect [35], once the population drops to the critical density, the species is likely to become extinct. For species under weak Allee effect [11], when the species density is low, they still have a certain degree of self-sustaining ability, which means that even if the species density is small, they can naturally grow to a certain extent. Understanding and considering the Allee effect is crucial for sustainable fishing in the fishery economy. Considering the Allee effect can help fishery managers develop reasonable fishing quotas and fishing bans to ensure the health of fish populations and the sustainable use of fishery resources. Lin [23] studied a single-species logistic model incorporating the Allee effect and explored how the Allee effect impacts species stability and extinction risk. Ashutosh [27] developed a fish capture model with logistic growth and Allee effect and found periodic fishing to yield higher economic benefits for fish populations. Liu et al. [24] studied the dynamic behavior of the Leslie Power model with weak Allee effect and fear effect. However, there is limited research on the effects of different Allee effects on fisheries economic models. Therefore, it is necessary for this article to consider the impact of different Allee effects on system dynamics.

Fast-slow systems have been widely applied in fields such as physics, chemistry, pharmacology, and ecology. A key feature of these systems is that their different variables vary over two or more time scales and such systems are typically handled by geometric singular perturbation theory [9]. In ecosystems, considering the difference in growth rates between prey and predators, the relationship between the two can be established using a fast-slow system [6, 21, 32]. Saha et al. [31] investigated a predator-prey model with Beddington–DeAngelis response, revealed rich dynamics including relaxation oscillations, canard cycles, and canard explosions. Li and Zhang [22] discussed the dynamic behavior of a fast-slow Leslie–Gower predator-prey model with constant harvesting. As mentioned in reference [3], there is a significant disparity between the rate of change in fishing effort and that in fish species. Therefore, the fast-slow system is also applicable to the fishery economic model, and discussing the fast-slow dynamics of the fishery economic model is also very interesting.

In the natural environment, the number and structure of biological populations are affected by a variety of random factors, such as climate change and random fluctuations in food resources. Stochastic differential equations are frequently employed to simulate random fluctuations in biological systems, as a result, they play an important role in studying the dynamic analysis of systems [14,26,29,42]. Yu [41] proposed and explored a single species model with Allee effect driven by correlated colored noise. Wang [36] studied a population model with Allee effect affected by both additive and multiplicative noise, and the results showed that correlated noise has a complex impact on the final population size distribution. Han and Jiang [12] considered and studied a stochastic predator-prey system with general infinite delay, and provided the necessary conditions for species persistence and extinction. Overall, environmental noise has a complex impact on the final distribution of population size.

Based on the above analysis, although some scholars have proposed that there is a signif-

icant difference between the rate of change in capture effort and the growth rate of species, few have specifically discussed the fast-slow dynamic properties of fast-slow fishery economic models. Therefore, we consider the Allee effect in fish populations and the influence of external factors on both fish populations and catches, and establish a stochastic fast-slow fishery economic model. We use singular perturbation techniques to study the complex fast-slow dynamics of the model and discuss the bifurcation behavior of the random fast-slow system. The structure of this article is as follows: In Section 2, a fast-slow fishery economic model with Allee effect is proposed, and the existence of equilibrium is discussed. In Section 3, we discuss the bifurcation behavior of deterministic system, which can generate transcritical bifurcation and Hopf bifurcation. In Section 4, we use singular perturbation theory to discuss the singular Hopf bifurcation and relaxation oscillation generated by fast-slow system, and investigate the existence of stationary distributions for stochastic fast-slow reduction system. In Section 5, we consider the time scale parameter ε as a general parameter and discuss the existence of stationary distribution for stochastic systems with weak Allee effects, as well as the dynamic behavior generated by the stochastic system. In Section 6, the conclusion and outlook are elaborated.

2 Model establishment and equilibrium analysis

2.1 Model establishment

In this section, we consider a single population fishery economic model, which takes the following form:

$$\begin{cases} \dfrac{dx}{dt} = rx\left(1-\dfrac{x}{K}\right)(x-A) - qEx, \\ \dfrac{dE}{dt} = m\left(pqx-c\right)E, \end{cases} \tag{2.1}$$

where the growth of the fish population follows logistic growth, x represents the density of the fish population at time t, E represents the effort required for capture, which is positively correlated with the total profit. Table 2.1. provides the biological explanations for the parameters in the model.

Parameter	Biological Interpretation
r	Intrinsic growth rate of fish stocks
K	Maximum environmental capacity of fish stocks
A	Allee effect threshold, where $0 < A < K$ indicates strong Allee effect, and $-K < A < 0$ indicates weak Allee effect
m	Adjustment coefficient of E
p	The price per unit of catch of fish stocks
q	Capture coefficient
c	Unit fishing cost of fish stocks

Table 2.1: Definition of Parameters in system (2.1)

Perform a dimensionless transformation on system (2.1),

$$x \to \frac{x}{K}, \quad t \to rt,$$

we have

$$\begin{cases} \dfrac{dx}{dt} = x\left(1-x\right)\left(Kx-A\right) - \alpha E x & =: f(x,E,\varepsilon), \\ \dfrac{dE}{dt} = \varepsilon\left(\beta p x - c\right)E & =: \varepsilon g(x,E,\varepsilon), \end{cases} \tag{2.2}$$

where new dimensionless parameters are $\alpha = \frac{q}{r}$, $\beta = qK$, $\varepsilon = \frac{m}{r}$. These parameters are positive. Since m is an adjustment parameter for E, which is a very small number, there is $m \ll r$, resulting in $0 < \varepsilon \ll 1$. At this point, system (2.2) is a fast-slow fishery economic system.

Let $\tau = \varepsilon t$, the system (2.2) becomes that

$$\begin{cases} \varepsilon\dfrac{dx}{d\tau} = x\left(1-x\right)\left(Kx-A\right) - \alpha E x & =: f(x,E,\varepsilon), \\ \dfrac{dE}{d\tau} = \left(\beta p x - c\right)E & =: g(x,E,\varepsilon). \end{cases} \tag{2.3}$$

Under nonnegative initial conditions, the dynamics of the system will be limited within the first quadrant. We name t as the fast time scale and τ as the slow time scale. When $0 < \varepsilon \ll 1$, x evolves on a fast time scale t and E evolves on a slow time scale τ. Therefore, we refer to x as a fast variable and E as a slow variable.

2.2 Equilibrium analysis

In the section, the existence of equilibrium points and the stability of certain equilibrium points within system (2.2) will be discussed. From a biological perspective, we only focus on the dynamic behavior of system (2.2) in region $\mathbb{R}^2_+ = \{(x,E) : x \geq 0, E \geq 0\}$.

There are three boundary equilibrium points $S_1(0,0)$, $S_2(1,0)$ and $S_3(\frac{A}{K},0)$ in system (2.2). There exists a unique internal equilibrium point $S_*\left(x_*, E_*\right)$ if $\frac{A}{K} < \frac{c}{\beta p} < 1$, where $x_* = \frac{c}{\beta p}$, $E_* = \frac{(1-x_*)(Kx_*-A)}{\alpha}$.

The Jacobian matrix of system (2.2) at (x,E) is

$$J := \begin{pmatrix} -3Kx^2 + 2(K+A)x - A - \alpha E & -\alpha E \\ \varepsilon\beta p E & \varepsilon(\beta p x - c) \end{pmatrix}.$$

The Jacobian matrix at $S_1(0,0)$ is

$$J|_{S_1} = \begin{pmatrix} -A & 0 \\ 0 & -c\varepsilon \end{pmatrix},$$

and its corresponding eigenvalues are $\lambda_1 = -A$ and $\lambda_2 = -c\varepsilon$, where λ_1 is influenced by the Allee effect type. Therefore, under the strong Allee effect $0 < A < K$, S_1 is a stable node, and under the weak Allee effect $A < 0$, S_1 is an unstable node.

The Jacobian matrix at $S_2(1,0)$ is

$$J|_{S_2} = \begin{pmatrix} A-K & -\alpha \\ 0 & \varepsilon(\beta p - c) \end{pmatrix},$$

and its corresponding eigenvalues are $\lambda_1 = A - K$ and $\lambda_2 = \varepsilon(\beta p - c)$. The stability of equilibrium point S_2 is not affected by the Allee effect. When $c > \beta p$, S_2 is stable node, and when $c < \beta p$, S_2 is unstable node.

The Jacobian matrix at $S_3(\frac{A}{K}, 0)$ is

$$J|_{S_3} = \begin{pmatrix} A\left(1 - \frac{A}{K}\right) & -\frac{A\alpha}{K} \\ 0 & \varepsilon\left(\frac{\beta p A}{K} - c\right) \end{pmatrix},$$

and its corresponding eigenvalues are $\lambda_1 = A(1 - \frac{A}{K})$ and $\lambda_2 = \varepsilon(\frac{\beta p A}{K} - c)$. Under the strong Allee effect $0 < A < K$, $\lambda_1 < 0$, so S_3 is a saddle point for $c > \frac{\beta p A}{K}$ and S_3 is an unstable node for $c < \frac{\beta p A}{K}$. Under the weak Allee effect $A < 0$, S_3 is a non positive equilibrium point, we will not discuss it.

The Jacobian matrix at $S_*(x_*, E_*)$ (whose existence condition is $\frac{A}{K} < \frac{c}{\beta p} < 1$) is

$$J|_{S_*} = \begin{pmatrix} \frac{c}{\beta p}\left(A + K - \frac{2Kc}{\beta p}\right) & -\frac{\alpha c}{\beta p} \\ \frac{\varepsilon \beta p}{\alpha}\left(1 - \frac{c}{\beta p}\right)\left(\frac{Kc}{\beta p} - A\right) & 0 \end{pmatrix}.$$

The corresponding characteristic equation is

$$|\lambda E - J|_{S_*} = \lambda^2 + q_1 \lambda + q_2 = 0, \tag{2.4}$$

where $q_1 = -\frac{c}{\beta p}(A + K - \frac{2Kc}{\beta p})$, $q_2 = c\varepsilon(1 - \frac{c}{\beta p})(\frac{Kc}{\beta p} - A)$. Since $\frac{A}{K} < \frac{c}{\beta p} < 1$, we can obtain $q_2 > 0$. By using the Veda theorem, we can conclude that if $q_1 = 0$ i.e. $c = \frac{(A+K)\beta p}{2K}$, its eigenvalues are a pair of pure imaginary roots, so S_* is a center; if $q_1 > 0$, the real parts of its eigenvalues are all negative, so S_* is locally asymptotically stable; and if $q_1 < 0$, the real parts of its eigenvalues are all positive, S_* is unstable.

3 Bifurcation analysis

In this section, we mainly discuss the dynamic behavior of the system (2.2). We delve into the bifurcation behavior of the system (2.2) at the boundary equilibrium and analyze the existence and stability of its Hopf bifurcation at the internal equilibrium $S_*(x_*, E_*)$.

3.1 Transcritical bifurcation

Theorem 3.1. *For system (2.2), a transcritical bifurcation will occur near the equilibrium point S_2 as the bifurcation parameter c passes through $c^* = \beta p$.*

Proof. We know that S_2 is stable with $c > \beta p$ and S_2 is unstable with $c < \beta p$. That is, as the value of parameter c passes through βp, the stability of S_2 changes, so there may be a transcritical bifurcation. Next, we prove the bifurcation behavior at equilibrium point S_2 by using Sotomayor's theorem to .

Denote

$$X = (x, E)^{\mathrm{T}},\ F(X, c) = \begin{pmatrix} x(1 - x)(Kx - A) - \alpha E x \\ \varepsilon(\beta p x - c)E \end{pmatrix},$$

$J|_{S_2} = DF(S_2, \beta p)$ has a zero eigenvalue at $c^* = \beta p$, and its corresponding eigenvector is $\vartheta = (\alpha, A-K)^{\mathrm{T}} = (\vartheta_1, \vartheta_2)^{\mathrm{T}}$. The eigenvector corresponding to the zero eigenvalue of transpose matrix $D^{\mathrm{T}}F(S_2, \beta p)$ is $\omega = (0,1)^{\mathrm{T}}$. After calculation, it is easy to obtain the following formula:

$$F_c(S_2, \beta p) = \begin{pmatrix} 0 \\ 0 \end{pmatrix},$$
$$DF_c(S_2, \beta p)\vartheta = \begin{pmatrix} 0 \\ \varepsilon(K-A) \end{pmatrix},$$
$$D^2F_c(S_2, \beta p)(\vartheta, \vartheta) = \begin{pmatrix} \alpha^2(A-3K) \\ \varepsilon\beta p\alpha(A-K) \end{pmatrix}.$$

Furthermore, it can be obtained that

$$\omega^{\mathrm{T}}F_c(S_2, \beta p) = 0,$$
$$\omega^{\mathrm{T}}[DF_c(S_2, \beta p)\vartheta] = \varepsilon(K-A) \neq 0,$$
$$\omega^{\mathrm{T}}[D^2F_c(S_2, \beta p)(\vartheta, \vartheta)] = \varepsilon\beta p\alpha(A-K) \neq 0.$$

Therefore, according to Sotomayor's theorem, system (2.2) undergoes a transcritical bifurcation at equilibrium point S_2 if $c^* = \beta p$. □

3.2 Hopf bifurcation

In two-dimensional systems, singular Hopf bifurcation is a special case of Hopf bifurcation, therefore, it is necessary to discuss the existence and stability of Hopf bifurcation.

According to the analysis in Subsection 2.2, we know that S_* is a center if $c = \frac{(A+K)\beta p}{2K}$, and the stability of S_* changes as the c value passes through $\frac{(A+K)\beta p}{2K}$. Therefore, Hopf bifurcation may occur at this equilibrium point.

Lemma 3.2. *System (2.2) will generate supercritical Hopf bifurcation near the equilibrium point $S_*(x_*, y_*)$, as the bifurcation parameter c passes through $\tilde{c} = \frac{(A+K)\beta p}{2K}$.*

Proof. Select c as the bifurcation parameter, with a bifurcation parameter threshold $\tilde{c} = \frac{(A+K)\beta p}{2K}$ that satisfies $\det(J|_{S_*}) > 0$ and $\mathrm{tr}(J|_{S_*}) = 0$. When $c = \tilde{c} = \frac{(A+K)\beta p}{2K}$, equation (2.4) has a pair of pure imaginary roots $\pm\sqrt{q_2}$, where $q_2 = c\varepsilon(1 - \frac{c}{\beta p})(\frac{Kc}{\beta p} - A)$. Next, we will verify the transversality condition for Hopf bifurcation. Assuming that $\lambda = \varphi(c) + i\psi(c)$ a root of the characteristic equation (2.4), we can obtain that $\varphi(\tilde{c}) = 0$, $\psi(\tilde{c}) = \sqrt{q_2}$. Substituting $\lambda = \varphi(c) + i\psi(c)$ into equation (2.4) and separating the real and imaginary parts, we obtain

$$\begin{cases} \varphi^2 - \psi^2 + q_1\varphi + q_2 = 0, \\ 2\varphi\psi + q_1\psi = 0. \end{cases}$$

After taking the derivative of c at both ends of the above equation, we obtain

$$\begin{cases} -2\psi\psi' + q_1\varphi' + q_2' = 0, \\ 2\varphi' + q_1' = 0. \end{cases}$$

After further calculation, we obtain $\frac{d\varphi}{dc}|_{c=\tilde{c}} = -\frac{A+K}{2\beta p} \neq 0$, which satisfies the transversality condition for Hopf bifurcation. Next, we will discuss the stability of Hopf bifurcation, it can

help determine under what conditions ecosystems can maintain equilibrium. We take the transformation $\bar{x} = x - x_*$, $\bar{E} = E - E_*$ to move (x_*, E_*) to the origin. Then dropping the bars, the system (2.2) performs Taylor expansion at the origin, and we obtain:

$$\begin{cases} \dfrac{dx}{dt} = a_{10}x + a_{01}E + a_{20}x^2 + a_{11}xE + a_{02}E^2 \\ \qquad\quad + a_{30}x^3 + a_{21}x^2E + a_{12}xE^2 + a_{03}E^3 + o(|x,E|^4), \\ \dfrac{dE}{dt} = b_{10}x + b_{01}E + b_{20}x^2 + b_{11}xE + b_{02}E^2 \\ \qquad\quad + b_{30}x^3 + b_{21}x^2E + b_{12}xE^2 + b_{03}E^3 + o(|x,E|^4), \end{cases} \tag{3.1}$$

where

$$\begin{aligned} &a_{10} = x_*(A + K - 2Kx_*), \quad a_{01} = -\alpha x_*, \quad a_{20} = -3Kx_* + A + K, \\ &a_{11} = -\alpha, \quad a_{30} = -K, \quad b_{10} = \frac{\varepsilon\beta p}{\alpha}(1 - x_*)(Kx_* - A), \quad b_{11} = \varepsilon\beta p, \\ &a_{02} = a_{21} = a_{12} = a_{03} = b_{01} = b_{20} = b_{02} = b_{30} = b_{21} = b_{12} = b_{03} = 0. \end{aligned}$$

The Jacobian matrix of system (3.1) at $(0,0)$ is

$$J|_{(0,0)} = \begin{pmatrix} x_*(A + K - 2Kx_*) & -\alpha x_* \\ \dfrac{\varepsilon\beta p}{\alpha}(1 - x_*)(Kx_* - A) & 0 \end{pmatrix}.$$

Through simple calculations, we can obtain $\mathrm{tr}(J|_{(0,0)}) = 0$ and $\det(J|_{(0,0)}) = \varepsilon\beta p x_*(1 - x_*)(Kx_* - A) > 0$ at $c = \tilde{c}$. Thus, $J|_{(0,0)}$ has a pair of pure imaginary eigenvalue

$$\lambda = \pm i\sqrt{\varepsilon\beta p x_*(1 - x_*)(Kx_* - A)} \quad \text{for } c = \tilde{c}.$$

Furthermore, the first Lyapunov coefficient l_1 [30] for determining the stability of the limit cycle is given:

$$l_1 = -\frac{3\pi}{2a_{01}D^{\frac{3}{2}}}\sum_{i=1}^{8}\xi_i,$$

where

$$\begin{aligned} &D = a_{10}b_{01} - a_{01}b_{10}, \quad \xi_1 = \varepsilon\alpha\beta p x_*(1 - x_*)(Kx_* - A)(A + K - 2Kx_*), \\ &\xi_2 = -\varepsilon\alpha\beta p x_*^2(A + K - 2Kx_*)(\varepsilon\beta p - 3Kx_* + A + K), \quad \xi_3 = \xi_4 = 0, \\ &\xi_5 = 2\alpha x_*^2(A + K - 2Kx_*)(A + K - 3Kx_*)^2, \quad \xi_6 = 0, \\ &\xi_7 = \left(\varepsilon\alpha\beta p x_*(1 - x_*)(Kx_* - A) + 2\alpha x_*^2(A + K - 2Kx_*)^2\right)(3Kx_* - A - K), \\ &\xi_8 = 3\alpha K x_*^3(A + K - 2Kx_*)^2 - 3\varepsilon\alpha\beta p K x_*^2(1 - x_*)(Kx_* - A). \end{aligned}$$

After substituting $x_* = \frac{c}{\beta p}$ and $\tilde{c} = \frac{(A+K)\beta p}{2K}$ into the calculation, and since $|A| < K$, we obtain

$$\begin{aligned} l_1 &= \left(\frac{3\pi K}{\alpha(A + K)\left(\frac{1}{2}\right)^{\frac{3}{2}}\left(\frac{\varepsilon\beta p A^3}{4K^2} - \frac{p\beta\varepsilon A^2}{4K} - \frac{A\beta p\varepsilon}{4} + \frac{K\beta p\varepsilon}{4}\right)^{\frac{3}{2}}}\right)\left(-\frac{K^2\alpha\beta p\varepsilon}{8} - \frac{A^4\alpha\beta p\varepsilon}{8K^2} + \frac{A^2\alpha\beta p\varepsilon}{4}\right) \\ &= -\left(\frac{3\pi K}{\alpha(A + K)\left(\frac{1}{2}\right)^{\frac{3}{2}}\left(\frac{\varepsilon\beta p}{4K^2}(K - A)^2(K + A)\right)^{\frac{3}{2}}}\right)\frac{\alpha\beta p\varepsilon}{8K^2}(K^2 - A^2)^2 \\ &= -\frac{6\sqrt{2}\pi K^2}{(K - A)\sqrt{\varepsilon\beta p(K + A)}} < 0. \end{aligned}$$

Therefore, system (2.2) generates a supercritical Hopf bifurcation near the equilibrium point $S_*(x_*, E_*)$. □

3.3 Numerical simulation

In this section, we verify the conclusions given earlier through numerical simulations. For system (2.2) with strong Allee effect, we select parameter $K = 3$, $A = 0.8$, $\alpha = 0.17$, $\varepsilon = 0.5$, $\beta = 1.5$, $p = 3$ (The data source from Table 3.2.).

Parameter	Reference range	Data sources
r	$[0.3, 0.9]$	[4,28]
K	$[2, 10]$	[33]
A	$[-1, 0) \cup (0, 1]$	[38,43]
m	$[0.01, 0.4]$	[10]
p	$[3, 15]$	[5]
q	$[0.1, 1.5]$	[5,39]
c	$[1, 15]$	[5]

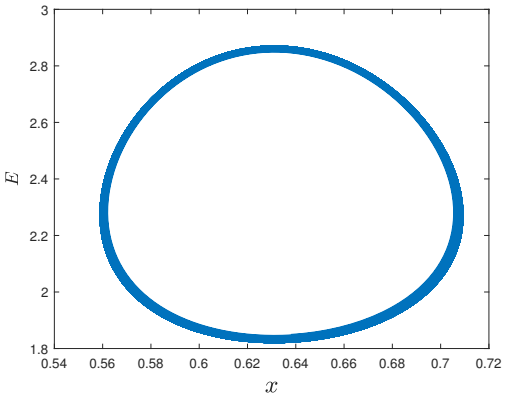

Table 3.1: Parameter selection range in Model (2.1).

Parameter	Reference range
K	$[2, 10]$
A	$[-1, 0) \cup (0, 1]$
$\alpha = \frac{q}{r}$	$[0.1, 1.5]$
$\beta = qK$	$[0.2, 15]$
p	$[3, 15]$
c	$[1, 15]$
$\varepsilon = \frac{m}{r}$	[0.01,1.3]

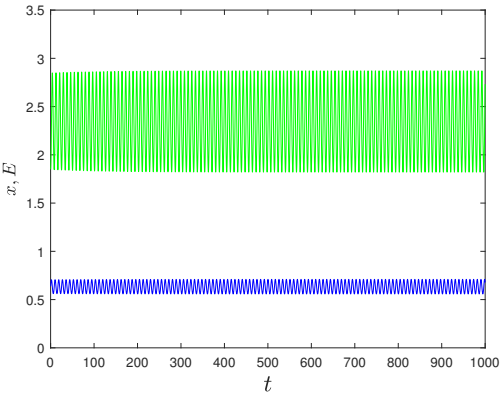

Table 3.2: Range of parameter values in system (2.2).

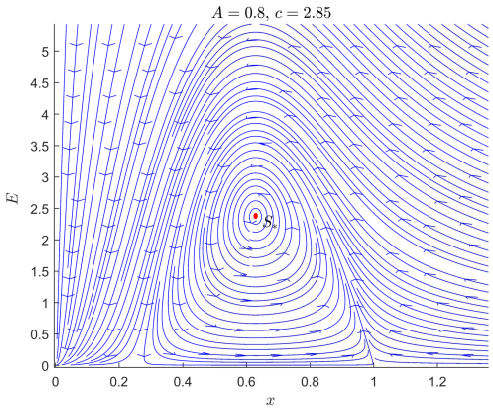
After calculation, it can be concluded that the bifurcation parameter value $c_H = 2.85$, and $S_*(x_*, E_*) = (0.6311, 2.3725)$. According to Lemma 3.2, it is known that a supercritical Hopf bifurcation will occur. As shown in Figure 3.1(a). Figure 3.1(b) is a time series graph of x and E. Figure 3.1(c) is the phase diagram of system (2.2). Furthermore, selecting parameter $\varepsilon = 0.5$, $c = 2.89 > c_H$, we can obtain that the equilibrium point S_* is locally asymptotically stable. (See Fig. 3.2).



For system (2.2) with weak Allee effect, we select parameter $K = 3$, $A = -0.3$, $\alpha = 0.17$, $\varepsilon = 0.5$, $\beta = 1.5$, $p = 3$ (the data source from Table 3.2.). After calculation, it can be concluded that the bifurcation parameter value $c_H = 2.025$, and $S_*(x_*, E_*) = (0.4444, 5.3377)$. As shown in Figure 3.1(d-f).

4 Singular perturbation analysis

In this section, we use singular perturbation theory [9] to discuss the fast-slow dynamic behavior of system (2.2). Under the strong Allee effect, system (2.2) will generate a singular Hopf bifurcation near the internal equilibrium point. Under the weak Allee effect, the dynamical behavior generated by system (2.2) is more complex, resulting not only in singular Hopf bifurcations but also relaxation oscillations.

4.1 Asymptotic expansion of critical manifolds

Let $\varepsilon \to 0$, system (2.2) becomes

$$\begin{cases} \dfrac{dx}{dt} = f(x, E, 0), \\ \dfrac{dE}{dt} = 0, \end{cases} \tag{4.1}$$

which is called the fast subsystem or layer equation, and the corresponding flow is called fast flow. Let $\varepsilon \to 0$, system (2.3) can be reduced to a differential algebraic system given by

$$\begin{cases} 0 = f(x, E, 0), \\ \dfrac{dE}{d\tau} = g(x, E, 0), \end{cases} \tag{4.2}$$

which is called the slow subsystem, and the flow it generates is called slow flow. The slow flow is constrained in set $C_0 = \left\{(x, E) \in \mathbb{R}^2_+, f(x, E, \varepsilon) = 0\right\}$. C_0 is called the critical manifold, which consists of two parts and is given by

$$\begin{aligned} C_0 = C_{10} \cup C_{20} &= \left\{(x, E) \in \mathbb{R}^2_+,\ x = 0\right\} \\ &\cup \left\{(x, E) \in \mathbb{R}^2_+,\ E = u_0(x),\ u_0(x) = \frac{(1-x)(Kx - A)}{\alpha},\ \frac{A}{K} < x < 1,\ E > 0\right\}, \end{aligned} \tag{4.3}$$

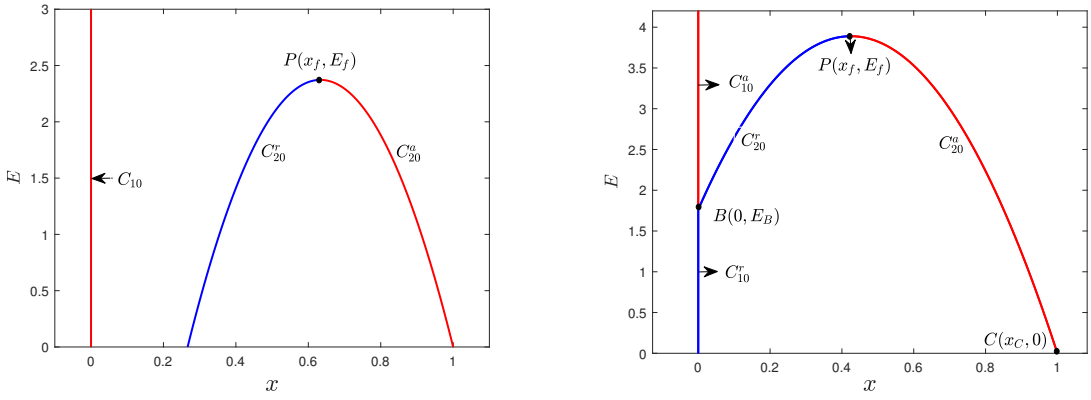
which is the critical manifold of system (2.2) with strong Allee effect($0 < A < K$). The critical manifold C_{20} is similar to a parabola, with its maximum value being the fold point $P(x_f, E_f)$, where $x_f = \frac{A+K}{2K}$ and $E_f = \frac{(1-x_f)(Kx_f - A)}{\alpha}$. The nonhyperbolic fold point divides the critical manifold C_0 into two parts: the attracting sub-manifold $C_0^a = C_{20}^a \cup C_{10} = \{(x, E) \in \mathbb{R}^2_+, x_f < x < 1\} \cup C_{10}$ and the repelling sub-manifold $C_0^r = C_{20}^r = \left\{(x, E) \in \mathbb{R}^2_+, \frac{A}{K} < x < 1\right\}$ (see Figure 4.1(a)).

For weak Allee effect ($A < 0$), the slow flow generated by the slow subsystem is limited to the critical manifold

$$\begin{aligned} C_0 = C_{10} \cup C_{20} &= \left\{(x, E) \in \mathbb{R}^2_+,\ x = 0\right\} \\ &\cup \left\{(x, E) \in \mathbb{R}^2_+,\ E = u_0(x),\ u_0(x) = \frac{(1-x)(Kx - A)}{\alpha},\ 0 < x < 1,\ E > 0\right\}. \end{aligned} \tag{4.4}$$

After calculation, we obtain a maximum point $P(x_f, E_f)$, where $x_f = \frac{A+K}{2K}$, $E_f = \frac{(1-x_f)(Kx_f - A)}{\alpha}$, a transcritical point $B(0, E_B) = (0, -\frac{A}{\alpha})$, and a boundary point $C(x_C, 0) = (1, 0)$. The critical manifold C_0 can be partitioned into two segments:

$$\begin{aligned} C_0^a = C_{10}^a \cup C_{20}^a &= \left\{(x, E) \in \mathbb{R}^2_+, x = 0, E > -\frac{A}{\alpha}\right\} \cup \left\{(x, E) \in \mathbb{R}^2_+, x_f < x < 1\right\}, \\ C_0^r = C_{10}^r \cup C_{20}^r &= \left\{(x, E) \in \mathbb{R}^2_+, x = 0, 0 < E < -\frac{A}{\alpha}\right\} \cup \left\{(x, E) \in \mathbb{R}^2_+, 0 < x < x_f\right\}, \end{aligned}$$



where C_0^a is normally attracting and C_0^r is normally repelling (see Figure 4.1(b)). According to the Fenichel's Theorem [19], there exists a locally invariant manifold C_ε with differential homeomorphism at C_{20}. The Hausdorff distance from C_ε to C_{20} is $O(\varepsilon)$, and the flow on C_ε converges to a slow flow when ε tends to 0. Therefore, C_ε can be seen as a small perturbation of C_{20}, given by:

$$C_\varepsilon := u_0(x) + \varepsilon u_1(x) + \varepsilon^2 u_2(x) + \cdots = C_{20} + O(\varepsilon), \tag{4.5}$$

where $u_0(x)$ is the critical manifold of C_{20} as given by (4.3). In addition, we use C_ε^a and C_ε^r represent the perturbed attracting sub-manifold and repelling sub-manifold, respectively. Due to the local invariance of approximating manifold C_ε, we have

$$\frac{dE}{dt} = \frac{dE}{dx}\frac{dx}{dt} = \left(\frac{du_0}{dx} + \varepsilon\frac{du_1}{dx} + \varepsilon^2\frac{du_2}{dx} + \dots\right)\frac{dx}{dt}. \tag{4.6}$$

Substituting $\frac{dE}{dt}$ and $\frac{dx}{dt}$ into equation (4.6), and by comparing the coefficients of ε, it can be

(a) (b)

Figure 4.1: The critical manifold. (a) The critical manifold of system (2.2) with strong Allee effect. (b) The critical manifold of system (2.2) with weak Allee effect. The blue lines represent the repelling sub-manifold of the critical manifold, and the red lines represent the attracting sub-manifold of the critical manifold.

obtained that

$$u_1(x) = \frac{(c - \beta p x)u_0}{\alpha x \frac{du_0}{dx}}.$$

By comparing the coefficients of ε^2, it can be concluded that

$$u_2(x) = \frac{(c - \beta p x - \alpha x \frac{du_1}{dx})u_1}{\alpha x \frac{du_1}{dx}}.$$

Using the same method, $u_j(x), j = 3, 4, \ldots$ can be obtained. But according to Fenichel's theorem, perturbation manifolds cannot be extended at fold points (x_f, E_f) that lose hyperbolic properties [6].

4.2 Singular Hopf bifurcation

In this section, we discuss the existence of singular Hopf bifurcation of system (2.2). And we do not limit the threshold of the Allee effect, that is, whether it is strong or weak Allee effect, system (2.2) will produce singular Hopf bifurcation.

According to the analysis in Subsection 2.2, the system has an internal equilibrium point (x_*, E_*) for $\frac{A}{K} < \frac{c}{\beta p} < 1$. The Jacobian matrix at this point is

$$J|^t_{S_*} = \begin{pmatrix} \frac{c}{\beta p}\left(A + K - \frac{2Kc}{\beta p}\right) & -\frac{\alpha c}{\beta p} \\ \frac{\varepsilon \beta p}{\alpha}\left(1 - \frac{c}{\beta p}\right)\left(\frac{Kc}{\beta p} - A\right) & 0 \end{pmatrix},$$

where t represents the Jacobian matrix of the system at S_* at a fast time scale.

According to the Hopf bifurcation principle, we need to solve the Hopf bifurcation threshold to satisfy that the trace of $J|^t_{S_*}$ is equal to 0 and the determinant value of $J|^t_{S_*}$ is greater than 0, which means that $q_1 = 0$ and $q_2 > 0$ in (2.4). Taking c as the bifurcation parameter, we obtain the bifurcation threshold

$$c_H = \frac{(A+K)\beta p}{2K},$$

and the equilibrium (x_H, E_H) at $c = c_H$, where $x_H = \frac{c}{\beta p}$, $E_H = \frac{(1-x_*)(Kx_*-A)}{\alpha}$. This point coincides perfectly with the fold point. At the Hopf bifurcation threshold, $J|^t_{S_*}$ has a pair of pure imaginary eigenvalues:

$$\lambda_H(\sqrt{\varepsilon}) = \pm i\sqrt{\frac{(K-A)^2(A+K)\beta p\varepsilon}{8K^2}}.$$

Theorem 4.1. *Set $0 < \varepsilon \ll 1$. Assuming (x_f, E_f) is the generic folded singularity of system (2.2), system (2.2) undergoes a singular Hopf bifurcation in a certain domain of x_f when $c = c_H$, resulting in a stable canard cycles. In addition, there exists a singular Hopf bifurcation curve $\delta = \delta_H(\sqrt{\varepsilon})$ such that (x_f, E_f) is stable when $\delta < \delta_H(\sqrt{\varepsilon})$ and*

$$\delta_H(\sqrt{\varepsilon}) = -\frac{a_1 + a_5}{2}\varepsilon + \mathcal{O}(\varepsilon^{\frac{3}{2}}). \tag{4.7}$$

Proof. First, we discuss that (x_f, E_f) is a generic folded singularity. By calculation, it can be concluded that (x_f, E_f) satisfies the following conditions:

$$\begin{aligned} f(x_f, E_f) &= 0, \qquad f_x(x_f, E_f) = 0, \\ f_{xx}(x_f, E_f) &\neq 0, \qquad f_y(x_f, E_f) \neq 0, \end{aligned}$$

and

$$g(x_f, E_f) = 0,$$

thus (x_f, E_f) is a fold singularity. In addition, it satisfies the condition:

$$g_x(x_f, E_f) \neq 0, \quad g_c(x_f, E_f) \neq 0,$$

thus (x_f, E_f) is a generic fold singularity.

In order to study the local behavior of system (2.2) near $P(x_f, E_f)$, we perform coordinate transformation

$$u = x - x_*, \quad v = E - E_*, \quad \delta = c - c_H,$$

and system (2.2) becomes

$$\begin{cases} \dfrac{du}{dt} = -vh_1(u, v, \delta, \varepsilon) + u^2 h_2(u, v, \delta, \varepsilon) + \varepsilon h_3(u, v, \delta, \varepsilon), \\ \dfrac{dv}{dt} = \varepsilon \left\{ uh_4(u, v, \delta, \varepsilon) - \delta h_5(u, v, \delta, \varepsilon) + vh_6(u, v, \delta, \varepsilon) + o(|u, v, \delta|^3) \right\}, \end{cases} \tag{4.8}$$

where

$$\begin{aligned} h_1(u, v, \delta, \varepsilon) &= \alpha u + \alpha x_*, \\ h_2(u, v, \delta, \varepsilon) &= A + K - 3Kx_* - Ku, \\ h_3(u, v, \delta, \varepsilon) &= 0, \\ h_4(u, v, \delta, \varepsilon) &= \beta p v + \beta p E_*, \\ h_5(u, v, \delta, \varepsilon) &= v + E_*, \\ h_6(u, v, \delta, \varepsilon) &= \beta p x_* - c_H. \end{aligned}$$

According to the theory in [19], we have obtained

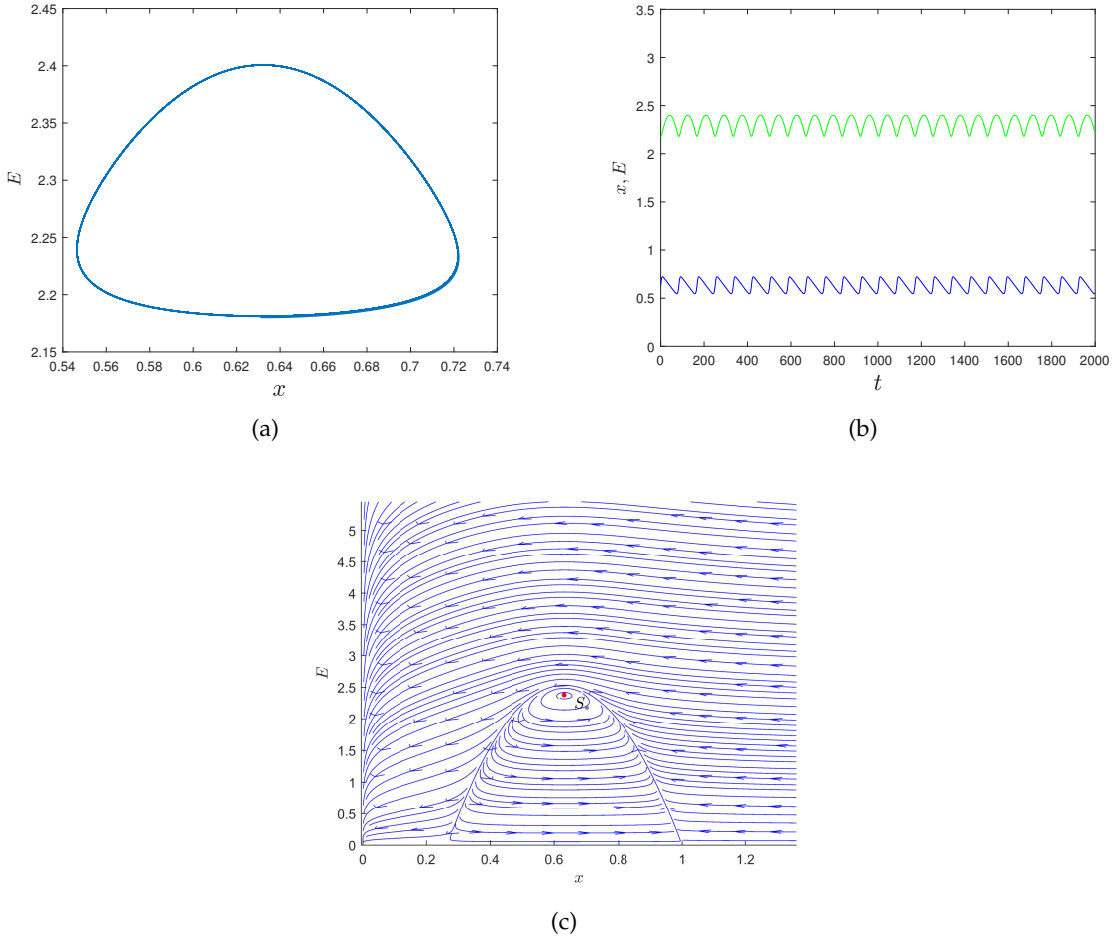
$$\begin{aligned} a_1 &= \frac{\partial h_3}{\partial u}(0,0,0,0) = 0, \\ a_2 &= \frac{\partial h_1}{\partial u}(0,0,0,0) = \alpha, \\ a_3 &= \frac{\partial h_2}{\partial u}(0,0,0,0) = -K, \\ a_4 &= \frac{\partial h_4}{\partial u}(0,0,0,0) = 0, \\ a_5 &= h_6(0,0,0,0) = \beta p x_* - c_H. \end{aligned} \tag{4.9}$$

After further calculation, the Hopf bifurcation curve is obtained to be

$$\delta_H(\sqrt{\varepsilon}) = -\frac{a_1 + a_5}{2}\varepsilon + \mathcal{O}(\varepsilon^{\frac{3}{2}}) = \mathcal{O}(\varepsilon^{\frac{3}{2}}),$$

and the maximum canard curve is

$$\delta_c(\sqrt{\varepsilon}) = -\Big(\frac{a_1 + a_2}{2} + \frac{A}{8}\Big)\varepsilon + \mathcal{O}(\varepsilon^{\frac{3}{2}}) = \frac{\alpha + 3K}{8} + \mathcal{O}(\varepsilon^{\frac{3}{2}}). \qquad \square$$



Compared with the Hopf bifurcation in Subsection 3.1, we can find that the singular Hopf bifurcation coincides exactly with the case of the aforementioned Hopf bifurcation. Thus, the stability of periodic solutions generated by singular Hopf bifurcation is the same as that of Hopf bifurcation. According to Lemma 3.2, system (2.2) undergoes a supercritical singular Hopf bifurcation for $l_1 < 0$. According to [19], we can calculate that system (2.2) will generate a singular supercritical Hopf bifurcation by calculating $A_1 = -a_2 + 3a_3 - 2a_4 + 2a_5 = -\alpha - 3K < 0$. The conclusion obtained from Lemma 3.2 is also consistent.

Through numerical simulation, we verify the above conclusion. A canard without head will be generated, when $K = 3$, $A = 0.8$, $\alpha = 0.17$, $\varepsilon = 0.05$, $\beta = 1.5$, $p = 3$, $c = 2.8446$, (see Figure 4.2). Compared with Hopf bifurcation, under the influence of perturbation parameter ε, the bottom of the limit cycle generated by the singular Hopf bifurcation will be flatter. By comparing Figure 3.1(a) with Figure 4.2(a), it can be seen.

Remark 4.2. Fishing effort refers to the amount of work invested in a fishery using the same fishing operation method over a period of time, reflecting the mortality level of the captured resource population. The emergence of Hopf bifurcation and singular Hopf bifurcation indicates that the system will experience periodic fluctuations, which means that population density and capture effort will show periodic changes. This also means that there is a dynamic balance between population density and mortality rate, and the ecosystem is in a state of dynamic equilibrium.

4.3 Relaxation oscillation

Compared with system (2.2) with strong Allee effect, system (2.2) with weak Allee effect produce more complex dynamical behavior, resulting to relaxation oscillations. This section mainly discusses the relaxation oscillations generated by system (2.2) with weak Allee effect ($A < 0$).

(a) (b)

(c)

Figure 4.2: Phase plane analysis of system (2.2) for $\varepsilon = 0.05$ and $c = 2.8446$. (a) The canard without head generated by the system (2.2), when $K = 3$, $A = 0.8$, $\alpha = 0.17$, $\varepsilon = 0.05$, $\beta = 1.5$, $p = 3$, $c = 2.8446$. (b) $x - t$ (blue) and $E - t$ (green) time series diagram. (c) The phase diagram.

To discuss the existence of relaxation oscillations when $0 < x_* < x_f$, system (2.2) is expressed as follows:

$$\begin{cases} \dfrac{dx}{dt} = x f_1(x, E, \varepsilon), \\ \dfrac{dE}{dt} = \varepsilon g(x, E, \varepsilon), \end{cases} \tag{4.10}$$

where $(x, E) \in \mathbb{R}^2_+$, $0 < \varepsilon \ll 1$, $f_1(x, E, \varepsilon) = (1 - x)(Kx - A) - \alpha E$ and $g(x, E, \varepsilon) = (\beta p x - c) E$. f_1 and g are sufficiently smooth and satisfy the following conditions:

$$f_1(x, E, \varepsilon) < 0, \quad g(x, E, \varepsilon) < 0, \quad \text{for } E > E_B > 0,$$
$$f_1(x, E, \varepsilon) > 0, \quad \text{for } E < E_B.$$

For $\varepsilon = 0$, the E-axis consists of the attracting part with $E > E_B$ and the repelling part with $E < E_B$. For a very small ε ($\varepsilon > 0$), the trajectory that starts from the point (x_0, E_0) ($x_0 > 0$ is quite small, $E > E_B$) gets attracted to the E-axis. Subsequently, it drifts downwards, and when it passes through $E = E_B$, it is repelled outside the E-axis. For a very small $\varepsilon(\varepsilon > 0)$, the

trajectory intersects again with the line $x = x_0$ at the point whose E-coordinate value is $m_\varepsilon(E_0)$, such that $\lim_{\varepsilon\to 0} m_\varepsilon(E_0) = m_0(E_0)$, where $m_0(E_0)$ is is calculated by the following integration:

$$\int_{E_0}^{m_0(E_0)} \frac{f_1(0,E,0)}{g(0,E,0)} dE = 0. \tag{4.11}$$

The function $E_0 \to m_0(E_0)$ implicitly defined above is called the entry-exit function [8,37](see Figure 4.3).

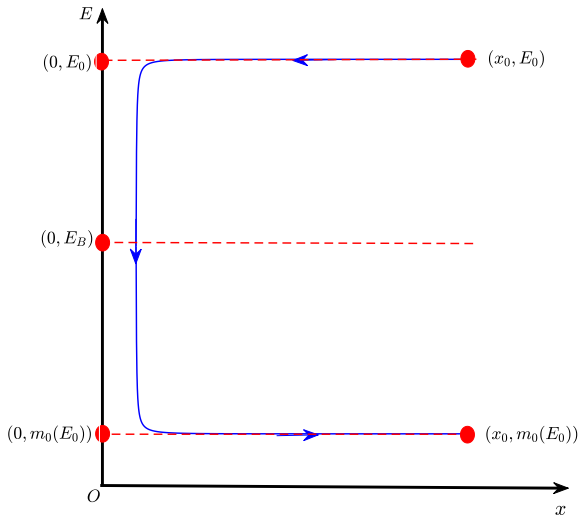


Figure 4.3: The entry-exit function. For system (2.2), when $\varepsilon = 0$, the branch of the E-axis is composed of the attracting part of $E > E_B$ and the repelling part of $E < E_B$. When $0 < \varepsilon \ll 1$, a typical orbit of system (2.2) starts at (x_0, E_0), where $E_0 > E_B$, and $x_0 > 0$ is very small, is attracted to the E-axis (not crossing the E-axis), gradually moves downwards along the E-axis until it reaches near $(0, m_0(E_0))$. Then it is repelled by the E-axis, and ends at point $(x_0, m_0(E_0))$.

On the basis of this, we have obtained the following results:

Lemma 4.3. *There exists a unique $\tilde{E}$ where $0 < \tilde{E} < -\frac{A}{\alpha}$, such that*

$$G(E) = \int_{E_f}^{E} \frac{f_1(0,s,0)}{g(0,s,0)} ds = 0. \tag{4.12}$$

Proof. We have

$$\begin{aligned} G(E) &= \int_{E_f}^{E} \frac{f_1(0,s,0)}{g(0,s,0)} ds \\ &= \int_{E_f}^{E} \frac{A+\alpha s}{cs} ds \\ &= \frac{A}{c} \ln \frac{E}{E_f} + \frac{\alpha}{c}(E - E_f) \to +\infty \quad \text{as } E \to 0^+. \end{aligned} \tag{4.13}$$

Furthermore, it can be calculated that

$$G'(E) = \frac{A+\alpha s}{cs}, \quad \text{for } 0 < E < -\frac{A}{\alpha}. \tag{4.14}$$

Therefore, G_E is strictly monotonically decreasing when $0 < E < -\frac{A}{\alpha}$. Again,

$$G\left(-\frac{A}{\alpha}\right) = \int_{E_f}^{-\frac{A}{\alpha}} \frac{A+\alpha s}{cs} ds < 0. \tag{4.15}$$

Thus there exists a unique $\tilde{E}$ where $0 < \tilde{E} < -\frac{A}{\alpha}$, such that $G(\tilde{E}) = 0$. □

The points $P(x_f, E_f)$ and $B(0, E_B)$ on the critical manifolds C_{10} and C_{20} that lose their hyperbolic properties are fold point and transcritical point, respectively. For fold point $P(x_f, E_f)$, we have

$$\frac{\partial f}{\partial E}|_{P(x_f,E_f)} = -\alpha x_f \neq 0,$$

as $c < \frac{(A+K)\beta p}{2K}$ and $g(x_f, E_f) \neq 0$ as $0 < x_* < x_f$. In addition, we have

$$\frac{\partial f}{\partial x^2}|_{P(x_f,E_f)} = -6Kx_f + 2(A+K) \neq 0,$$

consequently, $P(x_f, E_f)$ is a generic fold point as well as also a jump point, at which point the fast fiber flow leaves the critical manifold C_{20}.

For the transcritical point $B(0, E_B)$, we have

$$\begin{aligned} \frac{\partial f}{\partial x}|_{B(0,E_B)} &= 0, \\ \frac{\partial f}{\partial E}|_{B(0,E_B)} &= 0, \\ g(0, E_B) &= \frac{Ac}{\alpha} < 0, \\ \begin{vmatrix} \frac{\partial^2 f}{\partial x^2} & \frac{\partial^2 f}{\partial x \partial E} \\ \frac{\partial^2 f}{\partial x \partial E} & \frac{\partial^2 f}{\partial E^2} \end{vmatrix}_{B(0,E_B)} &= -\alpha^2 < 0, \end{aligned}$$

therefore, $B(0, E_B)$ is a generic transcritical point and jump point, at which point the fast flow is removed from the critical manifold C_{20}.

Define a singular fast-slow cycle Γ_0: the trajectory starts from $A(0, E_f)$, follows the slow flow along the E-axis to $C(0, \tilde{E})$. At $C(0, \tilde{E})$, it is repelled to the right, following the fast flow until it intersects with the attraction branch at point $D(\tilde{x}, \tilde{E})$. Then it follows the slow flow C_{20}^a to point $P(x_f, E_f)$, and finally follows the fast flow to the left back to point $A(0, E_f)$. Therefore, Γ_0 has four singular orbits, where $P(x_f, E_f)$ and $B(0, E_B)$ is the jump point, $A(0, E_f)$ and $D(\tilde{x}, \tilde{E})$ is the drop point (as shown by the red line in Figure 4.4).

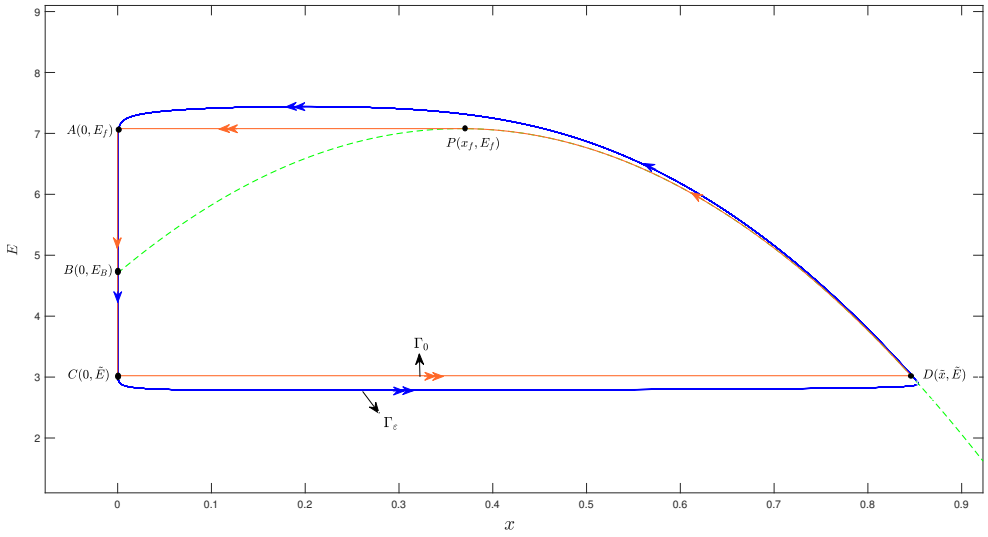

Figure 4.4: Representation the singular orbit Γ_0(red) and the relaxation oscillation orbit Γ_ε(blue) when $\varepsilon > 0$. The critical manifold of system (2.2) is represented by a green dashed line. Point $P(x_f, E_f)$ represents the maximum point of curve $E = u_0(x)$. The intersection point between curve $E = u_0(x)$ and the E-axis is $B(0, E_B)$. The branch on the E-axis is hyperbolic attracting with $E > E_B$ and The branches on the E-axis are hyperbolic repelling with $E < E_B$. The branch between P and B is hyperbolic repelling, while the right half branch of P is hyperbolic attracting. Double arrows denote fast flow. Single arrows denote slow flow.

Theorem 4.4. *If* $\frac{A}{K} < \frac{c}{\beta p} < 1$, $c < \frac{(A+K)\beta p}{2K}$ *and* U *is a small neighborhood of* Γ_0 *for system* (2.2). *Then, for any sufficiently small* $\varepsilon > 0$, *there exists a unique limit cycle* $\Gamma_\varepsilon \in U$. *The limit cycle* Γ_ε *i attracting, and its characteristic multiplier is bounded by* $-C/\varepsilon$ *for a constant* $C > 0$. *Moreover, the limit cycle* Γ_ε *converges to* Γ_0 *in the Hausdoff distance when* ε *approaches 0.*

Proof. According to the Fenichel's theorem [9], $C^a_{10} = \{(x, E) \in \mathbb{R}^2_+, x = 0, E > -\frac{A}{\alpha}\}$ and $C^a_{20} = \{(x, E) \in \mathbb{R}^2_+, x_f < x < 1\}$ are the attracting part of the critical manifold, perturbing the nearby slow manifolds $C^a_{20,\varepsilon}$ and $C^a_{10,\varepsilon}$. By analyzing the dynamics near the fold point, the slow flow $C^a_{20,\varepsilon}$ follows the critical manifold C^a_{20} until it reaches the area near the generic fold point $P(x_f, E_f)$, and then jumps to another attracting branch C^a_{10}.

We consider a small cross-section Δ that intersects to C^a_{10} at a point between P and A, and track two trajectories Γ^1_ε and Γ^2_ε starting from Δ. According to the Fenichel's theorem [9] and Theorem 7.4.1 in [19], Γ^1_ε and Γ^2_ε will be attracted to the slow manifold C^a_{10} at an exponential velocity $\mathcal{O}(e^{\frac{1}{\varepsilon}})$. When passing through the generic transcritical point $B(0, E_B)$, $\Gamma^{1,2}_\varepsilon$ will contract exponentially with each other until they reach a neighborhood of $C^a_{20,\varepsilon}$. Applying Fenichel's theorem again, it is known that Γ^1_ε and Γ^2_ε will be attracted to the branch C^a_{20}, passing through point $P(x_f, E_f)$, and finally returning to A.

Therefore, we obtained a return map Σ: $\Delta \to \Delta$ induced by the flow of system (2.2) with $0 < \varepsilon \ll 1$. Σ is a compressed map when the trajectories contract with each other at a rate $\mathcal{O}(e^{\frac{1}{\varepsilon}})$. According to the principle of compression map, Σ has a unique stable fixed point, which is the expected limit cycle Γ_ε(As shown by the blue line in Figure 4.4). Since contraction

is exponential, the characteristic multiplier of Γ_ε has an upper bound of $-C/\varepsilon$ for $C > 0$. Applying the Fenichel's theorem [9] and Theorem 7.4.1 in [19], it is obtained that the limit cycle Γ_ε converges to Γ_0 in the Hausdoff distance when $\varepsilon \to 0$. □

Remark 4.5. For the fishery economy, relaxation oscillations usually rotate counterclockwise. This is due to the input of food by the aquaculture plant, which leads to an increase in fish density. After the increase in fish density, the workload for catching also increases. Correspondingly, as the amount of capture effort increases, the density of fish schools will also decrease. As the number of fish schools decreases, the workload for catching will also decrease. After going through these steps, the system returned to its initial state and continued to oscillate counterclockwise. This means that the system is in a dynamic equilibrium, with a focus on the capture effort increasing at a slow time scale compared to fish density. For aquaculture, this means that its economy is turnover, allowing for optimized resource allocation and sustained economic activities.

4.4 Stochastic differential system

In nature, biological populations are inevitably subject to random disturbances from the external environment, such as storms, earthquakes, natural enemies, etc. Similarly, the capture of population is also affected by weather and natural disasters. Therefore, a random perturbation term is added to discuss the existence of stationary distribution of the system's solution. We assume that the random disturbance is white noise type, which is proportional to x and E in system (2.2). Therefore, the system with added random disturbance is described as:

$$\begin{cases} dx = [x(1-x)(Kx-A) - \alpha Ex]dt + \sigma_f x dB_1(t) = f(x,E)dt + \sigma_f x dB_1(t), \\ dE = \varepsilon(\beta px - c)Edt + \sqrt{\varepsilon}\sigma_g E dB_2(t) = \varepsilon g(x,E)dt + \sqrt{\varepsilon}\sigma_g E dB_2(t). \end{cases} \tag{4.16}$$

Perform a time scale transformation of $\tau = \varepsilon t$, the above equation is transformed into

$$\begin{cases} dx = \dfrac{1}{\varepsilon}[x(1-x)(Kx-A) - \alpha Ex]d\tau + \dfrac{\sigma_f x}{\sqrt{\varepsilon}} dB_1(\tau) = \dfrac{1}{\varepsilon} f(x,E)dt + \dfrac{\sigma_f x}{\sqrt{\varepsilon}} dB_1(\tau), \\ dE = (\beta px - c)Ed\tau + \sigma_g E dB_2(\tau) = g(x,E)d\tau + \sigma_g E dB_2(\tau), \end{cases} \tag{4.17}$$

where $B_i(\tau)$, $i = 1,2$ is the standard Brownian motion on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$, σ_f and σ_g represents noise intensity.

Theorem 4.6. *For any $(x(0), E(0)) \in \mathbb{R}^2_+$, as $\varepsilon \to 0$, solution of (4.17) converges weakly to $E(\cdot)$ that is a solution of the stochastic differential equation*

$$dE(\tau) = \left(\beta pE \int_{x(0)}^{\infty} x\mu_E(x)dx - cE\right) d\tau + \sigma_g E dB_2(\tau). \tag{4.18}$$

Proof. According to [17], we need to calculate the invariant measure $\mu_E(x)$ of equation (4.17)-1, that is, to calculate the Fokker–Planck equation corresponding to equation (4.17)-1:

$$\frac{\partial P(x,\tau|E)}{\partial \tau} = -\frac{\partial}{\partial x}\left\{\frac{1}{\varepsilon}\left(x(1-x)(Kx-A) - \alpha Ex\right)p(x,\tau|E)\right\} + \frac{1}{2}\frac{\partial^2}{\partial x^2}\left(\frac{\sigma_f^2 x^2}{\varepsilon} p(x,\tau|E)\right) = 0.$$

By transforming $\tau = \varepsilon t$, the above equation is transformed into

$$\frac{\partial P(x,t|E)}{\partial t} = -\frac{\partial}{\partial x}\left\{\left(x(1-x)(Kx-A) - \alpha Ex\right)p(x,t|E)\right\} + \frac{1}{2}\frac{\partial^2}{\partial x^2}\left(\sigma_f^2 x^2 p(x,t|E)\right).$$

Solving $\frac{\partial P(x,t|E)}{\partial t} = 0$, we obtain

$$\mu_E(x) = Cx^{-N} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\},$$

where $N = \frac{2(A+\alpha E)}{\sigma_f^2} + 2$, C is a normalization constant that satisfies

$$C\int_{x(0)}^{\infty} x^{-N} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\} dx = 1.$$

To ensure that C is computable, we prove that the integral $\int_{x(0)}^{\infty} x^{-N} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\}dx$ converges. For the proof of integral convergence, please refer to the appendix.

According to the Khasminskii's limit theorem [16] and Theorem 5.1 in [40], in the extreme case $\varepsilon \to 0$, the evolution of the slow variable E can be described by a simplified stochastic differential equation, as follows

$$dE(\tau) = g_{red}(E)d\tau + \sigma_{red}(E)dB_2(\tau), \tag{4.19}$$

where

$$g_{red}(E) = \int_{x(0)}^{\infty} (\beta p x - c)E\mu_E(x)dx,$$
$$\sigma_{red}^2(E) = \int_{x(0)}^{\infty} \sigma_g^2 E^2 \mu_E(x)dx.$$

Since $\int_{x(0)}^{\infty} \mu_E(x)dx = 1$, we obtain that

$$g_{red}(E) = \beta p E \int_{x(0)}^{\infty} x\mu_E(x)dx - cE,$$
$$\sigma_{red}^2(E) = \sigma_g^2 E^2.$$

Therefore, $\sigma_{red}(E) = \sigma_g E$,

$$\int_0^{\infty} x\mu_E(x)dx = \frac{\int_{x(0)}^{\infty} x^{-N+1} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\} dx}{\int_{x(0)}^{\infty} x^{-N} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\} dx}.$$

Similarly, we also need to prove that $\int_{x(0)}^{\infty} x^{-N+1} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\}dx$ is convergent, as shown in the appendix. Furthermore, substituting $g_{red}(E)$ and $\sigma_{red}(E)$ into eq. (4.19), we have

$$dE(\tau) = \left(\beta p E \int_{x(0)}^{\infty} x\mu_E(x)dx - cE\right)d\tau + \sigma_g E dB_2(\tau).$$

□

Theorem 4.7. *System* (4.18) *has a globally unique positive solution, for any initial value* $(x(0), E(0)) \in \mathbb{R}_+^2$.

Proof. We verify the existence and uniqueness of the global positive solution by proving that system(4.18) satisfies the Lipschitz condition and linear growth condition.

Taking $L = \left|\beta p(\int_{x(0)}^{\infty} x\mu_E(x)dx)\right| + |c| + |\sigma_g|$, and we calculate that

$$\begin{aligned}
&|g_{red}(E_1) - g_{red}(E_2)| + |\sigma_{red}(E_1) - \sigma_{red}(E_2)| \\
&= \left|\beta p(\int_{x(0)}^{\infty} x\mu_E(x)dx) - c\right| |E_1 - E_2| + |\sigma_g||E_1 - E_2| \\
&= \left(\left|\beta p(\int_{x(0)}^{\infty} x\mu_E(x)dx) - c\right| + |\sigma_g|\right) |E_1 - R_2| \\
&\leqslant \left(\left|\beta p(\int_{x(0)}^{\infty} x\mu_E(x)dx)\right| + |c| + |\sigma_g|\right) |E_1 - E_2| \leqslant L|E_1 - E_2|,
\end{aligned}$$

and

$$\begin{aligned}
|g_{red}(E)| + |\sigma_{red}(E)| &= \left(\left|\beta p(\int_{x(0)}^{\infty} x\mu_E(x)dx) - c\right| + |\sigma_g|\right) |E| \\
&\leqslant \left(\left|\beta p(\int_{x(0)}^{\infty} x\mu_E(x)dx)\right| + |c| + |\sigma_g|\right) |E| \\
&\leqslant L(1 + |E|).
\end{aligned}$$

Therefore, the Lipschitz condition and linear growth condition are satisfied. □

Theorem 4.8. *For any $(x(0), E(0)) \in \mathbb{R}^2_+$, if $2\beta p \int_{x(0)}^{\infty} x\mu_E(x)dx < \sigma_g^2 + 2c$ is met, the system (4.18) exhibits a stationary distribution.*

Proof. The FPK equation for system (4.18) is

$$\frac{\partial P(E)}{\partial \tau} = \frac{\partial}{\partial E}\left(\beta pE\int_{x(0)}^{\infty} x\mu_E(x)dx - cE\right) p(E) + \frac{1}{2}\frac{\partial^2}{\partial E^2}\sigma_g^2 E^2 p(E).$$

In order to obtain the probability density function of the stationary distribution of $E(\tau)$, we need to solve for $\frac{\partial P(E)}{\partial \tau} = 0$. The calculated result is as follows

$$p(E) = ME^{-\frac{2\sigma_g^2 - 2\left(\beta p\int_{x(0)}^{\infty} x\mu_E(x)dx - c\right)}{\sigma_g^2}},$$

where M is a normalization constant.

Below we prove that $\int_{E(0)}^{+\infty} p(E)dE = 1$ which is holds, it indicates the existence of the probability density function of $E(\tau)$, which also proves the existence of a stationary distribution for system (4.18).

We prove that the integral

$$\int_{E(0)}^{+\infty} E^{-\frac{2\sigma_g^2 - 2\left(\beta p\int_{x(0)}^{\infty} x\mu_E(x)dx - c\right)}{\sigma_g^2}} dE$$

is convergent. Based on the condition

$$2\beta p\int_{x(0)}^{\infty} x\mu_E(x)dx < \sigma_g^2 + 2c,$$

we obtain

$$-\frac{2\sigma_g^2 - 2\left(\beta p\int_{x(0)}^{\infty} x\mu_E(x)dx - c\right)}{\sigma_g^2} > 1.$$

According to the convergence rule of integrals, when $-\frac{2\sigma_g^2-2\left(\beta p\int_{x(0)}^{\infty}x\mu_E(x)dx-c\right)}{\sigma_g^2}>1$, the integral is convergent. At this point, there must exist a constant M that makes $\int_{E(0)}^{+\infty}p(E)dE=1$. Thus, Theorem 4.8 is proven. □

Remark 4.9. Calculating the integral $\int_{x(0)}^{\infty}x^{-N}\exp\left\{\frac{2(K+A)}{\sigma_f^2}x-\frac{K}{\sigma_f^2}x^2\right\}dx$ is too complex, and we have not provided an exact solution for the integral here. We have only proven that the integral is convergent. For more accurate results, one can use Matlab or Maple to find its numerical solution.

5 Stochastic model with weak Allee effect

In this section, we consider the time scale parameter ε as a regular parameter and discuss the stochastic behavior of the system (4.17). We discussed the existence of a stationary distribution for system (4.17) and the stochastic bifurcation of the system (4.17).

5.1 Existence and uniqueness of global positive solutions

When discussing the dynamic behavior of biological systems, the first thing we need to focus on is whether the system has a global positive solution. So we presented the theorem about the existence of a unique global positive solution for system (4.17):

Theorem 5.1. *Let $-K<A<0$, for any initial value taken from $(x(0),E(0))\in\mathbb{R}_+^2$, system (4.17) has a unique global positive solution $(x(\tau),E(\tau))$(where $\tau\geq 0$). And the solution is always within $\mathbb{R}_+^2$ with probability 1, which means that for any $\tau\geq 0$, $(x(\tau),E(\tau))\in\mathbb{R}_+^2$ almost surely (a.s.).*

Proof. For any initial value $(x(0),E(0))\in\mathbb{R}_+^2$, the system always has a solution $(x(\tau),E(\tau))\in\mathbb{R}_+^2$ at $t\in[0,\tau_e)$, τ_e is the moment of explosion. To prove that the solution is a global solution, it is only necessary to prove that $\tau_e=\infty$ a.s. Assuming that $n_0\geq 1$ is sufficiently large such that $(x(0),E(0))\in(\frac{1}{n_0},n_0)$. For any integer $n>n_0$, define the stopping time:

$$\tau_n=\inf\left\{\tau\in(0,\tau_e):\ \min\left\{x(\tau),E(\tau)\right\}\leq\tfrac{1}{n}\ \text{or}\ \max\left\{x(\tau),E(\tau)\right\}\geq n\right\},$$

where we assume that $inf\,\emptyset=\infty$ in this article (as is common, $\emptyset$ denotes the empty set). Obviously, τ_n monotonically increases when $n\to\infty$. Let $\tau_\infty=\lim_{n\to\infty}\tau_n$, where $\tau_\infty\leq\tau_n$ a.s. If $\tau_\infty=\infty$ a.s. holds, then $\tau_e=\infty$ a.s also holds, and there is $(x(\tau),E(\tau))\in\mathbb{R}_+^2$ for all $\tau\geq 0$, so we only need to prove that $\tau_\infty=\infty$ a.s. Otherwise, there will be a pair of constants $T>0$, $\eta\in(0,1)$, such that $P\left\{\tau_n\leq T\right\}>\eta$. Therefore, there is an integer $n_1\geq n_0$ such that $P\left\{\tau_n\leq T\right\}\geq\eta$ for all $n>n_1$.

Define a C^2-function $V:\mathbb{R}_+^2\to\mathbb{R}$ by

$$V(x(\tau),E(\tau))=x-a-a\ln\frac{x}{a}+b(E-1-\ln E),\tag{5.1}$$

where a and b are positive constants, it is easy to obtain that $V(x,E)$ is a nonnegative function. Using Itô's formula, we obtain

$$dV(x,E)=LV(x,E)d\tau+\frac{\sigma_f}{\sqrt{\varepsilon}}(x-a)dB_1(\tau)+b\sigma_g(E-1)dB_2(\tau),\tag{5.2}$$

where $LV(x,E)$: $\mathbb{R}^2_+ \to \mathbb{R}$ is defined as follows:

$$\begin{aligned} LV(x,E) = & -\frac{K}{\varepsilon}x^3 + \frac{A+K}{\varepsilon}x^2 - \frac{A}{\varepsilon}x + \frac{\alpha}{\varepsilon}xE + \frac{\alpha K}{\varepsilon}x^2 - \frac{\alpha(A+K)}{\varepsilon}x \\ & + \frac{aA}{\varepsilon} + \frac{\alpha a}{\varepsilon}E + b\beta pxE - bcE - b\beta px + bc + \frac{a\sigma_f^2}{2\varepsilon} + \frac{b\sigma_g^2}{2} \\ = & -\frac{K}{\varepsilon}x^3 + \frac{A+K+aK}{\varepsilon}x^2 - \frac{A+a(A+K)+b\varepsilon\beta p}{\varepsilon}x \\ & + \left(\frac{\alpha a}{\varepsilon} - bc\right)E + \left(b\beta p - \frac{\alpha}{\varepsilon}\right)xE + \frac{aA}{\varepsilon} + bc + \frac{a\sigma_f^2}{2\varepsilon} + \frac{b\sigma_g^2}{2}, \end{aligned}$$

Take $a = \frac{c}{\beta p}$, $b = \frac{\alpha}{\varepsilon\beta p}$, so that $\frac{\alpha a}{\varepsilon} - bc = 0$ and $b\beta p - \frac{\alpha}{\varepsilon} = 0$, then

$$\begin{aligned} LV(x,E) = & -\frac{K}{\varepsilon}x^3 + \frac{A+K+aK}{\varepsilon}x^2 - \frac{A+a(A+K)+b\varepsilon\beta p}{\varepsilon}x + \frac{aA}{\varepsilon} + bc + \frac{a\sigma_f^2}{2\varepsilon} + \frac{b\sigma_g^2}{2} \\ \le & \, b_1 + \frac{aA}{\varepsilon} + bc + \frac{a\sigma_f^2}{2\varepsilon} + \frac{b\sigma_g^2}{2} =: M, \end{aligned}$$

where $b_1 = \sup_{x\in(0,+\infty)}\left\{-\frac{K}{\varepsilon}x^3 + \frac{A+K+aK}{\varepsilon}x^2 - \frac{A+a(A+K)+b\varepsilon\beta p}{\varepsilon}x\right\}$, M is a constant. Then we can obtain

$$dV(x,E) \le Md\tau + \frac{\sigma_f}{\sqrt{\varepsilon}}(x-a)dB_1(\tau) + b\sigma_g(E-1)dB_2(\tau). \tag{5.3}$$

Integrating from 0 to $\tau_n \wedge T$ at both sides of (5.3), we have:

$$\begin{aligned} V(x(\tau_n\wedge T), E(\tau_n\wedge T)) \le & \, V(x(0),E(0)) + M(x(\tau_n\wedge T)) \\ & + \int_0^{\tau_n\wedge T}\frac{\sigma_f}{\sqrt{\varepsilon}}(x-a)dB_1(\tau) + b\int_0^{\tau_n\wedge T}\sigma_g(E-1)dB_2(\tau). \end{aligned}$$

By taking the expected values from both sides of the above equation, we can obtain

$$\begin{aligned} EV(x(\tau_n\wedge T), E(\tau_n\wedge T)) & \le V(x(0),E(0)) + ME(\tau_n\wedge T) \\ & \le V(x(0),E(0)) + MT. \end{aligned} \tag{5.4}$$

Therefore, let $\Omega_n = \{\omega\in\Omega, \tau_n = \tau_n(\omega) \le T\}$, it can be obtained that $P(\Omega_n) > \eta$ for all $n \ge n_0$. For each $\omega\in\Omega_n$, $x(\tau,\omega)$ and $E(\tau,\omega)$ have at least one equal to n or $\frac{1}{n}$, then we get

$$\begin{aligned} & V(x(0),E(0)) + MT \\ & \quad \ge E(I_{\Omega_n}V(x(\tau_n,\omega),E(\tau_n,\omega)) \\ & \quad \ge \eta\left[b(n-1-\ln n)\wedge b\left(\frac{1}{n}-1-\ln\frac{1}{n}\right)\wedge\left(n-a-a\ln\frac{n}{a}\right)\wedge\left(\frac{1}{n}-a+\ln an\right)\right], \end{aligned}$$

where $I_{\Omega_n(\omega)}$ is the indicative function of Ω_n. If $n\to\infty$, a contradiction arises where $\infty > V(x(0),E(0)) + MY = \infty$. Therefore, there is $\tau_\infty = \infty$ a.s. □

5.2 Stationary distribution and ergodic properties

A stationary distribution is characterized by the fluctuation of the solution of a stochastic system within a certain neighborhood of the positive equilibrium point of the corresponding deterministic system and can be regarded as weak stability. Next, we provide sufficient conditions for the existence of a stationary distribution in system (4.17).

Theorem 5.2. *Assuming* $\frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha} < \frac{c+\frac{\sigma_g^2}{c}}{c}$, $\varepsilon < \alpha c$ *and* $\beta p < \frac{1}{\varepsilon}$, *the system* (4.17) *has a stationary distribution and it has the ergodic property for any initial value* $(x(0), E(0)) \in \mathbb{R}_+^2$.

Proof. Define C^2-function V_1 as follows:

$$V_1(x,E) = v(x,E) + \alpha kE - v(x_1,E_1),$$

where $v(x,E) = kx - \frac{\varepsilon^2 k}{\alpha}\ln x + \frac{k}{c}\ln E + \frac{1}{E^\rho}$, k and $\rho(0<\rho<1)$ are positive numbers, $(x_1,E_1) = (\frac{\varepsilon^2}{\alpha}, (\frac{k}{c\rho})^{-\frac{1}{\rho}})$ is the minimum value point of $v(x,E)$.

Using Itô's formula, we get

$$\begin{aligned} LV_1 = & \frac{k}{\varepsilon}[x(1-x)(Kx-A) - \alpha xE] - \frac{\varepsilon k}{\alpha}[(1-x)(Kx-A) - \alpha E] \\ & + \frac{k}{c}(\beta px - c) - \rho E^{-\rho}(\beta px - c) + \alpha k(\beta px - c)E + \frac{k\varepsilon\sigma_f^2}{2\alpha} - \frac{k\sigma_g^2}{2c} + \frac{1}{2}\rho(\rho+1)\sigma_g^2 E^{-\rho} \\ = & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K) + \varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{\varepsilon k(A+K)}{\alpha}x - \frac{kA}{\varepsilon}x + \frac{k\beta p}{c}x \\ & - k(\alpha c - \varepsilon)E - k\left(\frac{\alpha}{\varepsilon} - \alpha\beta p\right)xE - \rho\beta pxE^{-\rho} + \rho E^{-\rho}\left(c + \frac{1}{2}\rho(\rho+1)\sigma_g^2\right) \\ & - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right). \end{aligned} \tag{5.5}$$

Considering a bounded closed set

$$U_{\eta_1} = \left\{(x,E) \in \mathbb{R}_+^2, \eta_1 \le x \le \frac{1}{\eta_1}, \eta_1 \le E \le \frac{1}{\eta_1}\right\}.$$

Furthermore, we can obtain

$$\mathbb{R}_+^2 \setminus U_{\eta_1} = U_1 \cup U_2 \cup U_3 \cup U_4,$$

where

$$\begin{aligned} U_1 &= \left\{(x,E) \in \mathbb{R}_+^2, E > \frac{1}{\eta_1}\right\}; \qquad & U_2 &= \left\{(x,E) \in \mathbb{R}_+^2, 0 < x < \eta_1\right\}; \\ U_2 &= \left\{(x,E) \in \mathbb{R}_+^2, 0 < E < \eta_1\right\}; \qquad & U_4 &= \left\{(x,E) \in \mathbb{R}_+^2, x > \frac{1}{\eta_1}\right\}. \end{aligned}$$

We choose $\eta_1 > 0$ as a sufficiently small constant and satisfy the following conditions:

$$B_1 - k(\alpha c - \varepsilon)\frac{1}{\eta_1} + \rho\eta_1^\rho(c + \frac{1}{2}(\rho+1)\sigma_g^2) \le -1, \tag{5.6}$$

$$\frac{2\beta p\eta_1}{c\left(\frac{c+\frac{\sigma_g^2}{2}}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right)} < \frac{1}{2}, \tag{5.7}$$

$$\frac{2\varepsilon\eta_1}{\frac{c+\frac{\sigma_g^2}{2}}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}} < \frac{1}{2}, \tag{5.8}$$

$$D_1 - \frac{\alpha k(A+K) + \varepsilon^2 kK}{\alpha\varepsilon\eta_1} < -1, \tag{5.9}$$

where B_2 and D_2 are positive constants that can be determined from the following inequalities (5.10), (5.12). Next, we prove that LV_1 is negative in regions U_i, $i = 1, 2, 3, 4$.

Case 1: If $(x, E) \in U_1$, we have

$$\begin{aligned} LV_1 \leq & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{\alpha kA+\varepsilon^2 k(A+K)}{\alpha\varepsilon}x \\ & + \frac{k\beta p}{c}x - k(\alpha c-\varepsilon)E + \rho E^{-\rho}\left(c+\frac{1}{2}\rho(\rho+1)\sigma_g^2\right) \\ \leq & B_1 - k(\alpha c-\varepsilon)E + \rho E^{-\rho}\left(c+\frac{1}{2}\rho(\rho+1)\sigma_g^2\right) \\ \leq & B_1 - k(\alpha c-\varepsilon)\frac{1}{\eta_1} + \rho\eta_1^{\rho}\left(c+\frac{1}{2}\rho(\rho+1)\sigma_g^2\right), \end{aligned} \tag{5.10}$$

where

$$B_1 = \sup_{x\in(0,+\infty)}\left\{-\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{\alpha kA+\varepsilon^2 k(A+K)}{\alpha\varepsilon}x + \frac{k\beta p}{c}x\right\}.$$

According to condition (5.6), we can obtain that $LV_1 \leq -1$ on U_1.

Case 2: If $(x, E) \in U_2$, one can see that

$$\begin{aligned} LV_1 \leq & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{kA}{\varepsilon}x + \frac{k\beta p}{c}x - k(\alpha c-\varepsilon)E \\ & + \rho E^{-\rho}\left(c+\frac{1}{2}\rho(\rho+1)\sigma_g^2\right) - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right) + \frac{k\beta p}{c}x \\ \leq & C_1 - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right) + \frac{k\beta p}{c}x \\ \leq & C_1 - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right) + \frac{k\beta p}{c}\eta_1, \end{aligned} \tag{5.11}$$

where

$$\begin{aligned} C_1 = \sup_{(x,E)\in\mathbb{R}_+^2}\Big\{ & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{kA}{\varepsilon}x + \frac{k\beta p}{c}x \\ & -k(\alpha c-\varepsilon)E + \rho E^{-\rho}\left(c+\frac{1}{2}\rho(\rho+1)\sigma_g^2\right)\Big\}. \end{aligned}$$

If we choose $k = \dfrac{2C_1}{\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}}$, we can obtain

$$LV_1 \leq -C_1 + \frac{2\beta p C_1\eta_1}{c\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right)}.$$

It follows from (5.7), we can obtain $LV_1 \leq -\frac{C_1}{2}$ on U_2.

Case 3: If $(x, E) \in U_3$, we have

$$\begin{aligned} LV_1 \leq & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{kA}{\varepsilon}x + \frac{k\beta p}{c}x - k(\alpha c-\varepsilon)E \\ & + \rho E^{-\rho}\left(c + \frac{1}{2}\rho(\rho+1)\sigma_g^2\right) - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right) + k\varepsilon E \\ \leq & C_1 - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right) + k\varepsilon E \\ \leq & C_1 - k\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right) + k\varepsilon\eta_1, \end{aligned}$$

where $k = \frac{2C_1}{\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}}$, C_1 is given by (5.11), then we can obtain

$$LV_1 \leq -C_1 + \frac{2\varepsilon C_1\eta_1}{c\left(\frac{(c+\frac{\sigma_g^2}{2})}{c} - \frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}\right)}.$$

According to condition (5.8), we can obtain $LV_1 \leq -\frac{C_2}{2}$ on U_3.

Case 4: If $(x, E) \in U_4$, one can see that

$$\begin{aligned} LV_1 \leq & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{kA}{\varepsilon}x + \frac{k\beta p}{c}x - k(\alpha c-\varepsilon)E \\ & + \rho E^{-\rho}\left(c + \frac{1}{2}\rho(\rho+1)\sigma_g^2\right) - \frac{\alpha kA+\varepsilon^2 k(A+K)}{\alpha\varepsilon}x \\ \leq & D_1 - \frac{\alpha kA+\varepsilon^2 k(A+K)}{\alpha\varepsilon}x \\ \leq & D_1 - \frac{\alpha kA+\varepsilon^2 k(A+K)}{\alpha\varepsilon\eta_1}, \end{aligned} \tag{5.12}$$

where

$$\begin{aligned} D_1 = \sup_{x\in(0,+\infty)}\Bigg\{ & -\frac{kK}{\varepsilon}x^3 + \frac{\alpha k(A+K)+\varepsilon^2 kK}{\alpha\varepsilon}x^2 - \frac{kA}{\varepsilon}x + \frac{k\beta p}{c}x \\ & -k(\alpha c-\varepsilon)E + \rho E^{-\rho}\left(c + \frac{1}{2}\rho(\rho+1)\sigma_g^2\right)\Bigg\}. \end{aligned}$$

According to condition (5.9), we can conclude that $LV_1 \leq -1$ on U_4. Thus we can obtain that for a enough small η, $LV_1 \leq -\max\left\{1, \frac{C_1}{2}\right\}$ for all $(x, E) \in \mathbb{R}^2_+ \setminus U_{\eta_1}$.

In addition, the diffusion matrix of system (4.17) is

$$\begin{pmatrix} \frac{\sigma_f^2}{\varepsilon}x^2 & 0 \\ 0 & \sigma_g^2 E^2 \end{pmatrix}.$$

Choose

$$M_1 = \min_{(x,E)\in\mathbb{R}^2_+\setminus U_{\eta_1}} \left\{ \frac{\sigma_f^2}{\varepsilon}x^2, \sigma_g^2 E^2 \right\},$$

we have

$$\frac{\sigma_f^2}{\varepsilon}x^2\xi_1^2 + \sigma_g^2 E^2\xi_2^2 \geq M_1|\xi^2|, \ \ (x,E)\in\mathbb{R}^2_+\setminus U_{\eta_1}, \ \ \xi = (\xi_1,\xi_2)\in\mathbb{R}^2_+.$$

Therefore, the system has a stationary distribution and it has the ergodic property. □

Combining Theorem 4.6 and 4.7, we can conclude that both the system (4.17) without random reduction and the system (4.18) after random reduction have globally unique positive solutions. And under certain conditions, they have stationary distribution.

Remark 5.3. The existence of a stationary distribution indicates that under current fishing and environmental conditions, fish populations can maintain a relatively healthy quantity state, which is conducive to the sustainable development of fisheries. For fisheries practitioners and managers, a stationary distribution is an important reference for formulating fishing strategies and fisheries management policies. It can help determine a reasonable fishing intensity to achieve a balance between economic and ecological benefits. If the stable distribution of fish populations indicates relatively abundant resources, then it is appropriate to reduce aquaculture inputs and increase fishing output; On the contrary, if the stable distribution shows that the resources are at an unstable or low level, it is necessary to increase aquaculture efforts and control fishing intensity to ensure the sustainable development of the fishery economy.

5.3 Stochastic stability

In this section, the stability and bifurcation behavior of the stochastic system (4.16) near its internal equilibrium point S_* will be discussed. In order to obtain stochastic differential equations in small parameter form, we introduce the following standard rescalings [26]:

$$K = \varepsilon\tilde{K}, \quad A = \varepsilon\tilde{A}, \quad \alpha = \varepsilon\tilde{\alpha}, \quad \sigma_f = \sqrt{\varepsilon}\tilde{\sigma}_f,$$

where $0 < \varepsilon \ll 1$ is the time scale parameter. And system (4.16) is transformed into:

$$\begin{cases} dx = \varepsilon[x(1-x)(\tilde{K}x - \tilde{A}) - \tilde{\alpha}Ex]dt + \sqrt{\varepsilon}\tilde{\sigma}_f x dB_1(t) =: \varepsilon\tilde{f}(x,E,\varepsilon)dt + \tilde{\sigma}_f x dB_1(t), \\ dE = \varepsilon(\beta p x - c)Edt + \sqrt{\varepsilon}\sigma_g E dB_2(t) =: \varepsilon g(x,E)dt + \sqrt{\varepsilon}\sigma_g E dB_2(t), \end{cases} \tag{5.13}$$

which system (5.13) is a regular stochastic differential equation. In order to better study the dynamic behavior near the equilibrium point $\tilde{S}_*(\tilde{x}_*, \tilde{E}_*)$ where $\tilde{x}_* = \frac{c}{\beta p}$, $w\tilde{E}_* = \frac{(1-\tilde{x}_*)(\tilde{K}\tilde{x}_* - \tilde{A})}{\tilde{\alpha}}$, we translate it to the origin and perform a polar coordinate transformation $x = \tilde{x}_* + r\cos\theta$, $E = \tilde{E}_* + r\sin\theta$, and system (5.13) is transformed into the following form:

$$\begin{cases} dr = \varepsilon f_1(r,\theta,\varepsilon)dt + \sqrt{\varepsilon}g_{11}(r,\theta,\varepsilon)dB_1(t) + \sqrt{\varepsilon}g_{12}(r,\theta,\varepsilon)dB_2(t), \\ d\theta = \varepsilon f_2(r,\theta,\varepsilon)dt + \sqrt{\varepsilon}g_{21}(r,\theta,\varepsilon)dB_1(t) + \sqrt{\varepsilon}g_{22}(r,\theta,\varepsilon)dB_2(t), \end{cases} \tag{5.14}$$

where

$$\begin{aligned} f_1(r,\theta) &= r\left((\tilde{A} + \tilde{K} - 2\tilde{K}\tilde{x}_*)\tilde{x}_*\cos^2\theta - \tilde{\alpha}\tilde{x}_*\sin\theta\cos\theta + \beta p\tilde{E}_*\sin\theta\cos\theta\right) \\ &\quad + r^2\left(-3(\tilde{K}\tilde{x}_* - \tilde{A} - \tilde{K})\cos^3\theta - \tilde{\alpha}\sin\theta\cos^2\theta + \beta p\sin^2\theta\cos\theta\right) - r^3\tilde{K}\cos^4\theta, \\ g_{11}(r,\theta) &= \tilde{\sigma}_f r\cos^2\theta,\ g_{12}(r,\theta) = \sigma_g r\sin^2\theta, \\ f_2(r,\theta) &= \left(\beta p\tilde{E}_*\cos^2\theta - (\tilde{A} + \tilde{K} - 2\tilde{K}\tilde{x}_*)\tilde{x}_*\sin\theta\cos\theta + \tilde{\alpha}\tilde{x}_*\sin^2\theta\right) \\ &\quad + r\left(\beta p\sin\theta\cos^2\theta + (3\tilde{K}\tilde{x}_* - \tilde{A} - \tilde{K})\sin\theta\cos^2\theta + \tilde{\alpha}\sin^2\theta\cos\theta\right) + r^3\tilde{K}\sin\theta\cos^3\theta, \\ g_{21}(r,\theta) &= -\tilde{\sigma}_f\sin\theta\cos\theta,\ g_{22}(r,\theta) = \sigma_g\sin\theta\cos\theta. \end{aligned}$$

According to the Khasminskii's limit theorem in [16,44], when the intensities of noise σ_f and σ_g are small and $\varepsilon \to 0$, on the time interval of ε^{-1} magnitude, the process $\{r(t),\theta(t)\}$ of system (5.14) weakly converges to a two-dimensional Markov diffusion process. Through the application of the stochastic averaging method, a stochastic differential equation as follows is obtained.

$$\begin{cases} dr = f_r(r)dt + \sigma_{11}(r)dB_r(t) + \sigma_{12}(r)dB_\theta(t), \\ d\theta = f_\theta(r)dt + \sigma_{21}(r)dB_r(t) + \sigma_{22}(r)dB_\theta(t), \end{cases} \tag{5.15}$$

where $B_r(t)$ and $B_\theta(t)$ are independent standard Wiener processes, and the coefficients of system (5.15) satisfy

$$\begin{aligned} f_r &= \varepsilon\left(\frac{(\tilde{A}+\tilde{K}-2\tilde{K}\tilde{x}_*)r\tilde{x}_*}{2} + \frac{5r}{8}(\tilde{\sigma}_f^2+\sigma_g^2) - \frac{r}{4}\tilde{\sigma}_f\sigma_g - \frac{3r^3\tilde{K}}{8}\right) \\ &= \frac{(A+K-2Kx_*)rx_*}{2} + \frac{5r}{8}(\sigma_f^2+\varepsilon\sigma_g^2) - \frac{r}{4}\sqrt{\varepsilon}\sigma_f\sigma_g - \frac{3r^3K}{8}, \\ f_\theta &= \frac{\varepsilon}{2}(\tilde{\alpha}\tilde{x}_* + \beta p\tilde{E}_*) = \frac{1}{2}(\alpha x_* + \varepsilon\beta pE_*), \\ \sigma_{12} &= \sigma_{21} = 0, \\ \sigma_{11}^2 &= \frac{3\varepsilon r^2}{8}\left(\tilde{\sigma}_f^2+\sigma_g^2+\frac{2}{3}\tilde{\sigma}_f\sigma_g\right) = \frac{3r^2}{8}\left(\sigma_f^2+\varepsilon\sigma_g^2+\frac{2}{3}\sqrt{\varepsilon}\sigma_f\sigma_g\right), \\ \sigma_{22}^2 &= \frac{\varepsilon}{8}(\tilde{\sigma}_f-\sigma_g)^2 = \frac{1}{8}(\sigma_f-\varepsilon\sigma_g)^2. \end{aligned}$$

We can easily conclude that in system (5.15), the modulus equation and phase equation are decoupled. In order to study the stability and branching phenomena of system (4.16), we only need to discuss the mean modulus equation of system (5.15), which is

$$dr = f_r(r)dt + \sigma_{11}(r)dB_r(t). \tag{5.16}$$

For convenience, we introduce the following notation:

$$c_1 = \frac{(A+K-2Kx_*)x_*}{2},\ c_2 = 5(\sigma_f^2+\varepsilon\sigma_g^2) - 2\sqrt{\varepsilon}\sigma_f\sigma_g, c_3 = 3K,\ c_4 = 3\left(\sigma_f^2+\varepsilon\sigma_g^2+\frac{2}{3}\sqrt{\varepsilon}\sigma_f\sigma_g\right).$$

Therefore, we can rewrite system (5.16) as

$$dr = \left(\left(c_1+\frac{c_2}{8}\right)r - \frac{c_4}{8}r^3\right)dt + \left(\frac{c_4}{8}r^2\right)^{\frac{1}{2}}dB_r(t). \tag{5.17}$$

We know that $r=0$ is a fixed point of system (5.16), corresponding to the trivial solution of the original system (4.17). This section discusses the stability of the fixed points of system (5.16), as well as the stability of the singularity S_* of system (4.17).

We adopt the Lyapunov exponent method to determine the local stability of the trivial solution of system (5.17). Consider the linear Itô stochastic differential equation for system (5.17):

$$dr = \left(c_1+\frac{c_2}{8}\right)rdt + \left(\frac{c_4}{8}r^2\right)^{\frac{1}{2}}dB_r(t). \tag{5.18}$$

By utilizing the solution of Itô's stochastic differential equation, we can obtain a solution of (5.18):

$$r(t) = r(0)\exp\left\{\int_0^t\left(c_1+\frac{c_2}{8}-\frac{c_4}{16}\right)ds + \int_0^t\left(\frac{c_4}{8}\right)^{\frac{1}{2}}dB_r(s)\right\}.$$

We obtained the Lyapunov exponent of system (5.17), which is given

$$\lambda(t) = \lim_{t\to\infty} \frac{1}{t} \ln \|r(t)\| = \lim_{t\to\infty} \frac{1}{2t} \ln r(t) = \frac{1}{2}\left(c + \frac{c_2}{8} - \frac{c_4}{16}\right). \tag{5.19}$$

Therefore, the trivial solution of system (5.18) is asymptotically stable with a probability of 1, when $\lambda < 0$, i.e. $c_1 + \frac{c_2}{8} - \frac{c_4}{16} < 0$. Moreover, it has robustness against high-order random disturbances, which results in the asymptotic stability of the trivial solution of the original nonlinear system (5.17) with probability 1.

Therefore, we can obtain that:

Theorem 5.4. *If $\lambda < 0$, i.e. $c_1 + \frac{c_2}{8} - \frac{c_4}{16} < 0$, the trivial solution of system (5.17) is locally asymptotically stable with probability 1. If $\lambda > 0$, i.e. $c_1 + \frac{c_2}{8} - \frac{c_4}{16} > 0$, the trivial solution of system (5.17) is unstable. If $\lambda = 0$, i.e. $c_1 + \frac{c_2}{8} - \frac{c_4}{16} = 0$, system (5.17) may experience bifurcation.*

We use singular boundary theory to discuss the global stability of S_* of system (4.17). According to the theory of singular boundaries, when $r \to 0^+$, $\sigma_{11} = 0$, therefore $r = 0$ is the first type of singular boundary. After calculation, the diffusion index α_l, drift index β_l, and characteristic value c_l can be obtained that

$$\alpha_l = 2, \quad \beta_l = 1, \quad c_l = \lim_{r\to 0^+} \frac{2f_r(r)r^{\alpha_l - \beta_l}}{\sigma_{11}^2(r)} = \frac{16c_1 + 2c_2}{c_4}.$$

Therefore, it can be concluded that:

(a) When $c_l < 1$, i.e. $c_4 > 16c_1 + 2c_2$, the bound $r = 0$ is attractively natural;

(b) When $c_l > 1$, i.e. $c_4 < 16c_1 + 2c_2$, the bound $r = 0$ is repulsively nature;

(c) When $c_l = 1$, i.e. $c_4 = 16c_1 + 2c_2$, the bound $r = 0$ is strictly natural.

The right boundary $r = \infty$ is the second type of singular boundary, because when $r \to \infty$, $|f_r| \to \infty$. By calculation, the diffusion index $\alpha_r = 2$ and the drift index $\beta_r = 3$ can be obtained. Additionally, since $f_r(\infty) < 0$, the right boundary $r = \infty$ is an entrance boundary.

We know that all solutions of the system will enter from the right boundary and then be attracted to the left boundary, when $r = 0$ is attractively nature and $r = \infty$ is an entrance boundary. This implies that the trivial solution of system (5.17) is globally stable, which coincides with the conclusion derived by employing the Lyapunov exponent method. In other words, the trivial solution of the system is both locally and globally stable.

Therefore, we provide the following theorem:

Theorem 5.5. *The trivial solution of system (5.17) is globally stable for $c_4 > 16c_1 + 2c_2$. The trivial solution of system (5.17) is unstable for $c_4 < 16c_1 + 2c_2$. System (5.17) may undergo bifurcation for $c_4 = 16c_1 + 2c_2$.*

Remark 5.6. We refer to the method in reference [26] and transform system (4.16) into system (5.13) by introducing appropriate transformations. It should be pointed out that reference [26] uses the regular perturbation method to transform the original system into a weakly perturbed system, while the processing method in this paper differs from it. Specifically, since the system (4.16) already contains a small parameter ε, we only implement the transformation on the first equation of system (4.16). Although the transformed system (5.13) has similarities in form with weakly perturbed systems, due to significant differences in magnitude between $\tilde{f}(x, E, \varepsilon)$

and $g(x,E)$ (where $\tilde{f}(x,E,\varepsilon) = O(1/\varepsilon)$ and $g(x,E) = O(1)$), the system (5.13) still maintains typical fast-slow system characteristics. This property is mainly reflected in: There is a clear separation in the time scale of system variables; The evolution rates of fast variable x and slow variable E maintain a difference in magnitude between $O(1)$ and $O(\varepsilon)$; This conclusion differs fundamentally from the weak perturbation system obtained through regular perturbation in reference [26] in terms of mathematical properties, and also reflects the characteristics of the processing method proposed in this paper.

5.4 Stochastic bifurcation

In this section, we will study the bifurcation behavior of the system from a dynamic perspective.

Theorem 5.7. *Stochastic system* (5.17) *will generate a D-bifurcation as the value of bifurcation parameter* c_4 *passed through* $16c_1 + 2c_2$.

Proof. Consider the linear stochastic differential equation (5.18), which is equivalent to a Stratonovich stochastic differential equation:

$$dr = \left(c_1 + \frac{c_2}{8} - \frac{c_4}{16}\right) r dt + \left(\frac{c_4}{8} r^2\right)^{\frac{1}{2}} dB_r(t). \tag{5.20}$$

Let $m_1(r) = (c_1 + \frac{c_2}{8} - \frac{c_4}{16})r$, $\sigma_1(r) = (\frac{c_4}{8}r^2)^{\frac{1}{2}}$, system (5.20) can be rewritten as

$$dr = m_1(r)dt + \sigma_1(r)dB_r(t). \tag{5.21}$$

The continuous dynamic system generated by it is

$$\varphi(t)x = x + \int_0^t m_1(\varphi(s)x)ds + \int_0^t \sigma_1(\varphi(s)x)dB_r(s),$$

where $m_1(r) = 0$ and $\sigma_1(0) = 0$, thus 0 is a fixed point of $\varphi(x)$. Since $m_1(r)$ is bounded, the condition $\sigma_1(0) \neq 0$ is satisfied for any $m_1(r) \neq 0$, ensuring that there exists at most one stationary probability density. We have

$$\frac{\partial p}{\partial t} = -\frac{\partial}{\partial r}\left(\left(c_1 + \frac{c_2}{8}\right) p\right) + \frac{1}{2}\frac{\partial^2}{\partial r^2}\left(\left(\frac{c_4}{8} r^2\right) p\right). \tag{5.22}$$

which is the FPK equation for system (5.18).

Solving for $\frac{\partial p}{\partial t} = 0$, we obtain

$$p(r) = c \mid \sigma_1^{-1}(r) \mid \exp\left(\int_0^r \frac{2m_1(s)}{\sigma_1^2(s)} ds\right), \tag{5.23}$$

where c is constant. The system (5.22) has two possible equilibrium states: fixed point and non trivial stationary motion. The density of the invariant measure δ_0 for the former is $\delta(x)$, while the density of the invariant measure v for the latter is (5.23). As calculated, the solution for system (5.21) is

$$r(t) = r(0) \exp\left[\int_0^t (m_1'(r) + \frac{\sigma_1(r)\sigma_1''(r)}{2})ds + \int_0^t \sigma_1'(r)dB_r(s)\right]. \tag{5.24}$$

The Lyapunov exponent of a stochastic dynamical system with regard to the measure μ is

$$\lambda_{\varphi}(\mu) = \lim_{t\to\infty} \frac{1}{t} \ln \|r(t)\| . \tag{5.25}$$

Substitute (5.24) into(5.25), we obtain that

$$\begin{aligned}\lambda\varphi(\delta_0) &= \lim_{t\to+\infty} \frac{1}{t}\left[\ln r(0) + m_1'(0)\int_0^t ds + \sigma_1'(r)\int_0^t dB_r(s)\right] \\ &= m_1'(0) + \sigma_1'(0)\lim_{t\to+\infty}\frac{B_r(t)}{t} = m_1'(0) = c_1 + \frac{c_2}{8} - \frac{c_4}{16}.\end{aligned}$$

For the invariant measure v with a density of (5.23), the Lyapunov exponent is

$$\begin{aligned}\lambda_{\varphi}(v) &= \lim_{t\to\infty}\frac{1}{t}\int_0^t \left(m_1' + \frac{\sigma_1\sigma_1''}{2}\right)(r)ds \\ &= -32\sqrt{2}c_4^{\frac{3}{2}}\left(c_1 + \frac{c_2}{8} - \frac{c_4}{16}\right)^2 \exp\left(\frac{16}{c_4}\left(\frac{c_2}{8} - \frac{c_4}{16}\right)\right) < 0.\end{aligned}$$

In conclusion, if $c_4 > 16c_1 + 2c_2$, the fixed-point invariant measure is stable; if $c_4 < 16c_1 + 2c_2$, it is unstable; if $c_4 = 16c_1 + 2c_2$, system (5.17) undergoes a D-bifurcation. □

Theorem 5.8. *Stochastic system* (5.17) *will generate P-bifurcation as the value of bifurcation parameter* c_4 *passed through* $8c_1 + c_2$.

Proof. Based on the amplitude $r(t)$ of the stochastic differential equation, we calculate its FPK equation as follows:

$$\frac{\partial p}{\partial r} = \left\{\left((c_1 + \frac{c_2}{8})r - \frac{c_3}{8}r^3\right)p\right\} + \frac{1}{2}\frac{\partial^2}{\partial r^2}\left((\frac{c_4}{8}r^2)p\right),$$

whose initial condition is

$$p(r,t|r_0,t_0) \to \delta(r - r_0), \quad t \to t_0,$$

where $p(r,t|r_0,t_0)$ represents the transition probability density of the diffusion process $r(t)$. The invariant measure of $r(t)$ is the steady-state probability density function $p_{st}(r)$, which serves as the solution to the following degenerate system:

$$-\frac{\partial}{\partial r}\left\{\left(\left(c_1 + \frac{c_2}{8}\right)r - \frac{c_3}{8}r^3\right)p\right\} + \frac{1}{2}\frac{\partial^2}{\partial r^2}\left(\frac{c_4}{8}r^2\right)p = 0.$$

By calculation, it can be concluded that

$$p_{st}(r) = \begin{cases} \dfrac{r^{\frac{16c_1+2c_2-2c_4}{c_4}} e^{-\frac{c_3}{c_4}r^2}}{\Gamma\left(\frac{8c_1+c_2}{c_4}\right)\left(\frac{c_4}{c_3}\right)^{\frac{8c_1+c_2}{c_4}}}, & c_4 < 16c_1 + 2c_2, \\ \delta_0, & c_4 \geq 16c_1 + 2c_2. \end{cases} \tag{5.26}$$

According to Namachivaya's theory, the extremum of invariant measures can explain the key characteristics of correlated nonlinear stochastic systems. If r_* represents the maximum value point of $p_{st}(r)$, the sample trajectory is likely to remain in the vicinity of r_* with a high probability, suggesting that r_* is stable in a probabilistic sense. Conversely, if $p_{st}(r)$ has a

minimum value, the situation is reversed.

To solve for the extremum of $p_{st}(r)$, we need to solve the following equation:

$$\frac{\left(\frac{16c_1+2c_2-2c_4}{c_4}-\frac{2c_3}{c_4}r^2\right)r^{\frac{16c_1+2c_2-3c_4}{c_4}}e^{-\frac{c_3}{c_4}r^2}}{\Gamma\left(\frac{8c_1+c_2}{c_4}\right)\left(\frac{c_4}{c_3}\right)^{\frac{8c_1+c_2}{c_4}}}=0.$$

By simple calculation, we obtain $r=0$ or $r_*=\sqrt{\frac{8c_1+c_2-c_4}{c_3}}$. The system reaches its maximum value at r_* if $c_4<8c_1+c_2$. Therefore, we can prove the following three situations:

Case (i): If $8c_1+c_2<c_4<16c_1+2c_2$ and $r\to 0^+$, $p_{st}(r)$ tends to infinity. At this time, the sample trajectory of the system is concentrated around $r=0$.

Case (ii): If $\frac{16c_1+2c_2}{3}<c_4<8c_1+c_2$, $p_{st}(r)$ attains its maximum at $r=r_*$ and its minimum at $r=0$. However, $p_{st}(r)$ is not differentiable at $r=0$ in this scenario.

Case (iii): If $c_4<\frac{16c_1+2c_2}{3}$, $p_{st}(r)$ attains its maximum at $r=r_*$ and its minimum at $r=0$. At this time, $p_{st}(r)$ is differentiable at $r=0$, and it is easy to find that $p_{st}(r)$ is smooth at $r=0$.

Based on the above analysis, we know that the shape of $p_{st}(r)$ will change from a monotonic to a unimodal as the c_4 value exceeds $8c_1+c_2$. System (5.17) generates a stochatic P-bifurcation if $c_4=\frac{16c_1+2c_2}{3}$. □

Remark 5.9. The sample trajectory of the system is concentrated around $r=0$ for $8c_1+c_2<c_4<16c_1+2c_2$, indicating a high probability of a small population size, which is not conducive to population growth. As c_4 decreases, the peak value of $p_{st}(r)$ narrows and shifts to the right (see Figure 5.2(a) and Figure 5.2(b)), indicating a higher probability of a larger population size, which is beneficial for population growth.

5.5 Numerical simulation

In this section, we will use data simulation to verify the correctness of the above theory.

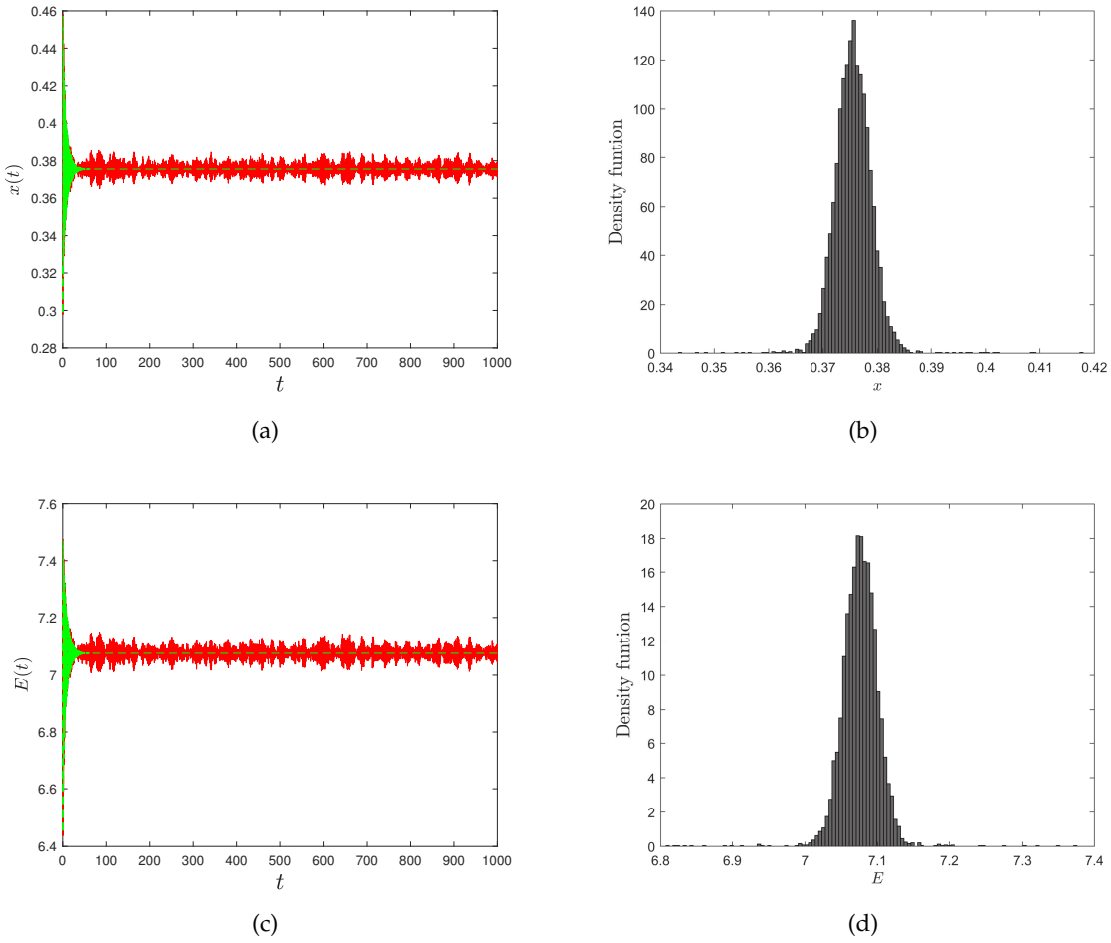
We select parameter $K=3$, $A=-0.8$, $\alpha=0.17$, $\varepsilon=0.1$, $\beta=1.5$, $p=3$, $c=1.69$, $\sigma_f=0.001$ and $\sigma_g=0.001$ and $\sigma_g=0.001$ in system (4.17), which satisfy the conditions

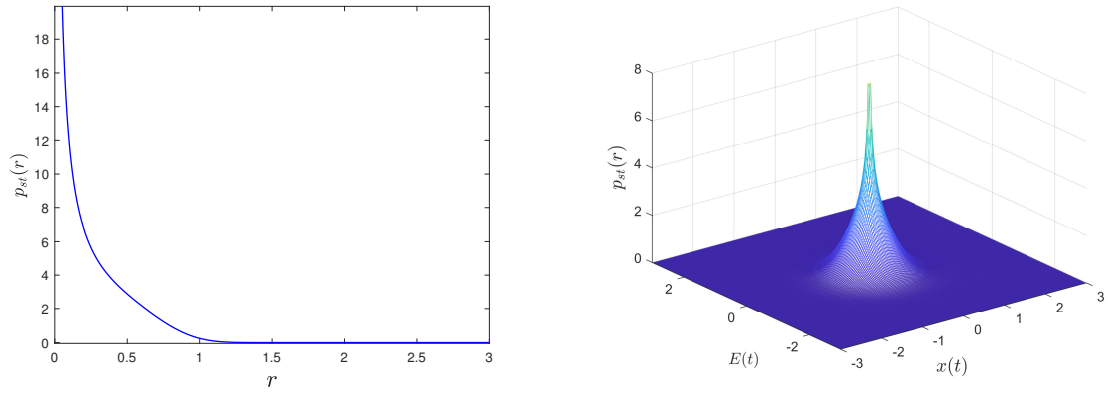
$$\frac{\varepsilon(A+\frac{\sigma_f^2}{2})}{\alpha}<\frac{c+\frac{\sigma_g^2}{c}}{c},\quad \varepsilon<\alpha c\quad\text{and}\quad \beta p<\frac{1}{\varepsilon}$$

(the data source from Table 3.2.). According to Theorem 5.2, it is known that system (4.17) has a stationary distribution. In a sense, it also indicates that small-scale noise is beneficial for system stability. As shown in Figure 5.1. The values of $x(t)$ and $E(t)$ in Figure 5.1(a) and Figure 5.1(c) oscillate slightly around the equilibrium point of the deterministic system. The bar charts in Figure 5.1(b) and Figure 5.1(d) show that system (4.17) exhibits a stationary distribution.

Next, we will verify the conclusion of stochastic bifurcation through numerical simulation. We select parameters $c_1=0.25$, $c_2=3$, $c_3=10$ and $c_4=5$ so that they satisfy the case (i) in the proof of Theorem 5.8. Figure 5.2 shows the stationary probability density $p_{st}(r)$ of system (5.17), from which we can see that $p_{st}(r)$ tends towards infinity when $r\to 0^+$.

We select parameters $c_1=0.25$, $c_2=3$, $c_3=10$ and $c_4=3.5$ so that they satisfy the case (ii). Figure 5.3 shows the graph of $p_{st}(r)$, from which we can see that $p_{st}(r)$ reaches its maximum at $r=r_*$ and its minimum at $r=0$.





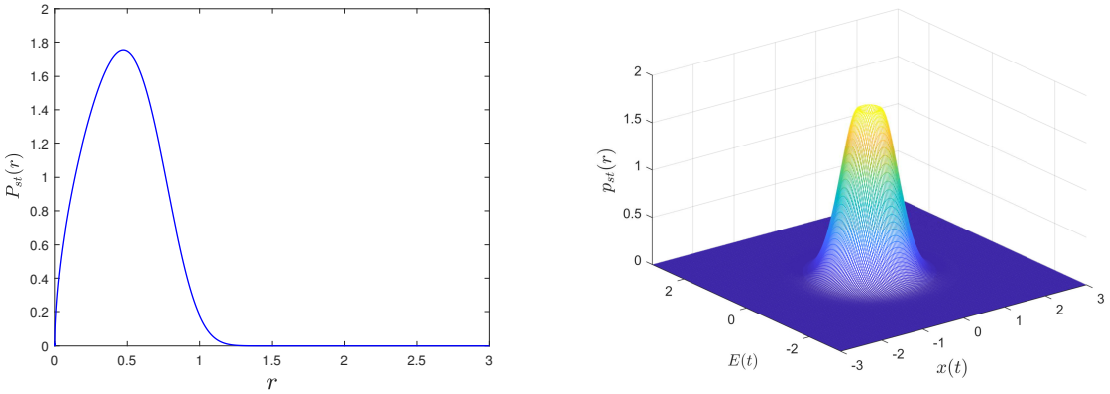


Figure 5.1: (a,c): Comparison of the solutions $x(t)$ and $E(t)$ of system (4.17) with the corresponding deterministic system solutions. The red line stands for the solution of the stochastic system, and the green line stands for the solution of the corresponding deterministic system. (b,d): The histogram of the probability density functions of x, E populations.

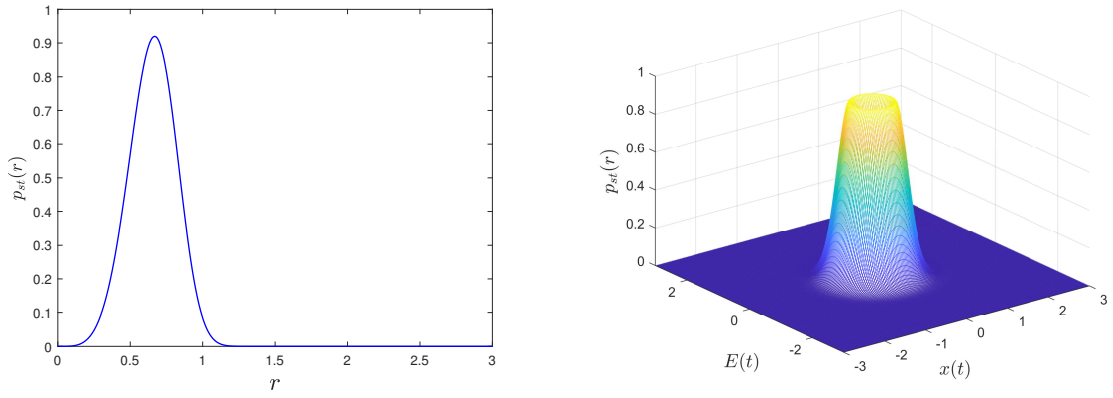
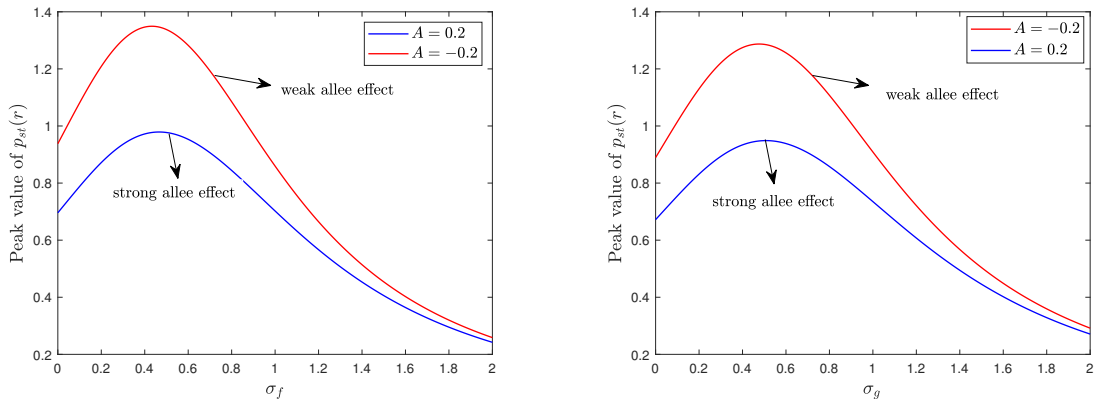
(a) (b)

Figure 5.2: The stationary probability density $p_{st}(r)$ of system (5.17) with $c_1 = 0.25$, $c_2 = 3$, $c_3 = 10$ and $c_4 = 5$.



(a) (b)

Figure 5.3: The stationary probability density $p_{st}(r)$ of system (5.17) with $c_1 = 0.25$, $c_2 = 3$, $c_3 = 10$ and $c_4 = 3.5$.

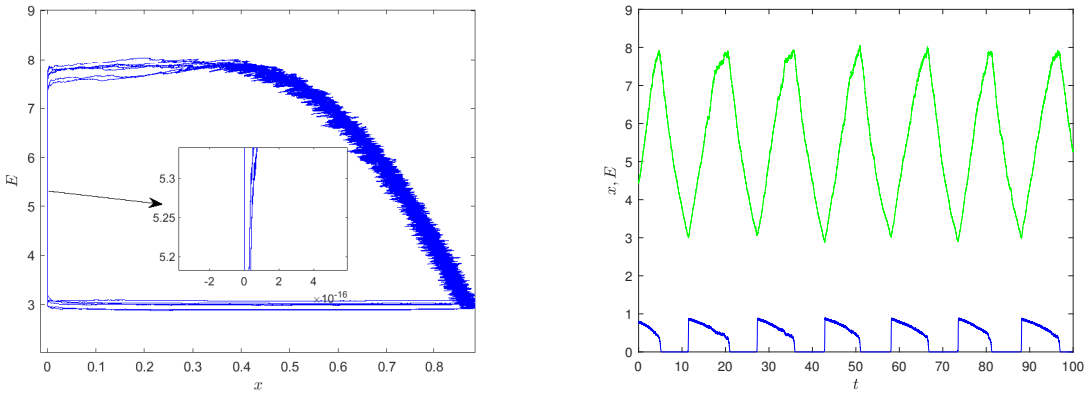


We select parameters $c_1 = 0.25$, $c_2 = 3$, $c_3 = 10$ and $c_4 = 2$ so that they satisfy the case (iii). Figure 5.4 shows the graph of $p_{st}(r)$, from which we can see that $p_{st}(r)$ reaches its maximum at $r = r_*$ and its minimum at $r = 0$.

We compare the effects of noise intensity σ_f and σ_g on the peak value of probability density $p_{st}(r)$ under strong and weak Allee effect. Selecting parameter $K = 3$, $A = 0.2$, $\alpha = 0.2$, $\varepsilon = 0.9$, $\beta = 1.1$, $p = 2.5$, $c = 1$, $\sigma_g = 0.7$ and $K = 3$, $A = -0.2$, $\alpha = 0.2$, $\varepsilon = 0.9$, $\beta = 1.1$, $p = 2.5$, $c = 1$, $\sigma_g = 0.7$, we plotted the graph of peak versus σ_f(see Figure 5.5(a)). Selecting parameter $K = 3$, $A = 0.2$, $\alpha = 0.2$, $\varepsilon = 0.9$, $\beta = 1.1$, $p = 2.5$, $c = 1$, $\sigma_f = 0.7$ and $K = 3$, $A = -0.2$, $\alpha = 0.2$, $\varepsilon = 0.9$, $\beta = 1.1$, $p = 2.5$, $c = 1$, $\sigma_f = 0.7$, we plotted the graph of peak versus σ_g(see Figure 5.5(b)). From the graph, we can observe that as the values of σ_f and σ_g increase, the peak value of $p_{st}(r)$ first increases and then decreases, indicating that the survival probability of the population will be higher under appropriate noise intensity. This is also consistent with reality, indicating that moderate harsh environments can promote

(a) (b)

Figure 5.4: The stationary probability density $p_{st}(r)$ of system (5.17) with $c_1 = 0.25$, $c_2 = 3$, $c_3 = 10$ and $c_4 = 2$.



(a) (b)

Figure 5.5: (a) The effect of parameter σ_f on the peak value of $p_{st}(r)$. (b) The effect of parameter σ_g on the peak value of $p_{st}(r)$.

the reproduction of biological populations, while extreme natural environments can lead to the extinction of organisms. From Figure 5.5, it can also be observed that the probability of population survival under weak Allee effects is higher than that under strong Allee effects.

Finally, we discuss the impact of random noise on relaxation oscillations [1] through numerical simulation. Choosing parameter $K = 2$, $A = -0.5$, $\alpha = 0.17$, $\varepsilon = 0.01$, $\beta = 0.4$, $p = 1$, $c = 0.14$, $\sigma_f = 0.02$ and $\sigma_g = 0.02$, We have plotted the influence diagram noise on relaxation oscillation (see Figure 5.6). We found that noise will fluctuate near the relaxation oscillation, that is, the noise will approximately stabilize near the relaxation oscillation of deterministic system.

Remark 5.10. Environmental fluctuations highlight the importance of ecosystem protection. The fishery bioeconomic model can help evaluate the role of ecosystem conservation measures in responding to environmental fluctuations. For example, after setting up a marine protected area in a fishing ground, during environmental fluctuations, the fish population

(a) (b)

Figure 5.6: (a) The influence diagram noise on relaxation oscillation. (b) $x-t$ (blue) and $E-t$ (green) time series diagram.

within the protected area may serve as a "source" to provide juvenile fish supplements to surrounding fishing grounds, thereby maintaining the stability of the entire fishing ecosystem. Fishery managers also need to adjust their fishing strategies based on environmental fluctuations. During periods of significant environmental fluctuations, stricter fishing restrictions may be necessary, such as reducing fishing quotas and extending fishing bans. This is because environmental fluctuations have already caused natural pressure on fish populations, and overfishing may make it difficult for populations to recover, leading to the depletion of fishery resources. The fishery bioeconomic model can simulate the effects of different fishing strategies under environmental fluctuations, providing scientific decision-making basis for managers.

6 Conclusion

This paper investigates the bifurcation behavior of a class of stochastic fast slow single population fishery economic models with Allee effect.

For the deterministic fast-slow system (2.2) with strong Allee effect, we studied the fast-slow dynamic behavior of the system and revealed that as the bifurcation parameters change, the system produces stable canard circle, which happen to coincide with the Hopf bifurcation of the normal system. Compared to the strong Allee effect, for deterministic fast-slow systems (2.2) with weak Allee effect, more complex dynamic properties will be generated, not only canard circle, but also a fast-slow periodic cycle (relaxation oscillation). The existence of canard circle and relaxation oscillations indicates that the system will have a periodic oscillation, which means that the system is in dynamic equilibrium. For the aquaculture industry, it is beneficial for fishermen to optimize resource allocation and sustain economic turnover.

For the stochastic fast-slow fishery economic system, we discussed the existence of a stationary distribution for the system (4.18)after stochastic reduction. And with the time scale parameter as a general parameter, we studied the existence of stationary distribution and stochastic bifurcation behavior of the system (4.17). We conclude that both strong Allee effect and weak Allee effect, the system system (4.18) has a stationary distribution, and as the bifurcation parameter c_4 changes, stochastic P-bifurcation and stochastic D-bifurcation will

occur. Then we compared the changes in peak density of stationary distributions under different Allee effects, and concluded that under the same noise influence, weak Allee effects are more conducive to population survival (see Figure 5.5). Using the image (Figure 5.6) to describe the effect of the time scale parameter c on relaxation oscillations, we found that random fluctuations tend to stabilize near relaxation oscillations.

On the basis of this article, there is still relevant work that can be further studied. In this article, we only considered single population models, and in the future, we can study the relevant properties and bifurcation studies of multiple population models, as well as the bifurcation behavior of systems at multiple time scales.

Appendix

We provide a proof of convergence for the integrals $I_1 = \int_{x(0)}^{+\infty} x^{-N} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\}dx$ and $I_2 = \int_{x(0)}^{+\infty} x^{-N+1} \exp\left\{\frac{2(K+A)}{\sigma_f^2}x - \frac{K}{\sigma_f^2}x^2\right\}dx$.

Let $u = \frac{x}{\sigma_f}$, we obtain

$$\begin{aligned} I_1 &= \sigma_f^{-N+1} \int_{x(0)}^{+\infty} u^{-N} \exp\left\{-Ku^2 + \frac{2(K+A)u}{\sigma_f}\right\} du \\ &= \sigma_f^{-N+1} e^{\frac{(K+A)^2}{K\sigma_f^2}} \int_{x(0)}^{+\infty} u^{-N} \exp\left\{-K\left(u - \frac{K+A}{K\sigma_f}\right)^2\right\} du, \quad \text{taking } y = u - \frac{K+A}{K\sigma_f}, \\ &= \sigma_f^{-N+1} e^{\frac{(K+A)^2}{K\sigma_f^2}} \int_{x(0)-\frac{K+A}{K\sigma_f}}^{+\infty} \left(y + \frac{K+A}{K\sigma_f}\right)^{-N} e^{-Ky^2} dy. \end{aligned}$$

By calculation, we can conclude that e^{-Ky^2} is monotonically decreasing and bounded on the interval $(x(0) - \frac{K+A}{K\sigma_f}, +\infty)$. Since $N > 2$, we can obtain that

$$\int_{x(0)-\frac{K+A}{K\sigma_f}}^{+\infty} \left(y + \frac{K+A}{K\sigma_f}\right)^{-N} dy = \int_{x(0)}^{+\infty} u^{-N} du,$$

is convergent. Therefore, according to the Abel convergence criterion, we conclude that the integral I_1 is convergent. Similarly, we can also conclude that I_2 converges.

Communicated by Christian Pötzsche

Abstract. With the goal of deriving the existence of a dominated splitting, Quas, Thieullen and Zarrabi introduced the concept of strong fast invertibility for linear cocycles in 2019. Here, we take a closer look at strongly fast invertible systems with bounded coefficients. By linking the dimensions at which a system admits strong fast invertibility to the multiplicities of Lyapunov exponents, we are able to give a full characterization of regular strongly fast invertible systems similar to that of systems with stable Lyapunov exponents. In particular, we show that the stability of Lyapunov exponents implies strong fast invertibility (even in the absence of regularity). Central to our arguments are certain induced systems on spaces of exterior products that represent the evolution of volumes.

Finally, we derive convergence results for the computation of Lyapunov exponents via Benettin's algorithm using perturbation theory. While the stronger assumption of stable Lyapunov exponents clearly leaves more freedom on how to choose stepsizes, we derive conditions for the stepsizes with which convergence can be ensured even if a system is only strongly fast invertible.

Keywords: strong fast invertibility, Lyapunov exponents, linear dynamical systems, Benettin's algorithm, convergence analysis.

2020 Mathematics Subject Classification: 34D08, 37M25.

1 Introduction

Strong fast invertibility is a new property for dynamical systems introduced by Quas, Thieullen and Zarrabi in 2019 [21]. While it originally served as an ingredient to ensure uniform invertibility of a cocycle along its fastest growing direction (hence the name), strong fast invertibility can be best describes using the evolution of volumes: A linear system is L-dim. strongly fast invertible according to [21] if and only if there is a constant $c > 0$ such that

$$\frac{\| \wedge^L X(t,\tau)\|}{\| \wedge^L X(s,\tau)\|} \leq \| \wedge^L X(t,s)\| \leq c \frac{\| \wedge^L X(t,\tau)\|}{\| \wedge^L X(s,\tau)\|}$$

✉ Email: fnoethen.contact@gmail.com

for all $t \geq s \geq \tau$, where $\wedge^L X(t,s)$ denotes L-fold exterior product of the Cauchy matrix of the system (see Lemma 3.29). In other words, the maximal growth of L-volumes over a time interval can be computed (up to a constant independent of the interval) by bisecting the interval and computing the maximal growths of L-volumes on the subintervals.

By combining strong fast invertibility with a uniform singular value gap, Quas et al. prove the existence of a *dominated equivariant uniform splitting* of the dynamics, i.e., a splitting into equivariant fast and slow subspaces such that the angle between them is bounded from below and solutions corresponding to the fast subspace grow uniformly exponentially faster than solutions corresponding to the slow subspace. Using an equivalent notion, one may also call the splitting *integrally separated* [22, Definition 2.3].

The latter terminology is usually applied in studies of Lyapunov exponents. In particular, the existence of an integrally separated splitting is necessary to ensure the stability of Lyapunov exponents. Essentially, given an integrally separated splitting, the stability of Lyapunov exponents boils down to the stability on the subspaces of the splitting:

Theorem ([1, Theorem 5.4.9], [3])**.** *Assume a linear system with bounded coefficients and Lyapunov exponents $\lambda_1 > \cdots > \lambda_p$ with multiplicities $d_1 + \cdots + d_p = d$. The Lyapunov exponents are stable if and only if there exists a Lyapunov transformation reducing the system to block diagonal form*

$$\dot{y} = \operatorname{diag}(B_1(t), \dots, B_p(t))y,$$

where $B_i(t) \in \mathbb{R}^{d_i \times d_i}$ is upper triangular, such that the following hold:

(i) all non-trivial solutions of $\dot{y}_i = B_i(t)y_i$ have characteristic exponent λ_i,

(ii) λ_i is stable for $\dot{y}_i = B_i(t)y_i$,

(iii) there are constants $a, b > 0$ such that

$$\|Y_i(t,s)^{-1}\|^{-1} \geq be^{a(t-s)}\|Y_{i+1}(t,s)\|$$

for all $t \geq s$, where $Y_i(t,s)$ denotes the Cauchy matrix of $\dot{y}_i = B_i(t)y_i$.

One of our two main goals is to provide a characterization of strong fast invertibility that allows a direct comparison to stability of Lyapunov exponents via the above theorem. To connect strong fast invertibility, a property that concerns the evolution of volumes, to Lyapunov exponents, we work with certain induced systems on spaces of exterior products. These systems allow us to link Lyapunov exponents to volume growth assuming the original system is regular. Our characterization theorem is the following:

Theorem. *Assume a linear system with bounded coefficients and Lyapunov exponents $\lambda_1 > \cdots > \lambda_p$ with multiplicities $d_1 + \cdots + d_p = d$. If the system is regular and strongly fast invertible at dimensions $d_1 + \cdots + d_l$ for $l = 1, \dots, p$, then there exists a Lyapunov transformation reducing the system to block diagonal form*

$$\dot{y} = \operatorname{diag}(B_1(t), \dots, B_p(t))y,$$

where $B_i(t) \in \mathbb{R}^{d_i \times d_i}$ is upper triangular, such that the following hold:

(i) all non-trivial solutions of $\dot{y}_i = B_i(t)y_i$ have characteristic exponent λ_i,

(ii) there is a constant $b > 0$ such that

$$\|Y_i(t,s)^{-1}\|^{-1} \geq b\|Y_{i+1}(t,s)\|$$

for all $t \geq s$, where $Y_i(t,s)$ denotes the Cauchy matrix of $\dot{y}_i = B_i(t)y_i$.

Conversely, any block diagonal system $\dot{y} = B(t)y$ satisfying (i) and (ii) is strongly fast invertible at dimensions $d_1 + \cdots + d_l$ for $l = 1, \ldots, p$.

In particular, our theorem provides an equivalent characterization of strong fast invertibility for systems that are regular and have bounded coefficients. Moreover, it shows that the stability of Lyapunov exponents implies strong fast invertibility at the respective dimensions. More aspects, such as another characterization in the case of simple Lyapunov spectra, can be found in our article. However, we note that there are still interesting aspects to explore that we did not pursue here.

Our second main goal is to derive convergence results for the computation of Lyapunov exponents. More precisely, we focus on *Benettin's algorithm* [4,5] as it is the most fundamental and common algorithm to compute Lyapunov exponents. Its underlying idea is to propagate a set of linear perturbations that are reorthonormalized periodically. The Lyapunov exponents are then computed as averages of volume expansion via the rescaling factors from the orthonormalization procedure.

While it is not difficult to prove convergence of Benettin's algorithm in the absence of numerical errors, integration errors can accumulate and persist. This happens especially if the stepsizes are kept constant. In practice, it is hard to quantify these error, since the exact Lyapunov exponents are usually unknown.

Major efforts have been made by Dieci, Van Vleck and co-authors. They advocate the use of adaptive stepsizes to bound the local integration error and were able to prove error estimates for computed Lyapunov exponents of linear systems that are regular and have stable Lyapunov exponents [10, 11]. While Dieci and Van Vleck proved that the asymptotic limits of the computed exponents can be made arbitrarily close to the true Lyapunov exponents by decreasing the error tolerance or the fixed stepsize, true convergence requires to simultaneously increase the integration time and decrease the stepsizes. This was already conjectured by Mc Donald and Higham in their error analysis for autonomous linear systems in 2001 [17, Section 5].

By tackling both limits simultaneously, we derive new convergence results that differentiate between systems with stable Lyapunov exponents and systems that are only strongly fast invertible. The main difference between the respective convergence results are the requirements for stepsizes. While stepsizes h_n such that

$$\sum_{n=1}^{\infty} h_n = \infty \quad \text{and} \quad h_n \to 0$$

are enough to achieve convergence for systems with stable Lyapunov exponents, we need stricter assumptions to compute Lyapunov exponents for strongly fast invertible systems:

$$\sum_{n=1}^{\infty} h_n = \infty \quad \text{and} \quad \sum_{n=1}^{\infty} h_n^{p+1} < \infty,$$

where $p > 0$ is the order of consistency of the numerical integrator.

Finally, we provide three numerical examples to highlight the effects of different types of stepsizes (adaptive, constant and varying) on the computation of Lyapunov exponents. While the first example is linear and in accordance with our convergence theory, the other two examples are nonlinear and serve as an outlook suggesting that similar convergence properties may be valid for more general classes of systems.

2 Exterior products and powers

Exterior products are a handy tool when it comes to studying the evolution of volumes and hence also Lyapunov exponents. In this section we briefly introduce them and some of their properties. Our main reference is [2, Section 3.2.3].

For $1 \leq L \leq d$, the L-fold *exterior power* of $\mathbb{R}^d$ is the space $\wedge^L \mathbb{R}^d$ consisting of alternating L-linear forms on the dual space $(\mathbb{R}^d)^* \cong \mathbb{R}^d$. A basis can be obtained by taking *exterior products* of basis elements of $\mathbb{R}^d$. For example, the set

$$\{e_I := e_{i_1} \wedge \cdots \wedge e_{i_L} \mid I = (i_1, \ldots, i_L) \text{ with } 1 \leq i_1 < \cdots < i_L \leq d\},$$

where e_i is the i-th unit vector of $\mathbb{R}^d$, defines a natural basis of $\wedge^L \mathbb{R}^d$. In particular, $\wedge^L \mathbb{R}^d$ has dimension $\binom{d}{L}$.

Not all elements of $\wedge^L \mathbb{R}^d$ are *decomposable*, i.e., of the form $u_1 \wedge \cdots \wedge u_L$. Some elements are *indecomposable* and can only be expressed as linear combinations of decomposable elements.

Given subspaces $U, V \subset \mathbb{R}^d$, we define induced subspaces

$$(\wedge^k U) \wedge (\wedge^{L-k} V) := \operatorname{span}\{u_1 \wedge \cdots \wedge u_k \wedge v_{k+1} \wedge \cdots \wedge v_L \mid u_i \in U, v_i \in V\} \subset \wedge^L \mathbb{R}^d$$

as spans of the corresponding induced decomposable elements.

By bilinear extension from the set of decomposable elements to $\wedge^L \mathbb{R}^d$, the following defines a scalar product on $\wedge^L \mathbb{R}^d$:

$$\langle u_1 \wedge \cdots \wedge u_L, v_1 \wedge \cdots \wedge v_L \rangle := \det(\langle u_i, v_j \rangle)_{ij}.$$

In particular, the induced norm of a decomposable element $u_1 \wedge \cdots \wedge u_L$ is the L-volume of the parallelepiped spanned by $u_1, \ldots, u_L$:

$$\|u_1 \wedge \cdots \wedge u_L\| = \sqrt{\det(\langle u_i, u_j \rangle)_{ij}}.$$

Throughout this article norms without annotation always denote euclidean norms or associated matrix norms.

Lemma 2.1. *We have*

(i) $\|u_1 \wedge \cdots \wedge u_L\| \leq \|u_1 \wedge \cdots \wedge u_k\| \cdot \|u_{k+1} \wedge \cdots \wedge u_L\|$

for $u_1, \ldots, u_L \in \mathbb{R}^d$ *and*

(ii) $\langle \hat{u} \wedge \hat{v}, \hat{u}' \wedge \hat{v}' \rangle = \langle \hat{u}, \hat{u}' \rangle \langle \hat{v}, \hat{v}' \rangle$,

(iii) $\|\hat{u} \wedge \hat{v}\| = \|\hat{u}\| \, \|\hat{v}\|$

for $\hat{u}, \hat{u}' \in \wedge^k U$ *and* $\hat{v}, \hat{v}' \in \wedge^{L-k} V$ *with* $U, V \subset \mathbb{R}^d$ *orthogonal.*

Proof. (i) can be found in [2, Subsection 3.2.3].

Let $U, V \subset \mathbb{R}^d$ with $U \perp V$. Choose bases $(u_i)_i$ of U and $(v_j)_j$ of V. We denote the elements of the induced bases of $\wedge^k U$ and $\wedge^{L-k} V$ by u_I and v_J respectively. Since

$$\langle u_I \wedge v_J, u_{I'} \wedge v_{J'} \rangle$$

is the determinant of a block diagonal matrix, it is equal to the product of the determinants of both blocks, which is

$$\langle u_I, u_{I'} \rangle \langle v_J, v_{J'} \rangle.$$

Thus, (ii) holds on basis elements and by bilinearity of the inner product on arbitrary elements.

Assertion (iii) follows immediately from (ii) by setting $\hat{u} = \hat{u}'$ and $\hat{v} = \hat{v}'$. □

Next, we discuss several constructions for linear maps. The L-fold exterior power of $A \in \mathbb{R}^{d\times d}$ is defined via

$$(\wedge^L A)(u_1 \wedge \cdots \wedge u_L) := Au_1 \wedge \cdots \wedge Au_L.$$

Similarly, one may define

$$((\wedge^k A) \wedge (\wedge^{L-k} B))(u_1 \wedge \cdots \wedge u_L) := Au_1 \wedge \cdots \wedge Au_k \wedge Bu_{k+1} \wedge \cdots \wedge Bu_L.$$

for $A, B \in \mathbb{R}^{d\times d}$. Another helpful construction is

$$\hat{A}^L(u_1 \wedge \cdots \wedge u_L) := \sum_{k=1}^{L} u_1 \wedge \cdots \wedge u_{k-1} \wedge Au_k \wedge u_{k+1} \wedge \cdots \wedge u_L.$$

Since we will make extensive use of these induced maps, we state and derive a list of basic properties for them.

Lemma 2.2. *The following are true for $A, B \in \mathbb{R}^{d\times d}$:*

(i) $\wedge^L I_{\mathbb{R}^d} = I_{\wedge^L \mathbb{R}^d}$,

(ii) $\wedge^L (AB) = (\wedge^L A)(\wedge^L B)$,

(iii) $(\wedge^L A)^{-1} = \wedge^L A^{-1}$ *if* $A \in GL(d, \mathbb{R})$,

(iv) $\widehat{\alpha A + \beta B}^L = \alpha \hat{A}^L + \beta \hat{B}^L$,

(v) $\| \wedge^L A\| = \sigma_1(A) \dots \sigma_L(A)$, *where* $\sigma_1 \geq \cdots \geq \sigma_d$ *denote the singular values,*

(vi) $\| \wedge^L A\| \leq \|A\|^L$,

(vii) $\|\hat{A}^L\| \leq L\|A\|$,

(viii) $\|(\wedge^k A) \wedge (\wedge^{L-k} B)\| \leq \binom{d}{L}^{\frac{1}{2}} \| \wedge^k A\| \, \| \wedge^{L-k} B\|$,

(ix) if $A[u_1, \dots, u_L] = QR$, *then* $\|(\wedge^L A)(u_1 \wedge \cdots \wedge u_L)\| = r_{11} \dots r_{LL}$, *where* $r_{ii} \geq 0$ *denote the diagonal elements of* R *ordered in decreasing size,*

(x) $\det(\wedge^L A) = \det(A)^{\binom{d-1}{L-1}}$.

Proof. (i)–(vii) and (x) can be found in [2, Subsection 3.2.3].

To show $(viii)$, write

$$I_1 = (i_1, \dots, i_k) \text{ and } I_2 = (i_{k+1}, \dots, i_L)$$

for a given tuple $I = (i_1, \dots, i_L)$ and estimate

$$\begin{aligned}
\|(\wedge^k A) \wedge (\wedge^{L-k} B)\| &= \sup_{\sum \alpha_I^2 = 1} \left\| ((\wedge^k A) \wedge (\wedge^{L-k} B)) \left(\sum \alpha_I e_I\right) \right\| \\
&\leq \sup_{\sum \alpha_I^2 = 1} \sum |\alpha_I| \, \|((\wedge^k A) e_{I_1}) \wedge ((\wedge^{L-k} B) e_{I_2})\| \leq \sup_{\sum \alpha_I^2 = 1} \sum |\alpha_I| \, \|(\wedge^k A) e_{I_1}\| \, \|(\wedge^{L-k} B) e_{I_2}\| \\
&\leq \binom{d}{L}^{\frac{1}{2}} \| \wedge^k A\| \, \| \wedge^{L-k} B\|.
\end{aligned}$$

Finally, we prove (ix):

$$\|(\wedge^L A)(u_1 \wedge \cdots \wedge u_L)\|^2 = \det(\langle Au_i, Au_j \rangle)_{ij} = \det((QR)^T (QR)) = \det(R^T R) = r_{11}^2 \dots r_{LL}^2.$$

□

Lemma 2.3. *Let $A = \operatorname{diag}(A_1, A_2) \in \mathbb{R}^{d\times d}$ and set $B := \operatorname{diag}(A_1, 0)$ and $C := \operatorname{diag}(0, A_2)$. The following are true:*

(i) $\wedge^L A = \sum_{k=0}^{L} (\wedge^k B) \wedge (\wedge^{L-k} C)$,

(ii) $\| \wedge^L A\| = \max_k \|(\wedge^k B) \wedge (\wedge^{L-k} C)\|$,

(iii) $\|(\wedge^k B) \wedge (\wedge^{L-k} C)\| \geq \| \wedge^k B\| \, \| \wedge^{L-k} C\|$.

Proof. Let $A_1 \in \mathbb{R}^{d_1\times d_1}$. Given a basis element

$$e_I = e_{i_1} \wedge \cdots \wedge e_{i_L},$$

choose j such that $i_j \leq d_1 < i_{j+1}$. It holds

$$(\wedge^L A)e_I = ((\wedge^j B) \wedge (\wedge^{L-j} C))e_I.$$

Moreover, all summands in

$$\sum_{k=0}^{L} ((\wedge^k B) \wedge (\wedge^{L-k} C))e_I$$

vanish except for $k = j$. Hence, the two maps in (i) coincide on basis elements e_I.

The subspaces

$$W_k := \left(\wedge^k \left(\mathbb{R}^{d_1} \times \{0\}\right)\right) \wedge \left(\wedge^{L-k} \left(\{0\} \times \mathbb{R}^{d-d_1}\right)\right)$$

for $k = 0, \ldots, L$ form an orthogonal decomposition of $\wedge^L \mathbb{R}^d$. Since

$$\operatorname{im}\left((\wedge^k B) \wedge (\wedge^{L-k} C)\right) \subset W_k$$

and

$$W_i \subset \ker\left((\wedge^k B) \wedge (\wedge^{L-k} C)\right)$$

for $i \neq k$, (ii) easily follows by means of this decomposition.

To prove (iii), we use (iii) of Lemma 2.1. It follows that

$$\begin{aligned}\|(\wedge^k A) \wedge (\wedge^{L-k} B)\| &\geq \max_{\|\hat{u}\wedge\hat{v}\|=1} \|(\wedge^k A)\hat{u} \wedge (\wedge^{L-k} B)\hat{v}\| = \max_{\|\hat{u}\|=1} \|(\wedge^k A)\hat{u}\| \max_{\|\hat{v}\|=1} \|(\wedge^{L-k} B)\hat{v}\| \\ &= \| \wedge^k A\| \, \| \wedge^{L-k} B\|,\end{aligned}$$

where maxima are with respect to $\hat{u} \wedge \hat{v} \in W_k$. □

Next, we relate the principle angles between two complementary subspaces of $\mathbb{R}^d$ to a principle angle on $\wedge^L \mathbb{R}^d$.

Proposition 2.4. *Let $\mathbb{R}^d = U \oplus V$ with $\dim U = L$. Set $\hat{U} := \wedge^L U$ and $\hat{V} := \left(\wedge^L V^\perp\right)^\perp$. Then*

$$\prod_{i=1}^{\min(L,d-L)} \sin\alpha_i(U, V) = \sin\alpha_1(\hat{U}, \hat{V}), \tag{2.1}$$

where $0 < \alpha_1 \leq \alpha_2 \leq \cdots \leq \frac{\pi}{2}$ are the principle angles between the respective subspaces.

Proof. First we pass to the orthogonal complement of V in order to work with two subspaces of the same dimension. According to [25] it holds

$$\prod_{i=1}^{\min(L,d-L)} \sin\alpha_i(U,V) = \prod_{i=1}^{L} \sin\left(\frac{\pi}{2} - \alpha_i(U,V^\perp)\right) = \prod_{i=1}^{L} \cos\alpha_i(U,V^\perp).$$

The concept of "higher dimensional angle" coined in [13] helps us to transition to $\wedge^L\mathbb{R}^d$. In fact, the higher dimensional angle $\theta(U,V^\perp)$ between two subspaces U and $V^\perp$ of the same dimension satisfies

$$\cos\theta(U,V^\perp) = \prod_{i=1}^{L} \cos\alpha_i(U,V^\perp)$$

and is defined via

$$\cos\theta(U,V^\perp) := \frac{\langle\alpha,\beta\rangle}{\|\alpha\|\,\|\beta\|},$$

where $\alpha,\beta \in \wedge^L\mathbb{R}^d$ are decomposable elements representing U and $V^\perp$, i.e., $\alpha = u_1\wedge\cdots\wedge u_L$ with $\operatorname{span}(u_1,\dots,u_L) = U$ and $\beta = v_1'\wedge\cdots\wedge v_L'$ with $\operatorname{span}(v_1',\dots,v_L') = V^\perp$. The latter is nothing else than the angle between α and β or the principle angle between their corresponding 1-dimensional subspaces:

$$\cos\theta(U,V^\perp) = \cos\alpha_1(\wedge^L U,\wedge^L V^\perp) = \cos\alpha_1(\hat{U},\hat{V}^\perp) = \sin\alpha_1(\hat{U},\hat{V}). \qquad \square$$

Corollary 2.5. *In Proposition 2.4 it holds*

$$\left(\wedge^L V^\perp\right)^\perp = \oplus_{k=0}^{L-1}\left((\wedge^k U)\wedge(\wedge^{L-k}V)\right).$$

In particular, equation (2.1) is true for

$$\begin{aligned} U &:= \operatorname{span}\{Ae_1,\dots,Ae_L\},\\ V &:= \operatorname{span}\{Ae_{L+1},\dots,Ae_d\},\\ \hat{U} &= \operatorname{span}\{(\wedge^L A)(e_1\wedge\cdots\wedge e_L)\},\\ \hat{V} &= \operatorname{span}\{(\wedge^L A)(e_{i_1}\wedge\cdots\wedge e_{i_L}) \mid \{i_1,\dots,i_L\} \neq \{1,\dots,L\}\} \end{aligned}$$

for any given $A \in GL(d,\mathbb{R})$.

Proof. The identity can be checked by using that both spaces have codimension 1 and by showing that the inner product between elements of the form

$$v_1'\wedge\cdots\wedge v_L' \in \wedge^L V^\perp$$

and

$$u_1\wedge\cdots\wedge u_k\wedge v_{k+1}\wedge\cdots\wedge v_L$$

with $u_i \in U$ and $v_i \in V$ vanishes for $k < L$. $\square$

3 Asymptotic properties of linear systems

Consider the linear differential equation

$$\dot{x} = A(t)x, \quad A \in C(\mathbb{R}_{\geq 0},\mathbb{R}^{d\times d}) \tag{3.1}$$

with bounded coefficients, i.e.,

$$M := \sup_t \|A(t)\| < \infty.$$

We write $X(t)$ for a fundamental matrix of equation (3.1) and $X(t,s) := X(t)X(s)^{-1}$, $t \geq s$, for the Cauchy matrix. By requiring that A is bounded, solutions grow or decay at most exponentially fast:

$$e^{-M(t-s)} \leq \|X(t,s)^{\pm 1}\| \leq e^{M(t-s)}$$

for all $t \geq s$.

In our article, equation (3.1) will be changed by so-called *Lyapunov transformations*. These transformations leave asymptotic properties[1] like boundedness of the system matrix, the Lyapunov spectrum, regularity, the stability of Lyapunov exponents, or strong fast invertibility invariant.

Definition 3.1 ([1, Definition 3.1.1])**.** $x = L(t)y$ is called *Lyapunov transformation* if L is continuously differentiable, everywhere invertible and $L, L^{-1}, \dot{L}$ are bounded. The transformed system $\dot{y} = B(t)y$ is given by

$$B(t) = L(t)^{-1}A(t)L(t) - L(t)^{-1}\dot{L}(t).$$

It is easy to see that Lyapunov transformations form a group with respect to multiplication. A particular Lyapunov transformation is obtained via the Gram–Schmidt procedure.

Proposition 3.2 ([1, Lemma 3.3.1 and Theorem 3.3.1])**.** *There is an orthogonal Lyapunov transformation such that the fundamental matrix $Y(t)$ of the transformed system is upper triangular.*

3.1 Characteristic exponents

In this subsection, we define characteristic exponents and Lyapunov exponents.

Definition 3.3 ([1, Definition 2.1.1])**.** The *characteristic exponent* of $f : [0,\infty) \to \mathbb{R}$ is given by

$$\chi[f] := \limsup_{t\to\infty} \frac{1}{t} \log|f(t)| \in \mathbb{R} \cup \{\pm\infty\}.$$

A few handy properties follow easily from the definition (see [1, Section 2.1] and [2, Lemma 3.2.1]):

(i) $\chi[c] = 0$ for $c \neq 0$

(ii) $\chi[cf] = \chi[f]$ for $c \neq 0$,

(iii) $\chi[|f|^c] = c\chi[f]$ for $c \in \mathbb{R}$ (set $0(\pm\infty) = 0$),

(iv) $\chi[f] \leq \chi[g]$ if $|f| \leq |g|$,

(v) $\chi[f+g] \leq \max(\chi[f], \chi[g])$ with equality if $\chi[f] \neq \chi[g]$,

(vi) $\chi[fg] \leq \chi[f] + \chi[g]$ (if the right-hand side makes sense).

[1] We will define all mentioned properties throughout our article.

In the context of dynamical systems, we apply characteristic exponents to measure the (upper) exponential growth of solutions $x(t)$:

$$\chi[x] := \chi[\|x\|] = \limsup_{t\to\infty} \frac{1}{t} \log \|x(t)\|.$$

Note that $\chi[x]$ is independent of the chosen norm because all norms on $\mathbb{R}^d$ are equivalent.[2]

Since solutions with distinct characteristic exponents are linearly independent, the characteristic exponents can take at most d values

$$\infty > M \geq \lambda_1 > \cdots > \lambda_p \geq -M > -\infty.$$

In particular, there is a filtration of subspaces of the space of solutions called *Lyapunov filtration*

$$\mathbb{R}^d \cong V_1 \supset \cdots \supset V_p \supset V_{p+1} := \{0\}$$

with $V_i := \{x \,|\, \chi[x] \leq \lambda_i\}$ satisfying

$$\chi[x] = \lambda_i \quad \Longleftrightarrow \quad x \in V_i \setminus V_{i+1}.$$

We set $d_i := \dim V_i - \dim V_{i+1}$.

Remark 3.4. Sometimes the Lyapunov filtration is defined on the space of initial vectors. In fact, both versions of filtration spaces are naturally isomorphic:

$$V_i' := \{v \mid \chi[X(t,0)v] \leq \lambda_i\} = \{x(0) \mid x \in V_i\}.$$

One may also define the filtration spaces using a given fundamental matrix $X(t)$:

$$V_{i,X} := \{v \mid \chi[X(t)v] \leq \lambda_i\}.$$

Definition 3.5. The *(forward) Lyapunov spectrum* $(\lambda_i, d_i)_{i=1,\ldots,p}$ of a system consists of its *Lyapunov exponents* λ_i together with their *multiplicities* d_i. Since we sometimes count Lyapunov exponents according to their multiplicities, we define $\Lambda_1, \ldots, \Lambda_d$ via

$$\Lambda_{d_1+\cdots+d_{i-1}+j} := \lambda_i \quad \text{for } j = 1, \ldots, d_i.$$

A Lyapunov exponent λ_i is called *simple* or *nondegenerate* if $d_i = 1$ and otherwise *degenerate*. If all Lyapunov exponents are simple, we call the Lyapunov spectrum *simple*.

Example 3.6. Let $\epsilon > 0$. We set $a_n := n^2 - \log n$ and $b_n := n^2$ and define $f_n \in C(\mathbb{R}_{\geq 0}, \mathbb{R})$ through

$$f_n = \begin{cases} 0, & t \in [0, a_n - \epsilon] \\ \frac{t-(a_n-\epsilon)}{\epsilon}, & t \in (a_n - \epsilon, a_n] \\ 1, & t \in (a_n, b_n] \\ \frac{b_n+\epsilon-t}{\epsilon}, & t \in (b_n, b_n + \epsilon] \\ 0. & t \in (b_n + \epsilon, \infty) \end{cases}$$

[2] In infinite dimensions the characteristic exponents generally depend on the chosen norm, although independence can be achieved on certain scales of Banach spaces [6].

For small ϵ the functions f_n have disjoint supports. Thus, the system matrix

$$A(t) := \begin{pmatrix} 1 & 0 \\ 0 & a_{22}(t) \end{pmatrix}$$

with $a_{22}(t) := \sum_{n\in\mathbb{N}} f_n(t)$ is bounded and continuous. A fundamental matrix is given by

$$X(t) := \begin{pmatrix} e^t & 0 \\ 0 & e^{\int_0^t a_{22}(\tau)\,d\tau} \end{pmatrix}.$$

Since

$$1 \leq e^{\int_0^{b_n+\epsilon} a_{22}(\tau)\,d\tau} \leq e^{\sum_{k=1}^{n}(\log(k)+2\epsilon)} = n!e^{2\epsilon n},$$

we have

$$0 \leq \frac{1}{t}\log e^{\int_0^t a_{22}(\tau)\,d\tau} \leq \frac{2\epsilon(n+1)}{n^2} + \frac{\log((n+1)!)}{n^2}$$

for $t \in [b_n, b_{n+1}+\epsilon]$. In particular, the system exhibits solutions with characteristic exponents:

$$\chi[X(t)e_1] = 1 \quad \text{and} \quad \chi[X(t)e_2] = 0.$$

Since the characteristic exponents are distinct, the columns of $X(t)$ realize the whole Lyapunov spectrum ($\lambda_1 = 1$ and $\lambda_2 = 0$) and can be used to compute the Lyapunov filtration ($V_{1,X} = \mathbb{R}^2$ and $V_{2,X} = \{0\} \times \mathbb{R}$).

We may always choose[3] a basis of solutions that realizes the whole Lyapunov spectrum. In that case

$$\sum_{i=1}^{d} \chi[x_i] = \sum_{i=1}^{p} d_i\lambda_i. \tag{3.2}$$

Definition 3.7 ([1, Definition 2.4.2])**.** A basis $x_1, \dots, x_d$ of solutions is called *normal* if $\sum_i \chi[x_i]$ is minimal, i.e., if equation (3.2) holds. Moreover, we call a fundamental matrix *normal* if its columns form a normal basis.

If we order a normal basis such that $\chi[x_i]$ decreases with i, then $\chi[x_i] = \Lambda_i$.

Proposition 3.8 ([1, Theorem 2.5.1, Corollary 2.5.1 and Remark 2.5.2])**.** *Any fundamental matrix $X(t) = [x_1, \dots, x_d]$ satisfies*

$$\sum_{i=1}^{d} \chi[x_i] \geq \sum_{i=1}^{p} d_i\lambda_i \geq \chi[\det X(t)].$$

If equality holds, then $X(t)$ is normal. However, $X(t)$ being normal does not imply equality in general.

The largest Lyapunov exponent can be expressed as the characteristic exponent of $\|X(t)\|$.

Proposition 3.9. *The largest Lyapunov exponent satisfies*

$$\lambda_1 = \chi[\|X(t)\|].$$

Proof. One inequality is trivial and the other follows from

$$\|X(t)\| \leq \sqrt{d}\max_i \|X(t)e_i\|_1,$$

where e_i is the i-th unit vector of $\mathbb{R}^d$. □

[3] Construct a basis by iteratively choosing d_i solutions in $V_i \setminus V_{i+1}$ for $i = p, \dots, 1$.

3.2 Regularity

We now introduce the notion of regularity, which implies that characteristic exponents of solutions can be obtained as limits instead of limes superiors.

Definition 3.10 ([2, p. 115])**.** We call a system *(forward) regular*[4] if

$$\sum_{i=1}^{p} d_i\lambda_i = \liminf_{t\to\infty} \frac{1}{t} \log|\det X(t)|.$$

In case of triangular systems regularity can be checked via the diagonal elements of the system matrix[5]. Moreover, one may check regularity of general systems through Perron's regularity test, which compares the Lyapunov spectra of the system and its adjoint system $\dot{y} = -A(t)^T y$ [1, Theorem 3.6.1].

Proposition 3.11 ([1, Theorem 3.9.1])**.** *Regular systems have sharp characteristic exponents, i.e., it holds*

$$\chi[x] = \lim_{t\to\infty} \frac{1}{t} \log\|x(t)\|.$$

Example 3.12. The system from Example 3.6 is regular: Indeed, the fundamental matrix

$$X(t) = \begin{pmatrix} e^t & 0 \\ 0 & e^{\int_0^t a_{22}(\tau)\,d\tau} \end{pmatrix}$$

is diagonal and our previous estimates show that the diagonal elements have sharp characteristic exponents:

$$1 + 0 = \lambda_1 + \lambda_2 = \lim_{t\to\infty} \frac{1}{t} \log e^t + \lim_{t\to\infty} \frac{1}{t} \log e^{\int_0^t a_{22}(\tau)\,d\tau} = \lim_{t\to\infty} \frac{1}{t} \log|\det X(t)|.$$

Alternatively, one may show that diagonal elements of the system matrix $A(t)$ have finite mean values.

All Lyapunov exponents of a regular system can be obtained via characteristic exponents of singular values of $X(t)$.

Proposition 3.13. *If equation* (3.1) *is regular, then*

$$\Lambda_i = \lim_{t\to\infty} \frac{1}{t} \log \sigma_i(X(t))$$

for all $i = 1, \dots, d$*, where* $\sigma_1 \geq \cdots \geq \sigma_d$ *denote the singular values.*

[4]The definition from Arnold's book is equivalent to [1, Definition 3.5.1]. This can be checked via [1, Lemma 3.5.1] and the Liouville–Ostrogradski formula

$$\det X(t) = \det X(t_0) e^{\int_{t_0}^t \operatorname{tr}(A(\tau))\,d\tau}.$$

[5][1, Corollary 3.8.1] states that a lower triangular system is regular if and only if its diagonal elements $a_{ii}(t)$ have finite mean values:

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t a_{ii}(s)\,ds < \infty.$$

Since adjoint systems of regular systems are regular ([1, Corollary 3.6.1]), the same holds true for upper triangular systems.

We prove Proposition 3.13 in the next subsection using induced systems on the space of exterior products. Next, let us state a result on singular vectors of $X(t)$.

Proposition 3.14. *If equation (3.1) is regular and $u_1(t), \dots, u_d(t)$ denote the right singular vectors of $X(t)$, then*

$$U_{i,X}(t) := \operatorname{span}(u_{d_1+\cdots+d_{i-1}+1}(t), \dots, u_{d_1+\cdots+d_i}(t))$$

converges to $U_{i,X} := V_{i+1,X}^{\perp} \cap V_{i,X}$ exponentially fast. More precisely, it holds

$$\limsup_{t\to\infty} \frac{1}{t} \log \max_{\substack{u\in U_{i,X}(t),\\ u'\in U_{j,X},\\ \|u\|=\|u'\|=1}} |\langle u, u'\rangle| \leq -|\lambda_i - \lambda_j|$$

for $i \neq j$.

Proof. Since equation (3.1) has bounded coefficients and its induced systems are regular (see Lemma 3.19), the deterministic version of the multiplicative ergodic theorem [2, Proposition 3.4.2] applies. In its proof, Arnold shows that the filtration $F_X(t)$ given by the spaces

$$V_{i,X}(t) := U_{p,X}(t) \oplus \cdots \oplus U_{i,X}(t)$$

converges exponentially fast to the Lyapunov filtration F_X given by the spaces

$$V_{i,X} = U_{p,X} \oplus \cdots \oplus U_{i,X}$$

using the metric δ (see [2, Equation 3.4.10]) on the manifold of filtrations. In particular, he shows that

$$\limsup_{n\to\infty} \frac{1}{n} \log \delta(F_X(n), F_X) \leq -h,$$

where $h > 0$ is a parameter also appearing in the definition of δ. Disentangling the metric yields the desired convergence statement for discrete time.

The version for continuous time follows as described in the proof of [2, Theorem 3.4.1] since

$$\limsup_{n\to\infty} \frac{1}{n} \sup_{0\leq t\leq 1} \log \|X(n+t, n)^{\pm 1}\| \leq 0. \qquad \square$$

If at least two singular values coincide, the singular value decomposition is not unique. However, according to Proposition 3.13 the singular values corresponding to different Lyapunov exponents are distinct for large t. In particular, the spaces $U_{i,X}(t)$ are uniquely defined for large t.

Corollary 3.15. *If equation (3.1) is regular and λ_1 is simple, then*

$$\lim_{t\to\infty} \frac{\|X(t)v\|}{\|X(t)\|} = \|v - P_{V_{2,X}} v\|$$

for $v \in \mathbb{R}^d$, where $P_{V_{2,X}}$ denotes the orthogonal projection onto $V_{2,X}$.

Proof. To prove the corollary, we use the two orthogonal decompositions $\mathbb{R}^d = U_{1,X} \oplus V_{2,X}$ and $\mathbb{R}^d = U_{1,X}(t) \oplus V_{2,X}(t)$ from Proposition 3.14 and its proof. Since $d_1 = 1$, there are unit vectors u_1 and $u_1(t)$ spanning $U_{1,X}$ and $U_{1,X}(t)$. Moreover, Proposition 3.14 implies

$$\lim_{t\to\infty} \|P_{V_{2,X}(t)} u_1\| = 0,$$

where $P_{V_{2,X}(t)}$ denotes the orthogonal projection onto $V_{2,X}(t)$. We estimate $\|X(t)u_1\| \leq \|X(t)\|$ and

$$\begin{aligned}\|X(t)u_1\| &= \|X(t)(\langle u_1, u_1(t)\rangle u_1(t) + P_{V_{2,X}(t)}u_1)\| \geq |\langle u_1, u_1(t)\rangle| \, \|X(t)\| - \|X(t)\| \, \|P_{V_{2,X}(t)}u_1\| \\ &= \left(\sqrt{1 - \|P_{V_{2,X}(t)}u_1\|^2} - \|P_{V_{2,X}(t)}u_1\|\right) \|X(t)\|.\end{aligned}$$

Thus, it holds

$$\lim_{t\to\infty} \frac{\|X(t)u_1\|}{\|X(t)\|} = 1.$$

Now, we decompose $v \in \mathbb{R}^d$ into $v = \langle v, u_1\rangle u_1 + v_2$ according to $\mathbb{R}^d = U_{1,X} \oplus V_{2,X}$. Since the system is regular and the characteristic exponents satisfy $\chi[X(t)v_2] \leq \lambda_2$ and $\chi[\|X(t)\|] = \lambda_1$, we have

$$\lim_{t\to\infty} \frac{\|X(t)v_2\|}{\|X(t)\|} = 0.$$

The claim of the corollary follows from

$$\frac{\|X(t)v\|}{\|X(t)\|} \leq |\langle v, u_1\rangle| \frac{\|X(t)u_1\|}{\|X(t)\|} + \frac{\|X(t)v_2\|}{\|X(t)\|}$$

and

$$\frac{\|X(t)v\|}{\|X(t)\|} \geq |\langle v, u_1\rangle| \frac{\|X(t)u_1\|}{\|X(t)\|} - \frac{\|X(t)v_2\|}{\|X(t)\|}.$$ □

3.3 Induced systems

Equation (3.1) induces a system on $\wedge^L\mathbb{R}^d$ via

$$\dot{\hat{x}} = \widehat{A(t)}^L \hat{x}. \tag{3.3}$$

In the following, we refer to equation (3.3) using the term *induced system*.

A fundamental matrix of the induced system can be obtained by taking the exterior power of a fundamental matrix of the original system:

Proposition 3.16. *It holds*

$$\frac{d}{dt}(\wedge^L X) = \hat{A}^L(\wedge^L X).$$

Proof. Since the determinant is multilinear, we have

$$\begin{aligned}\left\langle \frac{d}{dt}(\wedge^L X)e_I, e_J \right\rangle &= \frac{d}{dt}\langle Xe_{i_1} \wedge \cdots \wedge Xe_{i_L}, e_J\rangle = \sum_{k=1}^{L} \left\langle Xe_{i_1} \wedge \cdots \wedge \frac{d}{dt}(Xe_{i_k}) \wedge \cdots \wedge Xe_{i_L}, e_J \right\rangle \\ &= \left\langle \sum_{k=1}^{L} Xe_{i_1} \wedge \cdots \wedge AXe_{i_k} \wedge \cdots \wedge Xe_{i_L}, e_J \right\rangle = \left\langle \hat{A}^L(\wedge^L X)e_I, e_J \right\rangle.\end{aligned}$$ □

Several properties carry over from the original system to the induced system. For instance, the Lyapunov spectrum $(\lambda_{i,L}, d_{i,L})_{i=1,\ldots,p_L}$ of the induced system can be related to the spectrum of the original system if the system is regular (see also [2, Theorem 5.3.1]).

Theorem 3.17. *Let equation (3.1) be regular. The Lyapunov exponents $\lambda_{i,L}$ of the induced system are the different values given by*

$$\Lambda_{i_1} + \cdots + \Lambda_{i_L}$$

for indices $i_1 < \cdots < i_L$. The corresponding multiplicity $d_{i,L}$ is the number of combinations of indices for which $\lambda_{i,L}$ can be achieved. In particular,

$$\lambda_{1,L} = \Lambda_1 + \cdots + \Lambda_L.$$

If $L = d_1 + \cdots + d_l$, then $\lambda_{1,L}$ is simple and the second space of the Lyapunov filtration $V_{2,L}$ is given by

$$\operatorname{span}\{x_1 \wedge \cdots \wedge x_L \mid \operatorname{span}(x_1, \ldots, x_L) \cap V_{l+1} \neq \{0\}\}.$$

Remark 3.18. If equation (3.1) is not regular, the spectrum of the induced system can differ from what is described in Theorem 3.17.

Proof. In the absence of regularity, the fastest growing solutions do not necessarily span the fastest growing subspace. This can be the case if the characteristic exponents of the fastest growing solutions are only obtainable along distinct subsequences.

Indeed, one readily checks that

$$X(t) := \begin{pmatrix} e^{t\sin(\log(1+t))} & 0 & 0 \\ 0 & e^{t\cos(\log(1+t))} & 0 \\ 0 & 0 & e^{\frac{1}{2}t} \end{pmatrix}$$

is a normal fundamental matrix corresponding to a bounded, continuous system with Lyapunov exponents $\Lambda_1 = \Lambda_2 = 1$ and $\Lambda_3 = 1/2$. Since the characteristic exponents of the first two columns of $X = [x_1, x_2, x_3]$ are not sharp, the system is not regular. Moreover, one computes

$$\begin{aligned} \chi[x_1 \wedge x_2] &= \chi[e^{t(\sin(\log(1+t))+\cos(\log(1+t)))}] = \sqrt{2} \\ \chi[x_1 \wedge x_3] &= \chi[e^{t(\sin(\log(1+t))+\frac{1}{2})}] = \frac{3}{2} \\ \chi[x_2 \wedge x_3] &= \chi[e^{t(\cos(\log(1+t))+\frac{1}{2})}] = \frac{3}{2}. \end{aligned}$$

Since $x_1(t) \wedge x_3(t)$ and $x_2(t) \wedge x_3(t)$ are orthogonal for each t, any nontrivial linear combination of them has characteristic exponent $3/2$. In particular, $\Lambda_{1,2} = \Lambda_{2,2} = 3/2$ and $\Lambda_{3,2} = \sqrt{2}$. Thus, even though x_1 and x_2 have the highest characteristic exponents, their associated volume element has the lowest characteristic exponent. □

We prove Theorem 3.17 using the following lemma:

Lemma 3.19. *If equation (3.1) is regular, then the induced basis of a normal basis is normal and the induced system is regular.*

Proof. Let $x_1, \ldots, x_d$ be a normal basis such that $\chi[x_i] = \Lambda_i$. Since

$$\chi[x_{i_1} \wedge \cdots \wedge x_{i_L}] \leq \chi[x_{i_1}] + \cdots + \chi[x_{i_L}] = \Lambda_{i_1} + \cdots + \Lambda_{i_L},$$

we have

$$\sum_{i_1<\cdots<i_L} \Lambda_{i_1} + \cdots + \Lambda_{i_L} \geq \sum_{i_1<\cdots<i_L} \chi[x_{i_1} \wedge \cdots \wedge x_{i_L}] \geq \chi[\det(\wedge^L X(t))]$$
$$\geq \liminf_{t\to\infty} \frac{1}{t} \log |\det(\wedge^L X(t))| = \binom{d-1}{L-1} \liminf_{t\to\infty} \frac{1}{t} \log |\det X(t)| = \binom{d-1}{L-1} \sum_{i=1}^{d} \Lambda_i.$$

Each index i appears in precisely $\binom{d-1}{L-1}$ combinations of indices $i_1 < \cdots < i_L$. Hence, the above inequalities are actually equalities, proving that the induced basis is a normal basis and that the induced system is regular. □

The beginning of the proof of Lemma 3.19 implies the following:

Proposition 3.20. *It holds*

$$\lambda_{1,L} \leq \Lambda_1 + \cdots + \Lambda_L$$

independent of the regularity of equation (3.1).

Proof of Theorem 3.17. Let $x_1, \ldots, x_d$ be a normal basis such that $\chi[x_i] = \Lambda_i$. Since the induced basis is normal, it realizes the whole Lyapunov spectrum of the induced system. Our claims about the spectrum in Theorem 3.17 now follow from

$$\chi[x_{i_1} \wedge \cdots \wedge x_{i_L}] = \Lambda_{i_1} \wedge \cdots \wedge \Lambda_{i_L}.$$

Moreover, $V_{2,L}$ is spanned by solutions

$$x_{i_1} \wedge \cdots \wedge x_{i_L}$$

such that

$$\Lambda_{i_1} + \cdots + \Lambda_{i_L} < \Lambda_1 + \cdots + \Lambda_L.$$

If $L = d_1 + \cdots + d_l$, the latter is equivalent to $x_{i_L} \in V_{l+1}$, which proves that $V_{2,L}$ is a subset of the set defined in Theorem 3.17. On the other hand, their dimensions must coincide since the codimension of $V_{2,L}$ is $d_{1,L} = 1$ and neither set contains the solution $x_1 \wedge \cdots \wedge x_L$. □

As a direct consequence, we get Proposition 3.13.

Proof of Proposition 3.13. The previous lemma and Proposition 3.9 imply

$$\Lambda_L = (\Lambda_1 + \cdots + \Lambda_L) - (\Lambda_1 + \cdots + \Lambda_{L-1}) = \lim_{t\to\infty} \frac{1}{t} \log \| \wedge^L X(t)\| - \lim_{t\to\infty} \frac{1}{t} \log \| \wedge^{L-1} X(t)\|$$
$$= \lim_{t\to\infty} \frac{1}{t} \log \frac{\sigma_1(X(t)) \ldots \sigma_L(X(t))}{\sigma_1(X(t)) \ldots \sigma_{L-1}(X(t))} = \lim_{t\to\infty} \frac{1}{t} \log \sigma_L(X(t)).$$

□

Corollary 3.21. *If equation* (3.1) *is regular and* $L = d_1 + \cdots + d_l$, *then*

$$\lim_{t\to\infty} \frac{\|(\wedge^L X(t))\hat{v}\|}{\| \wedge^L X(t)\|} > 0$$

for every $\hat{v} \notin V_{2,L,X}$.

Proof. Since the induced system on the space of L-fold exterior products is regular and $\lambda_{1,L}$ is simple, the claim follows from Corollary 3.15. □

3.4 Stability of Lyapunov exponents

The stability of Lyapunov exponents has been widely studied. Here, we mainly state results listed in the overview from [1, Chapter V] and refer to [7] for the relation to integral separation.

Definition 3.22 ([1, Definition 5.2.1])**.** The Lyapunov exponents of equation (3.1) are called *stable* if for any $\epsilon > 0$ there exist a $\delta > 0$ such that the Lyapunov exponents of the continuously perturbed system $\dot{\tilde{x}} = (A(t) + Q(t))\tilde{x}$ with $\sup_{t\geq 0} \|Q(t)\| < \delta$ satisfy

$$|\Lambda_i - \tilde{\Lambda}_i| < \epsilon$$

for $i = 1, \dots, d$.

The stability of Lyapunov exponents can be characterized by a uniform gap between the exponential growth rates of solutions corresponding to different Lyapunov exponents (this property is called *integral separation*; see also [7]).

Theorem 3.23 ([1, Theorem 5.4.8])**.** *The Lyapunov exponents of a system with simple spectrum are stable if and only if there exists a fundamental matrix $X(t) = [x_1(t), \dots, x_d(t)]$ and constants $a, b > 0$ such that*

$$\frac{\|x_i(t)\|}{\|x_i(s)\|} \geq be^{a(t-s)} \frac{\|x_{i+1}(t)\|}{\|x_{i+1}(s)\|}$$

for all $t \geq s$.

In fact, one may use such a fundamental matrix to construct a Lyapunov transformation that reduces equation (3.1) to a diagonal system [1, Theorem 5.3.1].

The stability of Lyapunov exponents for systems with degenerate spectra can be characterized in a similar fashion by transforming the system to block diagonal form.

Theorem 3.24 ([1, Theorem 5.4.9], [3])**.** *The Lyapunov exponents of equation (3.1) are stable if and only if there exists a Lyapunov transformation reducing the system to block diagonal form*

$$\dot{y} = \operatorname{diag}(B_1(t), \dots, B_p(t))y,$$

where $B_i(t) \in \mathbb{R}^{d_i \times d_i}$ is upper triangular, such that the following hold:

(i) all non-trivial solutions of $\dot{y}_i = B_i(t)y_i$ have characteristic exponent λ_i,

(ii) λ_i is stable[6] for $\dot{y}_i = B_i(t)y_i$,

(iii) there are constants $a, b > 0$ such that

$$\|Y_i(t,s)^{-1}\|^{-1} \geq be^{a(t-s)}\|Y_{i+1}(t,s)\| \tag{3.4}$$

for all $t \geq s$, where $Y_i(t,s)$ denotes the Cauchy matrix of $\dot{y}_i = B_i(t)y_i$.

Example 3.25. Let us return to Example 3.6. The system

$$A(t) = \begin{pmatrix} 1 & 0 \\ 0 & a_{22}(t) \end{pmatrix}$$

[6] [1, Theorem 5.4.9] uses the condition $\overline{\omega}_i = \lambda_i = \Omega_i$, which is equivalent to the stability of λ_i on the subsystem (this follows from [1, Theorem 5.4.9] applied to the subsystem). The quantities $\overline{\omega}_i$ and Ω_i can be computed in terms of *lower* and *upper functions* for the subsystem (see [1, Definition 5.1.2, Definition 5.1.3 and p. 171]).

is already in block diagonal form such that the first block corresponds to $\lambda_1 = 1$ and the second block corresponds to $\lambda_2 = 0$. However, it does not satisfy (iii) of Theorem 3.24 since there are no constants $a, b > 0$ such that

$$e^{(b_n - a_n) - \int_{a_n}^{b_n} a_{22}(\tau)d\tau} = e^{\log n - \log n} = 1$$

is bounded from below by $be^{a(b_n - a_n)} = bn^a$ for all $n \in \mathbb{N}$.

Now, any Lyapunov transformation that maps to a system of the same block diagonal form satisfying (i) must be a diagonal transformation

$$L(t) = \begin{pmatrix} l_{11}(t) & 0 \\ 0 & l_{22}(t) \end{pmatrix}.$$

Since $l_{11}(t)$ and $l_{22}(t)$ are bounded from above and below by positive constants, the Lyapunov transformation does not change whether (iii) is satisfied or not. In particular, this proves that the Lyapunov exponents of the system cannot be stable.

Systems with stable Lyapunov exponents retain their spectra under perturbations that tend to zero.

Theorem 3.26 ([3])**.** *Assume equation* (3.1) *has stable Lyapunov exponents. If $Q(t)$ is a bounded, piecewise continuous perturbation such that*

$$\|Q(t)\| \to 0 \text{ as } t \to \infty,$$

then the perturbed system $\dot{\tilde{x}} = (A(t) + Q(t))\tilde{x}$ has the same Lyapunov spectrum.

While L^∞-perturbations of regular systems do not retain regularity in general, we have the following result:

Proposition 3.27. *If equation* (3.1) *is regular, has stable Lyapunov exponents, and $Q(t)$ is a bounded, piecewise continuous perturbation such that*

$$\|Q(t)\| \to 0 \text{ as } t \to \infty,$$

then the perturbed system is regular.

Proof. Theorem 3.26 implies that

$$\Lambda_1 + \cdots + \Lambda_d = \tilde{\Lambda}_1 + \cdots + \tilde{\Lambda}_d.$$

Moreover, due to the Liouville–Ostrogradski formula, we have

$$\det \tilde{X}(t) = \det \tilde{X}(0)\, e^{\int_0^t \operatorname{tr}(A(\tau)+Q(\tau))d\tau} = \det(\tilde{X}(0)X(0)^{-1}) \det X(t)\, e^{\int_0^t \operatorname{tr}(Q(\tau))d\tau}.$$

Since

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t \operatorname{tr}(Q(\tau))d\tau = 0,$$

regularity of the original system implies regularity of the perturbed system:

$$\begin{aligned} \Lambda_1 + \cdots + \Lambda_d = \tilde{\Lambda}_1 + \cdots + \tilde{\Lambda}_d &\geq \liminf_{t\to\infty} \frac{1}{t} \log |\det \tilde{X}(t)| = \liminf_{t\to\infty} \frac{1}{t} \log |\det X(t)| \\ &= \Lambda_1 + \cdots + \Lambda_d. \end{aligned}$$

□

3.5 Strong fast invertibility

In this subsection, we introduce *strong fast invertibility*, which is a weaker concept than the stability of Lyapunov exponents but still sufficient for their computation. Our main objectives are a characterization result that allows us to compare strong fast invertibility to the stability of Lyapunov exponents and perturbation results in preparation for the analysis of Benettin's algorithm.

3.5.1 Definition and relation to induced systems

Quas et al. introduce three notions of fast invertibility (weak/standard/strong) to analyze the existence of a dominated splitting for discrete-time systems [21]. Here, we focus solely on the strong version, since weak and standard fast invertibility are trivially satisfied for systems with bounded coefficients.

Definition 3.28 ([21])**.** Equation (3.1) is said to be *L-dimensionally strongly fast invertible*[7] if

$$c_{FI,L} := \sup_{t\geq s\geq \tau} \prod_{k=1}^{L} \frac{\sigma_k(X(t,s))\sigma_k(X(s,\tau))}{\sigma_k(X(t,\tau))} < \infty.$$

There are several equivalent formulations immediately visible from the definition.

Lemma 3.29. *The following are equivalent:*

(i) Equation (3.1) is L-dim. strongly fast invertible.

(ii) The induced system on $\wedge^L\mathbb{R}^d$ is 1-dim. strongly fast invertible.

(iii) There is a constant $c > 0$ such that

$$\frac{\| \wedge^L X(t,\tau)\|}{\| \wedge^L X(s,\tau)\|} \leq \| \wedge^L X(t,s)\| \leq c\frac{\| \wedge^L X(t,\tau)\|}{\| \wedge^L X(s,\tau)\|}$$

for all $t \geq s \geq \tau$.

(iv) $\sup_{t\geq s} \prod_{k=1}^{L} \frac{\sigma_k(X(t,s))\sigma_k(X(s))}{\sigma_k(X(t))} < \infty$ for any fundamental matrix $X(t)$.

(v) $\sup_{t\geq s\geq\tau\geq T} \prod_{k=1}^{L} \frac{\sigma_k(X(t,s))\sigma_k(X(s,\tau))}{\sigma_k(X(t,\tau))} < \infty$ for any $T > 0$.

Proof. The relation between strong fast invertibility and exterior products follows from Lemma 2.2. The third characterization is merely a reformulation of strong fast invertibility for the induced system. Equivalence of strong fast invertibility to the fourth characterization follows from

$$\frac{\| \wedge^L X(t,s)\| \| \wedge^L X(s)\|}{\| \wedge^L X(t)\|} \leq \| \wedge^L X(0)\| \| \wedge^L X(0)^{-1}\| \frac{\| \wedge^L X(t,s)\| \| \wedge^L X(s,0)\|}{\| \wedge^L X(t,0)\|}$$

and

$$\begin{aligned}
&\frac{\| \wedge^L X(t,s)\| \| \wedge^L X(s,\tau)\|}{\| \wedge^L X(t,\tau)\|} \\
&\quad = \frac{\| \wedge^L X(t,s)\| \| \wedge^L X(s)\|}{\| \wedge^L X(t)\|} \cdot \frac{\| \wedge^L X(s,\tau)\| \| \wedge^L X(\tau)\|}{\| \wedge^L X(s)\|} \cdot \frac{\| \wedge^L X(t)\|}{\| \wedge^L X(t,\tau)\| \| \wedge^L X(\tau)\|} \\
&\quad \leq \frac{\| \wedge^L X(t,s)\| \| \wedge^L X(s)\|}{\| \wedge^L X(t)\|} \cdot \frac{\| \wedge^L X(s,\tau)\| \| \wedge^L X(\tau)\|}{\| \wedge^L X(s)\|}.
\end{aligned}$$

[7] The name "fast invertibility" stems from the context of [21] as it ensures that the cocylce is uniformly invertible on the fastest subspace of the respective dimension (without assuming bounded coefficients).

Finally, using

$$\wedge^L X(T+t,t) \wedge^L X(t,s) = \wedge^L X(T+t,T+s) \wedge^L X(T+s,s),$$

and $\sup_t \|\hat{A}^L(t)\| \leq LM$, one may show the final characterization:

$$\frac{\|\wedge^L X(t,s)\| \, \|\wedge^L X(s,\tau)\|}{\|\wedge^L X(t,\tau)\|} \leq e^{6TLM} \frac{\|\wedge^L X(T+t,T+s)\| \, \|\wedge^L X(T+s,T+\tau)\|}{\|\wedge^L X(T+t,T+\tau)\|}. \qquad \square$$

Maybe the most intuitive of the above characterizations of strong fast invertibility is the third. It means that the maximal growth of L-volumes along any interval can be computed (up to a constant independent of the interval) by bisecting the interval and multiplying the maximal growths of L-volumes on the subintervals.

Proposition 3.30. *Every system is d-dim. strongly fast invertible.*

Proof. Since $\dim(\wedge^d \mathbb{R}^d) = 1$, we have $c_{FI,d} = 1$. $\square$

Example 3.31. The system from Example 3.6 is strongly fast invertible at dimensions 1 and 2: Due to the previous proposition, we only need to consider the first dimension. We compute the Cauchy matrix

$$X(t,s) := \begin{pmatrix} e^{t-s} & 0 \\ 0 & e^{\int_s^t a_{22}(\tau)\,d\tau} \end{pmatrix}.$$

Since $0 \leq a_{22}(t) \leq 1$, the first diagonal entry of $X(t,s)$ is always larger than the second for $t \geq s$. In particular, it holds

$$\sigma_1(X(t,s)) = e^{t-s},$$

which implies 1-dim. strong fast invertibility.

3.5.2 Characterization and comparison to stability of Lyapunov exponents

To derive the characterization theorem mentioned in the introduction, we first prove that regularity and strong fast invertibility imply the existence of a Lyapunov transformation that brings the system into block diagonal form.

Proposition 3.32. *Assume equation (3.1) has Lyapunov exponents $\lambda_1 > \cdots > \lambda_p$ with multiplicities $d_1 + \cdots + d_p = d$. If the system is regular and strongly fast invertible at dim. $d_1 + \cdots + d_l$ for $l = 1, \ldots, p$, then there is a Lyapunov transformation reducing the system to block diagonal form:*

$$\dot{y} = \operatorname{diag}(B_1(t), \ldots, B_p(t))y,$$

where $B_i \in \mathbb{R}^{d_i \times d_i}$ is upper triangular, such that all non-trivial solutions of $\dot{y}_i = B_i y_i$ have characteristic exponent λ_i.

We prove the proposition via induced systems using two auxiliary lemmata and the following result:

Theorem 3.33 ([1, Theorems 3.3.3 and 3.3.4])**.** *There exists a Lyapunov transformation reducing equation (3.1) to block diagonal form:*

$$\dot{y} = \operatorname{diag}(B_1(t), \ldots, B_k(t))y,$$

where $B_i \in \mathbb{R}^{n_i \times n_i}$ is upper triangular, if and only if there is a fundamental matrix

$$X = [X_1, \dots, X_k]$$

with $X_i \in \mathbb{R}^{d \times n_i}$ satisfying

$$\inf_t \frac{G(X)}{G(X_1) \dots G(X_k)} > 0, \tag{3.5}$$

where G denotes the Gram determinant.

Remark 3.34. Given a fundamental matrix $X(t)$ as in Theorem 3.33, the Lyapunov transformation is constructed by applying the Gram–Schmidt procedure to each block $X_i(t)$ individually, yielding

$$X(t) = [Q_1(t), \dots, Q_k(t)] \operatorname{diag}(R_1(t), \dots, R_k(t)) =: L(t)Y(t).$$

Lemma 3.35 ([1, Remark 3.3.4])**.** *Let $X = [X_1, X_2]$. It holds*

$$\frac{G(X)}{G(X_1)G(X_2)} = \prod_{i=1}^{l} \sin^2 \alpha_i(\operatorname{im} X_1, \operatorname{im} X_2),$$

where $\alpha_1 \le \dots \le \alpha_l$ are the principle angles.

Lemma 3.36. *If equation (3.1) is 1-dim. strongly fast invertible and $X = [X_1, X_2]$ is a fundamental matrix such that $X_1 \in \mathbb{R}^{d \times 1}$ has a higher characteristic exponent than the columns of $X_2 \in \mathbb{R}^{d \times (d-1)}$, then*

$$\inf_t \sin^2 \alpha_1(\operatorname{im} X_1(t), \operatorname{im} X_2(t)) > 0. \tag{3.6}$$

Proof. Let $X = [X_1, X_2]$ be as in the claim. We first apply the Gram–Schmidt procedure to bring X into upper triangular form. Indeed, the Gram–Schmidt procedure is an orthogonal Lyapunov transformation (Proposition 3.2). Thus, it leaves the fraction in equation (3.5) and hence also $\sin^2 \alpha_1(\operatorname{im} X_1, \operatorname{im} X_2)$ invariant. So, it is sufficient to check equation (3.6) for

$$Y = [Y_1, Y_2] = \begin{pmatrix} y_{11} & Y_{12} \\ 0 & Y_{22} \end{pmatrix}$$

in which y_{11} has a higher characteristic exponent than $\|Y_{12}\|$ and $\|Y_{22}\|$.

Given $s \ge 0$, we always find $t_s \ge s$ such that

$$\max_{\alpha \neq 0} \frac{\left| \frac{y_{11}(s)}{y_{11}(t_s)} Y_{12}(t_s)\alpha \right|}{\|Y_{22}(s)\alpha\|} \le 1$$

and $\|Y(t_s)\| \le 2|y_{11}(t_s)|$. In order to make use of strong fast invertibility, we compute the Cauchy matrix:

$$Y(t,s) = \begin{pmatrix} y_{11}(t,s) & Y_{12}(t,s) \\ 0 & Y_{22}(t,s) \end{pmatrix} = \begin{pmatrix} \frac{y_{11}(t)}{y_{11}(s)} & Y_{12}(t)Y_{22}(s)^{-1} - \frac{y_{11}(t)}{y_{11}(s)} Y_{12}(s)Y_{22}(s)^{-1} \\ 0 & Y_{22}(t)Y_{22}(s)^{-1} \end{pmatrix}.$$

Now, for $s \ge 0$ and $\alpha \neq 0$ it holds

$$\begin{aligned} \frac{|Y_{12}(s)\alpha|}{\|Y_{22}(s)\alpha\|} &\le 1 + \left| \frac{\frac{y_{11}(s)}{y_{11}(t_s)} Y_{12}(t_s)\alpha}{\|Y_{22}(s)\alpha\|} - \frac{Y_{12}(s)\alpha}{\|Y_{22}(s)\alpha\|} \right| = 1 + \frac{\left| \frac{y_{11}(s)}{y_{11}(t_s)} Y_{12}(t_s, s)Y_{22}(s)\alpha \right|}{\|Y_{22}(s)\alpha\|} \\ &\le 1 + \frac{\|Y_{12}(t_s, s)\| \, |y_{11}(s)|}{|y_{11}(t_s)|} \le 1 + 2\frac{\|Y(t_s, s)\| \, \|Y(s)\|}{\|Y(t_s)\|} \le \underbrace{1 + 2c_{FI,L} \, \|Y(0)\| \, \|Y(0)^{-1}\|}_{=:c}. \end{aligned}$$

Since

$$\left(\frac{\langle Y_1(t), Y_2(t)\alpha\rangle}{\|Y_1(t)\|\ \|Y_2(t)\alpha\|}\right)^2 = \left(\frac{\langle e_1, Y_2(t)\alpha\rangle}{\|Y_2(t)\alpha\|}\right)^2 = \frac{|Y_{12}(t)\alpha|^2}{|Y_{12}(t)\alpha|^2 + \|Y_{22}(t)\alpha\|^2} = \frac{1}{1+\left(\frac{|Y_{12}(t)\alpha|}{\|Y_{22}(t)\alpha\|}\right)^{-2}}$$
$$\leq \frac{1}{1+c^{-2}},$$

we have

$$\sin^2\alpha_1(\operatorname{im} Y_1, \operatorname{im} Y_2) = 1 - \cos^2\alpha_1(\operatorname{im} Y_1, \operatorname{im} Y_2) = 1 - \max_{\alpha\neq 0}\left(\frac{\langle Y_1(t), Y_2(t)\alpha\rangle}{\|Y_1(t)\|\ \|Y_2(t)\alpha\|}\right)^2$$
$$\geq 1 - \frac{1}{1+c^{-2}} > 0. \qquad \square$$

Proof of Proposition 3.32. Let $X(t) = [X_1, \dots, X_p]$ be an ordered normal fundamental matrix so that the columns of X_i have characteristic exponent λ_i. We first show that equation (3.5) holds with $n_1 = L$ and $n_2 = d - L$ if the system is strongly fast invertible at dim. $L = d_1 + \cdots + d_l$ and then apply Theorem 3.33 successively to arrive at the desired form.

Fix $L = d_1 + \cdots + d_l$ and set

$$U := \operatorname{im}[X_1, \dots, X_l] \quad \text{and} \quad V := \operatorname{im}[X_{l+1}, \dots, X_p].$$

Lemma 3.35 and Corollary 2.5 imply

$$\frac{G(X)}{G([X_1, \dots, X_l])G([X_{l+1}, \dots, X_p])} = \prod_{i=1}^{\min(L,d-L)} \sin^2\alpha_i(U,V) = \sin^2\alpha_1(\hat{U}, \hat{V}),$$

where

$$\hat{U} = \operatorname{span}\{(\wedge^L X)(e_1 \wedge \cdots \wedge e_L)\}$$

and

$$\hat{V} = \operatorname{span}\{(\wedge^L X)(e_{i_1} \wedge \cdots \wedge e_{i_L}) \mid \{i_1, \dots, i_L\} \neq \{1, \dots, L\}\}.$$

Now, let $Y = [Y_1, Y_2]$ be a matrix representation of $\wedge^L X$ with respect to the standard basis on $\wedge^L\mathbb{R}^d$. Order the induced basis starting with $e_1 \wedge \cdots \wedge e_L$ so that the first column Y_1 of Y represents $(\wedge^L X)(e_1 \wedge \cdots \wedge e_L)$. Then,

$$\sin^2\alpha_1(\hat{U}, \hat{V}) = \sin^2\alpha_1(\operatorname{im} Y_1, \operatorname{im} Y_2).$$

Due to regularity, Y_1 has characteristic exponent $\Lambda_1 + \cdots + \Lambda_L$ and the columns of Y_2 have lower characteristic exponents. Hence, Lemma 3.36 and the above arguments imply

$$\inf_t \frac{G(X)}{G([X_1, \dots, X_l])G([X_{l+1}, \dots, X_p])} > 0.$$

To arrive at the block diagonal form claimed in the proposition, we apply the transformation from Remark 3.34 successively. First, we use strong fast invertibility at dim. d_1 to make the first d_1 columns of X orthogonal to the rest. Assuming orthogonality of the first d_1 columns, strong fast invertibility at dim. $d_1 + d_2$ implies

$$0 < \inf_t \frac{G(X)}{G([X_{d_1}, X_{d_2}])G([X_{d_3}, \dots, X_{d_p}])} = \inf_t \frac{G(X)}{G(X_{d_1})G(X_{d_2})G([X_{d_3}, \dots, X_{d_p}])}.$$

Thus, we may apply another Lyapunov transformation to decouple the next subsystem and so on. $\square$

Using Proposition 3.32, we now may prove our characterization result for strong fast invertibility.

Theorem 3.37. *Assume equation (3.1) has Lyapunov exponents $\lambda_1 > \cdots > \lambda_p$ with multiplicities $d_1 + \cdots + d_p = d$. If the system is regular and strongly fast invertible at dim. $d_1 + \cdots + d_l$ for $l = 1, \dots, p$, then there exists a Lyapunov transformation reducing the system to block diagonal form*

$$\dot{y} = \operatorname{diag}(B_1(t), \dots, B_p(t))y,$$

where $B_i(t) \in \mathbb{R}^{d_i \times d_i}$ is upper triangular, such that the following hold:

(i) all non-trivial solutions of $\dot{y}_i = B_i(t)y_i$ have characteristic exponent λ_i,

(ii) there is a constant $b > 0$ such that

$$\|Y_i(t,s)^{-1}\|^{-1} \geq b\|Y_{i+1}(t,s)\| \tag{3.7}$$

for all $t \geq s$, where $Y_i(t,s)$ denotes the Cauchy matrix of $\dot{y}_i = B_i(t)y_i$.

Conversely, any block diagonal system $\dot{y} = B(t)y$ satisfying (i) and (ii) is strongly fast invertible at dim. $d_1 + \cdots + d_l$ for $l = 1, \dots, p$.

Proof. Let us first assume that the system is regular and strongly fast invertible at the respective dimensions. After applying Proposition 3.32, all that remains is to show that equation (3.7) is satisfied for the reduced system. To this end, fix $L = d_1 + \cdots + d_l$ and set $Y = Z_1 + Z_2$ with

$$Z_1 := \operatorname{diag}(Y_1, \dots, Y_L, 0, \dots, 0)$$

and

$$Z_2 := \operatorname{diag}(0, \dots, 0, Y_{L+1}, \dots, Y_p).$$

Due to Lemma 2.3, we have

$$\| \wedge^L Y\| = \max_k \|(\wedge^k Z_1) \wedge (\wedge^{L-k} Z_2)\|$$

and

$$\| \wedge^L Y\| \geq \| \wedge^{L-1} Z_1\| \, \|Z_2\| = \frac{\| \wedge^L Z_1\|}{\sigma_L(Z_1)}\|Z_2\|.$$

The singular value $\sigma_L(Z_1)$ can be estimated via

$$\sigma_L(Z_1) = \sigma_L(\operatorname{diag}(Y_1, \dots, Y_l)) = \| \operatorname{diag}(Y_1^{-1}, \dots, Y_l^{-1})\|^{-1} \leq \|Y_l^{-1}\|^{-1}.$$

Due to regularity, we have

$$\chi[\| \wedge^L Z_1\|] = \lambda_{1,L} > \lambda_{2,L} \geq \chi[\|(\wedge^k Z_1) \wedge (\wedge^{L-k} Z_2)\|]$$

for $k < L$, which implies

$$\| \wedge^L Y(t)\| = \| \wedge^L Z_1(t)\|$$

for t large enough. Moreover, it holds

$$\| \wedge^L Z_1(t,s)\| = \| \wedge^L \operatorname{diag}(Y_1(t,s), \dots, Y_l(t,s))\| = \frac{\| \wedge^L \operatorname{diag}(Y_1(t), \dots, Y_l(t))\|}{\| \wedge^L \operatorname{diag}(Y_1(s), \dots, Y_l(s))\|} = \frac{\| \wedge^L Z_1(t)\|}{\| \wedge^L Z_1(s)\|}$$

since $\wedge^L \mathbb{R}^L$ is one-dimensional. Combining the previous estimates, we get

$$\begin{aligned}\|Y_l(t,s)^{-1}\|^{-1} &\geq \frac{\|\wedge^L Z_1(t,s)\|}{\|\wedge^L Y(t,s)\|}\|Z_2(t,s)\| \geq \frac{\|\wedge^L Z_1(t,s)\|}{\|\wedge^L Y(t,s)\|}\|Y_{l+1}(t,s)\| \\ &= \frac{\|\wedge^L Z_1(t)\|}{\|\wedge^L Y(t,s)\|\,\|\wedge^L Z_1(s)\|}\|Y_{l+1}(t,s)\| \geq \frac{\|\wedge^L Y(t)\|}{\|\wedge^L Y(t,s)\|\,\|\wedge^L Y(s)\|}\|Y_{l+1}(t,s)\| \\ &\geq \frac{1}{c_{FI,L}\|\wedge^L Y(0)\|\,\|\wedge^L Y(0)^{-1}\|}\|Y_{l+1}(t,s)\|\end{aligned}$$

for large $t > 0$, which proves equation (3.7).

Next, we show that any block diagonal system as in Theorem 3.37 is strongly fast invertible at the respective dimensions. As before, fix $L = d_1 + \cdots + d_l$ and assume the decomposition $Y = Z_1 + Z_2$. Applying equation (3.7) repeatedly yields

$$\|Y_i^{-1}\|^{-1} \geq b\|Y_{i+1}\| \geq b\|Y_{i+1}^{-1}\|^{-1} \geq \cdots \geq b^k\|Y_{i+k}\|$$

and hence

$$\begin{aligned}\sigma_L(Z_1) = \sigma_L(\operatorname{diag}(Y_1,\dots,Y_l)) &= \|\operatorname{diag}(Y_1^{-1},\dots,Y_l^{-1})\|^{-1} = \min_{i=1,\dots,l}\|Y_i^{-1}\|^{-1} \\ &\geq b^{p-1}\max_{i=l+1,\dots,p}\|Y_i\| = b^{p-1}\|Z_2\|\end{aligned}$$

since $b \in (0,1]$ (set $s = t$ in equation (3.7)). Now, we estimate

$$\begin{aligned}\|\wedge^L Y\| &= \max_k \|(\wedge^k Z_1) \wedge (\wedge^{L-k} Z_2)\| \leq \max_k \binom{d}{L}^{\frac{1}{2}} \|\wedge^k Z_1\|\,\|\wedge^{L-k} Z_2\| \\ &\leq \max_k \binom{d}{L}^{\frac{1}{2}} \|\wedge^k Z_1\|\,\|Z_2\|^{L-k} \leq \max_k \binom{d}{L}^{\frac{1}{2}} \|\wedge^k Z_1\| b^{-(p-1)(L-k)}\sigma_L(Z_1)^{L-k} \\ &\leq \underbrace{\max_k \left(\binom{d}{L}^{\frac{1}{2}} b^{-(p-1)(L-k)}\right)}_{=:c} \|\wedge^L Z_1\|.\end{aligned}$$

Hence, we get

$$\sup_{t\geq s}\frac{\|\wedge^L Y(t,s)\|\,\|\wedge^L Y(s)\|}{\|\wedge^L Y(t)\|} \leq c^2 \underbrace{\sup_{t\geq s}\frac{\|\wedge^L Z_1(t,s)\|\,\|\wedge^L Z_1(s)\|}{\|\wedge^L Z_1(t)\|}}_{=1} < \infty. \qquad \square$$

Remark 3.38. When testing for strong fast invertibility (resp. for stability of Lyapunov exponents), it is enough to check the conditions of Theorem 3.37 (resp. Theorem 3.24) after transforming the original system to any block diagonal system of the form

$$\dot{y} = \operatorname{diag}(B_1(t),\dots,B_p(t))y$$

such that the non-trivial solutions of block $B_i(t) \in \mathbb{R}^{d_i\times d_i}$ have characteristic exponent λ_i.

Proof. Any Lyapunov transformation between systems of this form acts as Lyapunov transformations on the individual blocks, i.e., $L(t) = \operatorname{diag}(L_1(t),\dots,L_p(t))$. This implies that equation (3.7) (resp. stability of the Lyapunov exponents of the subsystems and equation (3.4)) holds for one such system if and only if it holds for all of them. $\square$

An immediate consequence of Theorem 3.37 is that stability of Lyapunov exponents implies strong fast invertibility.

Corollary 3.39. *Assume equation (3.1) has Lyapunov exponents $\lambda_1 > \cdots > \lambda_p$ with multiplicities $d_1 + \cdots + d_p = d$. If the Lyapunov exponents are stable, then the system is strongly fast invertible at dim. $d_1 + \cdots + d_l$ for $l = 1, \dots, p$.*

Remark 3.40. Example 3.6 shows that the converse of Corollary 3.39 is false in general (even with the help of regularity). There are regular systems that are strongly fast invertible at every dimension that do not have stable Lyapunov exponents.

In case the Lyapunov spectrum is simple, strong fast invertibility implies the existence of a fundamental system of solutions with uniformly separated growth.

Theorem 3.41. *If equation (3.1) is regular, has simple Lyapunov spectrum and is strongly fast invertible at every dimension, then there exists a fundamental matrix $X(t) = [x_1(t), \dots, x_d(t)]$ and a constant $b > 0$ such that*

$$\frac{\|x_i(t)\|}{\|x_i(s)\|} \geq b \frac{\|x_{i+1}(t)\|}{\|x_{i+1}(s)\|} \tag{3.8}$$

for all $t \geq s$.

Proof. According to Theorem 3.37 there is a Lyapunov transformation $L(t)$ bringing the system to diagonal form with fundamental matrix $Y = \operatorname{diag}(y_{11}, \dots, y_{dd})$ and a constant $b' > 0$ such that

$$\frac{|y_{ii}(t)|}{|y_{ii}(s)|} \geq b' \frac{|y_{(i+1)(i+1)}(t)|}{|y_{(i+1)(i+1)}(s)|}$$

for all $t \geq s$. The fundamental matrix $X = LY$ of the original system satisfies

$$\|x_i(t)\| = \|L(t)e_i\| \, |y_{ii}(t)|.$$

Since $L(t)$ is a Lyapunov transformation, the term $\|L(t)e_i\|$ is uniformly bounded from below and above by positive constants. equation (3.8) follows. □

Remark 3.42. There is a regular system with simple Lyapunov spectrum satisfying equation (3.8) that is not strongly fast invertible at every dimension.

Proof. Let $0 < \epsilon_n \leq 1/e$ be a sequence of numbers converging to zero. We set

$$c_n := \left(\frac{9}{4}\right)^n \prod_{k=1}^{n} \left(\frac{1}{\epsilon_k}\right)^{\frac{1}{\epsilon_k}}.$$

The numbers

$$\begin{aligned}
t_{n,0} &:= c_n, \\
t_{n,1} &:= c_n + \frac{2}{3(1-\epsilon_n)}, \\
t_{n,2} &:= c_n + \frac{2}{3(1-\epsilon_n)} + \frac{\log\left(\frac{1}{\epsilon_n}\right)}{1-\epsilon_n} - \frac{2}{3}, \\
t_{n,3} &:= c_n + \frac{2}{3(1-\epsilon_n)} + \frac{\log\left(\frac{1}{\epsilon_n}\right)}{1-\epsilon_n},
\end{aligned}$$

$$t_{n,4} := c_n + \frac{2}{3(1-\epsilon_n)} + \frac{\log\left(\frac{1}{\epsilon_n}\right)}{\epsilon_n(1-\epsilon_n)},$$
$$t_{n,5} := c_n + \frac{2}{3(1-\epsilon_n)} + \frac{\log\left(\frac{1}{\epsilon_n}\right)}{\epsilon_n(1-\epsilon_n)} + 1,$$
$$t_{n,6} := c_n + \frac{5}{3(1-\epsilon_n)} + \frac{\log\left(\frac{1}{\epsilon_n}\right)}{\epsilon_n(1-\epsilon_n)},$$

satisfy

$$t_{n,0} \leq \cdots \leq t_{n,6} \leq t_{n+1,0}.$$

On the partition introduced by these numbers, we define functions

$$f(t) := \begin{cases} 1, & t \in [0, t_{1,0}) \\ c_{n-1} p_{n,f}(t - t_{n,0}), & t \in [t_{n,0}, t_{n,1}) \\ c_{n-1} \frac{3}{2} e^{(1-\epsilon_n)(t-t_{n,1})}, & t \in [t_{n,1}, t_{n,4}) \\ c_{n-1} \frac{3}{2} \left(\frac{1}{\epsilon_n}\right)^{\frac{1}{\epsilon_n}} q_{n,f}(t - t_{n,4}), & t \in [t_{n,4}, t_{n,6}) \\ c_n, & t \in [t_{n,6}, t_{n+1,0}) \end{cases}$$

and

$$g(t) := \begin{cases} 1, & t \in [0, t_{1,2}) \\ c_{n-1} p_{n,g}(t - t_{n,2}), & t \in [t_{n,2}, t_{n,3}) \\ c_{n-1} \frac{3}{2} e^{t-t_{n,3}}, & t \in [t_{n,3}, t_{n,4}) \\ c_{n-1} \frac{3}{2} \left(\frac{1}{\epsilon_n}\right)^{\frac{1}{\epsilon_n}} q_{n,g}(t - t_{n,4}), & t \in [t_{n,4}, t_{n,5}) \\ c_n, & t \in [t_{n,5}, t_{n+1,2}) \end{cases}$$

using the polynomials

$$p_{n,f}(t) := \frac{9}{8}(1-\epsilon_n)^2 t^2 + 1,$$
$$p_{n,g}(t) := \frac{9}{8} t^2 + 1,$$
$$q_{n,f}(t) := -\frac{1}{2}(1-\epsilon_n)^2 t^2 + (1-\epsilon_n)t + 1,$$
$$q_{n,g}(t) := -\frac{1}{2} t^2 + t + 1,$$

for smoothing. The functions have the following properties:

- $f, g \in C^1(\mathbb{R}_{\geq 0}, \mathbb{R})$,
- f, g are monotonically increasing,
- $|f' - f|/|g|$ bounded,
- $|g'|/|g|$ bounded,
- $1 \leq f(t), g(t) \leq t$ for $t \geq 1$.

In particular,

$$\dot{x} = A(t)x := \begin{pmatrix} 1 & \frac{f'-f}{g} \\ 0 & \frac{g'}{g} \end{pmatrix} x$$

is a continuous, bounded system with fundamental matrix

$$X(t) = [x_1(t), x_2(t)] = \begin{pmatrix} e^t & f \\ 0 & g \end{pmatrix}.$$

The solution $x_2(t)$ has characteristic exponent zero and the system is regular.

To show property equation (3.8), we first remark that

$$\frac{|p'_{n,f}|}{|p_{n,f}|}, \frac{|q'_{n,f}|}{|q_{n,f}|} \leq 1$$

on the respective intervals used in the definition of f. Since

$$(\log f(t))' = \frac{f'(t)}{f(t)} \leq 1,$$

the mean value theorem implies

$$\frac{f(t)}{f(s)} \leq e^{t-s}$$

for $t \geq s$. In combination with $g(t) \leq \frac{3}{2} f(t)$, we get equation (3.8):

$$\frac{\|x_2(t)\|^2}{\|x_2(s)\|^2} = \frac{f^2(t) + g^2(t)}{f^2(s) + g^2(s)} \leq \frac{13}{4} \frac{f^2(t)}{f^2(s)} \leq \frac{13}{4} \frac{\|x_1(t)\|^2}{\|x_1(s)\|^2}$$

for $t \geq s$.

To show that the system is not 1-dim. strongly fast invertible, we prove that there is no Lyapunov transformation bringing the system into diagonal form. For our particular fundamental matrix, it holds

$$\left(\frac{\langle x_1, x_2 \rangle}{\|x_1\| \, \|x_2\|} \right)^2 = \frac{1}{1 + \left(\frac{f}{g}\right)^{-2}}.$$

Since $f(t_{n,3})/g(t_{n,3}) = 1/\epsilon_n \to \infty$, the above expression converges to 1 along the subsequence $(t_{n,3})_n$. Now, let $Y = [y_1, y_2]$ be an arbitrary fundamental matrix. By expanding y_1 and y_2 with respect to our particular solutions and by using

$$\lim_{t \to \infty} \frac{\|x_2(t)\|}{\|x_1(t)\|} = 0,$$

one computes

$$\lim_{n \to \infty} \left(\frac{\langle y_1(t_{n,3}), y_2(t_{n,3}) \rangle}{\|y_1(t_{n,3})\| \, \|y_2(t_{n,3})\|} \right)^2 = 1.$$

Thus,

$$\inf_t \frac{G(Y)}{G(y_1)G(y_2)} = 1 - \sup_t \left(\frac{\langle y_1, y_2 \rangle}{\|y_1\| \, \|y_2\|} \right)^2 = 0,$$

and Theorem 3.33 implies that there is no Lyapunov transformation bringing the system into diagonal form. In particular, the system cannot be 1-dim. strongly fast invertible according to Theorem 3.37. □

3.5.3 Perturbation theory

We now establish several perturbation results for strongly fast invertible systems. Since we plan to use them to derive convergence theorems for Benettin's algorithm and since numerical integration can be represented as a piecewise continuous dynamical system, the perturbation results are formulated for systems

$$\dot{x} = A(t)x \tag{3.9}$$

such that A is bounded and piecewise continuous. Moreover, we assume all perturbations in this subsection to be of the same class, i.e., bounded and piecewise continuous.

While strong fast invertibility is weaker than the stability of Lyapunov exponents, it is enough to ensure upper semicontinuity of $\lambda_{1,L}$.

Theorem 3.43. *Assume equation (3.9) is L-dim. strongly fast invertible. For any perturbation $Q(t)$, the largest Lyapunov exponent of the induced system satisfies*

$$\tilde{\lambda}_{1,L} \leq \lambda_{1,L} + Lc_{FI,L} \limsup_{t\to\infty} \frac{1}{t}\int_0^t \|Q(\tau)\|\,d\tau \leq \lambda_{1,L} + Lc_{FI,L}\|Q\|_{L^\infty}$$

Remark 3.44. Remember that

$$\lambda_{1,L} = \Lambda_1 + \cdots + \Lambda_L$$

for regular systems.

Proof. Let $\tilde{X}(t)$ be a fundamental matrix of the perturbed system. $\wedge^L\tilde{X}$ solves the induced equation

$$\frac{d}{dt}(\wedge^L\tilde{X}) = \widehat{A+Q}^L(\wedge^L\tilde{X}) = \hat{A}^L(\wedge^L X) + \hat{Q}^L(\wedge^L X)$$

and can be seen as a solution of a perturbed system to

$$\frac{d}{dt}(\wedge^L X) = \hat{A}^L(\wedge^L X).$$

The variation of constants formula implies

$$\wedge^L\tilde{X}(t,s) = \wedge^L X(t,s) + \int_s^t (\wedge^L X(t,\tau))\hat{Q}^L(\tau)(\wedge^L\tilde{X}(\tau,s))\,d\tau.$$

Using $\|\hat{Q}^L(t)\| \leq L\|Q(t)\|$, we first estimate

$$\begin{aligned}\frac{\|\wedge^L\tilde{X}(t,s)\|}{\|\wedge^L X(t,s)\|} &\leq 1 + L\int_s^t \frac{\|\wedge^L X(t,\tau)\|\,\|\wedge^L X(\tau,s)\|}{\|\wedge^L X(t,s)\|}\|Q(\tau)\|\frac{\|\wedge^L\tilde{X}(\tau,s)\|}{\|\wedge^L X(\tau,s)\|}\,d\tau\\ &\leq 1 + Lc_{FI,L}\int_s^t \|Q(\tau)\|\frac{\|\wedge^L\tilde{X}(\tau,s)\|}{\|\wedge^L X(\tau,s)\|}\,d\tau\end{aligned}$$

and then apply Grönwall's inequality to get

$$\frac{\|\wedge^L\tilde{X}(t,s)\|}{\|\wedge^L X(t,s)\|} \leq e^{Lc_{FI,L}\int_s^t\|Q(\tau)\|\,d\tau}.$$

The claim now follows from Proposition 3.9. □

Lemma 3.45. *Perturbations on finite intervals do not change the Lyapunov spectrum of a system or its induced systems.*

Proof. Since characteristic exponents are asymptotic quantities and since one may choose fundamental matrices $X(t)$ and $\tilde{X}(t)$ that coincide for large t, the claim follows. □

Theorem 3.46. *Assume equation (3.9) is L-dim. strongly fast invertible. If $Q(t)$ is a perturbation such that*

$$\|Q(t)\| \to 0 \text{ as } t \to \infty,$$

then

$$\tilde{\lambda}_{1,L} \leq \lambda_{1,L}.$$

Proof. The theorem is a direct consequence of Theorem 3.43. □

Equality in Theorem 3.46 can be achieved for L^1-perturbations.

Theorem 3.47. *Assume equation (3.9) is L-dim. strongly fast invertible. If $Q(t)$ is a perturbation such that*

$$\int_0^\infty \|Q(t)\|\, dt < \infty,$$

then

$$\tilde{\lambda}_{1,L} = \lambda_{1,L}.$$

The theorem follows directly from Theorem 3.46 using the following lemma.

Lemma 3.48. *Assume equation (3.9) is L-dim. strongly fast invertible. If $Q(t)$ is a perturbation such that*

$$\int_0^\infty \|Q(t)\|\, dt < \infty,$$

then the perturbed system is L-dim. strongly fast invertible. Moreover, $c_{FI,L}$ is continuous with respect to L^1-perturbations.

Proof. According to Lemma 3.29 strong fast invertibility can be tested on $[T, \infty)$ for any fixed $T > 0$. Thus, by setting $Q(t)$ to zero on a finite interval, we may assume that

$$\int_0^\infty \|Q(t)\|\, dt < \frac{\log(2)}{L c_{FI,L}} \tag{3.10}$$

without affecting whether the perturbed system is strongly fast invertible or not. The variation of constants formula implies

$$\wedge^L \tilde{X}(t,s) - \wedge^L X(t,s) = \int_s^t (\wedge^L X(t,\tau))\hat{Q}^L(\tau)(\wedge^L \tilde{X}(\tau,s))\, d\tau.$$

Thus, it holds

$$\begin{aligned} &1 + \frac{\| \wedge^L \tilde{X}(t,s) - \wedge^L X(t,s)\|}{\| \wedge^L X(t,s)\|} \\ &\quad \leq 1 + L \int_s^t \frac{\| \wedge^L X(t,\tau)\| \, \| \wedge^L X(\tau,s)\|}{\| \wedge^L X(t,s)\|} \|Q(\tau)\| \left(1 + \frac{\| \wedge^L \tilde{X}(\tau,s) - \wedge^L X(\tau,s)\|}{\|(\wedge^L X(\tau,s)\|}\right) d\tau. \end{aligned}$$

Through Grönwall's inequality we get

$$1 + \frac{\| \wedge^L \tilde{X}(t,s) - \wedge^L X(t,s)\|}{\| \wedge^L X(t,s)\|} \leq e^{L c_{FI,L} \int_s^t \|Q(\tau)\|\, d\tau}$$

and due to equation (3.10)

$$\begin{aligned}\| \wedge^L \tilde{X}(t,s)\| &\geq \| \wedge^L X(t,s)\| \left(1 - \frac{\| \wedge^L \tilde{X}(t,s) - \wedge^L X(t,s)\|}{\| \wedge^L X(t,s)\|}\right) \\ &\geq \| \wedge^L X(t,s)\| \left(2 - e^{Lc_{FI,L}\int_s^t \|Q(\tau)\|\, d\tau}\right).\end{aligned}$$

Combining the last estimate with the one from the proof of Theorem 3.43 yields

$$\frac{\| \wedge^L \tilde{X}(t,\tau)\| \, \| \wedge^L \tilde{X}(\tau,s)\|}{\| \wedge^L \tilde{X}(t,s)\|} \leq \frac{\| \wedge^L X(t,\tau)\| \, \| \wedge^L X(\tau,s)\|}{\| \wedge^L X(t,s)\|} \cdot \frac{e^{Lc_{FI,L}\int_s^t \|Q(u)\|\, du}}{2 - e^{Lc_{FI,L}\int_s^t \|Q(u)\|\, du}},$$

which proves that the perturbed system is L-dim. strongly fast invertible.

Moreover, it follows that

$$\tilde{c}_{FI,L} \leq c_{FI,L} \frac{e^{Lc_{FI,L}\|Q\|_{L^1}}}{2 - e^{Lc_{FI,L}\|Q\|_{L^1}}},$$

which implies upper semicontinuity of $c_{FI,L}$ with respect to L^1-perturbations. Lower semicontinuity follows by switching roles, i.e., by viewing the original system as a perturbation of the perturbed system via $-Q(t)$. □

Corollary 3.49. *Assume equation (3.9) is regular and L-dim. strongly fast invertible. For every $\hat{v} \notin V'_{2,L}$, we find $\epsilon > 0$ such that*

$$\lim_{t\to\infty} \frac{1}{t} \log \|(\wedge^L \tilde{X}(t,0))\hat{v}\| = \Lambda_1 + \cdots + \Lambda_L$$

for any perturbation $Q(t)$ with

$$\int_0^\infty \|Q(t)\|\, dt < \epsilon.$$

Proof. Since characteristic exponents are invariant under multiplication of the solution by a nonzero constant, we may assume that $\|\hat{v}\| = 1$. It holds

$$\begin{aligned}\|(\wedge^L \tilde{X}(t,0))\hat{v}\| &\geq \|(\wedge^L X(t,0))\hat{v}\| - \|(\wedge^L \tilde{X}(t,0) - \wedge^L X(t,0))\hat{v}\| \\ &\geq \|(\wedge^L X(t,0))\hat{v}\| \left(1 - \frac{\| \wedge^L \tilde{X}(t,0) - \wedge^L X(t,0)\|}{\| \wedge^L X(t,0)\|} \frac{\| \wedge^L X(t,0)\|}{\|(\wedge^L X(t,0))\hat{v}\|}\right).\end{aligned}$$

Since the system is regular, Corollary 3.21 implies that

$$\lim_{t\to\infty} \frac{\| \wedge^L X(t,0)\|}{\|(\wedge^L X(t,0))\hat{v}\|} < \infty.$$

Now, according to the proof of Lemma 3.48, we may choose $\epsilon > 0$ small enough to ensure

$$\|(\wedge^L \tilde{X}(t,0))\hat{v}\| \geq c\|(\wedge^L X(t,0))\hat{v}\|$$

for some constant $c > 0$ independent of t. Hence, it holds

$$\liminf_{t\to\infty} \frac{1}{t} \log \|(\wedge^L \tilde{X}(t,0))\hat{v}\| \geq \liminf_{t\to\infty} \frac{1}{t} \log \|(\wedge^L X(t,0))\hat{v}\| = \lambda_{1,L}$$

and

$$\limsup_{t\to\infty} \frac{1}{t} \log \|(\wedge^L \tilde{X}(t,0))\hat{v}\| \leq \tilde{\lambda}_{1,L} = \lambda_{1,L}$$

due to Theorem 3.47. The claim follows since regularity implies $\lambda_{1,L} = \Lambda_1 + \cdots + \Lambda_L$. □

4 Computation of Lyapunov exponents

In this section we derive convergence results for the computation of Lyapunov exponents via *Benettin's algorithm* [4,5].

Assume $h_{\max} < \infty$ and let

$$\Phi : \mathbb{R}_{\geq 0} \times [0, h_{\max}] \to GL(d, \mathbb{R})$$

be a (linear) one-step method that is consistent of order $p > 0$.

Definition 4.1. We call Φ *consistent* if there is a constant $c_\Phi > 0$ such that

$$\|\Phi(t,h) - X(t+h,t)\| \leq c_\Phi h^{p+1}$$

for all $t \geq 0$ and $0 \leq h \leq h_{\max}$.

Given stepsizes $0 < h_n \leq h_{\max}$, we shorten our notation by defining

$$\Phi_n := \Phi(t_{n-1}, h_n)$$

and

$$\Phi^n := \Phi_n \dots \Phi_1.$$

A similar notation will be adopted for X.

4.1 Benettin's algorithm

The idea behind Benettin's algorithm can be explained via exterior products: Since $V_{2,L}$ is a proper subspace of the space of solutions of the induced system on $\wedge^L \mathbb{R}^d$, the solution to Lebesgue-almost every initial condition $v_1 \wedge \dots \wedge v_L$ has characteristic exponent $\lambda_{1,L}$. Using $X(t)[v_1, \dots, v_L] = Q(t)R(t)$, it holds

$$\chi[r_{11}(t) \dots r_{LL}(t)] = \chi[(\wedge^L X(t))(v_1 \wedge \dots \wedge v_L)] = \lambda_{1,L}$$

and hence, for regular systems, the Lyapunov exponents can be computed as

$$\Lambda_i = \lim_{t \to \infty} \frac{1}{t} \log r_{ii}(t)$$

for Lebesgue-almost every tuple of initial vectors, which is the core idea behind Benettin's algorithm.

The propagated vectors[8] (columns of V_n) are reorthonormalized periodically to prevent numerical singularities. If not, they could collapse onto the fastest expanding direction rendering them numerically indistinguishable, which makes it impossible to compute their associated volumes. Analytically, however, intermediate orthonormalizations do not play a role since the associated volumes stay the same. Indeed, we get the same output analytically if we perform the QR-decomposition only once at the end:

$$\Phi^n V_0 = \Phi_n \dots \Phi_2 \Phi_1 V_0 = \Phi_n \dots \Phi_2 V_1 R_1 = \dots = V_n (R_n \dots R_1).$$

[8] The propagated vectors from Benettin's algorithm are more than a mere byproduct for Lyapunov exponents. For instance, they have been exploited by Ginelli et al. [12] and by Wolfe–Samelson [24] in their algorithms to compute covariant Lyapunov vectors (see [18,19] for a theoretical analysis).

Algorithm 1: Benettin's algorithm [4,5]

Input: number of integration steps N, stepsizes $(h_n)_{n=1}^N$
Output: computed Lyapunov exponents $\mu_1, \dots, \mu_d$

$V_0 = \text{rand(d)}$ // set random initial vectors
for n = *1:N* **do**
  $W = \Phi_n V_{n-1}$ // evolve
  $[Q_n, R_n] = \text{qr}(W)$ // orthonormalize
  $V_n = Q_n$ // set new vectors
for i = *1:d* **do**
  $\mu_i(N) = \frac{1}{t_N} \sum_{n=1}^N \log(R_n)_{ii}$ // average

One may adjust the frequency of orthonormalizations depending on how fast V_n becomes singular. Furthermore, in practice it makes sense to compute the Lyapunov exponents as a running average during the propagation loop to save memory and to monitor convergence properties.

While the algorithm works perfectly fine analytically, there are some numerical challenges. In practice several types of errors influence the output of Benettin's algorithm. For example, errors are introduced by numerical integration, by limiting the integration time, by finite-precision computing or through errors of the underlying equations[9].

4.2 Convergence results

For all results in this subsection, we assume:

- $0 < h_n \leq h_{\max}$,
- $t_n = h_1 + \cdots + h_n \to \infty$,
- Φ is consistent of order $p > 0$.

Before deriving the desired convergence theorems for Benettin's algorithm, we introduce two auxiliary systems: a piecewise constant approximation of our original system and a piecewise constant system representing the numerical integration.

If $\|X_n - I\| < 1$, the logarithm of X_n exists and is equal to

$$\log X_n = \sum_{k=1}^{\infty} (-1)^{k+1} \frac{(X_n - I)^k}{k}.$$

We set

$$A_n := \frac{1}{h_n} \log X_n.$$

A_n is well-defined for small stepsizes since

$$\|X_n - I\| \leq \int_{t_{n-1}}^{t_n} \|A(s) X(s, t_{n-1})\| \, ds \leq M e^{h_{\max} M} h_n.$$

[9] If the linear system is derived as the linearization along a solution of a nonlinear system, integration errors from computing the solution of the nonlinear system can result in errors in the derived linear equations of order $O(1)$. In that case our perturbation results for linear theory are ineffective and nonlinear theory is necessary to study the computational error.

Similarly, we set

$$B_n := \frac{1}{h_n} \log \Phi_n$$

whenever $\|\Phi_n - I\| < 1$. Consistency of the numerical integrator and the previous estimate imply that B_n is well-defined for small stepsizes as well.

We have the following relation between A_n and B_n:

Lemma 4.2. *There is a constant*[10] $c > 0$ *independent of the stepsizes such that*

$$\|A_n - B_n\| \leq c h_n^p$$

for small h_n.

Proof. Assume h_n is small enough such that

$$\max(\|\Phi_n - I\|, \|X_n - \Phi_n\|) \leq \frac{1}{4}. \tag{4.1}$$

The logarithms of X_n and Φ_n exist. Moreover, it holds

$$\|\log(X_n) - \log(\Phi_n)\| \leq \sum_{k=1}^{\infty} \frac{\|(X_n - I)^k - (\Phi_n - I)^k\|}{k}.$$

Using

$$\|(M+E)^k - M^k)\| \leq \|E\| 2^k \max(\|M\|, \|E\|)^{k-1}$$

with $M := \Phi_n - I$ and $E := X_n - \Phi_n$, we estimate

$$\|A_n - B_n\| = \frac{1}{h_n} \|\log(X_n) - \log(\Phi_n)\| \leq \frac{1}{h_n} \left(\sum_{k=1}^{\infty} \frac{4}{2^k k} \right) \|X_n - \Phi_n\|.$$

The claim follows from consistency of the numerical integrator. □

We may regard A_n as a perturbation of the original system on $[t_{n-1}, t_n)$. The size of the perturbation depends on the continuity property of A.

Lemma 4.3. *If* A *is globally Lipschitz continuous, then there is a constant* $c > 0$ *independent of the stepsizes such that*

$$\sup_{t \in [t_{n-1}, t_n)} \|A(t) - A_n\| \leq c h_n$$

for small h_n.

Proof. If h_n is small enough such that equation (4.1) holds, then

$$\|X_n - I\| \leq \frac{1}{2}$$

and

$$\|\log(X_n) - (X_n - I)\| \leq \left(\sum_{k=2}^{\infty} \frac{\|X_n - I\|^{k-2}}{k} \right) \|X_n - I\|^2 \leq \underbrace{\left(\sum_{k=2}^{\infty} \frac{4}{2^k k} \right) M^2 e^{2h_{\max} M}}_{=:C} h_n^2.$$

[10] A more detailed analysis of the constant for systems with stable Lyapunov exponents can be found in [10].

Thus, it holds

$$\begin{aligned}\|A(t) - A_n\| &= \left\|A(t) - \frac{1}{h_n}\log X_n\right\| \leq \left\|A(t) - \frac{1}{h_n}(X_n - I)\right\| + Ch_n \\ &\leq \frac{1}{h_n}\int_{t_{n-1}}^{t_n} \|A(t) - A(s)X(s, t_{n-1})\|\, ds + Ch_n.\end{aligned}$$

for $t \in [t_{n-1}, t_n)$. Now, the claim follows from

$$A(t) - A(s)X(s, t_{n-1}) = A(t) - A(s) + A(s)(X(t_{n-1}, t_{n-1}) - X(s, t_{n-1}))$$

via Lipschitz continuity of A. □

In the following, we only consider stepsizes such that $h_n \to 0$. While we cannot guarantee that A_n and B_n are well-defined for small n, there is $N \geq 0$ such that A_n and B_n are well-defined for $n \geq N$. We define

$$A_{pc}(t) := \begin{cases} 0, & t \in [0, t_{N-1}) \\ A_n, & t \in [t_{n-1}, t_n) \text{ for } n \geq N \end{cases}$$

and

$$B_{pc}(t) := \begin{cases} 0, & t \in [0, t_{N-1}) \\ B_n. & t \in [t_{n-1}, t_n) \text{ for } n \geq N \end{cases}$$

By possibly increasing N, we ensure that A_{pc} and B_{pc} are bounded and can be estimated using the previous lemmata.[11]

Let us denote the Cauchy matrix corresponding to A_{pc} by $X_{pc}(t, s)$. If $n \geq m \geq N - 1$, then

$$X_{pc}(t_n, t_m) = e^{h_n A_n} \dots e^{h_{m+1} A_{m+1}} = X(t_n, t_m).$$

Hence, A_{pc} can be seen as a piecewise constant approximation of our original system (for large t).

Lemma 4.4. *The Lyapunov spectra of the original system and the piecewise constant approximation coincide. The same holds for their induced systems. Moreover, if the original system is regular, then the piecewise constant approximation is regular.*

Proof. Since

$$X_{pc}(t, t_{N-1}) = e^{(t - t_{n-1})A_n} X(t, t_{n-1})^{-1} X(t, t_{N-1})$$

for $t \in [t_{n-1}, t_n)$ and $n \geq N$, the growth rates of solutions with the same initial condition differ by at most a constant:

$$\left(\frac{\|X_{pc}(t, t_{N-1})v\|}{\|X(t, t_{N-1})v\|}\right)^{\pm 1} \leq e^{h_{\max}(\|A_{pc}\|_\infty + M)}$$

for any $v \neq 0$. Hence, the Lyapunov spectra of the original system and the piecewise constant approximation coincide. The remaining statements follow similarly. □

[11] This is the case if equation (4.1) is satisfied for $n \geq N$.

We write $\tilde{X}_{pc}(t,s)$ for the Cauchy matrix corresponding to B_{pc} and note that

$$\tilde{X}_{pc}(t_n,t_m) = \Phi_n \dots \Phi_{m+1}$$

for $n \geq m \geq N-1$. In particular, fixing the fundamental matrix $\tilde{X}_{pc}(t)$ satisfying $\tilde{X}_{pc}(t_{N-1}) = \Phi^{N-1}$, we have

$$\tilde{X}_{pc}(t_n) = \tilde{X}_{pc}(t_n,t_{N-1})\tilde{X}_{pc}(t_{N-1}) = \Phi_n \dots \Phi_N \Phi^{N-1} = \Phi^n$$

for $n \geq N-1$. Thus, B_{pc} can be understood as representing the numerical integration. It follows that

$$\begin{aligned}\mu_1(n) + \dots + \mu_L(n) &= \sum_{i=1}^{L} \frac{1}{t_n} \sum_{k=1}^{n} \log(R_k)_{ii} = \frac{1}{t_n} \log \left(\prod_{i=1}^{L} (R_n \dots R_1)_{ii} \right) \\ &= \frac{1}{t_n} \log \|(\wedge^L \Phi_n)(v_1 \wedge \dots \wedge v_L)\| = \frac{1}{t_n} \log \|(\wedge^L \tilde{X}_{pc}(t_n))(v_1 \wedge \dots \wedge v_L)\|\end{aligned}$$

for $n \geq N-1$. Since the stepsizes and B_{pc} are bounded, we have

$$\begin{aligned}\limsup_{n\to\infty} \mu_1(n) + \dots + \mu_L(n) &= \limsup_{n\to\infty} \frac{1}{t_n} \log \|(\wedge^L \tilde{X}_{pc}(t_n))(v_1 \wedge \dots \wedge v_L)\| \\ &= \limsup_{t\to\infty} \frac{1}{t} \log \|(\wedge^L \tilde{X}_{pc}(t))(v_1 \wedge \dots \wedge v_L)\|.\end{aligned}$$

Thus, Benettin's algorithm computes $\tilde{\lambda}_{1,L}$ of B_{pc} for Lebesgue-almost every tuple of initial vectors:

$$\limsup_{n\to\infty} \mu_1(n) + \dots + \mu_L(n) = \tilde{\lambda}_{1,L}. \tag{4.2}$$

In particular, if B_{pc} is regular, then

$$\lim_{n\to\infty} \mu_1(n) + \dots + \mu_L(n) = \tilde{\Lambda}_1 + \dots + \tilde{\Lambda}_L. \tag{4.3}$$

Theorem 4.5. *Assume equation (3.1) is globally Lipschitz continuous and has stable Lyapunov exponents. If $h_n \to 0$, then*

$$\limsup_{n\to\infty} \mu_1(n) + \dots + \mu_i(n) \leq \Lambda_1 + \dots + \Lambda_i$$

for all i and Lebesgue-almost every tuple of initial vectors.[12]

Proof. Since there are constant $c_1, c_2 > 0$ independent of the stepsizes such that

$$\sup_{t\in[t_{n-1},t_n)} \|A(t) - B_{pc}(t)\| \leq \sup_{t\in[t_{n-1},t_n)} \|A(t) - A_n\| + \|A_n - B_n\| \leq c_1 h_n + c_2 h_n^p$$

for $n \geq N$, B_{pc} is a perturbation of the original system such that $\|Q(t)\| \to 0$. In particular, Theorem 3.26 implies that B_{pc} has the same Lyapunov spectrum as the original system. Now, equation (4.2) and Proposition 3.20 imply the theorem. □

[12] A version of the estimate for finite time can be found in [11]. The authors relate the error to the departure from normality of the R-matrices obtained during Benettin's algorithm.

Theorem 4.6. *Assume equation (3.1) is globally Lipschitz continuous, regular and has stable Lyapunov exponents. If $h_n \to 0$, then*

$$\lim_{n\to\infty} \mu_i(n) = \Lambda_i$$

for all i and Lebesgue-almost every tuple of initial vectors.

Proof. The claim follows similarly to the last theorem using Proposition 3.27 and equation (4.3) instead of equation (4.2). □

Remark 4.7. If the stability of Lyapunov exponents transfers from A to A_{pc}, then the assumption that A is globally Lipschitz continuous can be dropped in Theorems 4.5 and 4.6.

Next, we derive convergence results for strongly fast invertible systems. For this, we need the following lemma:

Lemma 4.8. *The original system is L-dim. strongly fast invertible if and only if its piecewise constant approximation is L-dim. strongly fast invertible.*

Proof. The claim follows from

$$e^{(t_n-t)A_n} X_{pc}(t,s) e^{(s-t_{m-1})A_m} = X_{pc}(t_n, t_{m-1}) = X(t_n, t_{m-1}) = X(t_n, t) X(t, s) X(s, t_{m-1})$$

for $s \in [t_{m-1}, t_m)$ and $t \in [t_{n-1}, t_n)$, $n \geq m \geq N$, and the fact that strong fast invertibility can be tested on $[t_{N-1}, \infty)$ (see Lemma 3.29). □

Theorem 4.9. *Assume equation (3.1) is L-dim. strongly fast invertible. If $h_n \to 0$, then*

$$\limsup_{n\to\infty} \mu_1(n) + \cdots + \mu_L(n) \leq \Lambda_1 + \cdots + \Lambda_L$$

for Lebesgue-almost every tuple of initial vectors.

Proof. Since A_{pc} is L-dim. strongly fast invertible and its induced systems have the same Lyapunov spectra as the induced systems of the original system, Theorem 3.46 and Proposition 3.20 imply

$$\tilde{\lambda}_{1,L} \leq \lambda_{1,L} \leq \Lambda_1 + \cdots + \Lambda_L.$$

The claim follows from equation (4.2). □

Theorem 4.10. *Assume equation (3.1) is regular and L-dim. strongly fast invertible. If*

$$\sum_{n=1}^{\infty} h_n^{p+1} < \infty,$$

then

$$\limsup_{n\to\infty} \mu_1(n) + \cdots + \mu_L(n) = \Lambda_1 + \cdots + \Lambda_L$$

for Lebesgue-almost every tuple of initial vectors.

Proof. Lemma 4.2 and the stepsize condition ensure that

$$\int_0^{\infty} \|A_{pc}(t) - B_{pc}(t)\| \, dt < \infty.$$

Now, the proof is as in Theorem 4.9 using Theorem 3.47 and regularity:

$$\tilde{\lambda}_{1,L} = \lambda_{1,L} = \Lambda_1 + \cdots + \Lambda_L.$$

□

Since we do not know if regularity transfers form the original to the numerical system, Theorem 4.10 only ensures convergence to the Lyapunov exponents as a limes superior. However, when fixing a tuple of initial vectors, we can ensure convergence as a limit if the stepsizes decay fast enough.

Theorem 4.11. *Assume equation (3.1) is regular and L-dim. strongly fast invertible. For Lebesgue-almost every tuple of initial vectors, we have the following: If $\sum_{n=1}^{\infty} h_n^{p+1}$ is small enough, then*

$$\lim_{n\to\infty} \mu_1(n) + \cdots + \mu_L(n) = \Lambda_1 + \cdots + \Lambda_L.$$

Proof. The theorem follows from Corollary 3.49. □

Remark 4.12. The condition "$\sum_{n=1}^{\infty} h_n^{p+1}$ small enough" in Theorem 4.11 depends on the chosen initial vectors. Indeed, following the associated proofs, we require smaller stepsizes the smaller the first principle angle between $\operatorname{span}(v_1, \dots, v_L)$ and V'_{l+1}.

Finally, when applied to the right dimensions, Theorems 4.10 and 4.11 ensure that we may approximate the Lyapunov exponents of strongly fast invertible systems using Benettin's algorithm.

Corollary 4.13. *Assume equation (3.1) is regular and strongly fast invertible at dim. $d_1 + \cdots + d_l$ for $l = 1, \dots, p$. If*

$$\sum_{n=1}^{\infty} h_n^{p+1} < \infty,$$

then

$$d_i\lambda_i = \limsup_{n\to\infty} \mu_1(n) + \cdots + \mu_{d_1+\cdots+d_i}(n) - \limsup_{n\to\infty} \mu_1(n) + \cdots + \mu_{d_1+\cdots+d_{i-1}}(n)$$

for all i and for Lebesgue-almost every tuple of initial vectors. In particular, if the Lyapunov spectrum is simple, then

$$\lambda_i = \limsup_{n\to\infty} \mu_1(n) + \cdots + \mu_i(n) - \limsup_{n\to\infty} \mu_1(n) + \cdots + \mu_{i-1}(n)$$

for all i and for Lebesgue-almost every tuple of initial vectors.

Corollary 4.14. *Assume equation (3.1) is regular and strongly fast invertible at dim. $d_1 + \cdots + d_l$ for $l = 1, \dots, p$. For Lebesgue-almost every tuple of initial vectors, we have the following: If $\sum_{n=1}^{\infty} h_n^{p+1}$ is small enough, then*

$$d_i\lambda_i = \lim_{n\to\infty} \mu_{d_1+\cdots+d_{i-1}+1}(n) + \cdots + \mu_{d_1+\cdots+d_i}(n)$$

for all i. In particular, if the Lyapunov spectrum is simple, then

$$\lambda_i = \lim_{n\to\infty} \mu_i(n)$$

for all i.

5 Numerical examples

To showcase Benettin's algorithm, we present three numerical examples: a linear system, the Lorenz-63 and the Lorenz-96 model. While the linear system satisfies the assumptions required in our convergence analysis, the other two systems are nonlinear and exhibit additional errors that are not accounted for in our analysis. Moreover, not all Lyapunov exponents of the Lorenz models are known analytically.

All systems will be integrated using a fifth-order Runge–Kutta method (RK5) with

1. adaptive stepsizes[13],
2. constant stepsizes, and
3. two types of varying stepsizes[14] ($h_n = \frac{h_0}{\sqrt[2]{n}}$ and $h_n = \frac{h_0}{\sqrt[3]{n}}$).

In case of adaptive stepsizes, we apply the Dormand–Prince method (DP54) which uses a fourth-order Runge–Kutta method (RK4) in addition to RK5 to estimate the integration error. Since the computational costs per integration step for each approach are close[15], we can roughly associate the total computational costs to the number of integration steps to compare the performance of Benettin's algorithm for the different stepsizes.

The corresponding MATLAB code can be found in [20].

5.1 Linear system

Let

$$B(t) = \begin{pmatrix} \lambda_1 & f(t) & 0 \\ 0 & \lambda_1 & 0 \\ 0 & 0 & \lambda_2 \end{pmatrix}$$

be a block-triangular matrix with $\lambda_1 > \lambda_2$ and a bounded continuous function f. One may check that the system $\dot{y} = B(t)y$ is regular and has stable Lyapunov exponents λ_1 and λ_2 due to Theorem 3.24[16]. In particular, the system is strongly fast invertible at dimensions $d_1 = 2$ and $d_1 + d_2 = 3$. These properties remain valid under Lyapunov transformations.

To get a specific example, we set $\lambda_1 = 1$, $\lambda_2 = 0$ and $f(t) = \sin(t) + 1/(t^2+1)$ and transform $\dot{y} = B(t)y$ to

$$\dot{x} = A(t)x := (LBL^{-1} + \dot{L}L^{-1})(t)x$$

[13] We use adaptive stepsizes in accordance with [9, Section 3.1] for linear systems and with [8, pp. 13–14] for nonlinear systems.

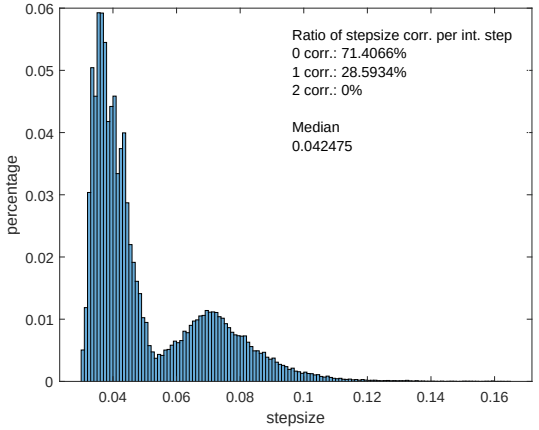
[14] We chose varying stepsizes such that

$$\sum_{n=1}^{\infty} h_n^{p+1} < \infty.$$

[15] DP54 uses the same function evaluations as RK5 and hence only increases the computational costs per step by a small amount. The possibly largest increase in costs for the adaptive method comes from stepsize corrections that require to repeat the integration step. However, at least in our examples, the increase was relatively low (a factor of ∼1.3 for the linear system and ∼1.0 for the Lorenz systems).

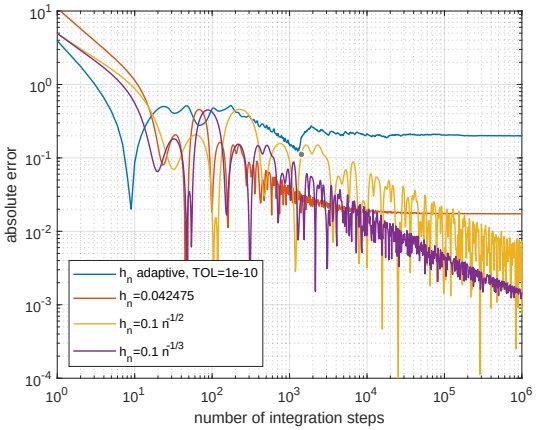
[16] Condition (iii) follows from

$$Y_1(t,s) = e^{\lambda_1(t-s)} \begin{pmatrix} 1 & \int_s^t f(\tau)\,d\tau \\ 0 & 1 \end{pmatrix}$$



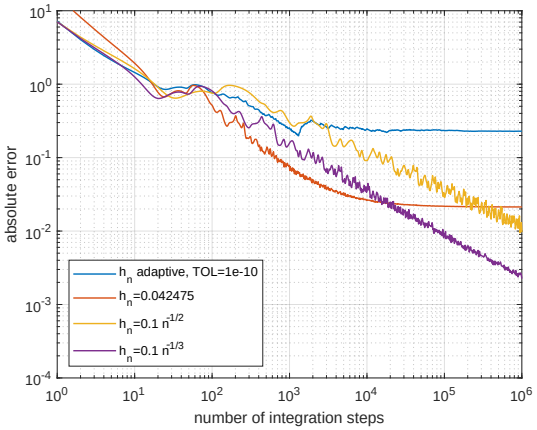
and $Y_2(t,s) = e^{\lambda_2(t-s)}$. Stability of the subsystem for λ_1 can be checked by showing $\overline{\omega}_1 = \lambda_1 = \Omega_1$ using that the constant function equal to λ_1 is a lower and upper function for the first subsystem.

using the composition $L(t)$ of two Lyapunov transformations

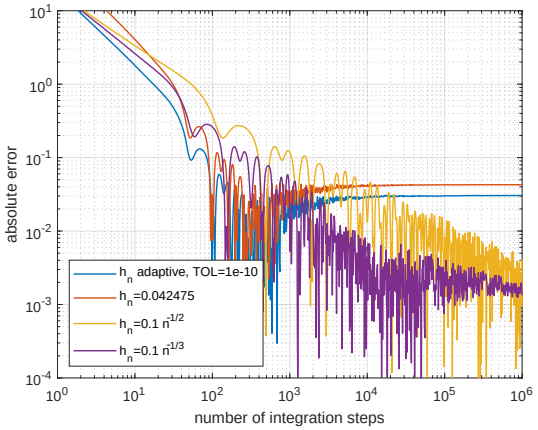


$$\begin{pmatrix} 1 & \sin(t) & \cos(t) \\ 0 & 1 & \sin(t) \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos(\sqrt{2}t) & 0 & \sin(\sqrt{2}t) \\ 0 & 1 & 0 \\ -\sin(\sqrt{2}t) & 0 & \cos(\sqrt{2}t) \end{pmatrix}.$$

While our theory only ensures convergence of Benettin's algorithm for $2\lambda_1$ and λ_2, we apply the algorithm to compute each individual exponent without regarding the degeneracy. The Lyapunov exponents are approximated using the different stepsizes mentioned in the beginning of Section 5. We start with the adaptive approach and take the median of the accepted stepsizes (Figure 5.1a) as the constant stepsizes for the second approach. The approximated Lyapunov exponents of all approaches are compared to their exact values ($\Lambda_1 = 1$, $\Lambda_2 = 1$ and $\Lambda_3 = 0$) and plotted against the number of integration steps (Figures 5.1b, 5.1c and 5.1d).

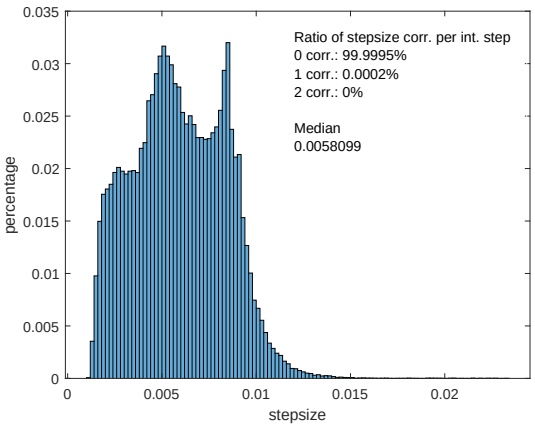


For all three Lyapunov exponents, we see that adaptive and constant stepsizes lead to an accumulation of integration errors that persists in the limit. On the other hand, the errors obtained with varying stepsizes show a steady decay as we would expect from our theory.

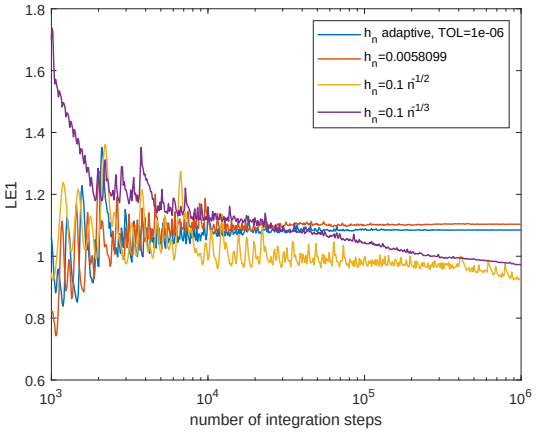


(a) PDF of accepted stepsizes

(b) LE1 (error)

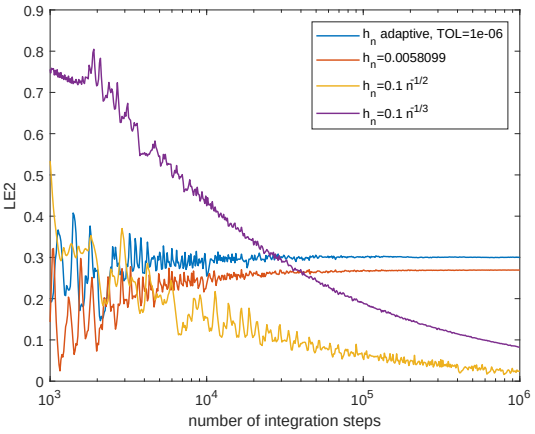


(c) LE2 (error)

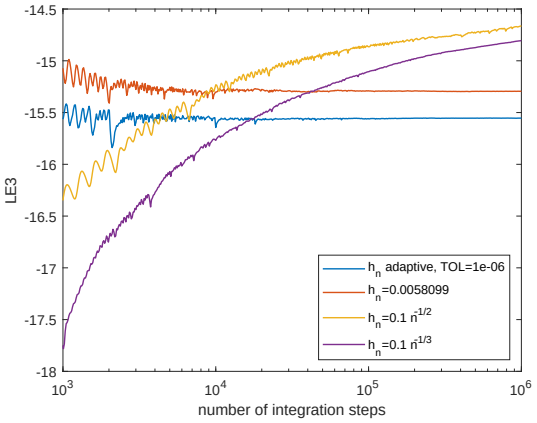


(d) LE3 (error)

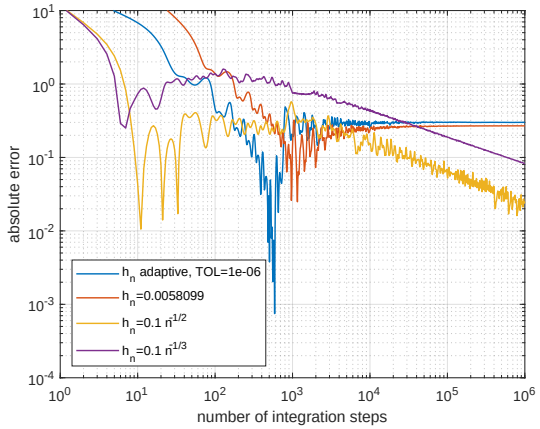
Figure 5.1: The Lyapunov exponents of the system $\dot{x} = A(t)x$ from Subsection 5.1 are approximated using Benettin's algorithm with different stepsizes. The first plot shows the PDF of the accepted stepsizes of the adaptive approach, while the other plots show the errors between computed Lyapunov exponents and their exact values. To save memory, the PDF was formed over every 10th integration step.



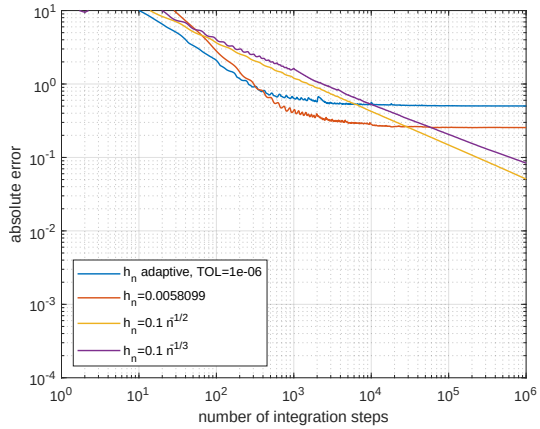
5.2 Lorenz-63 model



(a) PDF of accepted stepsizes



(b) LE1



(c) LE2

(d) LE3

(e) LE2 (error)

(f) LE sum (error)

Figure 5.2: The Lyapunov exponents of the Lorenz-63 model from Subsection 5.2 are approximated using Benettin's algorithm with different stepsizes. The first plot shows the PDF of the accepted stepsizes of the adaptive approach, while the other plots show the computed Lyapunov exponents and their errors. To save memory, the PDF was formed over every 10th integration step.

Our second example is the Lorenz-63 model [15] (a reduced model for thermal convection)

given by the equations

$$\left.\begin{aligned} \dot{x}_1 &= \sigma(x_2 - x_1) \\ \dot{x}_2 &= x_1(\rho - x_3) - x_2 \\ \dot{x}_3 &= x_1 x_2 - \beta x_3 \end{aligned}\right\} := f(x)$$

with $\sigma = 10$, $\beta = 8/3$ and $\rho = 28$ as the classical parameters. The system is famous for its unpredictable behavior despite being deterministic. It exhibits a so-called *strange attractor* (the *Lorenz attractor*), which is a minimal attracting flow-invariant set that is neither a steady state nor a periodic orbit and which has a positive largest Lyapunov exponent[17]. So far, the existence of the attractor and the existence of a physical ergodic invariant measure that admits a positive largest Lyapunov exponent is only known as a consequence of the computer-aided proof by Tucker [23].

To compute the Lyapunov exponents, we require a background trajectory lying on the attractor. This is problematic, since the Lorenz attractor has Lebesgue measure zero. In particular, the initial state of our background trajectory will almost surely lie outside of the attractor. While the trajectory may be close to the attractor after a transient, a rigorous analysis would require continuity properties of the Lyapunov exponents that extend to a neighborhood of the attractor. However, in general, the Lyapunov exponents vary only measurably with the base point. Moreover, integration errors can lead to an error of order $O(1)$ in the background trajectory as well as in the derived linear system. This may drastically change the computed Lyapunov exponents.

Despite the open challenges, we try to approximate the Lyapunov exponents and compare our methods for the known cases, that is, the second Lyapunov exponent and the sum of all Lyapunov exponents. The second Lyapunov exponent corresponds to the tangent vector of the background trajectory, which is a solution of the linearized equations that is neither exponentially growing nor decaying, and thus must be zero. The sum of all three Lyapunov exponents must be equal to the trace of the Jacobian as it is constant. Indeed, it holds

$$\begin{aligned} \Lambda_1 + \Lambda_2 + \Lambda_3 &= \lim_{t\to\infty} \frac{1}{t} \log |\det(X(t))| \\ &= \lim_{t\to\infty} \frac{1}{t} \int_0^t \operatorname{tr}(Df(x(s)))ds = -(\sigma + 1 + \beta) \end{aligned}$$

for any solution $x(t)$ along which the linearized system $X(t)$ is regular. Exact values of the first and the third Lyapunov exponent are unknown.

The Lyapunov exponents are computed in a similar fashion to Subsection 5.1. This time, however, we require a background trajectory along which to propagate linear perturbations. In order to start close to the attractor, we first compute a transient starting from a randomly chosen state. After the transient, we couple the nonlinear system to its linearization. This way, we can compute the background trajectory and propagate linear perturbations simultaneously.

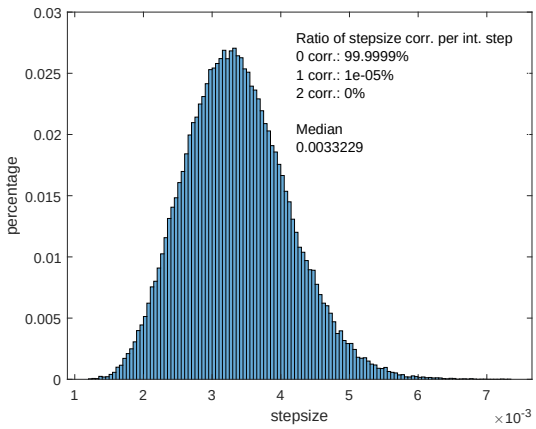
In this example, the adaptive approach requires almost no stepsize corrections (Figure 5.2a) and is thus well comparable to the other approaches in terms of computational costs per step. As before, we observe that Lyapunov exponents computed with adaptive and constant stepsizes seem to converge to different values depending on the given tolerance or stepsize (Figures 5.2b, 5.2c and 5.2d). A meaningful comparison between the different approaches is

[17] For nonlinear systems, the Lyapunov exponents are obtained from the linearized flow along nonlinear trajectories. If the nonlinear system has an ergodic invariant measure, the Lyapunov exponents coincide for almost every trajectory. Hence, we may associate Lyapunov exponents with the attractor (or measure) instead of the trajectory.

only possible for the second and the sum of all Lyapunov exponents (Figures 5.2e and 5.2f). We note that, similar to the linear example, the accuracy for adaptive and constant stepsizes are limited, while varying stepsizes seem to admit convergence properties that lead to the true Lyapunov exponents.

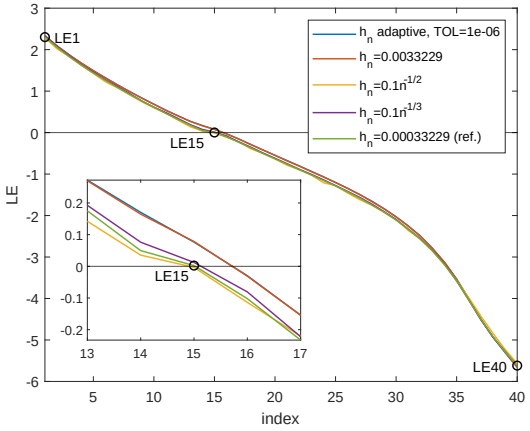
5.3 Lorenz-96 model

Our third example is the Lorenz-96 model [16], which was created to test numerical weather prediction. The model simulates the effects of external forcing, damping and advection on a scalar physical quantity, which lives on a periodic lattice representing a circle of latitude. Different from the Lorenz-63 model, the Lorenz-96 model treats each variable on the lattice the same. By changing the number of variables, one may study the effects of increased spacial resolution on the predictability (or chaoticity) of the system. There already are studies of spatiotemporal chaos in the Lorenz-96 model in which spectra of Lyapunov exponents have been computed [14].



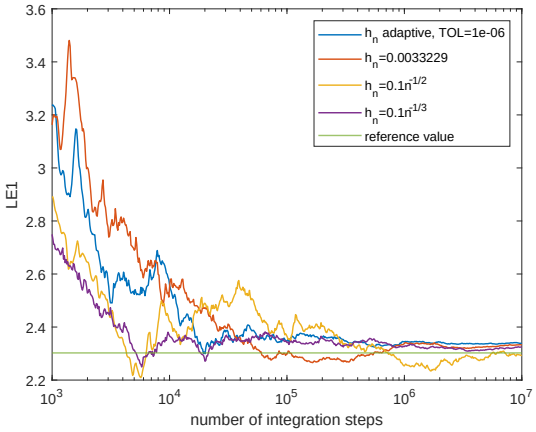
The Lorenz-96 model with $d \geq 4$ variables is given by the equations

$$\dot{x_i} = (x_{i+1} - x_{i-2})x_{i-1} - x_i + F$$

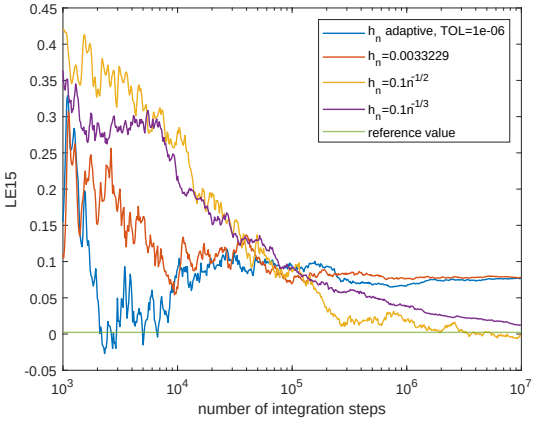


with periodic indices, i.e., $x_{i+kd} := x_i$ for $k \in \mathbb{Z}$. We choose $d = 40$ and a forcing parameter of $F = 10$ to allow for chaotic dynamics. Under the same conditions, [14] computed the Lyapunov spectrum and noticed that the shape of the spectrum does not change while increasing the number of variables from 40 to 50. They used constant stepsizes of $h_n = 1/64$ and integrated the trajectory for $T = 5 \times 10^5$ units of time or $N = 64T$ timesteps. The first $2/3$ of the trajectory were used as a transient to approach the attractor before computing the Lyapunov exponents.

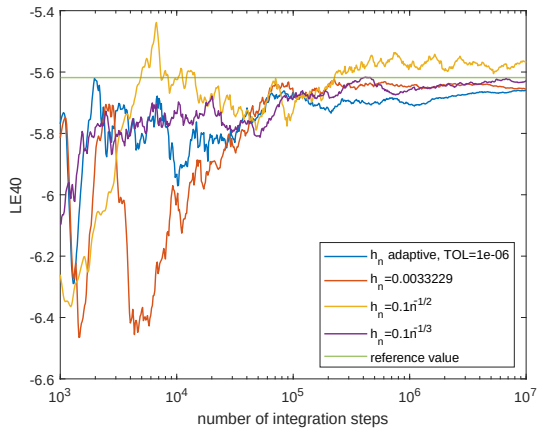
Here, we explore the effects of different stepsizes on the Lyapunov spectrum in terms of the approaches mentioned in the beginning of Section 5. Similar to the Lorenz-63 model, we know that at least one Lyapunov exponent must vanish and that the sum of all Lyapunov exponents must be equal to the trace of the Jacobian, which is $-d$. However, it is not clear which index corresponds to the vanishing Lyapunov exponent. Instead of looking at each individual exponent, we compare the Lyapunov spectra of the different approaches to a reference spectrum computed with a high-resolution run. The latter is performed with ten times the number of integration steps than the other runs and with constant stepsizes that are ten times smaller than the constant stepsizes from the low-resolution run. While a higher resolution heuristically provides better estimates of the Lyapunov exponents, we still have to expect persistent errors.



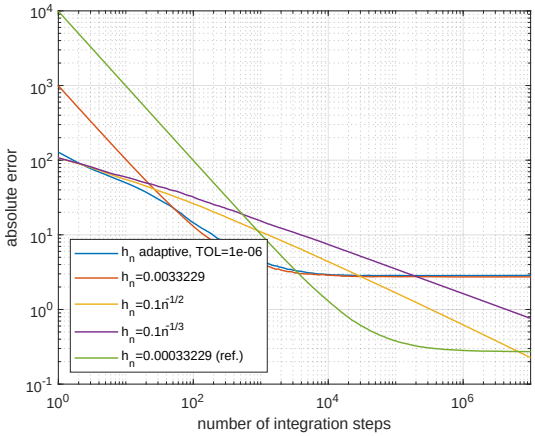
Our computed Lyapunov spectra (Figure 5.3b) take on similar shapes to the spectrum in [14, Figure 5]. We see that the spectra computed with varying stepsizes are closer to the reference spectrum than the ones computes with adaptive or constant stepsizes. The differences between the spectra vary with the specific Lyapunov exponent. A more detailed picture showing the computed extremal Lyapunov exponents and the near-zero exponent of the high-resolution run can be seen in (Figures 5.3c, 5.3d and 5.3e). Concerning the sum of all Lyapunov exponents, we observe a similar behavior as in the other two examples (Figure 5.3f).



(a) PDF of accepted stepsizes



(b) LE spectrum



(c) LE1

(d) LE15

(e) LE40

(f) LE sum (error)

Figure 5.3: The Lyapunov exponents of the Lorenz-96 model from Subsection 5.3 are approximated using Benettin's algorithm with different stepsizes. The first plot shows the PDF of the accepted stepsizes of the adaptive approach, the second plot shows the computed spectra after 10^7 integration steps (10^8 steps for the reference), and the other plots compare the computed Lyapunov exponents to the reference (final value of the exponent after 10^8 steps). To save memory, the PDF was formed over every 100th integration step.

Abstract. We prove the uniqueness of positive radial solution to the (p,q)-Laplacian problem

$$\begin{cases} -\Delta_p u - \Delta_q u = \lambda f(u) \ \text{ in } \Omega, \\ u = 0 \ \text{ on } \partial\Omega, \end{cases}$$

where $p > q > 1$, $\Delta_r u = \operatorname{div}(|\nabla u|^{r-2}\nabla u)$, $\Omega = B(0,1)$ is the open unit ball in $\mathbb{R}^N$, $f : (0,\infty) \to \mathbb{R}$ is q-sublinear at ∞ with possible semipositone structure at 0, and $\lambda > 0$ is a large parameter.

Keywords: (p,q)-Laplacian, positive solutions, uniqueness.

2020 Mathematics Subject Classification: 34B15, 34B18.

1 Introduction

In this paper, we study the uniqueness of positive radial solutions for the (p,q)-Laplacian boundary value problem

$$\begin{cases} -\Delta_p u - \Delta_q u = \lambda f(u) \text{ in } \Omega, \\ u = 0 \text{ on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is the open unit ball in $\mathbb{R}^N$, $p > q > 1$, $\Delta_r u = \operatorname{div}(|\nabla u|^{r-2}\nabla u(|\nabla u|^{r-2}\nabla u)$, $f : (0,\infty) \to \mathbb{R}$ is p-sublinear at ∞ i.e. $\lim_{u\to\infty} \frac{f(u)}{u^{p-1}} = 0$ and λ is a positive parameter. The (p,q)-Laplacian problems occurred in a variety of applied areas such as quantum physics, plasma physics, and reaction diffusion to name a few, see e.g. [2, 4, 6, 13, 14, 23]. When f is p-sublinear at ∞, the existence of positive solutions to (1.1) for λ large was recently established in [1] under the mere additional natural condition that $\liminf_{u\to\infty} u^\beta f(u) > 0$ and $\limsup_{u\to 0^+} u^\beta |f(u)| < \infty$ for some $\beta \in [0,1)$, which extended previous results in [10, 20]. When $p = q$, the uniqueness of positive solutions to (1.1) for all $\lambda > 0$ was established in the pioneering work [3] for $p = 2$ when $\frac{f(u)}{u}$ is strictly decreasing on $(0,\infty)$, and subsequently extended to the

✉Corresponding author. Email: dang@math.msstate.edu

case $p > 1$ in [11]. When this monotonicity condition is assumed only for u large, uniqueness results for λ large were obtained under additional hypotheses in [5,7–9,12,15–19,21,22,24–26], where the semipositone case i.e. $-\infty < f(0) < 0$ is allowed in [18]. Note that previous uniqueness proofs depend on the homogeneity of the p-Laplace and cannot be extended to the (p,q)-Laplace operator. In this paper, we shall establish the uniqueness of positive solutions to (1.1) for λ large when f is q-sublinear at ∞ with possible semipositone structure at 0, which has not been obtained in the literature to the best of our knowledge. Related uniqueness results for (1.1) in a bounded domain of $\mathbb{R}^N$ can be found in [10,13]. In [13, Theorem 2.2], the uniqueness of positive solutions for all $\lambda > 0$ was established when $z^{1-q}f(z)$ is decreasing for $z > 0$ and the assumption that any two positive solutions u_i, $i = 1,2$, of (1.1) satisfy $\Delta_p u_i \in L^\infty(\Omega)$, and $u_i/u_j \in L^\infty(\Omega), i \neq j$. The uniqueness for λ large in the semipositone case was observed in [10] for the special Dirichlet two-point boundary problem

$$\begin{cases} -((u')^3)' - u'' = \lambda f(u) \ \text{ in } (0,1), \\ u(0) = u(1) = 0, \end{cases}$$

where $f(u) = (u+1)^\gamma - 2$ for some $\gamma \in (0,3)$. Note that this observation is generated by *Mathematica* and does not constitute an analytical proof.

Since we are looking for radial solutions for (1.1), it reduces to finding solutions of the ODE problem

$$\begin{cases} -(r^{N-1}\phi(u'))' = \lambda r^{N-1} f(u), \ 0 < r < 1, \\ u'(0) = 0, \ u(1) = 0, \end{cases} \tag{1.2}$$

where $\phi(x) = \phi_p(x) + \phi_q(x)$, $\phi_r(x) = |x|^{r-2}x$.

We make the following assumptions.

(A1) $f : (0,\infty) \to \mathbb{R}$ is continuous and f is increasing on $[L,\infty)$ for some $L > 0$.

(A2) $\limsup_{z\to\infty} \frac{zf'(z)}{f(z)} < q - 1$.

(A3) There exists $\gamma \in [0,1)$ such that $\limsup_{z\to 0^+} z^{\gamma+1}|f'(z)| < \infty$ and $f(0^+) < \infty$ if $\gamma = 0$.

By a positive solution of (1.2), we mean a function $u \in C^1[0,1]$ with $u > 0$ on $[0,1)$ and satisfying (1.2). Our main result is

Theorem 1.1. *Let (A1)–(A3) hold and suppose either*

(A4) $f(z) > 0$ *for* $z > 0$ *with* $\liminf_{z\to 0^+} \frac{f(z)}{z^{q-1}} > 0$.

or

(A5) $-\infty < f(0^+) < 0$ *and there exists* $\beta > 0$ *such that* $(z-\beta)f(z) > 0$ *for* $z \neq \beta$.

holds. Then there exists a constant $\bar{\lambda} > 0$ *such that* (1.2) *has a unique positive solution for* $\lambda > \bar{\lambda}$.

Remark 1.2.

(i) Note that (A2) implies $\frac{f(z)}{z^{q-1}}$ *is decreasing for* z *large and* $\lim_{z\to\infty} \frac{f(z)}{z^{q-1}} = 0$.

(ii) It is easily seen from (A3) that $\limsup_{z\to 0^+} z^\gamma |f(z)| < \infty$. *Since* $\liminf_{z\to\infty} z^\gamma f(z) > 0$ *and* $\limsup_{z\to 0^+} z^\gamma |f(z)| < \infty$ *, it follows from [1, Theorem 1.1] that* (1.2) *has a positive solution for* λ *large under the assumptions of Theorem 1.1.*

2 Preliminary results

Let $H(z) = \frac{\phi_p(z)}{f(z)}$. Then H is increasing for z large and $\lim_{z\to\infty} H(z) = \infty$ in view of Remark 1.2 (i).

Lemma 2.1. *Let $K > 0$. Then for $\lambda \gg 1$,*

(i) $H^{-1}(\lambda K) \le K^{\frac{1}{p-q}} H^{-1}(\lambda)$ *if* $K > 1$.

(ii) $H^{-1}(\lambda K) \ge K^{\frac{1}{p-q}} H^{-1}(\lambda)$ *if* $K < 1$.

Proof. Let $z_\lambda = H^{-1}(\lambda)$ and $\tilde{K} = K^{\frac{1}{p-q}}$. Then $z_\lambda \to \infty$ as $\lambda \to \infty$.

Suppose $K > 1$. Then $f(\tilde{K} z_\lambda) \le \tilde{K}^{q-1} f(z_\lambda)$ for λ large in view of Remark 1.2 (i), which implies

$$\frac{\phi_p(\tilde{K} z_\lambda)}{f(\tilde{K} z_\lambda)} \ge \tilde{K}^{p-q} \frac{\phi_p(z_\lambda)}{f(z_\lambda)} = \lambda \tilde{K}^{p-q} = \lambda K,$$

i.e. $\tilde{K} H^{-1}(\lambda) = \tilde{K} z_\lambda \ge H^{-1}(\lambda K)$ and (i) holds. If $K < 1$ then by replacing λ by λK and K by K^{-1} in (i), we obtain (ii). □

Lemma 2.2. *Let $\lambda, x, c > 0$. Then*

$$\phi^{-1}(\lambda x) \ge a \phi_p^{-1}(\lambda x)$$

for $\lambda x > c$, provided that $a^{p-1} + a^{q-1} c^{\frac{q-p}{p-1}} \le 1$.

Proof. Let $y = \phi_p^{-1}(\lambda x)$. Then

$$\phi(ay) = (ay)^{p-1} + (ay)^{q-1} = a^{p-1} \lambda x + a^{q-1} (\lambda x)^{\frac{q-1}{p-1}}. \tag{2.1}$$

Since $\lambda x > c$,

$$a^{q-1} (\lambda x)^{\frac{q-1}{p-1}} = a^{q-1} c^{\frac{q-1}{p-1}} \left(\frac{\lambda x}{c}\right)^{\frac{q-1}{p-1}} < a^{q-1} c^{\frac{q-1}{p-1}} \left(\frac{\lambda x}{c}\right) = a^{q-1} c^{\frac{q-p}{p-1}} \lambda x,$$

which together with (2.1) imply

$$\phi(ay) \le \left(a^{p-1} + a^{q-1} c^{\frac{q-p}{p-1}}\right) \lambda x \le \lambda x$$

if $a^{p-1} + a^{q-1} c^{\frac{q-p}{p-1}} \le 1$ i.e. $ay \le \phi^{-1}(\lambda x)$, which completes the proof. □

If (A4) holds then clearly positive solutions to (1.2) are decreasing on (0,1). The next result shows this is also true in the semipositone case under assumption (A5).

Lemma 2.3. *Let (A1) and (A5) hold. Then any positive solution u of (1.2) is decreasing on $(0,1)$ with $u(0) \ge \theta$, where $\theta > \beta$ is such that $(z-\theta)F(z) > 0$ for $z > 0$, $z \ne \theta$. Here $F(z) = \int_0^z f$.*

Proof. Let u be a positive solution of (1.2). Since $f(0^+) < 0$, it follows that $(r^{N-1}\phi(u'))' > 0$ for r near 1 and therefore $u'(r) < u'(1) \le 0$ for such r. Let $r_0 \in [0,1)$ be the smallest number such that $u' < 0$ on $(r_0, 1)$ and suppose $r_0 > 0$. Multiplying the equation in (1.2) by u' gives

$$G'(r) = -(N-1) r^{N-2} \Phi(u') + \lambda (n-1) r^{N-2} F(u) \quad \text{on } (0,1),$$

where $\Phi(z) = \int_0^z \phi$ and $G(r) = r^{N-1}(\phi(u')u' - \Phi(u') + \lambda F(u))$. Note that $G(1) = (1 - 1/p)|u'(1)|^p + (1 - 1/q)|u'(1)|^q \geq 0$.

We claim that $u(r_0) > \theta$. Indeed, if $u(r_0) \leq \theta$ then $u < \theta$ on $(r_0, 1)$, which implies G is decreasing on $(r_0, 1)$. Since $u'(r_0) = 0$, it follows that

$$0 \leq G(1) \leq G(r) < G(r_0) \leq 0 \quad \text{on } (r_0, 1),$$

a contradiction. Hence $u(r_0) > \theta$ and so $(r^{N-1}(\phi(u'))' < 0$ near r_0. Consequently, $u'(r) > 0$ for r near $r_0, r < r_0$. Let $r_1 \in [0, r_0)$ such that $u' > 0$ on (r_1, r_0) and $u'(r_1) = 0$. Since $r_0^{N-1}\phi(u'(r_0)) = 0 = r_1^{N-1}\phi(u'(r_1))$, there exists $r_2 \in (r_1, r_0)$ such that

$$-(r^{N-1}\phi(u'(r))'(r_2) = \lambda r_2^{N-1} f(u(r_2)) = 0$$

i.e. $u(r_2) = \beta$. Thus $\theta \in u((r_2, r_0])$ and there exists $r_3 \in (r_2, r_0)$ such that $u < \theta$ on $[r_2, r_3)$ and $u(r_3) = \theta$. Since $u' > 0$ on (r_1, r_0), $u < \theta$ on $[r_1, r_3)$ i.e. and so $G' < 0$ on $[r_1, r_3)$, which implies

$$0 \leq G(r_3) < G(r) < G(r_1) < 0,$$

a contradiction. Thus $r_0 = 0$, which completes the proof. □

Lemma 2.4. *Let $c > 0$ and suppose (A1), (A4) hold. Then*

$$\limsup_{x \to 0^+} \frac{\phi(cx)}{\check{f}(x)} < \infty,$$

where $\check{f}(x) = \inf_{y \geq x} f(y)$.

Proof. Since $\liminf_{y \to 0^+} \frac{f(y)}{y^{q-1}} > 0$, there exist constants $k, \delta > 0$ such that

$$f(y) \geq k\phi(cy) \quad \text{for } y \in (0, \delta). \tag{2.2}$$

Let $x < \delta$ and $y \geq x$. If $y < \delta$ then (2.2) gives

$$f(y) \geq k\phi(cx), \tag{2.3}$$

while if $y > \delta$ then

$$f(y) \geq k_0 = k_1\phi(c\delta) \geq k_1\phi(cx), \tag{2.4}$$

where $k_0 = \inf_{[\delta, \infty)} f > 0$ and $k_1 = k_0/\phi(c\delta)$.

Combining (2.3) and (2.4), we obtain

$$\check{f}(x) \geq k_2\phi(cx) \quad \text{for } x \in (0, \delta),$$

where $k_2 = \min(k, k_1)$, which completes the proof. □

The next result gives sharp lower and upper bound estimates for positive solution of (1.2) when λ is large.

Lemma 2.5. *Let the assumptions of Theorem 1.1 hold. Then there exist positive constants A_1, A_2, and λ_0 such that for $\lambda > \lambda_0$, any positive solution of (1.2) satisfies*

$$A_1 B_\lambda (1 - r) \leq u(r) \leq A_2 B_\lambda (1 - r) \tag{2.5}$$

for $r \in (0, 1)$, where $B_\lambda = \phi_p^{-1}\left(\lambda f(H^{-1}(\lambda))\right)$.

Proof. In what follows, $\lambda \gg 1$ or λ large means $\lambda > \lambda^*$ for some $\lambda^* > 0$ independent of u and λ.

Case 1. Suppose (A4) holds.

Let $\lambda > 0$ and u be a positive solution of (1.2). Then u is decreasing on $(0,1)$. By integrating, we get

$$-u'(r) = \phi^{-1}\left(\frac{\lambda}{r^{N-1}}\int_0^r s^{N-1} f(u)ds\right), \qquad 0 < r < 1.$$

Recalling that $\check{f}(x) = \inf_{y \geq x} f(y)$ and since $\check{f}$ is nondecreasing, we have

$$-u'(r) \geq \phi^{-1}\left(\frac{\lambda}{r^{N-1}}\int_0^{1/2} s^{N-1}\check{f}(u)ds\right) \geq \phi^{-1}\left(\lambda c_1 \check{f}\left(u\left(1/2\right)\right)\right) \quad \text{for } r > 1/2, \tag{2.6}$$

where $c_1 = \frac{1}{N2^N}$, which implies upon integrating on $(1/2,1)$ that

$$2u(1/2) \geq \phi^{-1}\left(\lambda c_1 \check{f}\left(u\left(1/2\right)\right)\right)$$

i.e.

$$\frac{\phi(2u(1/2))}{\check{f}\left(u\left(1/2\right)\right)} \geq \lambda c_1. \tag{2.7}$$

Since $\limsup_{x\to 0^+} \frac{\phi(2x)}{\check{f}(x)} < \infty$ in view of Lemma 2.4, we deduce from (2.7) that $u(1/2) \to \infty$ as $\lambda \to \infty$.

Hence $u(1/2) > 1$ for $\lambda \gg 1$, and so

$$\phi(2u(1/2)) \leq 2\phi_p(2u(1/2)) = 2^p \phi_p(u(1/2)),$$

which together with (2.7) and the fact that $f(z) = \check{f}(z)$ for $z > L$, gives

$$H(u(1/2)) = \frac{\phi_p(u(1/2))}{f\left(u\left(1/2\right)\right)} \geq \lambda c_2$$

where $c_2 = \min(c_1/2^p, 1)$. Hence by Lemma 2.1 (ii),

$$u(1/2) \geq H^{-1}(\lambda c_2) \geq c_3 H^{-1}(\lambda), \tag{2.8}$$

where $c_3 = c_2^{\frac{1}{p-q}}$. From (2.6) and (2.8), we get

$$-u'(r) \geq \phi^{-1}\left(\lambda c_1 f\left(c_3 H^{-1}(\lambda)\right)\right) \geq \phi^{-1}\left(\lambda c_1 c_3^{q-1} f\left(H^{-1}(\lambda)\right)\right) \quad \text{for } r > 1/2, \tag{2.9}$$

For $\lambda \gg 1, \lambda c_1 c_3^{q-1} f\left(H^{-1}(\lambda)\right) > 1$, from which (2.9) and Lemma 2.2 with $c = 1$ and $x = c_1 c_3^{q-1} f\left(H^{-1}(\lambda)\right)$ give

$$-u'(r) \geq a\phi_p^{-1}\left(\lambda c_1 c_3^{q-1} f\left(H^{-1}(\lambda)\right)\right) \equiv a_1 \phi_p^{-1}(\lambda f\left(H^{-1}(\lambda)\right) = a_1 B_\lambda \quad \text{for } r > 1/2, \tag{2.10}$$

where $B_\lambda = \phi_p^{-1}\left(\lambda f(H^{-1}(\lambda)\right)$ and $a > 0$ is such that $a^{p-1} + a^{q-1} \leq 1$ and $a_1 = a\phi_p^{-1}(c_1 c_3^{q-1})$.

Note that $B_\lambda \to \infty$ as $\lambda \to \infty$. Integrating (2.10) yields

$$u(r) \geq a_1 B_\lambda (1 - r) \tag{2.11}$$

for $r > 1/2$, while for $r < 1/2$,

$$u(r) > u(1/2) \geq \frac{a_1}{2} B_\lambda \geq \frac{a_1}{2} B_\lambda (1-r). \tag{2.12}$$

Combining (2.11) and (2.12), we obtain

$$u(r) \geq A_1 B_\lambda (1-r) \quad \text{for } r \in (0,1), \tag{2.13}$$

where $A_1 = a_1/2$ i.e. the lower bound estimate in (2.5) holds.

Let $C = \sup_{z\in(0,L)} z^\gamma f(z)$ and note that $0 < C < \infty$. Since $f > 0$ on $(0,\infty)$,

$$f(z) \leq \frac{C}{z^\gamma} + f(\max(z, L)) \tag{2.14}$$

for $z > 0$. Since $\|u\|_\infty \to \infty$ as $\lambda \to \infty$, $\|u\|_\infty > L$ for $\lambda \gg 1$ and hence (2.13)–(2.14) yield

$$f(u(\tau)) \leq \frac{C}{u^\gamma(\tau)} + f(\max(u(\tau), L)) \ \leq \frac{C_1}{B_\lambda^\gamma (1-\tau)^\gamma} + f(\|u\|_\infty),$$

for $\tau \in (0,1)$, where $C_1 = C/A_1^\gamma$. Thus

$$\begin{aligned}
u(r) &= \int_r^1 \phi^{-1}\left(\frac{\lambda}{s^{N-1}} \int_0^s \tau^{N-1} f(u) d\tau\right) ds \\
&\leq \int_r^1 \phi^{-1}\left(\frac{\lambda}{s^{N-1}} \int_0^s \tau^{N-1} \left(\frac{C_1}{B_\lambda^\gamma (1-\tau)^\gamma} + f(\|u\|_\infty)\right) d\tau\right) ds \\
&\leq \int_r^1 \phi^{-1}\left(\lambda \left(C_1 \int_0^s \frac{d\tau}{(1-\tau)^\gamma} + f(\|u\|_\infty)\right)\right) \leq \phi^{-1}\left(\lambda(C_2 + f(\|u\|_\infty))\right)(1-r) \\
&\leq \phi^{-1}(\lambda C_3 f(\|u\|_\infty))(1-r) \leq \phi_p^{-1}(\lambda C_3 f(\|u\|_\infty))(1-r)
\end{aligned} \tag{2.15}$$

for $r \in (0,1)$, where $C_2 = C_1 \int_0^1 \frac{d\tau}{(1-\tau)^\gamma}$ and $C_3 > 1$ is such that $(C_3 - 1) f(L) > C_2$.

In particular,

$$\|u\|_\infty \leq \phi_p^{-1}(\lambda C_3 f(\|u\|_\infty)),$$

which implies

$$H(\|u\|_\infty) = \frac{\phi_p(\|u\|_\infty)}{f(\|u\|_\infty)} \leq \lambda C_3,$$

and therefore

$$\|u\|_\infty \leq H^{-1}(\lambda C_3) \leq C_4 H^{-1}(\lambda), \tag{2.16}$$

in view of Lemma 2.1 (i), where $C_4 = C_3^{\frac{1}{p-q}}$.

Combining (2.15)–(2.16) and Remark 1.2 (i), we infer that

$$\begin{aligned}
u(r) &\leq \phi_p^{-1}(\lambda C_3 f\left(C_4 H^{-1}(\lambda)\right))(1-r) \leq \phi_p^{-1}(\lambda C_3 C_4^{q-1} f(H^{-1}(\lambda))(1-r) \\
&= A_2 \phi_p^{-1}(\lambda f(H^{-1}(\lambda))(1-r) \equiv A_2 B_\lambda (1-r)
\end{aligned}$$

for $r \in (0,1)$, where $A_2 = \phi_p^{-1}(C_3 C_4^{q-1})$ i.e. the upper bound estimate in (2.5) holds, which completes the proof.

Case 2. Suppose (A5) holds.

By Lemma 2.3, u is decreasing on $(0,1)$. Recall that $\beta, \theta > 0$ are such that $(z-\beta)f(z) > 0$ for $z \neq \beta$ and $(z-\theta)F(z) > 0$ for for $z \neq \theta$. Let $\rho = \frac{\beta+\theta}{2}$ and $\delta \in (0,1)$ be such that

$$\frac{\delta^N}{2N} \inf_{[\rho,\infty)} f - (1-\delta)K > 0, \tag{2.17}$$

where $K > 0$ is such that $f(z) \geq -K$ for all $z \in (0,\infty)$.

We will show that $u(\delta) \to \infty$ as $\lambda \to \infty$. To this end, we need to verify the following claims. Let $\beta_1 \in (0,\beta)$ and δ_0, δ_1 satisfy $\delta < \delta_0 < \delta_1 < 1$.

Claim 1. $u(\delta_1) > \beta_1$ *for* $\lambda \gg 1$.

Suppose to the contrary that $u(\delta_1) \leq \beta_1$. Then $u < \beta_1$ on $(\delta_1, 1)$, which implies

$$(r^{N-1}\phi(u'))' = -\lambda r^{N-1} f(u) \geq \lambda m r^{N-1} \quad \text{on } (\delta_1, 1), \tag{2.18}$$

where $m = -\sup_{(0,\beta_1)} f > 0$.

Let $\delta_2 \in (\delta_1, 1)$. By the Mean Value Theorem, there exists $\sigma \in (\delta_1, \delta_2)$ such that

$$|u'(\sigma)| = \frac{u(\delta_1) - u(\delta_2)}{\delta_2 - \delta_1} \leq \frac{\beta_1}{\delta_2 - \delta_1} \equiv \bar{\beta}.$$

Hence by integrating (2.18) on $(\sigma, 1)$, we obtain

$$0 \geq \phi(u'(1)) \geq \sigma^{N-1}\phi(u'(\sigma)) + \lambda m \int_\sigma^1 r^{N-1} dr \geq \lambda m \int_{\delta_2}^1 r^{N-1} dr - \phi(\bar{\beta}) > 0,$$

for λ large, a contradiction which proves the claim.

Claim 2. $u(\delta_0) > \rho$ *for* $\lambda \gg 1$.

Suppose to the contrary that $u(\delta_0) \leq \rho$. Then $u < \rho$ on $(\delta_0, 1)$ and therefore $G' < 0$ on $(\delta_0, 1)$, where G is defined in the proof of Lemma 2.3. Hence $G(r) \geq G(1) \geq 0$ on $(\tau_0, 1)$ i.e.

$$\phi(u')u' - \Phi(u') + \lambda F(u)) \geq 0 \quad \text{on } (\delta_0, 1),$$

or, equivalently,

$$(1 - 1/p)|u'|^p + (1 - 1/q)|u'|^q \geq -\lambda F(u) \quad \text{on } (\delta_0, 1). \tag{2.19}$$

By Claim 1 and the monotonicity of u,

$$\beta_1 \leq u \leq \rho \quad \text{on } (\delta_0, \delta_1),$$

and hence $\kappa \equiv \inf_{[\beta_1,\rho]}(-F(z)) > 0$. Consequently, (2.19) gives

$$|u'|^p + |u'|^q \geq \frac{\lambda q \kappa}{q-1} \equiv \lambda \kappa_0 \quad \text{on } (\delta_0, \delta_1).$$

For $\lambda\kappa_0 > 2$, this implies $|u'| > 1$ and hence $2|u'|^p \geq \lambda\kappa_0$ on (δ_0, δ_1) follows i.e.

$$-u' = |u'| \geq (\lambda\kappa_0/2)^{1/p} \quad \text{on } (\delta_0, \delta_1). \tag{2.20}$$

Integrating (2.20) on (δ_0, δ_1) gives

$$u(\delta_0) \geq (\lambda\kappa_0/2)^{1/p}(\delta_1 - \delta_0) > \rho$$

for $\lambda \gg 1$, a contradiction which proves Claim 2.

By Claim 2, $u > \rho$ on $(0, \delta_0)$ and hence

$$f(u) \geq \kappa_1 \quad \text{on } (0, \delta_0),$$

where $\kappa_1 = \inf_{[\rho,\infty)} f > 0$. This implies

$$u(\delta) = u(\delta_0) + \int_\delta^{\delta_0} \phi^{-1}\left(\frac{\lambda}{s^{N-1}}\int_0^s \tau^{N-1} f(u)d\tau\right) ds \geq (\delta_0 - \delta)\phi^{-1}\left(\lambda\kappa_1 \int_0^\delta \tau^{N-1}d\tau\right) ds,$$

and thus $u(\delta) \to \infty$ as $\lambda \to \infty$.

Hence for λ large, $u(\delta) > \rho$ and for $r > \delta$, we have

$$\int_0^r s^{N-1} f(u)ds = \int_0^\delta s^{N-1} f(u)ds + \int_\delta^r s^{N-1} f(u)ds \geq \frac{\delta^N}{N} f(u(\delta)) - (1-\delta)K \geq \frac{\delta^N}{2N} f(u(\delta))$$

in view of (2.17). Hence

$$-u'(r) = \phi^{-1}\left(\frac{\lambda}{r^{N-1}}\int_0^r s^{N-1} f(u)ds\right) \geq \phi^{-1}\left(\frac{\lambda\delta^N f(u(\delta)}{2N}\right), \tag{2.21}$$

for $r > \delta$, and upon integrating on $(\delta, 1)$, we get

$$u(\delta) \geq (1-\delta)\phi^{-1}\left(\frac{\lambda\delta^N f(u(\delta))}{2N}\right)$$

i.e.

$$\frac{\phi\left(cu(\delta)\right)}{f(u(\delta))} \geq \lambda D_1, \tag{2.22}$$

where $c = (1-\delta)^{-1}$ and $D_1 = \frac{\delta^N}{2N}$.

For $\lambda \gg 1$, $cu(\delta > 1$ and $\phi\left(cu(\delta)\right) \leq 2\phi_p(cu(\delta)) = 2\phi_p(c)\phi_p(\delta)$ and (2.22) becomes

$$H(u(\delta)) = \frac{\phi_p(u(\delta))}{f(u(\delta))} \geq \lambda D_2,$$

where $D_2 = \frac{D_1}{2\phi_p(c)} < 1$, which implies

$$u(\delta) \geq H^{-1}(\lambda D_2) \geq D_3 H^{-1}(\lambda) \tag{2.23}$$

follows, where $D_3 = D_2^{\frac{1}{p-q}}$.

Combining (2.21), (2.23), Remark 1.2 (i), and Lemma 2.2, we obtain for $\lambda \gg 1$,

$$\begin{aligned} -u'(r) &\geq \phi^{-1}\left(\frac{\lambda\delta^N f(D_3 H^{-1}(\lambda))}{2N}\right) \geq \phi^{-1}\left(\frac{\lambda\delta^N D_3^{q-1} f(H^{-1}(\lambda))}{2N}\right), \\ &\geq a\phi_p^{-1}\left(\frac{\lambda\delta^N D_3^{q-1} f(H^{-1}(\lambda))}{2N}\right) = D_4\phi_p^{-1}\left(\lambda f(H^{-1}(\lambda))\right), \end{aligned}$$

for $r \in (\delta, 1)$, where $D_4 = a\phi_p^{-1}(\frac{\delta^N D_3^{q-1}}{2N})$. Integrating this inequality gives

$$u(r) \geq D_4\phi_p^{-1}(\lambda f(H^{-1}(\lambda))(1-r) \quad \text{for } r \in (\delta, 1),$$

which, together with the monotonicity of u, gives the lower bound estimate in (2.5).

For the upper bound estimate, by increasing L if necessary, we can assume $L > \beta$ with $f(L) > 0$. Hence

$$f(z) \le C_1 + f(\max(z, L))$$

for $z > 0$, where $C_1 = \max_{[\beta,L]} f$.

Suppose $\|u\|_\infty > L$ and $C_2 > 1$ be such that

$$C_1 < (C_2 - 1)f(L) < (C_2 - 1)f(\|u\|_\infty).$$

Then

$$\begin{aligned} u(r) &= \int_r^1 \phi^{-1}\left(\frac{\lambda}{s^{N-1}}\int_0^s \tau^{N-1} f(u)d\tau\right) ds \le \int_r^1 \phi^{-1}\left(\frac{\lambda}{s^{N-1}}\int_0^s \tau^{N-1}\left(C_1 + f(\|u\|_\infty)\right) d\tau\right) ds \\ &\le \int_r^1 \phi^{-1}\left(\frac{\lambda}{s^{N-1}}\int_0^s \tau^{N-1}\left(C_2 f(\|u\|_\infty)\right) d\tau\right) ds \le \phi^{-1}\left(\lambda(C_2 f(\|u\|_\infty)\right)(1-r) \\ &\le \phi_p^{-1}(\lambda C_2 f(\|u\|_\infty))(1-r) \end{aligned}$$

for $r \in (0,1)$. The rest of the proof uses the same arguments as in the upper bound estimate for Case 1, which completes the proof. □

Lemma 2.6. *Let $\alpha \in (0,1)$ and $\tau > 0$. Then*

$$\min(\tau, 1)(1-\alpha) \le 1 - \alpha^\tau \le \max(\tau, 1)(1-\alpha). \tag{2.24}$$

Proof. Suppose $\tau < 1$. Then $1 - \alpha^\tau \le 1 - \alpha$. By the Mean Value Theorem with $g(\alpha) = (1-\alpha)^\tau$,

$$(1-\alpha)^\tau = |g(\alpha) - g(1)| = (1-\alpha)\frac{\tau}{(1-\xi)^{1-\tau}} \ge \tau(1-\alpha),$$

for some $\xi \in (\alpha, 1)$ i.e. (2.24) holds. The case $\tau > 1$ is proved in the same way. □

The existence of a positive solution to (1.1) in a general bounded domain is based on the following result:

Lemma 2.7 ([1, Theorem 1.1])**.** *Suppose*

(A1) $f : (0,\infty) \to \mathbb{R}$ *is continuous and* $\lim_{u\to\infty} \frac{f(u)}{u^{p-1}} = 0$.

(A2) There exist constants $A, L > 0$ and $0 \le \beta < 1$ such that

$$f(u) \ge \frac{A}{u^\beta} \quad \text{for } u > L$$

and

$$\limsup_{u\to 0^+} u^\beta |f(u)| < \infty.$$

Then there exists a constant $\lambda_0 > 0$ such that (1.1) has a positive solution u_λ for $\lambda > \lambda_0$ with $\inf_\Omega \frac{u_\lambda}{d} \to \infty$ as $\lambda \to \infty$, where $d(x)$ denotes the distance from x to $\partial\Omega$.

3 Proof of Theorem 1.1

By Lemma 2.7, (1.2) has a positive solution for λ large. Let u, v be such solutions. In view of Lemma 2.5, there exists a maximum constant $\alpha \in (0,1]$ such that $\alpha v \le u \le \alpha^{-1} v$ on $(0,1)$. Then $\alpha \ge A_1/A_2 \equiv \alpha_0$ by (2.5). Recalling that $L > 0$ is such that f is increasing on (L, ∞). By using (A2) and increasing L if necessary, we can assume that $f(L) > 0$ and $z^{-q_0} f(z)$ is decreasing on $[L, \infty)$ for some $q_0 \in (0, q-1)$. We will show that $\alpha \ge 1$. Suppose to the contrary that $\alpha < 1$. Suppose $\lambda > \lambda_0$, where λ_0 is defined in Lemma 2.5.

Let $L_1 = \alpha_0^{-1} L$. Then

$$v(1/2) > L_1$$

for $\lambda > \lambda^*$ for some $\lambda^* > 0$ independent of u, v.

For $r \le 1/2$,

$$u(r) \ge \alpha v(r) \ge \alpha_0 v(1/2) > \alpha_0 L_1 = L,$$

which implies

$$f(u(r)) \ge f(\alpha v(r)) \ge \alpha^{q_0} f(v(r)). \tag{3.1}$$

Suppose $r > 1/2$.

Case 1. $v(r) \ge L_1$

Then $u(r) > L$ and therefore (3.1) holds.

Case 2. $v(r) < L_1$.

Then

$$u(r) \le \alpha_0^{-1} v(r) < \alpha_0^{-1} L_1 \equiv L_2.$$

Let $K_0 = \sup_{z \in (0, L_2)} z^\gamma |f(z)|$ and $K_1 = \sup_{z \in (0, L_2)} z^{\gamma+1} |f'(z)|$. Then $K_0, K_1 < \infty$ by (A3) and (A5). Then the lower bound estimate in Lemma 2.5 gives,

$$|f(v(r))| \le \frac{K_0}{v^\gamma(r)} \le \frac{K_0}{A_1^\gamma B_\lambda^\gamma (1-r)^\gamma}, \tag{3.2}$$

which implies in view of Lemma 2.6,

$$f(v(r)) \ge \alpha^{q_0} f(v(r)) - (1 - \alpha^{q_0}) |f(v(r))| \ge \alpha^{q_0} f(v(r)) - \frac{K_0 c_{q_0} (1-\alpha)}{A_1^\gamma B_\lambda^\gamma (1-r)^\gamma}, \tag{3.3}$$

where $c_{q_0} = \max(1, q_0)$, and

$$\begin{aligned} |f(u(r)) - f(v(r))| = |u(r) - v(r)| |f'(\xi)| &\le \frac{K_1 (1-\alpha) v(r)}{\alpha \xi^{\gamma+1}} \\ &\le \frac{K_1 (1-\alpha)}{\alpha_0^{2+\gamma} v^\gamma(r)} \le \frac{K_1 (1-\alpha)}{\alpha_0^{2+\gamma} A_1^\gamma B_\lambda^\gamma (1-r)^\gamma} \end{aligned} \tag{3.4}$$

for some ξ between $u(r)$ and $v(r)$. From (3.3) and (3.4), we deduce that

$$f(u(r)) \ge f(v(r)) - |f(u(r)) - f(v(r))| \ge \alpha^{q_0} f(v(r)) - \frac{K_2 (1-\alpha)}{B_\lambda^\gamma (1-r)^\gamma}, \tag{3.5}$$

where $K_2 = (K_0 c_{q_0} + K_1 \alpha_0^{-2-\gamma}) / A_1^\gamma$. Hence (3.5) holds for $r > 1/2$ in both cases.

Let $q_1 \in (q_0, q-1)$. Then for $r > 1/2$, it follows from (3.2), (3.5) and Lemmas 2.5–2.6 that

$$\begin{aligned} f(u(r)) - \alpha^{q_1} f(v(r)) &\geq (\alpha^{q_0} - \alpha^{q_1}) f(v(r)) - \frac{K_2(1-\alpha)}{B_\lambda^\gamma (1-r)^\gamma} \\ &\geq -\frac{(1-\alpha^{q_1-q_0})K_0}{A_1^\gamma B_\lambda^\gamma (1-r)^\gamma} - \frac{K_2(1-\alpha)}{B_\lambda^\gamma (1-r)^\gamma} \geq -\frac{K_3(1-\alpha)}{B_\lambda^\gamma (1-r)^\gamma}, \end{aligned} \tag{3.6}$$

where $K_3 = K_0 A_1^{-\gamma} \max(1, q_1 - q_0) + K_2$.

We claim next that

$$\phi(u') \leq \alpha^{q_1} \phi(v') \tag{3.7}$$

on $(0,1)$. Using the formula

$$-r^{N-1}[\phi(u'(r))) - \alpha^{q_1}\phi(v'(r)] = \lambda \int_0^r s^{N-1}(f(u) - \alpha^{q_1} f(v))ds, \tag{3.8}$$

for $r \in (0,1)$, we see from (3.1) that for $r \leq 1/2$,

$$f(u(s)) - \alpha^{q_1} f(v(s)) \geq (\alpha^{q_0} - \alpha^{q_1}) f(v(s)) > 0 \tag{3.9}$$

for $s \leq 1/2$ i.e. (3.7) holds on $(0, 1/2]$. For $r > 1/2$, it follows from (3.6), (3.8), (3.9), and Lemma 2.6 that

$$\begin{aligned} -r^{N-1}(\phi(u') - \alpha^{q_1}\phi(v')) &= \lambda \left(\int_0^{1/2} s^{N-1}(f(u) - \alpha^{q_1} f(v))ds + \int_{1/2}^r s^{N-1}(f(u) - \alpha^{q_1} f(v))ds \right) \\ &\geq \lambda \left[(\alpha^{q_0} - \alpha^{q_1}) \int_0^{1/2} s^{N-1} f(v) ds - \frac{K_3(1-\alpha)}{B_\lambda^\gamma} \int_{1/2}^1 \frac{1}{(1-s)^\gamma} ds \right] \\ &\geq \lambda(1-\alpha) \left[K_4 f(v(1/2)) - \frac{K_3}{B_\lambda^\gamma} \int_\delta^1 \frac{1}{(1-s)^\gamma} ds \right] > 0, \end{aligned}$$

where $K_4 = \frac{\alpha_0^{q_0} \min(1, q_1 - q_0)}{N 2^N}$, provided that $\lambda > \bar{\lambda}$, where $\bar{\lambda} > \lambda_0$ is such that

$$K_4 f(L_1) - \frac{K_3}{B_\lambda^\gamma} \int_{1/2}^1 \frac{1}{(1-s)^\gamma} ds > 0.$$

Note that this is possible since $f(L_1) > 0$ and $B_\lambda \to \infty$ as $\lambda \to \infty$. Hence (3.7) holds on $(0,1)$, which implies

$$\phi(u') + \alpha^{q_1}\phi(|v'|) \leq 0. \tag{3.10}$$

Since

$$\phi\left(\alpha^{\frac{q_1}{q-1}}|v'|\right) = \alpha^{q_1}|v'|^{q-1} + \alpha^{\frac{q_1(p-1)}{q-1}}|v'|^{p-1} \leq \alpha^{q_1}(|v'|^{q-1} + |v'|^{p-1}) = \alpha^{q_1}\phi(|v'|),$$

it follows from (3.10) that

$$\phi(u') + \phi\left(\alpha^{\frac{q_1}{q-1}}|v'|\right) \leq 0,$$

i.e.

$$\phi(u') \leq -\phi\left(\alpha^{\frac{q_1}{q-1}}|v'|\right) = \phi\left(\alpha^{\frac{q_1}{q-1}} v'\right).$$

Hence $\left(u - \alpha^{\frac{q_1}{q-1}} v\right)' \leq 0$ on $(0,1)$ and since $u(1) = v(1) = 0$, it follows that $u \geq \alpha^{\frac{q_1}{q-1}} v$ on $(0,1)$, a contradiction with the maximality of α since $q_1 < q-1$. This completes the proof of Theorem 1.1. □

Communicated by Alberto Cabada

Abstract. In this paper we revisit previous results in the literature dealing with the stability of periodic solutions of periodic predator–prey Lotka–Volterra systems. These results provide stability criteria for the periodic orbits based on boundaries for the average of the coexistence states. In the way it was presented, these boundaries are independent of each other and thus provide a very practical sufficient condition for asymptotic stability. In this note we prove that this independent boundaries can be refined into an intertwined boundary, providing a more sharp sufficient condition.

Keywords: Lotka–Volterra systems, population dynamics, predator–prey model.

2020 Mathematics Subject Classification: 34D20, 34C25, 92D25.

1 Introduction

Consider the planar non-autonomous periodic Lotka-–Volterra system given by

$$\dot{u} = u(a(t) - b(t)u - c(t)v), \quad \dot{v} = v(d(t) + e(t)u - f(t)v), \tag{1.1}$$

with continuous and T-periodic coefficients, $T > 0$. Suppose that b, c, e and f are strictly positive functions. Under these conditions (1.1) models in the positive quadrant $\mathbb{R}^2_+ = \{(u,v) \in \mathbb{R}^2 \colon u > 0,\ v > 0\}$ a predator-prey interaction between two species in a T-periodic environment. In the last decades, there is a great effort of R. Ortega and coauthors for the understanding of the T-periodic orbits of (1.1). In what follows, we present a brief survey on the obtained results. System (1.1) can have three types T-periodic non-negative solutions $(u(t), v(t))$.

(a) The *trivial state*, given by $u(t) = v(t) = 0$ for every $t \in [0,T]$;

(b) The *semi-trivial state*, given by:

(i) $u(t) > 0$, $v(t) = 0$ for every $t \in [0,T]$, or

(ii) $u(t) = 0$, $v(t) > 0$ for every $t \in [0,T]$;

(c) The *coexistence state*, given by $u(t) > 0$ and $v(t) > 0$ for every $t \in [0,T]$.

✉ Email: paulo.santana@unesp.br

Observe that the trivial and semi-trivial states represents the extinction of at least one of the species. The question about the *existence* of coexistence states was completely solved by the authors in [4]. More precisely, let

$$\lambda = \frac{1}{T}\int_0^T a, \quad \mu = \frac{1}{T}\int_0^T d.$$

It follows from [4] that (1.1) has a semi-trivial state of type (i) (resp. (ii)) if, and only if, $\lambda > 0$ (resp, $\mu > 0$). Moreover, in this case the semi-trivial state $(\theta_\lambda(t), 0)$ (resp. $(0, \theta_\mu(t))$ is given by the unique positive T-periodic solution of

$$\dot{u} = u(a(t) - b(t)u) \quad \big(\text{resp. } \dot{v} = v(d(t) - f(t)v)\big).$$

In particular, if it exists then it is unique (of its type). From [4, Section 4] we have that the following statements hold (for the definition of *linear* and *asymptotic* stability, see Appendix A).

(a) The trivial state $(0, 0)$ is linearly stable if, and only if, $\lambda \leqslant 0$ and $\mu \leqslant 0$. Moreover, in this case it is also asymptotically stable in $\mathbb{R}^2_+$.

(b) The semi-trivial state $(\theta_\lambda, 0)$ is linearly stable if, and only if, $\lambda > 0$ and

$$\mu \leqslant -\frac{1}{T}\int_0^T e\theta_\lambda.$$

Moreover, in this case it is also asymptotically stable in $\mathbb{R}^2_+$.

(c) The semi-trivial state $(0, \theta_\mu)$ is linearly stable if, and only if, $\mu > 0$ and

$$\lambda \leqslant \frac{1}{T}\int_0^T c\theta_\mu.$$

Moreover, in this case it is also asymptotically stable in $\mathbb{R}^2_+$.

It can be proved [4, Theorem 4.1] that for a coexistence state to exist it is necessary to the trivial and semi-trivial states (when they exist) to be linearly unstable. That is, it is necessary

$$\mu > -\frac{1}{T}\int_0^T e\theta_\lambda, \quad \lambda > \frac{1}{T}\int_0^T c\theta_\mu. \tag{1.2}$$

On the other hand, it also follows from [4, Section 5] that (1.2) is as well a sufficient condition and thus we have a complete characterization on the existence of coexistence states for system (1.1). Moreover, it follows from [4, Theorem 5.1] that system (1.1) always has at most a finite number of coexistence states. With the existence completely characterized, the question turned to the finiteness, uniqueness and stability of the coexistence states. For this end, before we enunciate the obtained results, we introduce some technical notations.

Let $\mathbb{T}_T = \mathbb{R}/T\mathbb{Z}$ be endowed with the push-forward measure of the Lebesgue measure on $\mathbb{R}$ (see Bogachev [2, Section 3.6]). That is, the measure σ such that $\sigma(a, b) = b - a$, for $0 \leqslant a \leqslant b \leqslant T$. Given $p \in [1, \infty]$, let $L^p = L^p(\mathbb{T}_T)$ denote the usual Lebesgue L^p-space associated with $\mathbb{T}_T$. Since $\mathbb{T}_T$ has finite measure, we observe that

$$L^\infty \subset L^{p_2} \subset L^{p_1} \subset L^1,$$

where $1 \leqslant p_1 \leqslant p_2 \leqslant \infty$.

In particular, since the coefficients of (1.1) are continuous, it follows that they lie in L^∞ and thus also in L^p, for every $p \in [1,\infty]$. Let $\varphi \in L^p$. For simplicity we denote $\|\varphi\|_p = \|\varphi\|_{L^p}$, where $\|\cdot\|_{L^p}$ is the usual norm of the Banach space L^p. Let also

$$\varphi_L = \min_{t\in[0,T]}\{\varphi(t)\}, \quad \varphi_M = \max_{t\in[0,T]}\{\varphi(t)\}, \quad \overline{\varphi} = \frac{1}{T}\int_0^T \varphi,$$

be the minimum, maximum and average of φ. About the uniqueness of the coexistence states of (1.1), consider the statements

$$\overline{a} > 0, \quad -\left(\frac{e}{b}\right)_L < \frac{\overline{d}}{\overline{a}} < \left(\frac{f}{c}\right)_L, \tag{1.3}$$

and

$$\left(\frac{b}{e}\right)_L > \left(\frac{c}{f}\right)_M. \tag{1.4}$$

The authors in [1] proved that if (1.4) holds, then (1.1) has at most one coexistence state [1, Proposition 3.3]. As observed by the authors in [1, Remark 2, p. 11], if both (1.3) and (1.4) holds, then it follows from Tineo [8, Theorem 1.5] that (1.1) has exactly one coexistence state and it is *globally* asymptotically stable.

More sufficient conditions for asymptotically stability of coexistence states were obtained by R. Ortega and coauthors [1,5]. Such conditions can somewhat be called L_1*-condition* and L_∞*-condition* (see Remarks 2.3 and 2.4). In recent years V. Ortega and Rebelo [6] constructed a bridge between these two conditions, obtaining a L_p*-condition*, $p \in [1,\infty]$. Such condition requires that the L_p-norm of all possible coexistence states (u_0, v_0) to satisfy a given inequality. To this end, the authors in [6] also provide upper bounds for $\|u_0\|_p$ and $\|v_0\|_p$, independent from each other. This independence provides a *unified* sufficient condition for uniqueness and asymptotically stability of (u_0, v_0).

In this paper we obtain new *intertwined* upper bounds for $\|u_0\|_p$ and $\|v_0\|_p$, which in turn imply on new sufficient conditions for uniqueness and asymptotically stability of (u_0, v_0), that can be applied when the unified test is inconclusive. The paper is organized as follows. In Section 2 we state our main Theorem. At Section 3 we have some preliminary results to prove the main Theorem at Section 4. In Section 5 we provide an example where previous results in the literature are inconclusive, while ours is not. We also provide some further thoughts. Finally, we have an Appendix with some technicalities and illustrations.

2 Statement of the main result

Given $p \in [1,\infty)$ and $\varphi \in L^p$ non-negative, the L^p*-average* $\overline{\varphi}_p \in \mathbb{R}_{\geqslant 0}$ is given by,

$$\overline{\varphi}_p = \frac{1}{T^{\frac{1}{p}}}\left(\int_0^T \varphi^p\right)^{\frac{1}{p}} = \frac{1}{T^{\frac{1}{p}}}\|\varphi\|_p.$$

If $p = \infty$, then we define $\overline{\varphi}_\infty = \|\varphi\|_\infty$. Observe that $\overline{\varphi}_p \to \overline{\varphi}_\infty$ as $p \to \infty$.

Given a system of the form (1.1) and $p \in [1,\infty)$, let $C_p \subset \mathbb{R}^2$ be the set given by the points $(x,y) \in \mathbb{R}^2$ such that $x > 0$, $y > 0$ and

$$\begin{aligned} b_L U^{1-p}x^p + c_L V^{1-p}y^p \leqslant \overline{a} \leqslant b_M x + c_M y \\ -e_M x + f_L V^{1-p}y^p \leqslant \overline{d} \leqslant -e_L U^{1-p}x^p + f_M y, \end{aligned} \tag{2.1}$$

where,

$$U = \left(\frac{a}{b}\right)_M, \quad V = \left(\frac{d}{f}\right)_M + \left(\frac{e}{f}\right)_M U.$$

Let also $C_\infty \subset \mathbb{R}^2$ be the set given by

$$0 < x \leqslant U, \quad 0 < y \leqslant V.$$

For an illustration of C_p and more details about the definition of C_∞, see Appendix B. We observe that C_p is bounded and that it may be empty. Let also $\mathcal{J}\colon [1,\infty) \to \mathbb{R}$ be given by,

$$\mathcal{J}(q) = \int_0^{2\pi} \frac{1}{\left(|\cos\theta|^{2q} + |\sin\theta|^{2q}\right)^{\frac{1}{q}}}\, d\theta.$$

It follows from [6, Proposition 2.2] that,

$$\lim_{q\to\infty} \mathcal{J}(q) = 8.$$

Hence, we can continuously extend $\mathcal{J}$ to $[1,\infty]$ by defining $\mathcal{J}(\infty) = 8$. For more details about $\mathcal{J}(q)$, see Appendix C. Given $p \in [1,\infty]$, we recall that its *conjugate* $q \in [1,\infty]$ is given by the unique solution of $1/p + 1/q = 1$. In what follows q always denote the conjugate of p. Our main result is the following.

Theorem 2.1. *Consider a system of the form (1.1) and its respective set C_p, $p \in [1,\infty]$. Then the following statements hold.*

(a) If $(u(t), v(t))$ is a coexistence state, then $(\overline{u}_p, \overline{v}_p) \in C_p$. In particular, $C_p \neq \emptyset$ for every $p \in [1,\infty]$.

(b) Suppose we have at least one coexistence state. If

$$T\left(\sqrt{c_M e_M x_p y_p} + \frac{1}{2}(b_M x_1 + f_M y_1)\right) \leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}}$$

for every $(x_p, y_p) \in C_p$ and $(x_1, y_1) \in C_1$, then such coexistence state is unique and asymptotically stable.

Remark 2.2. As presented in the introduction, we recall that the existence of a coexistence state is completely characterized. Therefore, the hypothesis of having at least one is not a loss of generality.

It follows from Hölder's inequality that if $\varphi \geqslant 0$, then $\overline{\varphi}_{p_1} \leqslant \overline{\varphi}_{p_2}$ for $1 \leqslant p_1 \leqslant p_2 \leqslant \infty$. Hence, we can replace statement (b) of Theorem 2.1 for the following weak version.

(b') Suppose we have at least one coexistence state. If

$$T\left(\sqrt{c_M e_M x_p y_p} + \frac{1}{2}(b_M x_p + f_M y_p)\right) \leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}}$$

for every $(x_p, y_p) \in C_p$, then such coexistence state is unique and asymptotically stable.

Remark 2.3 (The L_1-condition)**.** Observe that if we replace $p = 1$ at Theorem 2.1(b), we obtain

$$T\left(\sqrt{c_M e_M xy} + \frac{1}{2}(b_M x + f_M y)\right) \leqslant 2$$

for every $(x, y) \in C_1$, where $C_1 \subset \mathbb{R}^2$ is the set bounded by $x > 0$, $y > 0$ and

$$\begin{aligned} b_L x + c_L y \leqslant \ \ \overline{a} \ \ &\leqslant b_M x + c_M y \\ -e_M x + f_L y \leqslant \ \ \overline{d} \ \ &\leqslant -e_L x + f_M y. \end{aligned}$$

This is precisely the L_1-condition obtained by R. Ortega [5, Theorem 5.2].

Remark 2.4 (The L_∞-condition)**.** Observe that if we replace $p = \infty$, $x = U$ and $y = V$ at Theorem 2.1(b'), we obtain

$$T\left(\sqrt{c_M e_M UV} + \frac{1}{2}(b_M U + f_M V)\right) \leqslant \pi. \tag{2.2}$$

This is the L_∞-condition obtained by R. Ortega and Amine [1, Proposition 4.5].

3 Preliminary results

In this section we recall the *L_p-condition* obtained by V. Ortega and Rebelo [6, Theorem 3.1] and also a technical lemma.

Theorem 3.1 (The L_p-condition)**.** *Suppose that all possible coexistence states (u, v) of system (1.1) satisfy*[1]

$$T^{\frac{1}{q}}\sqrt{\|eu\|_p \|cv\|_p} + \frac{1}{2}\|bu - fv\|_1 \leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}}, \tag{3.1}$$

where p and q are conjugated indices and $p, q \in [1, \infty]$. Then the coexistence state is unique and asymptotically stable. Moreover, any coexistence state (u, v) satisfies

$$\|u\|_p \leqslant \frac{\|a\|_p}{b_L}, \quad \|v\|_p \leqslant \frac{\|d\|_p}{f_L} + \frac{e_M}{f_L}\frac{\|a\|_p}{b_L}. \tag{3.2}$$

Lemma 3.2. *Let $(u(t), v(t))$ be a coexistence state of (1.1). Then $\|u\|_\infty \leqslant U$ and $\|v\|_\infty \leqslant V$.*

Proof. Let $\tau \in [0, T]$ be such that $u(\tau) = \max_{[0,T]} u(t)$. Since $u(\tau)$ is a local maximum, it follows that $\dot{u}(\tau) = 0$ and thus it follows from the first equation of (1.1) that

$$a(\tau) = b(\tau)u(\tau) + c(\tau)v(\tau) \geqslant b(\tau)u(\tau) \Rightarrow u(\tau) \leqslant \frac{a(\tau)}{b(\tau)} \leqslant U.$$

Similarly, if we let $\tau \in [0, T]$ be such that $v(\tau) = \max_{[0,T]} v(t)$, then it follows from the second equation of (1.1) that,

$$f(\tau)v(\tau) = d(\tau) + e(\tau)u(\tau) \Rightarrow v(\tau) \leqslant \frac{d(\tau)}{f(\tau)} + \frac{e(\tau)}{f(\tau)}u(\tau) \leqslant V.$$

This finishes the proof. □

For lower bound of the coexistence states of (1.1), we refer to [4, Lemma 5.5].

[1] Actually in their paper instead of the fraction $1/2$ in the expression, it appears the fraction $T/2$. But from equation (7) in that paper one can see that it is a typo.

4 Proof of Theorem 2.1

Before we prove the theorem, we observe that given $p \in [1,\infty]$ and $\varphi \in L^P$, it follows from Hölder's inequality that,

$$\|\varphi\|_1 \leqslant T^{1-\frac{1}{p}}\|\varphi\|_p. \tag{4.1}$$

Moreover, it follows from Littlewood's inequality that

$$\|\varphi\|_p \leqslant \|\varphi\|_1^{\frac{1}{p}}\|\varphi\|_\infty^{1-\frac{1}{p}},$$

and thus

$$\|\varphi\|_1 \geqslant \frac{1}{\|\varphi\|_\infty^{p-1}}\|\varphi\|_p^p. \tag{4.2}$$

Proof of Theorem 2.1. Let $(u(t),v(t))$ be a coexistence state of (1.1). Dividing the first equation of (1.1) by u we obtain,

$$\frac{\dot{u}}{u} = a(t) - b(t)u - c(t)v. \tag{4.3}$$

Integrating (4.3) in t, from 0 to T, we obtain

$$\int_0^T a = \int_0^T bu + \int_0^T cv,$$

and thus,

$$b_L\int_0^T u + c_L\int_0^T v \leqslant \int_0^T a \leqslant b_M\int_0^T u + c_M\int_0^T v. \tag{4.4}$$

Since $u \geqslant 0$ and $v \geqslant 0$, it follows from (4.4) that,

$$b_L\|u\|_1 + c_L\|v\|_1 \leqslant \int_0^T a \leqslant b_M\|u\|_1 + c_M\|v\|_1. \tag{4.5}$$

Applying (4.1) on the right-hand side of (4.5) we obtain

$$\int_0^T a \leqslant b_M T^{1-\frac{1}{p}}\|u\|_p + c_M T^{1-\frac{1}{p}}\|v\|_p. \tag{4.6}$$

Dividing (4.6) by T and knowing that $T^{-\frac{1}{p}}\|u\|_p = \overline{u}_p$ and $T^{-\frac{1}{p}}\|v\|_p = \overline{v}_p$ we obtain,

$$\overline{a} \leqslant b_M\overline{u}_p + c_M\overline{v}_p. \tag{4.7}$$

Similarly, applying (4.2) on the left-hand side of (4.5) we obtain,

$$\int_0^T a \geqslant b_L\frac{1}{\|u\|_\infty^{p-1}}\|u\|_p^p + c_L\frac{1}{\|v\|_\infty^{p-1}}\|v\|_p^p.$$

Hence, it follows from Lemma 3.2 that,

$$\int_0^T a \geqslant b_L\frac{1}{U^{p-1}}\|u\|_p^p + c_L\frac{1}{V^{p-1}}\|v\|_p^p. \tag{4.8}$$

Multiplying (4.8) by T^{-1} we obtain,

$$\overline{a} \geqslant b_L\frac{1}{U^{p-1}}\overline{u}_p^p + c_L\frac{1}{V^{p-1}}\overline{v}_p^p. \tag{4.9}$$

Let us now look to the second equation of (1.1). Dividing it by v and integrating it in t, from 0 to T, we obtain

$$\int_0^T d = -\int_0^T eu + \int_0^T fv,$$

and thus,

$$-e_M\|u\|_1 + f_L\|v\|_1 \leqslant \int_0^T d \leqslant -e_L\|u\|_1 + f_M\|v\|_1. \tag{4.10}$$

Applying (4.1) (resp. (4.2) and Lemma 3.2) on the positive (resp. negative) term of the right-hand side of (4.10) we obtain,

$$\int_0^T d \leqslant -e_L\frac{1}{U^{p-1}}\|u\|_p^p + f_M T^{1-\frac{1}{p}}\|v\|_p. \tag{4.11}$$

Multiplying (4.11) by T^{-1} we obtain,

$$\overline{d} \leqslant -e_L\frac{1}{U^{p-1}}\overline{u}_p^p + f_M\overline{v}_p. \tag{4.12}$$

Similarly, it follows from the left-hand side of (4.10) that,

$$\overline{d} \geqslant -e_M\overline{u}_p + f_L\frac{1}{V^{p-1}}\overline{v}_p^p. \tag{4.13}$$

Now observe that equations (4.7), (4.9), (4.12) and (4.13) are the four equations given at the definition (2.1) of the set C_p. Hence, we obtained statement (a) of Theorem 2.1.

Statement (b) follows directly from Theorem 3.1. More precisely, knowing that

$$\|eu\|_p \leqslant e_M\|u\|_p, \quad \|cv\|_p \leqslant c_M\|v\|_p, \quad \|bu - fv\|_1 \leqslant b_M\|u\|_1 + f_M\|v\|_1,$$

$\|u\|_1 = T\overline{u}_1$, $\|v\|_1 = T\overline{v}_1$, and $T^{\frac{1}{q}} = T/T^{\frac{1}{p}}$, one can see that the left-hand side of (3.1) can be majored by,

$$T\left(\sqrt{c_M e_M \overline{u}_p\overline{v}_p} + \frac{1}{2}(b_M\overline{u}_1 + f_M\overline{v}_1)\right).$$

Since every possible coexistence state (u, v) satisfies $(\overline{u}_p, \overline{v}_p) \in C_p$, we have from Theorem 3.1 that if

$$T\left(\sqrt{c_M e_M x_p y_p} + \frac{1}{2}(b_M x_1 + f_M y_1)\right) \leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}}$$

for every $(x_p, y_p) \in C_p$ and $(x_1, y_1) \in C_1$, then the coexistence state is unique and asymptotically stable. □

5 An example and further thoughts

At first glance, one could look at the proof of Theorem 2.1 and conclude that since the boundaries of C_p are obtained by majoration and minoration of the boundaries of C_1 (which in turn was obtained by R. Ortega [5, p. 11]), then no new information could be drawn from such theorem. However, as the next example will show, this is not the case.

Example 5.1. Consider a Lotka–Volterra system

$$\dot{u} = u(a - bu - cv), \quad \dot{v} = v(d + eu - fv), \tag{5.1}$$

with the coefficients being positive constant. We recall the sufficient condition

$$T\left(\sqrt{c_M e_M x_p y_p}+\frac{1}{2}(b_M x_1+f_M y_1)\right)\leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}} \tag{5.2}$$

of Theorem 2.1(b). Let $F(q)=\mathcal{J}(q)/2^{2-\frac{1}{q}}$, where $q=p/(p-1)$ is the conjugate of p, and let also $\mathcal{F}(p)=F(p/(p-1))$ (see Appendix C). Since the coefficients of (5.1) are constant, it is not hard to see that $C_1=\{(x_1,y_1)\}$ is a single point, given by the unique solution of

$$\begin{pmatrix} b & c \\ -e & f \end{pmatrix}\begin{pmatrix} x_1 \\ y_1 \end{pmatrix}=\begin{pmatrix} a \\ d \end{pmatrix}.$$

Let $k=(b_M x_1+f_M y_1)/2$ and observe that we can write (5.2) as $x_p^p y_p^p\leqslant h(p)$, where

$$h(p)=\left[\frac{1}{\sqrt{ce}}\left(\frac{\mathcal{F}(p)}{T}-k\right)\right]^{2p}.$$

We recall that $C_p\subset\mathbb{R}^2$ is the set bounded by $x>0$, $y>0$ and

$$\begin{aligned} b_L U^{1-p}x^p+c_L V^{1-p}y^p\leqslant \overline{a}\leqslant b_M x+c_M y \\ -e_M x+f_L V^{1-p}y^p\leqslant \overline{d}\leqslant -e_L U^{1-p}x^p+f_M y, \end{aligned} \tag{5.3}$$

if $p\in[1,\infty)$, and by

$$0<x\leqslant U,\quad 0<y\leqslant V,$$

if $p=\infty$ (for an illustration, see Appendix B). Therefore, since the left-hand side of (5.2) is an increasing function of x_p and y_p (recall that x_1 and y_1 are constant), we have from (5.3) that its maximum happens somewhere on the curve

$$bU^{1-p}x_p^p+cV^{1-p}y_p^p=a.$$

Hence, the maximum occurs at some point (x_p,y_p) such that

$$y_p^p=c^{-1}V^{p-1}(a-bU^{1-p}x_p^p). \tag{5.4}$$

Replacing (5.4) at $x_p^p y_p^p\leqslant h(p)$, we obtain

$$-\left[\frac{b}{c}\left(\frac{V}{U}\right)^{p-1}\right]w^2+\left[\frac{a}{c}V^{p-1}\right]w-h(p)\leqslant 0, \tag{5.5}$$

where $w=x_p^p$. The discriminant of (5.5) in relation to w is given by,

$$\Delta(p)=V^{p-1}\left[\frac{a^2}{c^2}V^{p-1}-4\frac{b}{c}\frac{1}{U^{p-1}}h(p)\right].$$

Therefore, to study its sign it is sufficient to study the sign of

$$G(p)=\frac{a^2}{c^2}V^{p-1}-4\frac{b}{c}\frac{1}{U^{p-1}}h(p).$$

From this reasoning we have that (5.2) is equivalent to (5.5). Since the leading coefficient of the left-hand side of (5.5) is negative, it follows that the inequality holds at a given $p\in[1,\infty)$ if, and only if, $G(p)\leqslant 0$.

Hence, we conclude that we can apply Theorem 2.1 at (5.1) at a given $p \in [1,\infty)$ if, and only if, $G(p) \leqslant 0$. Therefore, if for some choice of the coefficients we have

$$G(1) > 0, \quad G(p^*) < 0, \quad \lim_{p\to\infty} G(p) > 0, \tag{5.6}$$

for some $p^* \in (1,\infty)$, then the L_1 and L_∞-conditions (recall Remarks 2.3 and 2.4) will be inconclusive. Moreover, since the coefficients are constant we have

$$\frac{\|a\|_p}{b_L} = U, \quad \frac{\|d\|_p}{f_L} + \frac{e_M}{f_L}\frac{\|a\|_p}{b_L} = V,$$

and thus the upper bound (3.2) is reduced to $\overline{u}_p \leqslant U$ and $\overline{v}_p \leqslant V$. As a consequence, it follows that when applying the L_p-condition in the way it was stated at Theorem 3.1, the only known upper bounds for $\|u\|_p$ and $\|v\|_p$, $p \in [1,\infty]$, are given by U and V, respectively. Therefore, equation (3.1) is reduced to

$$T\left(\sqrt{c_M e_M UV} + \frac{1}{2}(b_M U + f_M V)\right) \leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}} \leqslant \pi, \tag{5.7}$$

with the last inequality following from Proposition C.1 (see also Figure C.1). Since the L_∞-condition is inconclusive, it follows that (2.2) does not hold and thus (5.7) also does not hold.

Therefore we conclude that if (5.6) holds, then the L_1 and L_∞-conditions are inconclusive, while the upper bounds (3.2) provided by the L_p-condition, in the way it was stated at Theorem 3.1, are too thick and also inconclusive. Nevertheless, Theorem 2.1 can still be applied at $p = p^*$, ensuring the uniqueness and asymptotically stability of the coexistence state.

In other words, Theorem 3.1 still holds, since it state that (3.1) must hold for all the *coexistence states* of the system. However, the practical upper bounds provided by (3.2) are too thick in the case of this example, while the upper bounds provided by Theorem 2.1 are not.

For an example of such situation, one can consider $T = 1$,

$$a = 2.0102, \quad b = 1, \quad c = 0.0051, \quad d = 2.0203, \quad e = 0.9898, \quad f = 2, \tag{5.8}$$

and see that (5.6) holds with $p^* = 2$.

Remark 5.2. We have assumed constant coefficients at Example 5.1 for the sake of simplicity. However, it follows from the continuous dependence of the boundaries of C_p, $p \in [1,\infty]$, in relation to the coefficient functions $a(t),\dots,f(t)$ that if the amplitude of such coefficients (i.e. $a_M - a_L,\dots,f_M - a_L$) is small enough and if their averages are close enough to (5.8), then the same conclusion holds. Moreover, the assumption $T = 1$ is no loss of generality since it can be obtained by time rescaling.

We think that one reason for Theorem 2.1 to be conclusive in some situations while the previous one are not is the fact that although the boundaries of C_p are obtained by inequalities on the boundaries of C_1, the function $\mathcal{F}(p)$ *also increases* (see Appendix C). Therefore, for a given $p \in (1,\infty)$, the function $\mathcal{F}(p)$ may have increased in such a way that it compensates the boundaries of C_p.

Moreover in comparison with the boundaries provided by (3.2), as anticipated in the introduction, the fact that the two inequalities are independent from each other provides a *unified* test for uniqueness and asymptotically stability of the coexistence states. More precisely, if

$$T^{\frac{1}{q}}\sqrt{c_M e_M \alpha_p \beta_p} + \frac{1}{2}(b_M\alpha_1 + f_M\beta_1) \leqslant \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}}$$

for some $p \in [1, \infty]$, where

$$\alpha_p = \frac{\|a\|_p}{b_L}, \quad \beta_p = \frac{\|d\|_p}{f_L} + \frac{e_M}{f_L}\frac{\|a\|_p}{b_L},$$

then we are done. However, if the unified test is inconclusive then the intertwined boundaries (2.1) of C_p can reduce the lack of possibilities of the averages of the coexistence states in such a way that for all *possible* coexistence states, inequality (3.1) still holds.

A Linearly stability, asymptotic stability and Floquet theory

Consider a system T-periodic system of differential equations

$$\dot{u} = H(t, u), \tag{A.1}$$

with $u \in \mathbb{R}^n$ and $H\colon \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ sufficiently smooth. Let $u_0(t)$ be a T-periodic solution of (A.1). The *linearization* of (A.1) at $u_0(t)$ is the T-periodic linear system given by

$$\dot{u} = D_u H(t, u_0(t))u, \tag{A.2}$$

where $D_u H$ denotes the Jacobian matrix of H with respect to the variable u. We say that $u_0(t)$ is *linearly stable* if all *Floquet exponents* (also known as *characteristics exponents*) associated to (A.2) have non-positive real part. Fore more details about Floquet Theory, we refer to [3, Section 3.5] and [7].

We say that u_0 is *stable* if for every neighborhood $V \subset \mathbb{R}^n$ of $u_0(0)$ there is a neighborhood $W \subset V$ of $u_0(0)$ such that if $u(t)$ is a solution of (A.1) with $u(0) \in W$, then $u(t) \in V$ for $t \geqslant 0$. Moreover, given an open set $U \subset \mathbb{R}^n$, we say that $u_0(t)$ is *asymptotically stable* in U if u_0 is stable and

$$\lim_{t\to\infty} |u_0(t) - u(t)| = 0,$$

for every solution $u(t)$ of (A.1) with $u(0) \in U$.

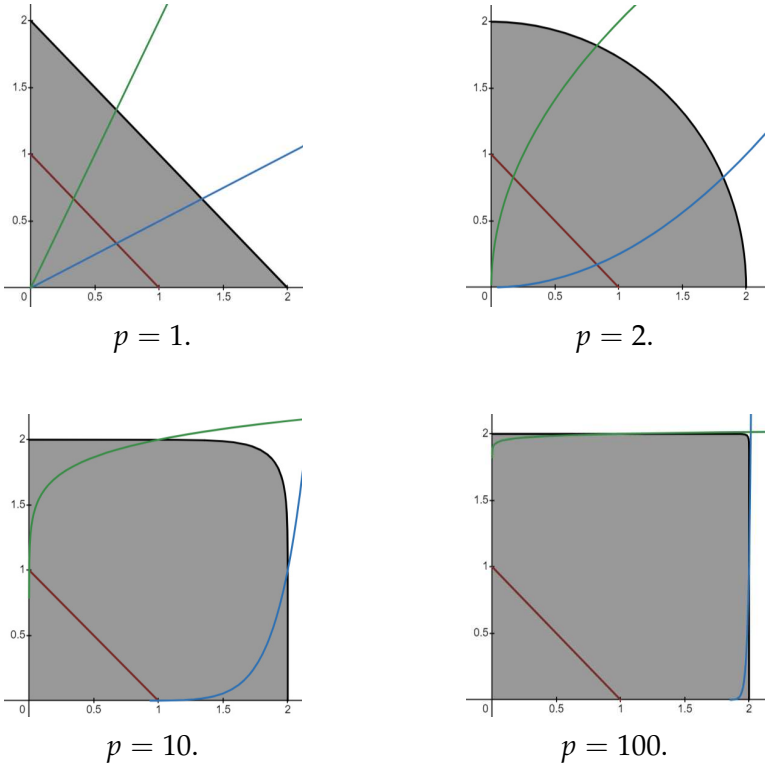
B Illustrations of the set C_p and construction of C_∞

We recall that $C_p \subset \mathbb{R}^2$ is the set bounded by $x > 0$, $y > 0$ and

$$\begin{aligned} b_L U^{1-p} x^p + c_L V^{1-p} y^p &\leqslant \overline{a} \leqslant b_M x + c_M y \\ -e_M x + f_L V^{1-p} y^p &\leqslant \overline{d} \leqslant -e_L U^{1-p} x^p + f_M y, \end{aligned}$$

for $p \in [1, \infty)$, and by

$$0 < x \leqslant U, \quad 0 < y \leqslant V,$$



for $p = \infty$. See Figure B.1. To obtain the definition of C^∞, consider the inequality

$$b_L U^{1-p} x^p + c_L V^{1-p} y^p \leqslant \overline{a}. \tag{B.1}$$

Since the left-hand side is strictly increasing in x and y it is clear that the maximum value of x occurs when $y = 0$. Hence, replacing $y = 0$ at (B.1) we obtain,

$$x \leqslant \left(\frac{\overline{a}}{b_L}\right)^{\frac{1}{p}} U^{\frac{1}{q}}.$$

Taking the limit $p \to \infty$ we obtain $x \leqslant U$. Similarly, by replacing $x = 0$ at (B.1) and taking the limit $p \to \infty$ one obtains $y \leqslant V$.

$p = 1.$ $p = 2.$

$p = 10.$ $p = 100.$

Figure B.1: Illustrations of C_p, given by the region bounded by the four curves, with parameters $\overline{a} = 2$, $\overline{d} = 2$, $b_M = 2$, $b_L = 1$, $c_M = 2$, $c_L = 1$, $e_M = 2$, $e_L = 1$, $f_M = 2$, $f_L = 1$, $U = 2$ and $V = 2$. The gray region (resp. black curve) corresponds to the inequality (resp. equality) $b_L U^{1-p} x^p + c_L V^{1-p} y^p \leqslant \overline{a}$. The red curve correspond to $b_M x + c_M y = \overline{a}$, while the green the blue ones correspond to $-e_M x + f_L V^{1-p} y^p = \overline{d}$ and $-e_L U^{1-p} x^p + f_M y = \overline{d}$, respectively. Together, they form the boundaries of C_p. Colors available in the online version.

C Properties of the maps $\mathcal{J}$, F and $\mathcal{F}$

We recall that $\mathcal{J}\colon [1,\infty) \to \mathbb{R}$ is the function given by,

$$\mathcal{J}(q) = \int_0^{2\pi} \frac{1}{\left(|\cos\theta|^{2q} + |\sin\theta|^{2q}\right)^{\frac{1}{q}}}\, d\theta. \tag{C.1}$$

Moreover, it follows from [6, Proposition 2.2] that

$$\lim_{q\to\infty} \mathcal{J}(q) = 8,$$

and thus we can continuously extend $\mathcal{J}$ to $[1,\infty]$ by defining $\mathcal{J}(\infty) = 8$. We also recall that $F, \mathcal{F}\colon [1,\infty] \to \mathbb{R}$ are the functions given by

$$F(q) = \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}}, \quad \mathcal{F}(p) = F\left(\frac{p}{p-1}\right) = \frac{\mathcal{J}\left(\frac{p}{p-1}\right)}{2^{1+\frac{1}{p}}}, \tag{C.2}$$

where $q = p/(p-1)$ is the conjugate of p. For a numerical plot of the graph of $\mathcal{F}(p)$, see Figure C.1.

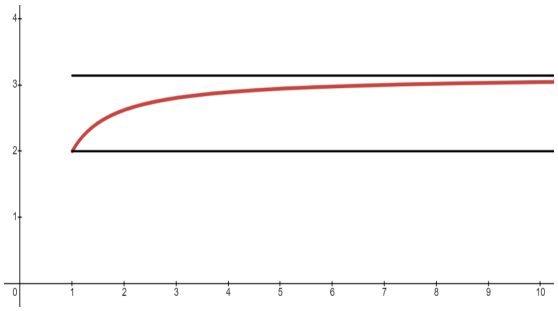


Figure C.1: Graph of the function $\mathcal{F}(p)$, in red. The black straight lines are the lower and upper bounds $y = 2$ and $y = \pi$, respectively. Colors available in the online version.

Proposition C.1. *The functions F and $\mathcal{F}$ are strictly decreasing and increasing, respectively.*

Proof. First we consider the function F. That is, we consider

$$F(q) = \frac{\mathcal{J}(q)}{2^{2-\frac{1}{q}}} = \int_0^{2\pi} 2^{\frac{1}{q}-2}\left(|\cos\theta|^{2q} + |\sin\theta|^{2q}\right)^{-\frac{1}{q}}\, d\theta. \tag{C.3}$$

Consider the integrand of the outermost right-hand side of (C.3),

$$g_1(\theta, q) = 2^{\frac{1}{q}-2}\left(|\cos\theta|^{2q} + |\sin\theta|^{2q}\right)^{-\frac{1}{q}}.$$

Differentiating it in relation to q we obtain

$$\frac{\partial g_1}{\partial q}(\theta, q) = g_1(\theta, q)\left[\frac{1}{q^2(\cos^{2q}\theta + \sin^{2q}\theta)} g_2(\theta, q) + \ln\left(2^{-1/q^2}\right)\right], \tag{C.4}$$

where

$$\begin{aligned} g_2(\theta, q) = {} & \cos^{2q}\theta\left[\ln(\cos^{2q}\theta + \sin^{2q}\theta) - \ln\cos^{2q}\theta\right] \\ & + \sin^{2q}\theta\left[\ln(\cos^{2q}\theta + \sin^{2q}\theta) - \ln\sin^{2q}\theta\right]. \end{aligned} \tag{C.5}$$

Since g_1 is strictly positive, it follows that the sign of (C.4) is given by the sign of,

$$\frac{1}{q^2(\cos^{2q}\theta + \sin^{2q}\theta)} g_2(\theta, q) + \ln\left(2^{-1/q^2}\right). \tag{C.6}$$

We claim that (C.6) is negative. Indeed, observe that (C.6) is negative if and only if,

$$g_2(\theta, q) \leqslant -q^2(\cos^{2q}\theta + \sin^{2q}\theta)\ln\left(2^{-1/q^2}\right).$$

Which by properties of the logarithm is equivalent to,

$$g_2(\theta, q) \leqslant (\cos^{2q}\theta + \sin^{2q}\theta)\ln 2.$$

Which in turn is equivalent to,

$$\begin{aligned} g_3(\theta, q) := {} & \cos^{2q}\left[\ln(\cos^{2q}\theta + \sin^{2q}\theta) - \ln(2\cos^{2q}\theta)\right] \\ & + \sin^{2q}\left[\ln(\cos^{2q}\theta + \sin^{2q}\theta) - \ln(2\sin^{2q}\theta)\right] \leqslant 0. \end{aligned} \tag{C.7}$$

Differentiating (C.7) in relation to θ we obtain,

$$\frac{\partial g_3}{\partial \theta}(\theta, q) = 2q \sin\theta \cos\theta \Big[\cos^{2(q-1)}\theta \big[\ln(2\cos^{2q}\theta) - \ln(\cos^{2q}\theta + \sin^{2q}\theta)\big] - \sin^{2(q-1)}\theta \big[\ln(2\sin^{2q}\theta) - \ln(\cos^{2q}\theta + \sin^{2q}\theta)\big]\Big]. \quad \text{(C.8)}$$

Clearly, the zeros of (C.8) in θ are given by $\theta \in \{0, \pi/2, \pi, 3\pi/2\}$ and by the zeros of

$$g_4(\theta, q) := \cos^{2(q-1)}\theta \big[\ln(2\cos^{2q}\theta) - \ln(\cos^{2q}\theta + \sin^{2q}\theta)\big] - \sin^{2(q-1)}\theta \big[\ln(2\sin^{2q}\theta) - \ln(\cos^{2q}\theta + \sin^{2q}\theta)\big]. \quad \text{(C.9)}$$

Observe that if $\theta_0 \in [0, 2\pi]$ is such that $\cos^2\theta_0 = \sin^2\theta_0$, then $g_4(\theta_0, q) = 0$. Reciprocally, we claim that if $\cos^2\theta_0 \neq 0 \sin^2\theta_0$, then $g_4(\theta_0, q) \neq 0$. Indeed, if $\cos^2\theta_0 > \sin^2\theta_0$, then it follows from the fact that the logarithm is a strictly increasing function that,

$$\ln(2\cos^{2q}\theta_0) > \ln(\cos^{2q}\theta_0 + \sin^{2q}\theta_0), \quad \ln(2\sin^{2q}\theta_0) < \ln(\cos^{2q}\theta_0 + \sin^{2q}\theta_0).$$

Hence, $g_4(\theta_0, q) > 0$. Similarly if $\cos^2\theta_0 < \sin^2\theta_0$, then $g_4(\theta_0, q) < 0$.

Therefore, we conclude that the extreme points $\theta_0 \in [0, 2\pi]$ of (C.7) are such that $\cos\theta_0 \sin\theta_0 = 0$ or $\cos^2\theta_0 = \sin^2\theta_0$. In any case, it is easy to see that (C.7) holds (with the equality holding only if $\cos^2\theta_0 = \sin^2\theta_0$), which in turn implies that the same holds for (C.4). Therefore, it follows from Leibniz integral rule that

$$F'(q) = \int_0^{2\pi} \frac{\partial g_1}{\partial q}(\theta, q)\, d\theta < 0.$$

That is, $F'(q)$ is strictly decreasing. Since $\mathcal{F}(p) = F(p/(p-1))$, it follows that

$$\mathcal{F}'(p) = -\frac{1}{(p-1)^2} F'\left(\frac{p}{p-1}\right) > 0,$$

and thus $\mathcal{F}$ is strictly increasing. □

Remark C.2. With the same reasoning of Proposition C.1, one can prove that $\mathcal{J}(q)$ is also strictly increasing. One just need to consider the integrand

$$h_1(\theta, q) = \frac{1}{\big(|\cos\theta|^{2q} + |\sin\theta|^{2q}\big)^{\frac{1}{q}}},$$

observe that

$$\frac{\partial h_1}{\partial q}(\theta, q) = \frac{h_1(\theta, q)}{q^2(\cos^{2q}\theta + \sin^{2q}\theta)} g_2(\theta, q),$$

with g_2 given by (C.5), and observe that since the logarithm is strictly increasing, it follows that

$$\ln(\cos^{2q}\theta + \sin^{2q}\theta) \geqslant \ln\cos^{2q}\theta, \quad \ln(\cos^{2q}\theta + \sin^{2q}\theta) \geqslant \ln\sin^{2q}\theta,$$

with equality holding only if $\cos\theta \sin\theta = 0$. The proof now follows from Leibniz integral rule.

Acknowledgments

We thank the reviewers for their careful and thoughtful comments and suggestions which helped us to improve the presentation of this paper.

Abstract. We investigate the existence and uniqueness of solutions to first-order Stieltjes differential problems, focusing on the role of the Stieltjes derivative and its kernel. Unlike the classical case, the kernel of the Stieltjes derivative operator is nontrivial, leading to non-uniqueness issues in Cauchy problems. We characterize this kernel by providing necessary and sufficient conditions for a function to have a zero Stieltjes derivative. To address the implications of this nontrivial kernel, we introduce a function space which serves as a suitable framework for studying Stieltjes differential problems. We explore its topological structure and propose a metric that facilitates the formulation of existence and uniqueness results. Our findings demonstrate that solutions to first-order Stieltjes differential equations are, in general, not unique, underscoring the need for a refined analytical approach to such problems.

Keywords: Stieltjes derivative, kernel of the derivative, Stieltjes differential equations, uniqueness, Cauchy problem.

2020 Mathematics Subject Classification: 34A12, 34A30, 34A36, 26A24, 46E30.

1 Introduction

The study of existence and uniqueness of solutions to Stieltjes differential problems has gained significant attention in recent years (see, for instance, [5, 9]). Regarding uniqueness, many results rely on classical techniques—such as Lipschitz conditions—and on an appropriate definition of the concept of solution. In the case of first-order problems, solutions are typically assumed to belong either to the space of Stieltjes absolutely continuous functions [9] or to the space of continuously Stieltjes differentiable functions [5], mirroring the classical setting.

These choices, however, are not merely natural consequences of the problem's structure. A key observation is that there exist Stieltjes differentiable functions with an everywhere zero

✉Corresponding author. Email: fernandoadrian.fernandez@usc.es

Stieltjes derivative that are not constant. In other words, the kernel of the Stieltjes derivative operator is larger than expected. As a direct consequence, the first-order Cauchy problem does not generally admit a unique solution if we consider solutions that are everywhere Stieltjes differentiable, possibly with a Stieltjes continuous derivative, but not necessarily Stieltjes continuous. This distinction between differentiable functions that are continuous and those that are not has been highlighted in the literature—see, for example, [6]—and stems from the absence of a mean value theorem for Stieltjes derivatives with the same strength as in the classical case. Nevertheless, certain versions of this result do exist, and we will explore some of them in this article.

Given this setting, a fundamental step is to determine the kernel of the Stieltjes derivative operator, as it parameterizes the solutions of the Cauchy problem. This is a nontrivial task, but we will provide several characterizations of the kernel along with necessary and sufficient conditions for a function to have a zero Stieltjes derivative.

The fact that we are working with differentiable functions that are not necessarily continuous raises a crucial question: *in which space are we operating?* We will introduce a function space, denoted $\mathcal{BD}$, which contains the kernel of the derivative and serves as a suitable framework for studying first-order Cauchy problems. Equipping this space with an appropriate topology is challenging. Even in the classical case, it is uncommon to work with the space of everywhere differentiable functions; instead, continuity of the derivative is usually imposed to obtain a Banach space structure. We will investigate under which conditions this is possible in our setting and propose a metric topology for the general case.

This work is structured to build a coherent development of the theoretical framework and main results. We begin in Section 2 by introducing the fundamental notions that will serve as the foundation for our analysis. A key concept in our formulation is that of derivators, which provide the necessary structure for defining and studying Stieltjes differential problems. We outline their role and significance before turning to the Stieltjes derivative itself. This derivative, which generalizes the classical notion of differentiation, possesses distinctive properties that set it apart from its conventional counterpart. To further clarify its behavior, we also discuss the set of points where a given derivator remains constant, as these play a crucial role in describing the kernel of the Stieltjes derivative operator.

Building on these preliminaries, Section 3 is devoted to a detailed study of the kernel of the Stieltjes derivative. We establish precise conditions that characterize when a function has a zero Stieltjes derivative and explore the implications of these results for uniqueness in first-order differential problems. To provide further insight, we complement the theoretical discussion with explicit examples that illustrate how the structure of the kernel depends on the choice of derivator.

In Section 4, we introduce the function space $\mathcal{BD}$, which is specifically designed to accommodate solutions to Stieltjes differential problems. Our objective is to capture the essential features of differentiability in this setting while ensuring a well-defined analytical framework. To this end, we examine the topological properties of $\mathcal{BD}$ and introduce a suitable metric structure that facilitates the development of an existence and uniqueness theory.

Finally, in Section 5, we present our main results on the existence and uniqueness of solutions to first-order Stieltjes differential equations. We show that first order problems have in general several solutions, thereby highlighting the subtleties introduced by the Stieltjes setting.

2 Preliminaries

Let $[a,b] \subset \mathbb{R}$ be an interval, $\mathbb{F}$ the field $\mathbb{R}$ or $\mathbb{C}$ and $g : \mathbb{R} \to \mathbb{R}$ a left-continuous non-decreasing function. We will refer to such functions as *derivators*. For these functions, we define the set $D_g = \{d_n\}_{n\in\Lambda}$ (where $\Lambda \subset \mathbb{N}$) as the set of all discontinuity points of g, namely, $D_g = \{t \in \mathbb{R} : \Delta g(t) > 0\}$ where $\Delta g(t) := g(t^+) - g(t)$, $t \in \mathbb{R}$, and $g(t^+)$ denotes the right hand side limit of g at t. We also define

$$C_g := \{t \in \mathbb{R} \,:\, g \text{ is constant on } (t-\varepsilon, t+\varepsilon) \text{ for some } \varepsilon > 0\}.$$

Observe that C_g is open in the usual topology of $\mathbb{R}$, so we can write

$$C_g = \bigcup_{n\in\widetilde{\Lambda}} (a_n, b_n), \tag{2.1}$$

where $\widetilde{\Lambda} \subset \mathbb{N}$ and $(a_k, b_k) \cap (a_j, b_j) = \emptyset$ for $k \neq j$. With this notation, we denote $N_g^- := \{a_n\}_{n\in\widetilde{\Lambda}} \backslash D_g$, $N_g^+ := \{b_n\}_{n\in\widetilde{\Lambda}} \backslash D_g$ and $N_g := N_g^- \cup N_g^+$.

Definition 2.1 ([5, Definition 3.7])**.** We define the *Stieltjes derivative*, or *g-derivative*, of a map $f : [a,b] \to \mathbb{C}$ at a point $t \in [0,T]$ as

$$f_g'(t) = \begin{cases} \lim\limits_{s\to t} \dfrac{f(s)-f(t)}{g(s)-g(t)}, & t \notin D_g \cup C_g, \\ \lim\limits_{s\to t^+} \dfrac{f(s)-f(t)}{g(s)-g(t)}, & t \in D_g, \\ \lim\limits_{s\to b_n^+} \dfrac{f(s)-f(b_n)}{g(s)-g(b_n)}, & t \in C_g,\ t \in (a_n, b_n), \end{cases}$$

where a_n, b_n are as in (2.1), provided the corresponding limits exist. In that case, we say that f is *g-differentiable at t*.

Remark 2.2. It is possible to further simplify the definition of the Stieltjes derivative at a point $t \in [a,b]$ by defining

$$t^* = \begin{cases} t, & t \notin C_g, \\ b_n, & t \in (a_n, b_n) \subset C_g, \end{cases}$$

with a_n, b_n as in (2.1). With this notation, we have that

$$f_g'(t) = \begin{cases} \lim\limits_{s\to t} \dfrac{f(s)-f(t)}{g(s)-g(t)}, & t \notin D_g \cup C_g, \\ \lim\limits_{s\to t^{*+}} \dfrac{f(s)-f(t^*)}{g(s)-g(t^*)}, & t \in D_g \cup C_g, \end{cases}$$

provided the corresponding limit exists. We will define the function f^* as $f^*(t) = f(t^*)$ for $t \in [a,b]$.

The following result includes some basic properties of this derivative.

Proposition 2.3 ([5, Proposition 3.9])**.** *Let $t \in [a,b]$. If $f_1, f_2 : [a,b] \to \mathbb{F}$ are g-differentiable at t, then:*

- *The function $\lambda_1 f_1 + \lambda_2 f_2$ is g-differentiable at t for any $\lambda_1, \lambda_2 \in \mathbb{F}$ and*

$$(\lambda_1 f_1 + \lambda_2 f_2)'_g(t) = \lambda_1 (f_1)'_g(t) + \lambda_2 (f_2)'_g(t).$$

- (Product rule). *The product $f_1 f_2$ is g-differentiable at t and*

$$(f_1 f_2)'_g(t) = (f_1)'_g(t) f_2(t^*) + (f_2)'_g(t) f_1(t^*) + (f_1)'_g(t)\,(f_2)'_g(t) \Delta g(t^*).$$

- (Quotient rule). *If $f_2(t^*)\,(f_2(t^*) + (f_2)'_g(t)\,\Delta g(t^*)) \neq 0$, the quotient f_1/f_2 is g-differentiable at t and*

$$\left(\frac{f_1}{f_2}\right)'_g(t) = \frac{(f_1)'_g(t) f_2(t^*) - (f_2)'_g(t) f_1(t^*)}{f_2(t^*)\,(f_2(t^*) + (f_2)'_g(t)\,\Delta g(t^*))}.$$

Furthermore, we have the following chain rule.

Proposition 2.4 ([5, Proposition 4.1]). *Let $x_0 \in [a,b]$, $f : [a,b] \to \mathbb{R}$ and $h : \mathbb{R} \to \mathbb{F}$. Then, the following hold:*

1. *If $x_0 \in [a,b] \backslash (C_g \cup D_g)$ and there exist $h'(f(x_0))$ and $f'_g(x_0)$, then $h \circ f$ is g-differentiable at x_0 and*
$$(h \circ f)'_g(x_0) = h'(f(x_0)) f'_g(x_0). \tag{2.2}$$
2. *If $x_0 \in C_g$ and there exist $h'(f(x_0))$ and $f'_g(x_0)$, then $h \circ f$ is g-differentiable at x_0 and*
$$(h \circ f)'_g(x_0) = h'(f(x_0^*)) f'_g(x_0),$$
Observe that if f is g-continuous, $f(x_0) = f(x_0^*)$ and we recover the formula (2.2).
3. *If $x_0 \in D_g$ and*
$$f(s) = f(x_0), \quad s \in (x_0, x_0 + \delta) \text{ for some } \delta > 0, \tag{2.3}$$
then $f'_g(x_0) = (h \circ f)'_g(x_0) = 0$. In particular, (2.2) holds provided $h'(f(x_0))$ exists.
4. *Suppose that $x_0 \in D_g$ and condition (2.3) does not hold. If $f(x_0^+)$ exists, h is continuous at $f(x_0^+)$ and the limit*
$$\lim_{s \to x_0^+} \frac{h(f(s)) - h(f(x_0))}{f(s) - f(x_0)}$$
exists, then there exist $f'_g(x_0)$ and $(h \circ f)'_g(x_0)$ and
$$(h \circ f)'_g(x_0) = \frac{h(f(x_0^+)) - h(f(x_0))}{f(x_0^+) - f(x_0)} f'_g(x_0).$$

Remark 2.5. It is clear from the proof of [5, Proposition 4.1], which is itself a continuation of the proof of [14, Proposition 2.56 and Proposition 3.15], that it is not necessary for h to be defined on $\mathbb{R}$. It is enough that $f([a,b])$ is contained in the domain of h and that the point at which h' is evaluated in each of the cases is an accumulation point of the domain.

We shall write as μ_g the Lebesgue–Stieltjes measure associated to g given by

$$\mu_g([c,d)) = g(d) - g(c), \quad c, d \in \mathbb{R},\ c < d.$$

We will use the term "g-measurable" for a set or function to refer to μ_g-measurability in the corresponding sense, and we denote by $\mathcal{L}^1_g(X,\mathbb{F})$ the set of Lebesgue–Stieltjes μ_g-integrable functions on a g-measurable set X with values in $\mathbb{F}$, whose integral we write as

$$\int_X f(s)\ \mathrm{d}\,\mu_g(s), \quad f \in \mathcal{L}^1_g(X,\mathbb{F}).$$

Similarly, we will talk about properties holding *g-almost everywhere* in a set X (shortened to *g-a.e.* in X), or holding for *g-almost all* (or, simply, *g-a.a.*) $x \in X$, as a simplified way to express that they hold μ_g-almost everywhere in X or for μ_g-almost all $x \in X$, respectively. $L^1_g(X,\mathbb{F})$ will be the Banach space associated to $\mathcal{L}^1_g(X,\mathbb{F})$ by taking equivalence classes of functions that are equal μ_g-a.e. The spaces $L^p_g(X,\mathbb{F})$ are defined as usual (they are L^p spaces with respect to the measure μ_g) and we will denote their respective norms by $\|\cdot\|_{L^p_g}$.

Definition 2.6 ([9, Definition 3.1])**.** A function $f:[a,b]\to\mathbb{F}$ is *g-continuous* at a point $t\in[a,b]$, or *continuous with respect to g* at t, if for every $\varepsilon>0$, there exists $\delta>0$ such that

$$|f(t)-f(s)|<\varepsilon, \quad \text{for all } s\in[0,T],\ |g(t)-g(s)|<\delta.$$

If f is g-continuous at every point $t\in[a,b]$, we say that f is g-continuous on $[a,b]$. We denote by $\mathcal{C}_g([a,b];\mathbb{F})$ the *set of g-continuous functions* on $[a,b]$; and by $\mathcal{BC}_g([a,b];\mathbb{F})$ the *set of bounded g-continuous functions* on $[a,b]$.

Definition 2.7. Given $k\in\mathbb{N}$, we define $\mathcal{C}^0_g([a,b];\mathbb{F}) := \mathcal{C}_g([a,b];\mathbb{F})$ and $\mathcal{C}^k_g([a,b];\mathbb{F})$ recursively as

$$\mathcal{C}^k_g([a,b]) := \{f\in\mathcal{C}^{k-1}([a,b];\mathbb{F}):\ (f_g^{(k-1)})'_g\in\mathcal{C}_g([a,b];\mathbb{F})\},$$

where $f_g^{(0)} := f$ and $f_g^{(k)} := (f_g^{(k-1)})'_g$, $k\in\mathbb{N}$. Similarly, given $k\in\mathbb{N}$, we define $\mathcal{BC}^0_g([a,b];\mathbb{F}) := \mathcal{BC}_g([a,b];\mathbb{F})$ and $\mathcal{BC}^k_g([a,b];\mathbb{F})$ recursively as

$$\mathcal{BC}^k_g([a,b];\mathbb{F}) := \{f\in\mathcal{C}^k_g([a,b];\mathbb{F}):\ f_g^{(n)}\in\mathcal{BC}_g([a,b];\mathbb{F}),\ \forall n=0,\dots,k\}.$$

We also define $\mathcal{C}^\infty_g([a,b];\mathbb{F}) := \bigcap_{n\in\mathbb{N}}\mathcal{C}^k_g([a,b];\mathbb{F})$ and $\mathcal{BC}^\infty_g([a,b];\mathbb{F}) := \bigcap_{n\in\mathbb{N}}\mathcal{BC}^k_g([a,b];\mathbb{F})$.

Definition 2.8 ([12, Definition 5.1])**.** A function $F:[a,b]\to\mathbb{R}$ is *absolutely continuous with respect to g* (or *g-absolutely continuous*) if to each $\varepsilon>0$ there is some $\delta>0$ such that for any family $\{(a_n,b_n)\}_{n=1}^m$ of pairwise disjoint open subintervals of $[a,b]$ the inequality

$$\sum_{n=1}^m (g(b_n)-g(a_n))<\delta$$

implies

$$\sum_{n=1}^m |F(b_n)-F(a_n)|<\varepsilon.$$

Theorem 2.9 ([12, Theorem 2.4])**.** *Assume that $f:[a,b)\longrightarrow\overline{\mathbb{R}}$ is integrable on $[a,b)$ with respect to μ_g and consider its indefinite Lebesgue–Stieltjes integral*

$$F(x)=\int_{[a,x)} f\,\mathrm{d}\,\mu_g \quad \textit{for all } x\in[a,b].$$

Then there is a g-measurable set $N\subset[a,b)$ such that $\mu_g(N)=0$ and

$$F'_g(x)=f(x) \quad \textit{for all } x\in[a,b]\backslash N.$$

Theorem 2.10 (Fundamental Theorem of Calculus for the Lebesgue–Stieltjes Integral [12, Theorem 5.4]). *A function $F : [a,b] \longrightarrow \mathbb{R}$ is g-absolutely continuous on $[a,b]$ if and only if the following three conditions are fulfilled:*

1. *There exists $F_g'(t)$ for g-almost all $t \in [a,b]$;*
2. *$F_g' \in \mathcal{L}_g^1([a,b))$; and*
3. *For each $t \in [a,b]$ we have*
$$F(t) = F(a) + \int_{[a,t)} F_g' \,\mathrm{d}\,\mu_g.$$

Definition 2.11. Given a function $p : [a,b] \to \mathbb{F}$, we say that it is *g-regressive* if
$$1 + p(t)\,\Delta g(t) \neq 0, \quad t \in [a,b] \cap D_g.$$

Given a g-regressive function $p \in \mathcal{L}_g^1([0,T);\mathbb{C})$, we define the *$g$-exponential map* associated to the map p as
$$\exp_g(p;t) := \exp\left(\int_{[0,t)} \widetilde{p}(s)\ \mathrm{d}\,\mu_g(s)\right), \quad t \in [a,b],$$
where, denoting by $\ln(z) := \ln|z| + i\,\mathrm{Arg}(z)$ the principal branch of the complex logarithm,
$$\widetilde{p}(s) := \begin{cases} p(s), & s \in [0,T) \setminus D_g, \\ \dfrac{\ln\left(1 + p(s)\,\Delta g(s)\right)}{\Delta g(s)}, & s \in [0,T) \cap D_g. \end{cases}$$

Observe that $\exp_g(p;t)$ can be written in the following way:
$$\exp_g(p;t) = \prod_{s \in [0,t) \cap D_g} (1 + p(s)\,\Delta g(s)) \exp\left(\int_{[0,t)\setminus D_g} p(s)\,\mathrm{d}\,\mu_g\right).$$

Remark 2.12. The g-exponential map belongs to $\mathcal{AC}_g([a,b];\mathbb{C})$, see [5, Theorem 4.2], and, furthermore, it is the only function in that space satisfying
$$\begin{cases} v_g'(t) = p(t)\,v(t), & g\text{-a.a. } t \in [a,b], \\ v(a) = 1. \end{cases}$$

In particular, if $p \in \mathcal{BC}_g([a,b];\mathbb{C})$, then $\exp_g(p;\cdot) \in \mathcal{BC}_g^1([a,b];\mathbb{C})$. Furthermore, if $p(t) = \lambda \in \mathbb{C}$, $t \in [a,b]$, then $\exp_g(p;\cdot) \in \mathcal{BC}_g^\infty([a,b];\mathbb{C})$.

3 The Mean Value Theorem for real-valued functions and the kernel of the Stieltjes derivative

Inspired by the ideas in [1, Theorem 1.67], in this section we propose a series of results that can be described as different versions of the Mean Value Theorem for the Stieltjes derivative as a result of imposing different levels of regularity on the function. These results will be then used to study the kernel of the Stieltjes derivative under the corresponding hypotheses. It is clear that a constant function will have zero g-derivative but, as we will see, not every function with zero g-derivative has to be constant.

3.1 g-absolutely continuous functions

We first start for a theorem in the case of functions with weak derivatives, that is, the space of absolutely continuous functions $\mathcal{AC}_g([a,b],\mathbb{F})$. We will be assuming that g is not constant throughout this work.

Theorem 3.1. *Let be $f \in \mathcal{AC}_g([a,b],\mathbb{R})$. Then*

$$\mu_g\left(\left\{t \in [a,b) \ : \ f'_g(t) \geq \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0,$$
$$\mu_g\left(\left\{t \in [a,b) \ : \ f'_g(t) \leq \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

Proof. We divide the proof in different cases.

1. If $\operatorname{ess\,inf} f'_g,\ \operatorname{ess\,sup} f'_g \in \mathbb{R}$, we consider the following cases:

(a) If $\operatorname{ess\,inf} f'_g = \operatorname{ess\,sup} f'_g$, then f'_g takes the same value c μ_g-a.e. and, by Theorem 3.1, $f(b)-f(a) = \int_{[a,b)} f'_g \,\mathrm{d}\,\mu_g = c(g(b)-g(a))$, so $c = \frac{f(b)-f(a)}{g(b)-g(a)}$ and, therefore,

$$\mu_g\left(\left\{t \in [a,b) \ : \ f'_g(t) = \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

(b) In the case where

$$\operatorname{ess\,inf} f'_g \leqslant \frac{f(b)-f(a)}{g(b)-g(a)} < \operatorname{ess\,sup} f'_g,$$

we have that

$$\mu_g\left(\left\{t \in [a,b) \ : \ f'_g(t) \geqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

Now, given

$$\varepsilon \in \left(0, \operatorname{ess\,sup} f'_g - \frac{f(b)-f(a)}{g(b)-g(a)}\right),$$

we define the following sets:

$$A = \left\{x \in [a,b) : \ f'_g(x) \in \left[\frac{f(b)-f(a)}{g(b)-g(a)} + \varepsilon, \operatorname{ess\,sup} f'_g\right]\right\}, \quad B = [a,b) \setminus A.$$

We have $\mu_g(A) > 0$. Indeed, assume, on the contrary, that $\mu_g(A) = 0$,

$$\operatorname{ess\,sup} f'_g \leq \frac{f(b)-f(a)}{g(b)-g(a)} + \varepsilon < \frac{f(b)-f(a)}{g(b)-g(a)} + \operatorname{ess\,sup} f'_g - \frac{f(b)-f(a)}{g(b)-g(a)} = \operatorname{ess\,sup} f'_g,$$

which leads to a contradiction. Therefore, we have that $\mu_g(A) > 0$. Now, assuming that

$$\operatorname{ess\,inf} f'_g = \frac{f(b)-f(a)}{g(b)-g(a)},$$

we have that

$$\begin{aligned} f(b)-f(a) &= \int_{[a,b]} f'_g \,\mathrm{d}\,\mu_g = \int_A f'_g \,\mathrm{d}\,\mu_g + \int_B f'_g \,\mathrm{d}\,\mu_g \\ &\geq \mu_g(A)\left(\frac{f(b)-f(a)}{g(b)-g(a)}+\varepsilon\right) + \mu_g(B)\,\operatorname{ess\,inf} f'_g \\ &= \mu_g(A)\left(\frac{f(b)-f(a)}{g(b)-g(a)}+\varepsilon\right) + \mu_g(B)\frac{f(b)-f(a)}{g(b)-g(a)} \\ &= (\mu_g(A)+\mu_g(B))\frac{f(b)-f(a)}{g(b)-g(a)} + \mu_g(A)\varepsilon \\ &= f(b)-f(a)+\mu_g(A)\varepsilon > f(b)-f(a), \end{aligned}$$

which leads to a contradiction. Therefore:

$$\operatorname{ess\,inf} f'_g < \frac{f(b)-f(a)}{g(b)-g(a)},$$

and thus:

$$\mu_g\left(\left\{t\in[a,b)\ :\ f'_g(t)\leqslant\frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right)>0.$$

(c) In the case where

$$\operatorname{ess\,inf} f'_g < \frac{f(b)-f(a)}{g(b)-g(a)} \leqslant \operatorname{ess\,sup} f'_g,$$

the procedure is analogous, and we will complete it for the sake of thoroughness. As a consequence of the preceding chain of inequalities,

$$\mu_g\left(\left\{t\in[a,b)\ :\ f'_g(t)\leqslant\frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right)>0.$$

Now, let us take

$$\varepsilon\in\left(0,\frac{f(b)-f(a)}{g(b)-g(a)}-\operatorname{ess\,inf} f'_g\right)$$

and define the following sets:

$$A=\left\{x\in[a,b)\colon\ f'_g(x)\in\left[\operatorname{ess\,inf} f'_g,\frac{f(b)-f(a)}{g(b)-g(a)}-\varepsilon\right]\right\},\quad B=[a,b)\setminus A.$$

We have $\mu_g(A)>0$. Indeed, if $\mu_g(A)=0$,

$$\operatorname{ess\,inf} f'_g \geq \frac{f(b)-f(a)}{g(b)-g(a)}-\varepsilon > \frac{f(b)-f(a)}{g(b)-g(a)}-\frac{f(b)-f(a)}{g(b)-g(a)}+\operatorname{ess\,inf} f'_g,$$

which leads to a contradiction. Therefore, we have that $\mu_g(A)>0$. Now, suppose that

$$\operatorname{ess\,sup} f'_g = \frac{f(b)-f(a)}{g(b)-g(a)},$$

then,

$$\begin{aligned} f(b)-f(a) &= \int_{[a,b)} f'_g \,\mathrm{d}\,\mu_g = \int_A f'_g \,\mathrm{d}\,\mu_g + \int_B f'_g \,\mathrm{d}\,\mu_g \\ &\leq \mu_g(A)\left(\frac{f(b)-f(a)}{g(b)-g(a)} - \varepsilon\right) + \mu_g(B)\operatorname{ess\,sup} f'_g \\ &= \mu_g(A)\left(\frac{f(b)-f(a)}{g(b)-g(a)} - \varepsilon\right) + \mu_g(B)\frac{f(b)-f(a)}{g(b)-g(a)} \\ &= (\mu_g(A)+\mu_g(B))\frac{f(b)-f(a)}{g(b)-g(a)} - \mu_g(A)\varepsilon \\ &= f(b)-f(a)-\mu_g(A)\varepsilon < f(b)-f(a), \end{aligned}$$

which leads to a contradiction. Therefore,

$$\operatorname{ess\,sup} f'_g > \frac{f(b)-f(a)}{g(b)-g(a)},$$

and, thus,

$$\mu_g\left(\left\{t\in[a,b) \;:\; f'_g(t) \geqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

2. If $\operatorname{ess\,inf} f'_g = -\infty$ and $\operatorname{ess\,sup} f'_g \in \mathbb{R}$, then:

$$\mu_g\left(\left\{t\in[a,b) \;:\; f'_g(t) \leqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

Let us see that the following also holds:

$$\mu_g\left(\left\{t\in[a,b) \;:\; f'_g(t) \geqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

We are in the following situation:

$$-\infty = \operatorname{ess\,inf} f'_g < \frac{f(b)-f(a)}{g(b)-g(a)} \leq \operatorname{ess\,sup} f'_g.$$

Given $\varepsilon > 0$, we define the following sets:

$$A = \left\{x\in[a,b) :\; f'_g(x) \leq \frac{f(b)-f(a)}{g(b)-g(a)} - \varepsilon\right\}, \quad B = [a,b)\setminus A.$$

We have, since $\operatorname{ess\,inf} f'_g = -\infty$, that $\mu_g(A) > 0$. Therefore, following the reasoning applied in section (c) of the previous point,

$$\mu_g\left(\left\{t\in[a,b) \;:\; f'_g(t) \geqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

3. If $\operatorname{ess\,sup} f'_g = +\infty$ and $\operatorname{ess\,inf} f'_g \in \mathbb{R}$, then:

$$\mu_g\left(\left\{t\in[a,b) \;:\; f'_g(t) \geqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

Let us see that the following also holds:

$$\mu_g\left(\left\{t \in [a,b) \ : \ f_g'(t) \leqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0.$$

We are in the following situation:

$$\operatorname{ess\,inf} f_g' \leqslant \frac{f(b)-f(a)}{g(b)-g(a)} < \operatorname{ess\,sup} f_g' = +\infty.$$

Given $\varepsilon > 0$, we define the following sets:

$$A = \left\{x \in [a,b) : \ f_g'(x) \geq \frac{f(b)-f(a)}{g(b)-g(a)} + \varepsilon\right\}, \quad B = [a,b) \setminus A.$$

We have, since $\operatorname{ess\,sup} f_g' = +\infty$, that $\mu_g(A) > 0$. Therefore, following the reasoning applied in section (b) of the previous point,

$$\mu_g\left(\left\{t \in [a,b) \ : \ f_g'(t) \leqslant \frac{f(b)-f(a)}{g(b)-g(a)}\right\}\right) > 0. \qquad \square$$

Corollary 3.2. *Let $f \in \mathcal{AC}_g([a,b],\mathbb{R})$. Then there exist $c,d \in [a,b]$ such that*

$$f_g'(c) \leqslant \frac{f(b)-f(a)}{g(b)-g(a)} \leqslant f_g'(d).$$

Proof. Taking into account that, by Theorem 2.10, the derivative of an g-absolutely continuous function exist g-a.e., and Theorem 3.1, we get the result. $\square$

Remark 3.3. It is clear that, in the conditions of the previous corollary, given $c \in \mathbb{R}$,

$$\mu_g\left(\left\{t \in [a,b] \ : \ f_g'(t) \geqslant c\right\}\right) + \mu_g\left(\left\{t \in [a,b] \ : \ f_g'(t) \leqslant c\right\}\right) \geqslant g(b)-g(a) > 0,$$

and, in particular, for the value $c = \frac{f(b)-f(a)}{g(b)-g(a)}$. Nevertheless, $\frac{f(b)-f(a)}{g(b)-g(a)}$ is the only value for which we can guarantee, a priori, that both sets have positive measure for every function f. Indeed, just take a $\mathcal{AC}_g$ function with constant derivative x. If $x = c$ both sets have measure $g(b)-g(a)$; otherwise, one has measure $g(b)-g(a)$ and the other measure zero.

Lemma 3.4. *Let $f \in \mathcal{AC}_g([a,b],\mathbb{R})$. Then f is constant if and only if f is g-differentiable on $[a,b]$ and $f_g' = 0$ μ_g-a.e.*

Proof. If f is constant, by the definition of g-derivative, f_g' exists everywhere in $[a,b]$ and $f_g' = 0$. Now assume $f_g' = 0$ μ_g-a.e. Since $f \in \mathcal{AC}_g([a,b],\mathbb{R})$, by Theorem 2.10, $f(t) = \int_{[a,t)} f_g'(s)\,\mathrm{d}\,s + f(a) = f(a)$, so f is constant. $\square$

3.2 Functions which are continuous with respect to g

One of the main tools in the proof of [1, Theorem 1.67] is the generalization of the Induction Principle for a given time scale, see [1, Theorem 1.7]. In our setting, we will use the following version of the Induction Principle on the real line that can be directly deduced from [2, Theorem 1].

Theorem 3.5 (Principle of real induction). *Let $c, d \in \mathbb{R}$ be such that $c < d$ and $S \subset [c, d]$. Then, $S = [c, d]$ if and only if the following conditions are satisfied:*

1. $c \in S$.
2. *If $x \in [c, d)$ is such that $x \in S$, then there exists $\delta > 0$ such that $[x, x + \delta] \subset S$.*
3. *If $x \in (c, d]$ is such that $[c, x) \subset S$, then $x \in S$.*

In this first step, we prove a version of the Mean Value Theorem for functions which are g-differentiable and g-continuous on an interval. This is, to some extent, the generalization of the set of hypotheses required for the Mean Value Theorem for the usual derivative. Nevertheless, instead of establishing this result under the mentioned conditions, we propose a formulation based on some of the properties that such functions present. We do so as we believe that this makes it easy to understand the improvements in the subsequent sections.

Theorem 3.6. *Let $f, h : [a, b] \to \mathbb{R}$ be such that the following conditions hold:*

(i) *The maps f and h are left-continuous on $(a, b]$.*

(ii) *If g is constant on some $[\alpha, \beta] \subset [a, b]$, then so are f and h.*

(iii) *For all $t \in [a, b]$, f and h are g-differentiable at t and $|f'_g(t)| \leqslant h'_g(t)$.*

Then for any $s, t \in [a, b]$,

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|. \tag{3.1}$$

Proof. Let $t \in [a, b]$. We shall prove that

$$|f(s) - f(t)| \leqslant h(s) - h(t), \quad \text{for all } s \in [a, b],\ s \geqslant t. \tag{3.2}$$

Observe that, if $t = b$, this is trivial, so we shall assume that $t < b$.

Let $\varepsilon > 0$ and define

$$S_\varepsilon = \{s \in [t, b] : |f(s) - f(t)| \leqslant h(s) - h(t) + \varepsilon(g(s) - g(t))\}.$$

Note that, in order to prove (3.2), it is enough to show that $S_\varepsilon = [t, b]$ as $\varepsilon > 0$ has been arbitrarily chosen. We do this by means of Theorem 3.5. In particular, we only need to check that 2 and 3 in Theorem 3.5 are satisfied as, by definition, $t \in S_\varepsilon$, which shows 1.

In order to check 2 in Theorem 3.5, let $s \in [t, b)$ be such that $s \in S_\varepsilon$. We study two cases separately: $s \in N_g^- \cup C_g$ and $s \notin N_g^- \cup C_g$.

First, if $s \in N_g^- \cup C_g$, then we find $\delta > 0$ such that g is constant on $[s, s + \delta]$. Hence, (ii) guarantees that f and h are also constant on $[s, s + \delta]$ and thus, since $s \in S_\varepsilon$, it follows that $[s, s + \delta] \subset S_\varepsilon$.

Otherwise, we have that $s \notin N_g^- \cup C_g$ in which case, since f and h are g-differentiable at s, we know that

$$f'_g(s) = \lim_{r \to s^+} \frac{f(r) - f(s)}{g(r) - g(s)}, \quad h'_g(s) = \lim_{r \to s^+} \frac{h(r) - h(s)}{g(r) - g(s)}.$$

Hence, there exists $\rho > 0$ such that if $r \in (s, s + \rho)$, then

$$\left| \frac{f(r) - f(s)}{g(r) - g(s)} - f'_g(s) \right| < \frac{\varepsilon}{2}, \quad \left| \frac{h(r) - h(s)}{g(r) - g(s)} - h'_g(s) \right| < \frac{\varepsilon}{2},$$

or, equivalently,

$$|f(r) - f(s) - f'_g(s)(g(r) - g(s))| < \frac{\varepsilon}{2}(g(r) - g(s)),$$
$$|h(r) - h(s) - h'_g(s)(g(r) - g(s))| < \frac{\varepsilon}{2}(g(r) - g(s)).$$

In particular, for any $r \in (s, s+\rho)$, we have that

$$|f(r) - f(s)| \leqslant (g(r) - g(s)) \left(|f'_g(s)| + \frac{\varepsilon}{2}\right),$$
$$h'_g(s)(g(r) - g(s)) < h(r) - h(s) + \frac{\varepsilon}{2}(g(r) - g(s)).$$

Hence, taking $\delta \in (0, \rho)$, it follows that for any $r \in [s, s+\delta]$,

$$\begin{aligned}
|f(r) - f(t)| &\leqslant |f(r) - f(s)| + |f(s) - f(t)| \\
&\leqslant (g(r) - g(s)) \left(|f'_g(s)| + \frac{\varepsilon}{2}\right) + h(s) - h(t) + \varepsilon(g(s) - g(t)) \\
&\leqslant (g(r) - g(s)) \left(h'_g(s) + \frac{\varepsilon}{2}\right) + h(s) - h(t) + \varepsilon(g(s) - g(t)) \\
&= h'_g(s)(g(r) - g(s)) + \frac{\varepsilon}{2}(g(r) - g(s)) + h(s) - h(t) + \varepsilon(g(s) - g(t)) \\
&\leqslant h(r) - h(s) + \frac{\varepsilon}{2}(g(r) - g(s)) + \frac{\varepsilon}{2}(g(r) - g(s)) + h(s) - h(t) + \varepsilon(g(s) - g(t)) \\
&= h(r) - h(t) + \varepsilon(g(r) - g(t)),
\end{aligned}$$

which shows that $[s, s+\delta] \subset S_\varepsilon$.

Finally, for 3 in Theorem 3.5, let $s \in (t, b]$ be such that $[t, s) \subset S_\varepsilon$. In that case, since f, g and h are left-continuous at s, we see that

$$\begin{aligned}
|f(s) - f(t)| &= \left|\lim_{r \to s^-} f(r) - f(t)\right| = \lim_{r \to s^-} |f(r) - f(t)| \\
&\leqslant \lim_{r \to s^-} (h(r) - h(t) + \varepsilon(g(r) - g(t))) = h(s) - h(t) + \varepsilon(g(s) - g(t)),
\end{aligned}$$

as we needed to show.

Hence, we have proven that (3.2) holds from which (3.1) follows. □

As a direct consequence of Theorem 3.6 and [9, Proposition 3.2] we have the anticipated version of the Mean Value Theorem for functions which are continuous with respect to g.

Corollary 3.7 (Mean Value Theorem for g-continuous functions)**.** *Let $f, h : [a, b] \to \mathbb{R}$ be g-continuous on $[a, b]$. If f and h are g-differentiable on $[a, b]$ and $|f'_g(t)| \leqslant h'_g(t)$ for all $t \in [a, b]$, then,*

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s, t \in [a, b].$$

Finally, we can use Corollary 3.7 to fully describe the kernel of the Stieltjes derivative operator on the set of g-continuous functions.

Theorem 3.8 (Kernel of the Stieltjes derivative for g-continuous functions)**.** *Let $f : [a, b] \to \mathbb{R}$ be g-continuous on $[a, b]$. Then, $f'_g(t) = 0$ for all $t \in [a, b]$ if and only if f is constant on $[a, b]$.*

Proof. It is clear from the definition of g-derivative that if f is constant, then $f'_g(t) = 0$ so we shall focus on the converse implication.

Assume $f'_g(t) = 0$ for all $t \in [a,b]$. Then, the map $h(t) = 0$, $t \in [a,b]$, is g-continuous and g-differentiable on $[a,b]$ with $h'_g(t) = 0$, $t \in [a,b]$. Furthermore, we have that $|f'_g(t)| \leqslant h'_g(t)$ for all $t \in [a,b]$, so Corollary 3.7 guarantees that $|f(s) - f(t)| = 0$ for all $s,t \in [a,b]$, which finishes the proof. □

To end this section we recall some interesting and already known results in this direction.

Theorem 3.9 ([13, Theorem 2.6]). *Let $g : \mathbb{R} \to \mathbb{R}$ be a left-continuous and nondecreasing function, continuous and increasing on an interval $[a,b] \subset \mathbb{R}$. Let $f : [a,b] \to \mathbb{R}$ be g-continuous on $[a,b]$ and g-differentiable on (a,b) satisfying $f(a) = f(b)$. Then, there exists $c \in (a,b)$ such that $f'_g(c) = 0$.*

As a consequence of this theorem, the authors prove the following corollary.

Corollary 3.10 ([13, Corollary 2.7]). *Let $g : \mathbb{R} \to \mathbb{R}$ be a left-continuous and nondecreasing function, continuous and increasing on an interval $[a,b] \subset \mathbb{R}$. Let $f : [a,b] \to \mathbb{R}$ be g-continuous on $[a,b]$ and g-differentiable on (a,b). Then, there exists $c \in (a,b)$ such that $f'_g(c) = \frac{f(b)-f(a)}{g(b)-g(a)}$.*

We note that in Theorem 3.9 it is required that g be continuous and increasing on the interval $[a,b]$, a hypothesis that, in our case, is not necessary. In any case, if the derivator satisfies the hypothesis of continuity and monotonicity in the interval $[a,b]$, the proof of Theorem 3.8 is a consequence of the Corollary 3.10.

3.3 Left-continuous functions

In this next step, we aim to prove a version of the Mean Value Theorem for functions that are not necessarily g-continuous but share one basic properties with them: left-continuity.

To that end, we shall denote by $\mathcal{I}_1$ the family of connected components of $[a,b]\backslash C_g$. We have the following result conveying some properties of this family.

Lemma 3.11. *The family $\mathcal{I}_1$ is nonempty consisting of singletons or closed subintervals of $[a,b]$. Furthermore, if $I \in \mathcal{I}_1$ is an interval, then $\min I + \varepsilon \notin C_g \cup N_g^-$, for all $\varepsilon \in [0, \max I - \min I)$.*

Proof. The hypotheses under which we define the Stieltjes derivative guarantee that $b \notin C_g$, which guarantees that $[a,b]\backslash C_g \neq \emptyset$ and, thus, $\mathcal{I}_1 \neq \emptyset$. Now, by definition, the elements of $\mathcal{I}_1$ are closed and connected subsets of the real line. Hence, the first part of the result follows.

Now, let $I \in \mathcal{I}_1$ be an interval and consider $t_* = \min I$. Observe that t_* is well-defined as I is closed. Furthermore, by definition, we have that $t_* \notin C_g$. Now, reasoning by contradiction, suppose $t_* + \varepsilon \in N_g^-$. Then, by definition, there exists $r > 0$ such that g is constant on $[t_* + \varepsilon, t_* + \varepsilon + r]$, which means that $(t_* + \varepsilon, t_* + \varepsilon + r) \subset C_g$. This is a contradiction since $(t_* + \varepsilon, t_* + \varepsilon + r) \cap I \neq \emptyset$. Hence, $t_* + \varepsilon \notin N_g^-$. □

We are now in position to prove a version of the Mean Value Theorem for left-continuous functions, in which the family $\mathcal{I}_1$ plays an important role.

Theorem 3.12 (Mean Value Theorem for left-continuous functions). *Let $f, h : [a,b] \to \mathbb{R}$ be left-continuous on $(a,b]$. If f and h are g-differentiable on $[a,b]$ and $|f'_g(t)| \leqslant h'_g(t)$ for all $t \in [a,b]$, then for each $I \in \mathcal{I}_1$,*

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s,t \in I. \tag{3.3}$$

Proof. Let $I \in \mathcal{I}_1$. If I is a singleton, then (3.3) is trivially satisfied so we shall assume that $I = [c,d]$ for some $c,d \in [a,b]$, $c < d$.

Let $t \in [c,d]$. Following the ideas in the proof of Theorem 3.6, we shall prove that

$$|f(s) - f(t)| \leqslant h(s) - h(t), \quad \text{for all } s \in [c,d],\ s \geqslant t, \tag{3.4}$$

from which the result follows. Once again, if $t = d$, (3.4) is trivially satisfied, so we shall assume that $t < d$.

Let $\varepsilon > 0$ and define

$$S_\varepsilon = \{s \in [t,d] : |f(s) - f(t)| \leqslant h(s) - h(t) + \varepsilon(g(s) - g(t))\}.$$

As in the proof of Theorem 3.6, (3.4) will be proved if we show that $S_\varepsilon = [t,d]$ using Theorem 3.5. Note that 1 is trivially satisfied and 3 can be checked in an analogous manner to the proof of Theorem 3.6, so we shall focus on 2.

Let $s \in [t,d)$ be such that $s \in S_\varepsilon$. Observe that the definition of $\mathcal{I}_1$ and Lemma 3.11 ensure that $s \notin C_g \cup N_g^-$, so, since f and h are g-differentiable at s, we know that

$$f'_g(s) = \lim_{r \to s^+} \frac{f(r) - f(s)}{g(r) - g(s)}, \quad h'_g(s) = \lim_{r \to s^+} \frac{h(r) - h(s)}{g(r) - g(s)}.$$

From here, checking 2 in Theorem 3.5 is analogous to reasoning used in the proof of Theorem 3.6 and we omit it. □

We can use this new version of the Mean Value Theorem to obtain a characterization of the left-continuous functions which have null Stieltjes derivative. The proof of the following result is analogous to that of Theorem 3.8 and we omit it.

Corollary 3.13. *Let $f : [a,b] \to \mathbb{R}$ be a left-continuous function on $(a,b]$ such that $f'_g(t) = 0$ for all $t \in [a,b]$. Then,*

$$f(t) = f(s), \quad \textit{for all } s,t \in I, \quad I \in \mathcal{I}_1.$$

The reciprocal implication in Corollary 3.13 does not hold, as the following example shows.

Example 3.14. Consider g to be the Cantor function, that is,

$$g(x) = \begin{cases} \displaystyle\sum_{n=1}^{\infty} \frac{c_n}{2^{n+1}}, & x = \displaystyle\sum_{n=1}^{\infty} \frac{c_n}{3^n} \in C \text{ for } c_n \in \{0,2\}; \\ \displaystyle\sup_{y \leq x,\, y \in C} g(y), & x \in [0,1] \backslash C, \end{cases}$$

where C is Cantor's set, that is,

$$C = \bigcap_{n=0}^{\infty} E_n,$$

where

$$
\begin{aligned}
E_0 &= [0,1]\,,\\
E_1 &= \left[0,\frac{1}{3}\right]\cup\left[\frac{2}{3},1\right],\\
E_2 &= \left[0,\frac{1}{9}\right]\cup\left[\frac{2}{9},\frac{1}{3}\right]\cup\left[\frac{2}{3},\frac{7}{9}\right]\cup\left[\frac{8}{9},1\right],\\
&\vdots\\
E_m &= \left[0,\frac{1}{3^m}\right]\cup\left[\frac{2}{3^m},\frac{3}{3^m}\right]\cup\left[\frac{6}{3^m},\frac{7}{3^m}\right]\cup\left[\frac{8}{3^m},\frac{9}{3^m}\right]\cup\cdots\\
&\quad\cdots\cup\left[\frac{3^m-3}{3^m},\frac{3^m-2}{3^m}\right]\cup\left[\frac{3^m-1}{3^m},1\right],\ m\in\mathbb{N}.
\end{aligned}
$$

Observe that g is continuous and increasing and, therefore, a derivator. Furthermore, $C_g = [0,1]\backslash C$. Since C is totally disconnected, $\mathcal{I}_1 = \{\{x\} \ : \ x \in C\}$ and the conclusion of Corollary 3.13 is vacuous. Still, we have that g is g-differentiable and $g'_g = 1$, not zero.

As a final note for this case, observe that, effectively, neither Theorem 3.12 nor Corollary 3.13 describe what happens to the functions involved on the set C_g. This is because the definition of Stieltjes derivative on the set C_g does not take into account the behavior of the functions in C_g. Without any extra hypotheses, it is not possible to describe the functions on a neighborhood of such points.

3.4 Stieltjes differentiable functions

In this final section, we aim to obtain a version of the Mean Value Theorem for g-differentiable functions, without imposing any other conditions. To that end, we need to refine the family $\mathcal{I}_1$. This refined family will be $\mathcal{I}_2$, the family of connected subsets of $[a,b]\backslash(C_g \cup N_g^+ \cup D_g)$, for which we have the following result.

Lemma 3.15. *The family $\mathcal{I}_2$ is nonempty and consists of either singletons or subintervals of $[a,b]$. Moreover, letting $t_* = \inf(I)$ for any $I \in \mathcal{I}_2$, we have that, for every $\varepsilon > 0$ such that $t_* + \varepsilon < \sup(I)$, it holds that $t_* + \varepsilon \notin C_g \cup N_g \cup D_g$. Furthermore, if $t_* \in I$, then $t_* \notin C_g \cup N_g \cup D_g$.*

Proof. Let $\varepsilon > 0$ be such that $t_* + \varepsilon < \sup(I)$. If $t_* + \varepsilon \in N_g^-$, there exists $r > 0$ such that g is constant on $[t_* + \varepsilon, t_* + \varepsilon + r]$. In particular, $(t_* + \varepsilon, t_* + \varepsilon + r) \subset C_g$. This is a contradiction since $(t_* + \varepsilon, t_* + \varepsilon + r) \cap I \neq \emptyset$. Hence, $t_* + \varepsilon \notin N_g^-$. The proof for the case $t_* \in I$ is analogous to the previous one. □

This new family of sets is enough to obtain a version of the Mean Value Theorem for g-differentiable functions in a similar fashion to Theorem 3.12.

Theorem 3.16 (Mean Value Theorem for Stieltjes differentiable functions)**.** *Let $f, h : [a,b] \to \mathbb{R}$ be g-differentiable functions on $[a,b]$. If $|f'_g(t)| \leqslant h'_g(t)$ for all $t \in [a,b]$ then, for each $I \in \mathcal{I}_2$,*

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s,t \in I. \tag{3.5}$$

Proof. Let $I \in \mathcal{I}_2$. If I is a singleton, then (3.5) is trivially satisfied, so we shall assume that $\overline{I} = [c,d]$ for some $c < d$. Let us examine each case individually.

- $I = (c, d]$. If we can prove that, given any $\varepsilon \in (0, d-c)$, it holds that

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s, t \in [c+\varepsilon, d],$$

we will be done, since for any two elements $t, s \in (c, d]$, it is always possible to find a value of $\varepsilon \in (0, d-c)$ such that $t, s \in [c+\varepsilon, d]$. Thus, (3.5) is satisfied.

Now take an arbitrary $\varepsilon \in (0, d-c)$, let $t \in [c+\varepsilon, d]$ and we shall show that

$$|f(s) - f(t)| \leqslant h(s) - h(t), \quad \text{for all } s \in [c+\varepsilon, d],\ s \geqslant t. \tag{3.6}$$

We will assume that $t < d$, since, in the case $t = d$, inequality (3.6) holds trivially. Now take $\widehat{\varepsilon} > 0$ and define:

$$S_{\widehat{\varepsilon}} = \{s \in [t, d] : |f(s) - f(t)| \leqslant h(s) - h(t) + \widehat{\varepsilon}(g(s) - g(t))\}.$$

As in the previous proofs, if we show that $S_{\widehat{\varepsilon}} = [t, d]$ for any $\widehat{\varepsilon} > 0$, (3.6) holds. Let us verify that the hypotheses of Theorem 3.5 are satisfied:

1. $t \in S_{\widehat{\varepsilon}}$ trivially (equality holds).
2. Let $s \in [t, d)$ such that $s \in S_{\widehat{\varepsilon}}$. Thanks to Lemma 3.15, $s \notin C_g \cup N_g \cup D_g$, so, since f and h are g-differentiable at s, we have

$$f'_g(s) = \lim_{r \to s} \frac{f(r) - f(s)}{g(r) - g(s)}, \quad h'_g(s) = \lim_{r \to s} \frac{h(r) - h(s)}{g(r) - g(s)}.$$

In particular,

$$f'_g(s) = \lim_{r \to s^+} \frac{f(r) - f(s)}{g(r) - g(s)}, \quad h'_g(s) = \lim_{r \to s^+} \frac{h(r) - h(s)}{g(r) - g(s)}$$

and we can proceed as in the proof of Theorem 3.6.

3. Let $s \in (t, d]$ such that $[t, s) \subset S_{\widehat{\varepsilon}}$. Since $s \in [c+\varepsilon, d] \subset (c, d] \in \mathcal{I}_2$, we have $s \notin C_g \cup N_g^+ \cup D_g$. In particular, we have that $g(r) < g(s)$ for all $r < s$. Hence, since f and h are g-differentiable at s, [12, Proposition 2.1] ensures that they are left-continuous at s, so it is enough to follow the arguments in Theorem 3.6 to finish the proof of the result.

- $I = [c, d)$. This case is similar to the previous one, and we must prove that, given any $\varepsilon \in (0, d-c)$, it holds that

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s, t \in [c, d-\varepsilon].$$

Thus, (3.5) is satisfied. The reasoning is analogous to the previous case: we take $t \in [c, d-\varepsilon]$, assuming that $t < d - \varepsilon$, since the case $t = d - \varepsilon$ is trivial. Given an arbitrary $\widehat{\varepsilon} > 0$, define

$$S_{\widehat{\varepsilon}} = \{s \in [t, d-\varepsilon] : |f(s) - f(t)| \leqslant h(s) - h(t) + \widehat{\varepsilon}(g(s) - g(t))\}.$$

and verify, using Theorem 3.5, that $S_{\widehat{\varepsilon}} = [t, d-\varepsilon]$. As a consequence, we obtain that

$$|f(s) - f(t)| \leqslant h(s) - h(t), \quad \text{for all } s \in [c, d-\varepsilon],\ s \geqslant t,$$

from which it follows that

$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s, t \in [c, d-\varepsilon].$$

- $I = (c, d)$. Analogous to the previous cases, if we prove that, given $\varepsilon \in (0, (d-c)/3)$, it holds that
$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s, t \in [c + \varepsilon, d - \varepsilon],$$
we will be done. The proof is a combination of the arguments used in the previous two points.
- $I = [c, d]$. In this case, we directly prove that
$$|f(s) - f(t)| \leqslant |h(s) - h(t)|, \quad s, t \in [c, d],$$
with the proof being analogous to the previous cases. □

Remark 3.17. Notice that in the interior of an interval such as I in Theorem 3.16, the restriction of g satisfies the hypothesis of Theorem 3.9 and Corollary 3.10 (that is, continuous and increasing).

As a direct consequence of Theorem 3.16, we can obtain the following result which can be described as a different version of the Mean Value Theorem under a boundedness assumption. Note that this formulation of the result is closer to the corresponding result for the usual derivative.

Corollary 3.18 (Mean Value Theorem for Stieltjes differentiable functions)**.** *Let $f : [a, b] \to \mathbb{R}$ be a g-differentiable function on $[a, b]$. Then, for each $I \in \mathcal{I}_2$,*
$$|f(\sup I^-) - f(\inf I^+)| \leqslant \sup_{u \in I} |f'_g(u)|(g(\sup I^-) - g(\inf I^+)). \tag{3.7}$$

Proof. Let $I \in \mathcal{I}_2$. By the definition of $\mathcal{I}_2$, $g(\sup I^-) - g(\inf I^+) > 0$. If $\sup_{u \in I} |f'_g(u)| = \infty$, there is nothing to prove, so we will assume that $\sup_{u \in I} |f'_g(u)| < \infty$. We shall only prove (3.7) whenever $\overline{I} = [c, d]$ with $c < d$, as the case when I is a singleton is trivial.

Given $\varepsilon \in (0, (d-c)/3)$, we define the following map:
$$h_\varepsilon : t \in [c + \varepsilon, d - \varepsilon] \to h_\varepsilon(t) = \sup_{u \in I} |f'_g(u)|(g(t) - g(c + \varepsilon)).$$
Clearly h_ε is g-differentiable on $[c + \varepsilon, d - \varepsilon]$ with
$$(h_\varepsilon)'_g(t) = \sup_{u \in I} |f'_g(u)|, \ \forall\, t \in [c + \varepsilon, d - \varepsilon].$$
So, it follows that $|f'_g(t)| \leqslant (h_\varepsilon)'_g(t)$, for all $t \in [c + \varepsilon, d - \varepsilon]$. Hence, applying Theorem 3.16 on the interval $[c + \varepsilon, d - \varepsilon]$ and noting that $[c + \varepsilon, d - \varepsilon]$ is the only connected component of $[c + \varepsilon, d - \varepsilon] \setminus (C_g \cup N_g^+ \cup D_g)$, we have that
$$|f(s) - f(t)| \leqslant |h_\varepsilon(s) - h_\varepsilon(t)| = \sup_{u \in I} |f'_g(u)||g(t) - g(s)|, \quad s, t \in [c + \varepsilon, d - \varepsilon].$$
In particular,
$$|f(d - \varepsilon) - f(c + \varepsilon)| \leqslant \sup_{u \in I} |f'_g(u)|(g(d - \varepsilon) - g(c + \varepsilon)),$$
so we can conclude the proof of the result by taking $\varepsilon \to 0^+$ if we show first that the limits $f(c^+)$ and $f(d^-)$ exist. Observe that $f(c^+)$ exists by the g-differentiability of f at $c \in D_g \cup N_g^+$. On the other hand, $f(d^-)$ exists because, given $\varepsilon \in \mathbb{R}^+$, and defining
$$M = \frac{\varepsilon}{2 \max\{1, \sup_{u \in I} |f'_g(u)|\}},$$

since g is left continuous at d, there exists $\delta \in \mathbb{R}^+$ such that $|g(t) - g(d)|, |g(s) - g(d)| < M$ if $t, s \in (c, d)$, $d - t, d - s < \delta$. Thus, given $t, s \in (c, d)$, $d - t, d - s < \delta$,

$$|f(s) - f(t)| \leqslant \sup_{u \in I} |f'_g(u)||g(t) - g(s)| \leq \sup_{u \in I} |f'_g(u)|(|g(t) - g(d)| + |g(d) - g(s)|) < \varepsilon,$$

which is enough to guarantee that $f(d^-)$ exists, as it implies that, for any sequence $\{x_n\}_{n \in \mathbb{N}} \subset (c, d)$ converging to d, $\{f(x_n)\}_{n \in \mathbb{N}}$ is a Cauchy sequence—cf. [11, p. 245]. □

Theorem 3.16 can also be used to describe some properties of functions in the kernel of the Stieltjes derivative as presented in the next result. The proof of the following result is in the style of the one for Theorem 3.8 and we omit it.

Corollary 3.19. *Let $f : [a, b] \to \mathbb{R}$ be such that $f'_g(t) = 0$ for all $t \in [a, b]$. Then,*

$$f(t) = f(s), \quad \text{for all } s, t \in I, \quad I \in \mathcal{I}_2.$$

Remark 3.20. The converse of Corollary 3.19 is not generally true. For example, if we consider g as the Cantor function that we defined in Example 3.14, we have that $C_g \cup N_g^+ \cup D_g = [0, 1] \setminus \widehat{C}$, where

$$\widehat{C} = \bigcap_{n=0}^{\infty} \widehat{E}_n,$$

with

$$\begin{aligned}
\widehat{E}_0 &= [0, 1], \\
\widehat{E}_1 &= \left[0, \frac{1}{3}\right] \cup \left(\frac{2}{3}, 1\right], \\
\widehat{E}_2 &= \left[0, \frac{1}{9}\right] \cup \left(\frac{2}{9}, \frac{1}{3}\right] \cup \left(\frac{2}{3}, \frac{7}{9}\right] \cup \left(\frac{8}{9}, 1\right], \\
&\vdots \\
\widehat{E}_m &= \left[0, \frac{1}{3^m}\right] \cup \left(\frac{2}{3^m}, \frac{3}{3^m}\right] \cup \left(\frac{6}{3^m}, \frac{7}{3^m}\right] \cup \left(\frac{8}{3^m}, \frac{9}{3^m}\right] \cup \cdots \\
&\quad \cdots \cup \left(\frac{3^m - 3}{3^m}, \frac{3^m - 2}{3^m}\right] \cup \left(\frac{3^m - 1}{3^m}, 1\right], \ m \in \mathbb{N}.
\end{aligned}$$

The set $\widehat{C}$ is totally disconnected, and therefore $\mathcal{I}_2 = \{\{x\} : x \in \widehat{C}\}$. Hence, $g(t) = g(s)$, for all $s, t \in I$, with $I \in \mathcal{I}_2$. However, $g'_g(t) = 1$ for all $t \in [0, 1]$.

Now we present some characterizations of those g-differentiable functions with g-derivative 0 everywhere.

Lemma 3.21. *$f : [a, b] \to \mathbb{R}$ satisfies $f'_g(t) = 0$ for all $t \in [a, b)$ if and only if $(fh)'_g = f^* h'_g$ for every g-differentiable function $h : [a, b) \to \mathbb{R}$.*

Proof. If $f'_g(t) = 0$ for all $t \in [a, b)$, given g-differentiable function $h : [a, b) \to \mathbb{R}$, by the product rule,

$$(fh)'_g(t) = f'_g(t)h(t^*) + h'_g(t)f(t^*) + f'_g(t)h'_g(t)\Delta g(t^*) = f(t^*)h'_g(t).$$

Now assume $(fh)'_g = f^* h'_g$ for every g-differentiable function $h : [a, b] \to \mathbb{R}$. By taking $h = 1$, this equality implies that f is g-differentiable and $f'_g = 0$. □

We now aim to characterize the functions whose g-derivative is zero, using the following observation. Clearly, if φ is constant, then any function of the form $f = \varphi \circ g$ has g-derivative zero. Conversely, suppose φ is differentiable, g is continuous, and $f = \varphi \circ g$ has vanishing g-derivative. Then, by Proposition 2.4, for any t in the domain of g, we have

$$0 = f'_g(t) = \varphi'_g(g(t^*))g'_g(t) = \varphi'_g(g(t)),$$

so φ'_g has to vanish on the image of g. A similar characterization should hold for any g-differentiable function f; it suffices to express f as a composition $f = \varphi \circ g$ for a suitable function φ. This is precisely the content of Lemma 3.22.

For the next result we will denote by A'_+ the set of accumulation points of A from the right and by f'_+ the derivative of f from the right.

Lemma 3.22. *Let $f : \mathbb{R} \to \mathbb{R}$ be a g-differentiable function. f satisfies $f'_g(t) = 0$ for all $t \in [a, b)$ if and only if there exists a function $\varphi : I \to \mathbb{R}$, where I is the smallest interval containing $g(\mathbb{R})$, such that*

1. *φ is constant on $[g(t), g(t^+)]$ for $t \in \mathbb{R}$,*
2. *$\varphi(g(t^*)) = f(t^*)$ for $t \in \mathbb{R}$,*
3. *$\varphi|_{g(\mathbb{R})}$ is differentiable on $[g(\mathbb{R})\backslash g(D_g \cup N_g)] \cap g(\mathbb{R})'$, differentiable from the right on the set $[g(\mathbb{R})\backslash g(D_g)] \cap g(\mathbb{R})' \cap g(N_g^+)$ and differentiable from the left on $[g(\mathbb{R})\backslash g(D_g)] \cap g(\mathbb{R})' \cap g(N_g^-)$ and the derivative on those sets is zero, and*
4. *$\varphi|_{g(\mathbb{R})}$ is differentiable from the right on $g(D_g) \cap g(\mathbb{R})'_+$ and $(\varphi|_{g(\mathbb{R})})'_+ = 0$ on that set.*

Proof. Assume first that there exists a differentiable function $\varphi : I \to \mathbb{R}$ satisfying conditions 1-4. Let $h = \varphi \circ g = \varphi|_{g(\mathbb{R})} \circ g$. First, g is g-differentiable and $g'_g = 1$. Now we consider different cases for $t \in [a, b)$.

We start by making the observation that the points in $\varphi(\mathbb{R})\backslash\varphi(\mathbb{R})'$ are points $x = \varphi(t)$ where $t \in D_g$ and g is constant on $(t - \varepsilon, t)$ and $(t, t + \varepsilon)$ for some ε.

If $g(t) \notin \varphi(\mathbb{R})'$, $g(t) \in D_g$ and φ is constant on $[g(t), g(t^+)]$, so, given that φ is continuous,

$$h'_g(t) := \lim_{s \to t^+} \frac{\varphi(g(s)) - \varphi(g(t))}{g(s) - g(t)} = \frac{\varphi(g(t^+)) - \varphi(g(t))}{g(t^+) - g(t)} = 0.$$

If $g(t) \in \varphi(\mathbb{R})'$, taking into account Remark 2.5, we can apply points 1–3 of Lemma 2.4 to deduce that h is g-differentiable and $h'_g(t) = 0$ if $t \notin D_g$ or $t \in D_g$ and condition (2.3) holds. Suppose now that $t \in D_g$ and condition (2.3) does not hold. $g(t^+)$ exists, φ is continuous from the right at $g(t^+)$, as it is differentiable form the right, and we have that

$$\lim_{s \to t^+} \frac{\varphi(g(s)) - \varphi(g(t))}{g(s) - g(t)} = \frac{\varphi(g(t^+)) - \varphi(g(t))}{g(t^+) - g(t)} = 0.$$

Thus, by point 4 of Lemma 2.4, $h'_g = 0$.

Since f is g-differentiable, by [6, Proposition 4.1], f^* is g differentiable as well and $(f^*)'_g = f'_g$. Thus, $f'_g(t) = (f^*)_g(t)' = h'_g(t) = 0$ for $t \in [a, b)$.

To show the converse, we modify the proof of [8, Theorem 3.13]. Let $c = \sup g(\mathbb{R}) \in (-\infty, \infty]$. We start by defining the function $\sigma(t) = \sup g^{-1}(x)$ for every $x \in (-\infty, c) \cap g(\mathbb{R})$. If $c \in g(\mathbb{R})$, we define $\sigma(c) = t$ for some $t \in \mathbb{R}$ such that $g(t) = g(c)$. This way, we have defined σ on $g(\mathbb{R})$. Since g is increasing and left continuous, $\sigma(g(t)) = t^*$ for every $t \in \mathbb{R}$.

Let

$$\varphi(x) := \begin{cases} f(\sigma(x)), & x \in g(\mathbb{R}), \\ \varphi(g(t)), & x \in (g(t), g(t^+)] \backslash g(\mathbb{R}),\ t \in \mathbb{R}. \end{cases}$$

Observe that φ is well defined and, as g is nondecreasing, we have defined φ on all of I. Furthermore, φ is constant on $[g(t), g(t^+)]$ and $\varphi(g(t^*)) = f(\sigma(g(t^*))) = f(t^*)$ for $t \in \mathbb{R}$.

Now we check that $\varphi|_{g(\mathbb{R})}$ is differentiable on $[g(\mathbb{R}) \backslash g(D_g \cup N_g)] \cap g(\mathbb{R})'$ (the other cases are similar) and $\varphi|'_{g(\mathbb{R})} = 0$. Given $t \in \mathbb{R}$, $g(t)$, is an accumulation point from the left in the set $g(\mathbb{R})$ because g is left continuous, so, given that $t^* \notin N_g^+$, we can consider

$$\lim_{\substack{y \to g(t)^- \\ y \in g(\mathbb{R})}} \frac{\varphi(y) - \varphi(g(t))}{y - g(t)} = \lim_{s \to t} \frac{\varphi(g(s)) - \varphi(g(t))}{g(s) - g(t)} = \lim_{s \to t^-} \frac{f(\sigma(g(s^*))) - f(\sigma(g(t^*)))}{g(s) - g(t)}$$

$$= \lim_{s \to t^-} \frac{f(s^*) - f(t^*)}{g(s) - g(t)} = (f^*)'_g(t) = f'_g(t) = 0.$$

If $g(t)$, is an accumulation point from the right in the set $g(\mathbb{R})$, and given that $t \notin N_g^-$ we conclude, in a similar manner, that

$$\lim_{\substack{y \to g(t)^+ \\ y \in g(\mathbb{R})}} \frac{\varphi(y) - \varphi(g(t))}{y - g(t)} = (f^*)'_g(t) = f'_g(t) = 0.$$

In any case, we have proven that the derivative is zero. Condition 4 is proven in a similar way. □

Remark 3.23. While Lemma 3.21 does not require f to be g-differentiable, Lemma 3.22 imposes this condition. The reason for this is that, although g-differentiability of f implies the same for f^*, with identical g-derivatives [6, Proposition 4.1], the reverse implication does not hold in general [6, Remark 4.3].

4 $\mathcal{BD}$-spaces

We now aim to define suitable function spaces, denoted by $\mathcal{BD}_g^k([a,b];\mathbb{F})$, for g-differentiable functions. To this end, we begin by establishing some basic properties of such functions, as these must be satisfied by any element of the proposed spaces. Moreover, we seek to ensure that these spaces provide a natural framework for the study of differential problems involving g-derivatives.

Remark 4.1. Taking into account Definition 2.1, given a derivator $g : [a,b] \to \mathbb{R}$ such that $a \notin N_g^-$ and $b \notin N_g^+ \cup D_g \cup C_g$, the following conditions will be necessary for the existence of the g-derivative in all of the points of $[a,b] \setminus (C_g \cup D_g)$ (see [5, Remark 3.3]):

- Given $t \in [a,b] \setminus (C_g \cup D_g \cup N_g)$, f is g-continuous at t. In particular, f is continuous at t since g-continuous functions are, in particular, continuous at the points where g is continuous.

- Given $t \in N_g^-$, f is left g-continuous at t, in the sense that, given $\varepsilon \in \mathbb{R}^+$, there exists $\delta \in \mathbb{R}^+$ such that, if $s < t$ with $g(t) - g(s) < \delta$ then, $|f(s) - f(t)| < \varepsilon$.

Observe that the function f might not be g-continuous at such points. Indeed, take for instance

$$g : x \in [0,3] \to g(s) = \begin{cases} x, & x \in [0,1], \\ 1, & x \in (1,2), \\ x-1, & x \in [2,3]. \end{cases} \tag{4.1}$$

Then,

$$f : x \in [0,3] \to f(x) = \begin{cases} x, & x \in [0,1], \\ x+1, & x \in (1,3], \end{cases}$$

is g-differentiable at $x = 1$ since

$$\lim_{s \to 1^-} \frac{f(s) - f(1)}{g(s) - g(1)} = \lim_{s \to 1^-} \frac{s-1}{s-1} = 1.$$

However, the function f is not g-continuous at $x = 1$ since g is continuous at that point.

- Given $t \in N_g^+$, f is right g-continuous at t, in the sense that, given $\varepsilon \in \mathbb{R}^+$, there exists $\delta \in \mathbb{R}^+$ such that, if $t < s$ with $g(s) - g(t) < \delta$ then, $|f(s) - f(t)| < \varepsilon$.

  As in the previous case, the function does not have to be g-continuous at such points. Indeed, take for instance g as before and

$$f : x \in [0,3] \to f(x) = \begin{cases} x, & x \in [0,2), \\ 2x+1, & x \in [2,3], \end{cases} \tag{4.2}$$

  f is g-differentiable at $x = 2$, but f is not g-continuous at such point.

- Given $t \in D_g$, the right limit $f(t^+) = \lim_{s \to t^+} f(s)$ exists.

We conclude that, interestingly enough, the g-differentiability of a function at a point of N_g does not imply the g-continuity of the function at the point. The g-differentiability of a function only guarantees the g-continuity at the points of $[a,b] \backslash (C_g \cup D_g \cup N_g)$.

Remark 4.2. It is important to highlight that it may happen that the g-derivative of a function has more points at which it is g-continuous than the function itself. For example, let us consider the derivator (4.1) and the function (4.2). The function f is g-continuous on $[0,1) \cup (2,3]$, however, its g-derivative,

$$f'_g : x \in [0,3] \to f'_g(x) = \begin{cases} 1, & x \in [0,1], \\ 2, & x \in (1,3], \end{cases}$$

is g-continuous on $[0,1) \cup (1,3]$. That is, f'_g is g-continuous on $(1,2]$, however, f is not g-continuous on $(1,2)$ (in order for f to be continuous on the interval $(1,2)$, it would have to be constant on that interval, which is false).

Lemma 4.3. *Let $[a,b] \subset \mathbb{R}$ be a closed interval of the real line. Let us assume that $a \notin N_g^-$ and $b \notin N_g^+ \cup D_g \cup C_g$. Given a function $f : [a,b] \to \mathbb{F}$ such that $f'_g(b_n)$ exists for some $n \in \widetilde{\Lambda}$, then there exists $f'_g(x)$ for all $x \in (a_n, b_n]$, and $f'_{g|_{(a_n,b_n]}}$ is g-continuous on $(a_n, b_n]$.*

Proof. The proof is straightforward considering that f'_g is constant on $(a_n, b_n]$ since $f'_g(x) = f'_g(b_n)$ for all $x \in (a_n, b_n]$. □

Building on the observations in Remark 4.1 regarding the properties of g-differentiable functions, we now introduce the space $\mathcal{BD}_g([a,b];\mathbb{F})$, consisting of functions that satisfy those same properties.

Definition 4.4. **($\mathcal{BD}_g([a,b];\mathbb{F})$ space)** Let $[a,b] \subset \mathbb{R}$ be a closed interval of the real line. Let us assume that $a \notin N_g^-$ and $b \notin N_g^+ \cup D_g \cup C_g$. We say that $f : [a,b] \to \mathbb{F}$ belongs to $\mathcal{BD}_g([a,b];\mathbb{F})$ if it is bounded in $[a,b]$, g-continuous on $[a,b] \setminus (C_g \cup N_g \cup D_g)$, left g-continuous on N_g^- and right g-continuous on N_g^+.

In order to define the spaces $\mathcal{BD}_g^k([a,b];\mathbb{F})$, with $k \in \mathbb{N}$, we will denote by $\mathcal{BD}_g^0([a,b];\mathbb{F})$ the space $\mathcal{BD}_g([a,b];\mathbb{F})$ and by $f_g^{(0)}$ the function f.

Definition 4.5 ($\mathcal{BD}_g^k([a,b];\mathbb{F})$ space, $k \in \mathbb{N}$)**.** Let $[a,b] \subset \mathbb{R}$ be a closed interval of the real line. Let us assume that $a \notin N_g^-$ and $b \notin N_g^+ \cup D_g \cup C_g$, we say that $f : [a,b] \to \mathbb{F}$ belongs to $\mathcal{BD}_g^k([a,b];\mathbb{F})$ if $f_g^{(k-1)} \in \mathcal{BD}_g^{k-1}([a,b];\mathbb{F})$ and there exists $(f^{(k-1)})_g'(t)$, for all $t \in [a,b]$ in terms of Definition 2.1, such that $(f^{(k-1)})_g' \in \mathcal{BD}_g^0([a,b];\mathbb{F})$. We write $\mathcal{BD}_g^\infty([a,b];\mathbb{F}) = \bigcap_{k\in\mathbb{N}} \mathcal{BD}_g^k([a,b];\mathbb{F})$.

In the next result we show that, in contrast with the case of the spaces $\mathcal{BC}_g^k([a,b];\mathbb{F})$, the spaces $\mathcal{BD}_g^k([a,b];\mathbb{F})$ are closed under the product of functions, showing that they have an algebra structure.

Lemma 4.6. *Given f_1, $f_2 \in \mathcal{BD}_g^k([a,b];\mathbb{F})$, with $k \in \mathbb{N}$, we have that $f_1 f_2 \in \mathcal{BD}_g^k([a,b];\mathbb{F})$.*

Proof. Let us see the case $k = 1$ (analogous for $k \in \mathbb{N}$, $k \geq 2$). Given f_1, $f_2 \in \mathcal{BD}_g^1([a,b];\mathbb{F})$, we have, by Proposition 2.3, that, the product $f_1 f_2$ is g-differentiable at $t \in [a,b]$ and

$$(f_1 f_2)_g'(t) = (f_1)_g'(t) f_2(t^*) + (f_2)_g'(t) f_1(t^*) + (f_1)_g'(t)\,(f_2)_g'(t)\Delta g(t^*).$$

In particular,

$$(f_1 f_2)_g'(t) = (f_1)_g'(t) f_2(t) + (f_2)_g'(t) f_1(t),\ \forall t \in [a,b]\setminus(D_g \cup C_g).$$

Hence, by the definition of space $\mathcal{BD}_g^1([a,b];\mathbb{F})$ we have that $(f_1 f_2)_g'$ is bounded in $[a,b]$, g-continuous on $[a,b] \setminus (C_g \cup N_g \cup D_g)$, left g-continuous on N_g^- and right g-continuous on N_g^+. □

Remark 4.7. In general we cannot ensure in general that $\mathcal{BD}_g^1([a,b];\mathbb{F}) \subset \mathcal{AC}_g([a,b];\mathbb{F})$ since the functions of $\mathcal{BD}_g^1([a,b];\mathbb{F})$ need not be left-continuous in D_g.

Remark 4.8. Under the hypotheses of Lemma 4.3, given $f \in \mathcal{BD}_g^k([a,b];\mathbb{F})$, we have that $f_g^{(l)}|_{(a_n,b_n]}$ is g-continuous on $(a_n,b_n]$, for all $n \in \widetilde{\Lambda}$ and for all $l = 1,\ldots,k$.

Observe that given $l \in \{1,\ldots,k\}$, we only have guaranteed left g-continuity of $f_g^{(l)}$ at $b_n \in D_g$, whereas if $b_n \in N_g^+$, the function $f_g^{(l)}$ is g-continuous at b_n. In both cases the function $f_g^{(l)}|_{(a_n,b_n]}$ is g-continuous on $(a_n,b_n]$.

Example 4.9. Let us consider the example we analyzed in Remark 4.2, in this case, $D_g = \emptyset$, $C_g = (1,2)$, $N_g^- = \{1\}$, and $N_g^+ = \{2\}$. Moreover,

- f is bounded, g-continuous on $[0,3] \setminus [1,2]$, g-continuous from the left at $x = 1$, and g-continuous from the right at $x = 2$.
- f_g' is bounded, g-continuous on $[0,3] \setminus [1,2]$, g-continuous from the left at $x = 1$, and g-continuous from the right at $x = 2$. In fact, f_g' is g-continuous on $[0,3] \setminus \{1\}$.
- $f_g^{(k)} = 0$ for all $k \geq 2$, in particular, it trivially holds that it is bounded, g-continuous on $[0,3] \setminus [1,2]$, g-continuous from the left at $x = 1$, and g-continuous from the right at $x = 2$.

Thus, $f \in \mathcal{BD}_g^k([a,b];\mathbb{F})$ for all $k \in \mathbb{N}$.

Remark 4.10. In the previous example, a very important property of the spaces $\mathcal{BD}_g^k([a,b];\mathbb{F})$ is revealed, namely that non-constant functions can exist whose g-derivative is zero.

We have that $\mathcal{BD}_g^k([a,b];\mathbb{F})$ is a normed vector space with the norm

$$\begin{aligned} \mathcal{BC}_g^k([a,b]) &\xrightarrow{\quad \|\cdot\|_k \quad} \mathbb{R} \\ f &\longmapsto \|f\|_k := \sum_{0 \leq i \leq k} \|f_g^{(i)}\|_\infty \end{aligned}$$

where $\|f\|_\infty := \sup_{x \in [a,b]} |f(x)|$ is the supremum norm, and $k \in \{0\} \cup \mathbb{N}$.

4.1 Sufficient conditions for a Banach space structure

In the following results we will assume that $[a,b] \subset \mathbb{R}$ and $g : \mathbb{R} \to \mathbb{R}$ is a derivator such that $a \notin N_g^-$ and $b \notin N_g^+ \cup D_g \cup C_g$.

Remark 4.11. We have that $(\mathcal{BD}_g([a,b];\mathbb{F}), \|\cdot\|_\infty)$ is a Banach space. Indeed: the properties in the definition of $\mathcal{BD}_g([a,b];\mathbb{F})$, g-continuity on $[a,b] \setminus (C_g \cup N_g \cup D_g)$, left g-continuity on N_g^- and right g-continuity on N_g^+ are preserved by the convergence in the supremum norm. Let us see that under some hypotheses concerning the derivator g we have that $(\mathcal{BD}_g^k([a,b];\mathbb{F}), \|\cdot\|_k)$ is also a Banach space for all $k \in \mathbb{N}$.

Lemma 4.12. *The following families of statements are equivalent:*

1. $N_g' \setminus N_g \subset D_g$ *and* $D_g' \subset D_g$.
2. (a) *For all* $x \in [a,b] \setminus (D_g \cup N_g \cup C_g)$ *there exists* $\delta > 0$ *such that* $[x-\delta, x+\delta] \subset [a,b] \setminus (D_g \cup N_g \cup C_g)$,
   (b) *for all* $x \in N_g^+$ *there exists* $\delta > 0$ *such that* $(x, x+\delta] \subset [a,b] \setminus (D_g \cup N_g \cup C_g)$ *and*
   (c) *for all* $x \in N_g^-$ *there exists* $\delta > 0$ *such that* $[x-\delta, x) \subset [a,b] \setminus (D_g \cup N_g \cup C_g)$.

Proof. Let us prove each of the implications separately.

1⇒2. On the one hand, $\overline{D_g \cup N_g \cup C_g} = C_g \cup N_g \cup D_g \cup N_g' \cup D_g' = C_g \cup N_g \cup D_g$, from which we deduce that $C_g \cup N_g \cup D_g$ is closed. Therefore, given an element $x \in [a,b] \setminus (C_g \cup N_g \cup D_g)$, there exists $\delta > 0$ such that $[x-\delta, x+\delta] \subset [a,b] \setminus (C_g \cup N_g \cup D_g)$.

Now let $x \in N_g^+$ (the case N_g^- is analogous), since D_g is a closed set, there exists an element $\delta_1 > 0$ such that $[x-\delta_1, x+\delta_1] \subset [a,b] \setminus D_g$. Since $x \notin D_g$, in particular, $x \notin N_g'$,

therefore, there exists an element $\delta_2 > 0$ such that $[x-\delta_2, x+\delta_2] \setminus \{x\} \subset [a,b] \setminus N_g$. Taking $\delta_3 = \min\{\delta_1, \delta_2\}$, we have $[x-\delta_3, x+\delta_3] \setminus \{x\} \subset [a,b] \setminus (N_g \cup D_g)$. Hence, $(x, x+\delta_3] \subset [a,b] \setminus (N_g \cup D_g)$ and, since the points of the set $N_g \cup D_g$ include the endpoints of the intervals that form the connected components of C_g, it follows that $(x, x+\delta_3] \subset [a,b] \setminus (C_g \cup N_g \cup D_g)$.

2⇒1. Let $x \in N_g$, and assume $x \in N_g^+$ (the case of N_g^- is analogous). By point 2. (b), we know that there exists an element $\delta > 0$ such that $(x, x+\delta] \subset [a,b] \setminus (C_g \cup N_g \cup D_g)$, in particular, $(x, x+\delta] \subset [a,b] \setminus (N_g \cup D_g)$. Additionally, there exists $\delta_2 > 0$ such that $[x-\delta_2, x) \subset C_g \subset [a,b] \setminus (N_g \cup D_g)$. Taking $\delta_3 = \min\{\delta_1, \delta_2\}$, we have $[x-\delta_3, x+\delta_3] \setminus \{x\} \subset [a,b] \setminus (N_g \cup D_g)$. Hence, $x \notin N_g' \cup D_g'$. Therefore, we have that $N_g \cap N_g' = N_g \cap D_g' = \emptyset$. Now, by point 2. (a), the set $C_g \cup N_g \cup D_g$ is closed in $[a,b]$, and since C_g is an open set, it follows that $N_g \cup D_g$ must be closed. Thus,

$$N_g \cup D_g = \overline{N_g \cup D_g} = N_g' \cup N_g \cup D_g \cup D_g'.$$

Finally, taking into account that $D_g \cap N_g = N_g \cap N_g' = N_g \cap D_g' = \emptyset$, we deduce that $N_g' \setminus N_g \subset D_g$ and $D_g' \subset D_g$. □

We recall the following result.

Lemma 4.13 ([5, Lemma 3.13]). *We have the continuous embedding $\mathcal{BC}_g^1([a,b]) \hookrightarrow \mathcal{AC}_g([a,b])$. Furthermore, for every $f \in \mathcal{BC}_g^1([a,b])$,*

$$f(x) = f(a) + \int_{[a,x)} f_g'(s)\, \mathrm{d}\,\mu_g(s), \quad \forall x \in [a,b].$$

The following result is a generalization of [5, Lemma 3.14]. The proof is essentially the same, but we include it here for completeness.

Lemma 4.14. *Let $h \in \mathcal{BD}_g^k([a,b];\mathbb{F})$ and consider the function*

$$H : x \in [a,b] \to H(x) = \int_{[a,x)} h(s)\, \mathrm{d}\,\mu_g(s).$$

We have that $H_g'(x) = h(x^*)$, for every $x \in [a,b]$, $h^* \in \mathcal{BD}_g^k([a,b];\mathbb{F})$, and, therefore, $H \in \mathcal{BD}_g^{k+1}([a,b];\mathbb{F})$.

Proof. On the one hand, since h and h^* have the same g-derivatives and $h \in \mathcal{BD}_g^k([a,b];\mathbb{F})$, we have that $h^* \in \mathcal{BD}_g^k([a,b];\mathbb{F})$. Furthermore, $H \in \mathcal{AC}_g([a,b];\mathbb{F})$ given that $h \in \mathcal{BD}_g([a,b];\mathbb{F}) \subset \mathcal{L}_g^1([a,b);\mathbb{F})$, so it is enough ot prove that $H_g'(x) = h(x^*)$ for every $x \in [a,b]$ to get the result. We study three different cases:

- If $x \in D_g$ it is clear that

$$\begin{aligned} H_g'(x) &= \lim_{s \to x^+} \frac{H(s) - H(x)}{g(s) - g(x)} \\ &= \lim_{s \to x^+} \frac{1}{g(s) - g(x)} \int_{[x,s)} h(s)\, \mathrm{d}\,\mu_g(s) \\ &= \lim_{s \to x^+} \frac{1}{g(s) - g(x)} \left(\int_{\{x\}} h(s)\, \mathrm{d}\,\mu_g(s) + \int_{(x,s)} h(s)\, \mathrm{d}\,\mu_g(s) \right) \\ &= \lim_{s \to x^+} \frac{h(x)\Delta^+ g(x)}{g(s) - g(x)} = h(x). \end{aligned}$$

- If $x \in [a,b]\backslash(C_g \cup D_g \cup N_g)$, let us compute the limit

$$\lim_{s\to x} \frac{H(s)-H(x)}{g(s)-g(x)},$$

on the domain where $g(s) \neq g(x)$. Fix $\varepsilon > 0$. Since h is g-continuous and g is continuous at x, there exists $\delta > 0$ such that $|h(u)-h(x)| < \varepsilon$ if $|u-x| < \delta$. Define $[\![x,s]\!] := [\min\{x,s\}, \max\{x,s\}]$. Now, for $s \in [a,b]$, $|u-s| < \delta$, we have that

$$\begin{aligned}
\left|\frac{H(s)-H(x)}{g(s)-g(x)} - h(x)\right| &= \left|\frac{\operatorname{sgn}(s-x)}{g(s)-g(x)} \int_{[\![x,s]\!]} h(u)\, \mathrm{d}\,\mu_g(u) - h(x)\right| \\
&= \frac{1}{|g(s)-g(x)|} \left|\int_{[\![x,s]\!]} (h(u)-h(x))\, \mathrm{d}\,\mu_g(u)\right| \\
&\leq \frac{1}{|g(s)-g(x)|} \int_{[\![x,s]\!]} |h(u)-h(x)|\, \mathrm{d}\,\mu_g(u) \\
&\leq \frac{1}{|g(s)-g(x)|} \int_{[\![x,s]\!]} \varepsilon\, \mathrm{d}\,\mu_g(u) = \varepsilon.
\end{aligned} \tag{4.3}$$

Thus,

$$\lim_{s\to x} \frac{H(s)-H(x)}{g(s)-g(x)} = h(x).$$

- If $x \in N_g^+\backslash D_g$, let us compute the limit

$$\lim_{s\to x^+} \frac{H(s)-H(x)}{g(s)-g(x)},$$

on the domain where $g(s) \neq g(x)$. Fix $\varepsilon > 0$. Since h is g-continuous from the right and g is continuous at x, there exists $\delta > 0$ such that $|h(u)-h(x)| < \varepsilon$ if $0 < |u-s| < \delta$. Repeating the calculations at (4.3), we conclude that

$$H_g'(x) = \lim_{s\to x^+} \frac{H(s)-H(x)}{g(s)-g(x)} = h(x).$$

- In the case $x \in N_g^-\backslash D_g$, the reasoning is analogous.
- Finally, if $x \in (a_n, b_n) \subset C_g$, it holds that

$$H_g'(x) = H_g'(b_n) = h(b_n) = h(x^*),$$

where the first equality comes from the definition of the g-derivative at the points of C_g and the last is a consequence of the definition of x^*. □

Theorem 4.15. *Assume $N_g' \setminus N_g \subset D_g$ and $D_g' \subset D_g$. Then $(\mathcal{BD}_g^k([a,b];\mathbb{F}), \|\cdot\|_k)$ is a Banach space.*

Proof. We present a similar reasoning in the one in the proof of [5, Theorem 3.13]. We will check the case $k = 1$ (the case $k \geq 2$ is analogous). Let $\{f_n\}_{n\in\mathbb{N}} \subset \mathcal{BD}_g^1([a,b])$ be a Cauchy sequence. Then, $\{f_n\}_{n\in\mathbb{N}} \subset \mathcal{BD}_g([a,b])$ and $\{(f_n)_g'\}_{n\in\mathbb{N}} \subset \mathcal{BD}_g([a,b])$ are Cauchy sequences in the Banach space $\mathcal{BD}_g([a,b])$, so there exist $f, h \in \mathcal{BD}_g([a,b])$ such that $f_n \to f$ and $(f_n)_g' \to h$ in $\mathcal{BD}_g([a,b])$. Let us check that $f_g'(x)$ exists for every $x \in [a,b]$ for all possible cases and that, furthermore, $f_g' = h$.

• Given $x \in D_g$, we have that

$$(f_n)'_g(x) = \frac{f_n(x^+) - f_n(x)}{\Delta g(x)} \to \frac{f(x^+) - f(x)}{\Delta g(x)} = f'_g(x),$$

therefore $h(x) = f'_g(x)$.

• Thanks to Lemma 4.12, given $x \in [a,b]\backslash(D_g \cup C_g \cup N_g)$, there exists $\delta > 0$ such that $[x-\delta, x+\delta] \subset [a,b]\backslash(D_g \cup N_g \cup C_g)$. We have that f_n is bounded and g-continuous in $[x-\delta, x+\delta]$ and so is $(f_n)'_g$. Therefore, by Lemma 4.13, $f_n|_{[x-\delta,x+\delta]} \in \mathcal{AC}_g([x-\delta, x+\delta]; \mathbb{F})$ and

$$f_n(t) - f_n(x-\delta) = \int_{[x-\delta,t)} (f_n)'_g(s)\ \mathrm{d}\,\mu_g(s),\ \forall t \in [x-\delta, x+\delta].$$

On the other hand,

$$\begin{aligned}\left|\int_{[x-\delta,t)} (f_n)'_g(s)\ \mathrm{d}\,\mu_g(s) - \int_{[x-\delta,t)} h(s)\ \mathrm{d}\,\mu_g(s)\right| &\\ \leq \int_{[x-\delta,t)} \left|(f_n)'_g(s) - h(s)\right|\ \mathrm{d}\,\mu_g(s) &\\ \leq \varepsilon(g(x+\delta) - g(x-\delta)),&\end{aligned}$$

where the last inequality is valid for every $n \geq N$, where $N \in \mathbb{N}$ is such that $\|(f_n)'_g - h\|_\infty \leq \varepsilon$, for every $n \geq N$. Then, we have that

$$\lim_{n\to\infty} \int_{[x-\delta,t)} (f_n)'_g(s)\ \mathrm{d}\,\mu_g(s) = \int_{[x-\delta,t)} h(s)\ \mathrm{d}\,\mu_g(s)$$

uniformly on $[x-\delta, x+\delta]$. Thus,

$$\lim_{n\to\infty} (f_n(t) - f_n(x-\delta)) = \lim_{n\to\infty} \int_{[x-\delta,t)} (f_n)'_g(s)\ \mathrm{d}\,\mu_g(s) = \int_{[x-\delta,t)} h(s)\ \mathrm{d}\,\mu_g(s)$$

uniformly on $[x-\delta, x+\delta]$. Hence,

$$f(t) = f(x-\delta) + \int_{[x-\delta,t)} h(s)\ \mathrm{d}\,\mu_g(s).$$

Since $h|_{[x-\delta,x+\delta]} \in \mathcal{BC}_g([x-\delta, x+\delta])$, by Lemma 4.14, we get that

$$f'_g(t) = h(t),\ \forall x \in [x-\delta, x+\delta],$$

as we wanted to show. Thus, we have that $f'_g(t) = h(t)$, for all $t \in [x-\delta, x+\delta]$. In particular, $f'_g(x) = h(x)$.

• For $x \in N_g^-$ (analogous for N_g^+) the reasoning is similar. In this case, thanks to Lemma 4.12, given $x \in N_g^-$, we have that there exists $\delta > 0$ such that $[x-\delta, x) \subset [a,b]\backslash(D_g \cup N_g \cup C_g)$. Now since f_n and $(f_n)'_g$ are left g-continuous at x, we have that $f_n|_{[x-\delta,x]} \in \mathcal{AC}_g([x-\delta, x]; \mathbb{F})$ and we can proceed in a way resembling that of the previous point.

• For $x \in (a_n, b_n) \subset C_g$, we have, thanks to the previous results, that $f'_g(x) = f'_g(b_n) = h(b_n)$, where $b_n \in N_g^+ \cup D_g$. Now, thanks to Remark 4.8, $(f_n)'_g|_{(a_n,b_n]}$ is g-continuous on $(a_n, b_n]$, in particular, $(f_n)'_g(x) = (f_n)'_g(b_n)$ for all $x \in (a_n, b_n]$. Therefore, by taking the limit as n tends to infinity, $h(x) = h(b_n)$ for all $x \in (a_n, b_n]$, thus $f'_g(x) = h(x)$ for all $x \in (a_n, b_n]$. □

Remark 4.16. The previous Theorem is in fact a characterization. Indeed, suppose $N_g' \setminus N_g \not\subset D_g$ (the case $D_g' \not\subset D_g$ being similar) and let us see that $\mathcal{BD}_g^1([a,b];\mathbb{F})$ is not a Banach space. There exists $t \in N_g' \setminus (C_g \cup D_g \cup N_g)$, which we may assume to be an accumulation point of N_g from the right in the interior of $[a,b]$ (when $t \in \{a,b\}$ or t is an accumulation point from the left we can argue analogously). In that case there exist a family of connected components of C_g, $\{(c_n,d_n)\}_{n\in\mathbb{N}}$, such that $d_1 > c_1 > \cdots > d_n > c_n > \cdots > t$ and $c_n, d_n \to t$. We may take $g(t) = 0$ without loss of generality and define

$$f_n(x) = \begin{cases} 0, & x < d_n, \\ \frac{1}{2}g(c_{k-1}), & d_k \le x < d_{k-1},\ k = 2,\dots,n, \\ g(b), & x \ge d_1. \end{cases}$$

Notice that whenever $n \le m$ and $x \ge d_n$, $f_n(x) = f_m(x)$. It is clear that $\{f_n\}_{n\in\mathbb{N}} \subset \mathcal{BD}_g^1([a,b];\mathbb{F})$ and $(f_n)_g' = 0$ for every n. Furthermore, by continuity of g at t, $\{f_n\}_{n\in\mathbb{N}}$ is Cauchy in $\mathcal{BD}_g^1([a,b];\mathbb{F})$; however, it cannot possibly converge in that space, since for any potential limit f we would have, for every n,

$$\frac{f(c_{n-1}) - f(t)}{g(c_{n-1}) - g(t)} = \frac{f_n(c_{n-1})}{g(c_{n-1})} = \frac{1}{2}\frac{g(c_{n-1})}{g(c_{n-1})} = \frac{1}{2} > 0 = (f_n)_g'(t).$$

Therefore $\mathcal{BD}_g^1([a,b];\mathbb{F})$ is not a Banach space.

The following example, in which $D_g = \emptyset$ and $N_g' \setminus N_g \not\subset \emptyset$, reinforces the previous remark.

Example 4.17. Let us take as the generator g the Cantor function defined in Example 3.14, and consider the sequence of functions $\{F_n\}_{n=0}^{\infty}$ defined by $F_0(x) = 1$ and, for all $n \ge 0$,

$$F_{n+1} : x \in [0,1] \to F_{n+1}(x) = \begin{cases} \frac{1}{2}F_n(3x), & 0 \le x < \frac{1}{3}, \\ \frac{1}{2}, & \frac{1}{3} \le x < \frac{2}{3}, \\ \frac{1}{2} + \frac{1}{2}F_n(3x-2), & \frac{2}{3} \le x \le 1. \end{cases} \tag{4.4}$$

As proved in [4], the sequence of functions defined by the recurrence formula (4.4) converges uniformly to the Cantor function on $[0,1]$. Additionally, $\{F_n\}_{n=0}^{\infty} \subset \mathcal{BD}_g([0,1];\mathbb{R})$ and it holds that $(F_n)_g'(x) = 0$, for all $x \in [0,1]$ and for all $n \ge 0$.

For instance, in Figure 4.1 we can observe both the function F_3 (in blue) and an approximation of the Cantor function g (in black), which corresponds to the derivator. The aim of this representation is to provide a visual intuition of the convergence of the sequence $\{F_n\}_{n\in\mathbb{N}}$ towards the Cantor function, while also highlighting the fact that each function F_n has zero g-derivative. We note that this function F_3 is g-continuous on N_g^- (in particular, left g-continuous), right g-continuous on N_g^+, and g-continuous on $[0,1] \setminus N_g$. Since the function is piecewise constant and satisfies the g-continuity conditions described above, we have that $(F_3)_g' = 0$.

Taking this into account, $\{F_n\}_{n=0}^{\infty} \subset \mathcal{BD}_g^1([0,1];\mathbb{R})$ is a Cauchy sequence in $\mathcal{BD}_g^1([0,1];\mathbb{R})$. Finally, it is clear that the function $g \in \mathcal{BD}_g^1([0,1];\mathbb{R})$, moreover, $g_g'(x) = 1$ for all $x \in [0,1]$. Therefore, the sequence $\{(F_n)_g'\}_{n=0}^{\infty}$ does not converge uniformly to g_g' on $[0,1]$, and thus the sequence $\{F_n\}_{n=0}^{\infty}$ is not convergent in $\mathcal{BD}_g^1([0,1];\mathbb{R})$.

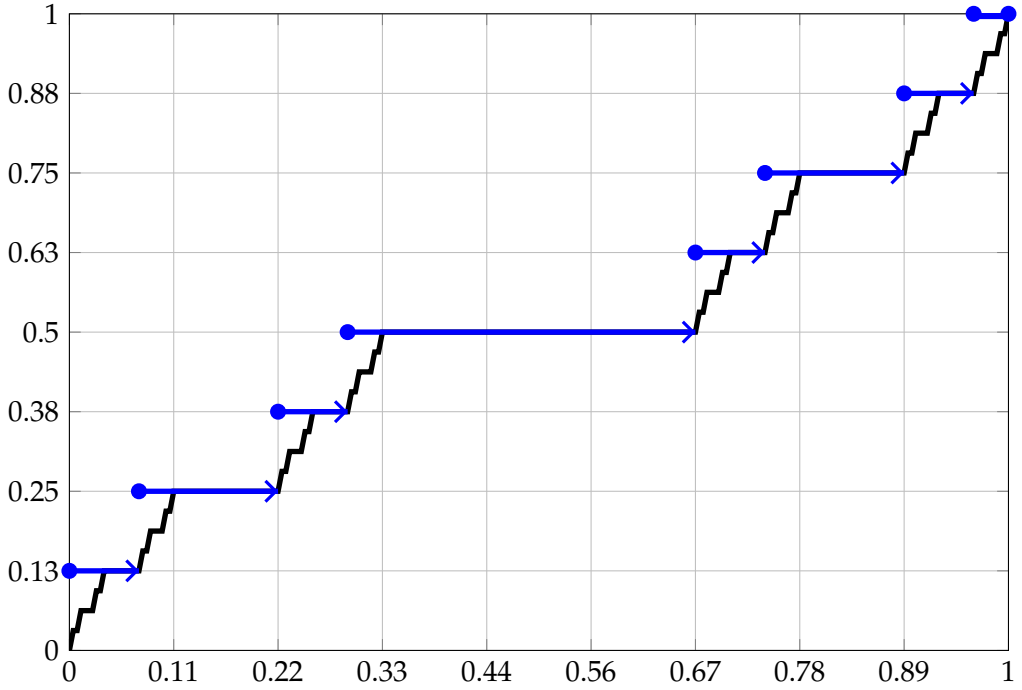

Figure 4.1: Graph of the function F_3 (in blue), along with an approximation of the Cantor function g (in black).

Proposition 4.18. *Assume $N_g' \setminus N_g \subset D_g$ and $D_g' \subset D_g$. Then $\mathcal{BC}_g^k([a,b];\mathbb{F})$ is a closed subspace of $\mathcal{BD}_g^k([a,b];\mathbb{F})$.*

Proof. It is clear that $\mathcal{BC}_g^k([a,b];\mathbb{F}) \subset \mathcal{BD}_g^k([a,b];\mathbb{F})$. Since the norm of $\mathcal{BC}_g^k([a,b];\mathbb{F})$ and that of $\mathcal{BD}_g^k([a,b];\mathbb{F})$ coincide on $\mathcal{BC}_g^k([a,b];\mathbb{F})$ and $\mathcal{BC}_g^k([a,b];\mathbb{F})$ is a Banach space, it is a closed subspace of $\mathcal{BD}_g^k([a,b];\mathbb{F})$. □

4.2 Complete metric space structure

Throughout this section, we will assume that $[a,b] \subset \mathbb{R}$ and $g : \mathbb{R} \to \mathbb{R}$ is a derivator such that $a \notin N_g^-$ and $b \notin N_g^+ \cup D_g \cup C_g$. We will also denote by $\mathcal{BD}_g^k([a,b])$ the space $\mathcal{BD}_g^k([a,b];\mathbb{R})$, for $k \geq 0$.

Cases such as the one shown in Example 4.17 give rise to the following question: can the space $\mathcal{BD}_g^1([a,b];\mathbb{R})$ be given, without any further assumptions, a structure that makes differentiation continuous? This would imply that with such structure, the kernel of the g-derivative is a closed subspace of $\mathcal{BD}_g^1$.

A Banach or even Fréchet space structure would be desirable, but this has proven to be a rather difficult problem; one could point out that if, in Example 4.17, the supremum norm is strengthened, for instance to the total variation norm, the sequence is no longer Cauchy. If the new norm is still not strong enough, as is the case for the total variation, continuity of the g-derivative may fail, and therefore the Banach space structure; if it is too strong, however (e.g. a g-Lipschitz type norm), it may be necessary to exclude functions that we would like to have in the space (such as the ones in Example 4.17, none of which are g-Lipschitz).

In this section we provide a less ambitious (although still interesting) approach. A key tool is introduced in the following definition.

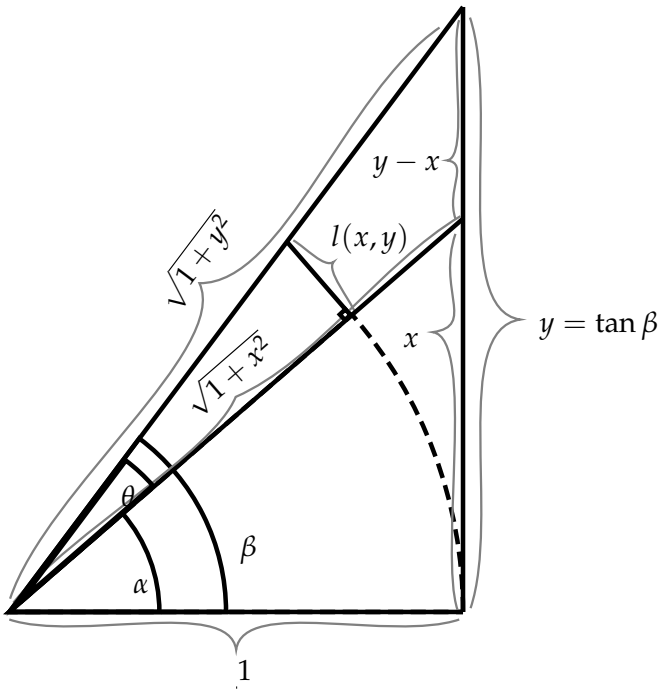

Figure 4.2: Geometric interpretation of the function l in two dimensions (without the cross product). In this figure we are assuming $y > x > 0$. Observe that $\alpha = \tan x$ and $y = \tan\beta$.

Definition 4.19. Given $x, y \in \mathbb{C}$, let

$$l(x,y) := \frac{|x-y|}{\sqrt{1+x^2}\sqrt{1+y^2}},$$

which is the *chordal distance* –see [3, 10].

Remark 4.20. The chordal distance between two complex numbers is the euclidean distance between their stereographic projections on the unit sphere. $(\mathbb{C}, l)$ is a metric space.

Remark 4.21. Another useful way of interpreting l in the case of $x, y \in \mathbb{R}$ is as $l(x,y) = \sin\theta$, where $\theta \in [0,\pi]$ is the angle between the vectors $(1,x)$ and $(1,y)$. To see this it is enough to note that

$$l(x,y) = \frac{\|(1,x,0)\times(1,y,0)\|_2}{\|(1,x,0)\|_2\|(1,y,0)\|_2},$$

and remember that $\|\vec{a}\times\vec{b}\|_2 = \|\vec{a}\|_2\|\vec{b}\|_2\sin\theta$, with $\theta \in [0,\pi]$ the (small) angle between the vectors $\vec{a}$ and $\vec{b}$.

In Figure 4.2 we show a geometric interpretation that does not rely on the cross product.

Definition 4.22. For $f, h \in \mathcal{BD}^1_g([a,b])$, we define

$$\Gamma(f,h) := \sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} l\left(\frac{f(s)-f(t)}{g(s)-g(t)}, \frac{h(s)-h(t)}{g(s)-g(t)}\right),$$

and from this,

$$d(f,h) := \|f-h\|_\infty + \|f'_g - h'_g\|_\infty + \Gamma(f,h).$$

Since l is a distance on $\mathbb{R}$, Γ is symmetric and satisfies the triangle inequality (on $\mathcal{BD}^1_g([a,b])$). Therefore, $(\mathcal{BD}^1_g([a,b]), d)$ is a metric space.

Theorem 4.23. *$(\mathcal{BD}^1_g([a,b]), d)$ is a complete metric space.*

Proof. It is clear that if $\{f_n\}_{n\in\mathbb{N}}$ is a Cauchy sequence in $(\mathcal{BD}^1_g([a,b]), d)$, there exist f and h such that $f_n \to f$ and $(f_n)'_g \to h$ in $(\mathcal{BD}([a,b]), \|\cdot\|_\infty)$. Let us see that $f'_g(t) = h(t)$ for every $t \in [a,b]$.

Let $t \in [a,b]$, and suppose that the g-derivative at that point is obtained by taking the right-hand limit (the remaining cases are analogous). Our goal is producing a bound in the following fashion

$$\left|\frac{f(s)-f(t)}{g(s)-g(t)} - h(t)\right| \leq \left|\frac{f(s)-f(t)}{g(s)-g(t)} - \frac{f_N(s)-f_N(t)}{g(s)-g(t)}\right| + \left|\frac{f_N(s)-f_N(t)}{g(s)-g(t)} - (f_N)'_g(t)\right| + \left|(f_N)'_g(t) - h(t)\right|,$$

where N is big enough and $s \in [t, s_N)$. Recalling its sine interpretation, for the metric l to approach zero one of the following need to happen:

- x and y both tend to infinity (or minus infinity),
- x tends to infinity, and y to minus infinity,
- x and y are close to each other (and do not approach plus or minus infinity).

That said, for a big N and s_N near t, we can bound the value $\frac{f_N(s)-f_N(t)}{g(s)-g(t)}$ (close to $(f_N)'_g(t)$, which is uniformly bounded). Since $\Gamma(f_n, f_N)$ is small if $n \geq N$, the only possibility in $[t, s_N)$ (if indices are chosen accordingly) is that $\left|\frac{f_n(s)-f_n(t)}{g(s)-g(t)} - \frac{f_N(s)-f_N(t)}{g(s)-g(t)}\right|$ is close to zero for $n \geq N$, and consequently also

$$\left|\frac{f(s)-f(t)}{g(s)-g(t)} - \frac{f_N(s)-f_N(t)}{g(s)-g(t)}\right|.$$

Thanks to all this, and the definition of d, $f'_g(t) = h(t)$.

Since $f_n \xrightarrow{\|\cdot\|_\infty} f$ (in particular there is pointwise convergence), the continuity of l guarantees that $f_n \xrightarrow{d} f$. □

Remark 4.24. Observe that the sequence $\{F_n\}_{n\in\mathbb{N}}$ defined in Example 4.17 is not a Cauchy sequence. Indeed, given $n, m \in n \in \mathbb{N}$, $n > m$, there exists a point $t \in [a,b]$ such that F_n has a jump at t whereas F_m is constant on an open interval containing that point. This implies that

$$\lim_{s\to t} \frac{F_n(s)-F_n(t)}{g(s)-g(t)} = \infty, \quad \lim_{s\to t} \frac{F_n(s)-F_n(t)}{g(s)-g(t)} = 0$$

so, taking into account Remark 4.21,

$$\Gamma(F_n, F_m) := \sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} l\left(\frac{F_n(s)-F_n(t)}{g(s)-g(t)}, \frac{F_m(s)-F_m(t)}{g(s)-g(t)}\right) = 1,$$

So $\{F_n\}_{n\in\mathbb{N}}$ cannot be a Cauchy sequence. Observe that this is a general behavior occurring when we have jumps appearing in constancy intervals.

As a consequence of the previous theorem we have the following corollary.

Corollary 4.25. *The differential operator* $\partial_g : (\mathcal{BD}^1_g([a,b],\mathbb{R}),d) \to (\mathcal{BD}([a,b],\mathbb{R}),\|\cdot\|_\infty)$, $\partial_g f = f'_g$ *is continuous.*

This structure has another desirable property.

Theorem 4.26. $(\mathcal{BC}^1_g([a,b]),d)$ *has the same topology* $(\mathcal{BC}^1_g([a,b]),\|\cdot\|_{\mathcal{BC}^1_g})$.

Proof. It is equivalent to check that for any $\{f_n\}_{n\in\mathbb{N}} \cup \{f\} \subset \mathcal{BC}^1_g([a,b])$ it holds that

$$f_n \xrightarrow{d} f \iff f_n \xrightarrow{\mathcal{BC}^1_g} f.$$

By definition of d, the first implication is immediate. For the second one, it is enough to note that for $f_n \xrightarrow{\mathcal{BC}^1_g} f$, we have the following bound for the difference quotients:

$$\begin{aligned}\sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} \left|\frac{f(s)-f(t)}{g(s)-g(t)} - \frac{f_n(s)-f_n(t)}{g(s)-g(t)}\right| &= \sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} \left|\frac{1}{g(s)-g(t)}\int_{[t,s)} (f'_g(u)-(f_n)'_g(u))\mathrm{d}g(u)\right| \\ &\leq \|f'_g-(f_n)'_g\|_\infty.\end{aligned}$$

Hence, $\Gamma(f_n,f)\to 0$, and $d(f_n,f)\to 0$. □

Remark 4.27. Thanks to Theorem 4.26, the inclusion $(\mathcal{BC}^1_g([a,b]),\|\cdot\|_{\mathcal{BC}^1_g}) \hookrightarrow (\mathcal{BD}^1_g([a,b]),d)$ is an embedding.

The next example dispels the possibility of $(\mathcal{BD}^1_g([a,b]),d)$ being a topological vector space.

Example 4.28. Consider the functions

$$g(x)=\begin{cases} x, & x\in[-1,0],\\ x+1, & x\in(0,1].\end{cases}, \qquad f(x)=\begin{cases}0, & x\in[-1,0),\\ 1, & x\in[0,1],\end{cases}$$

and also $h=-f$, $f_k=(1-\frac{1}{k})f$, $h_k=-(1+\frac{1}{k})f$. We will check that $d(f,f_k)\to 0$, $d(h,h_k)\to 0$, but $d(f+h,f_k+h_k)\nrightarrow 0$ (which implies that addition is not a continuous operation for the product topology of $\mathcal{BD}_g([-1,1])\times\mathcal{BD}_g([-1,1])$).

On one hand, $\|f-f_k\|_\infty=\frac{1}{k}\|f\|_\infty$ and $\|f'_g-(f_k)'_g\|_\infty=\|0-0\|_\infty=0$. On the other,

$$\begin{aligned}\Gamma(f,f_k) &:= \sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} l\left(\frac{f(s)-f(t)}{g(s)-g(t)}, \frac{f_k(s)-f_k(t)}{g(s)-g(t)}\right)\\ &= \sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} \frac{\left|-\frac{1}{k}\frac{f(s)-f(t)}{g(s)-g(t)}\right|}{\sqrt{1+\left(\frac{f(s)-f(t)}{g(s)-g(t)}\right)^2}\sqrt{1+\left(1+\frac{1}{k}\right)\left(\frac{f(s)-f(t)}{g(s)-g(t)}\right)^2}}\\ &\leq \frac{1}{k}\sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} \frac{\left|\frac{f(s)-f(t)}{g(s)-g(t)}\right|}{\sqrt{1+\left(\frac{f(s)-f(t)}{g(s)-g(t)}\right)^2}} \leq \frac{1}{k}\to 0,\end{aligned}$$

so we have that $f_k \xrightarrow{d} f$. The same reasoning is valid for h and h_k. Now,

$$\Gamma(f+h, f_k+h_k) = \Gamma\left(0, -\frac{2}{k}f\right) = \sup_{\substack{s,t\in[a,b]\\ g(s)\neq g(t)}} \frac{\left|-\frac{2}{k}\frac{f(s)-f(t)}{g(s)-g(t)}\right|}{\sqrt{1+\left(\frac{2}{k}\frac{f(s)-f(t)}{g(s)-g(t)}\right)^2}}.$$

Since f is not g-Lipschitz (take $t=0$ and $s=-1/n$) and $\lim_{x\to\infty}\frac{|x|}{\sqrt{1+x^2}}=1$, we have that $\Gamma(f+h, f_k+h_k)=1$ for each k. Consequently, $f_k+h_k \overset{d}{\nrightarrow} f+h$.

Remark 4.29. In the previous example, any f with zero g-derivative that is not g-Lipschitz could have been chosen.

4.3 Relation of $\mathcal{BD}$ spaces to other spaces

In this section, we will assume that $[a,b]\subset\mathbb{R}$ and $g:\mathbb{R}\to\mathbb{R}$ is a derivator such that $a\notin N_g^-$ and $b\notin N_g^+\cup D_g\cup C_g$. Let us examine the relationship between the space $\mathcal{BC}_g^k([a,b];\mathbb{F})$ and other more regular spaces.

We now define the Stieltjes–Sobolev spaces—see [8, Definition 5.1] and [15, Definition 3.2].

Definition 4.30. Let $p\in[1,\infty]$. We define the *Stieltjes–Sobolev spaces* as follows. $W_g^{0,1}([a,b),\mathbb{F}):=L_g^1([a,b),\mathbb{F})$, and, for $n\in\mathbb{N}$, $W_g^{n,1}([a,b),\mathbb{F}):=$

$$\left\{u\in L_g^1([a,b),\mathbb{F}) : \exists\,\widetilde{u}\in W_g^{n-1,1}([a,b),\mathbb{F}) \text{ s.t. } u(y)-u(x)=\int_x^y \widetilde{u}\,\mathrm{d}\,\mu_g,\ x,y\in[a,b)\right\}.$$

Observe that, due to Theorem 2.10, $W_g^{1,1}([a,b),\mathbb{F})=\mathcal{AC}([a,b),\mathbb{F})$.

Lemma 4.31. *Let $f\in\mathcal{BD}_g([a,b];\mathbb{F})$ be such that $f(t)=0$ μ_g-a.e. Then $f(t)=0$ for every $t\in[a,b]$.*

Proof. Let $A=\{t\in[a,b] : f(t)=0\}$. Since $f(t)=0$ μ_g-a.e., we have that $\mu_g(A)=\mu_g([a,b])$ and $\mu_g(X)=\mu_g(X\cap A)$ for any μ_g-measurable set $X\subset[a,b]$. Since $\mu_g(\{t\})>0$ for every $t\in D_g$, we conclude that $D_g\cap[a,b]\subset A$. Given $t\in(a,b)$, if there exists $\delta\in\mathbb{R}^+$, $\delta<\min\{t-a,b-t\}$, such that $[t-\delta,t+\delta)\cap A=\emptyset$, then

$$g(t+\delta)-g(t-\delta)=\mu_g([t-\delta,t+\delta))=\mu_g([t-\delta,t+\delta)\cap A)=0,$$

so $t\in C_g$. This implies that $A\cap(a,b)$ is dense in $(a,b)\backslash C_g$. Since $f\in\mathcal{BD}_g^0([a,b];\mathbb{F})$, f is g-continuous on $(a,b)\backslash(C_g\cup N_g\cup D_g)$ and, thus, continuous in that set. Given that $f|_A=0$ and $A\cap[(a,b)\backslash(C_g\cup N_g\cup D_g)]$ is dense in $(a,b)\backslash(C_g\cup N_g\cup D_g)$, we conclude that $f=0$ on $(a,b)\backslash(C_g\cup N_g\cup D_g)$.

We have proved that $D_g\cap[a,b]$, $(a,b)\backslash(C_g\cup N_g)\subset A$. It is left to see what happens on $N_g^+\backslash D_g$ and on $N_g^-\backslash D_g$. Given that $a\notin N_g^-$ and $b\notin N_g^+\cup D_g\cup C_g$, we do not have to consider a or b.

If $t\in N_g^+\backslash D_g$, since $t<b$, if there exists $\delta\in\mathbb{R}^+$, $\delta<\min\{b-t\}$, such that $[t,t+\delta)\cap A=\emptyset$, then

$$g(t+\delta)-g(t)=\mu_g([t,t+\delta))=\mu_g([t,t+\delta)\cap A=0,$$

so $t\notin N_g^+$, which is a contradiction. Therefore, we conclude that t is an accumulation point of $A\cap[a,b]$ from the right. Since f is right g-continuous and, thus, continuous from the right at $t\in N_g^+$, $f(t)=0$.

The argument is analogous for the case $t\in N_g^-\backslash D_g$, And we conclude that $f(t)=0$ for every $t\in[a,b]$. □

Remark 4.32. The condition $f \in \mathcal{BD}_g^1([a,b];\mathbb{F})$ in Lemma 4.31 is necessary as, in general, a function $f : \mathbb{R} \to \mathbb{R}$ can have g-derivative everywhere with $f_g' = 0$ μ_g-a.e., but $f_g' \neq 0$.

Indeed, let $g : \mathbb{R} \to \mathbb{R}$ be defined as

$$g(t) = t + \sum_{\substack{0<s<t \\ \frac{1}{s}\in\mathbb{Z}}} 2^{-s} + \sum_{\substack{t\leqslant s<0 \\ \frac{1}{s}\in\mathbb{Z}}} 2^{-s}.$$

Observe that $C_g = 0$, $D_g = \{\frac{1}{n}\}_{n\in\mathbb{Z}}$ and $\Delta g\left(\frac{1}{n}\right) = 2^{-|n|}$ for $n \in \mathbb{Z}$.

Define

$$f(t) := \begin{cases} \left\lfloor \frac{1}{x} \right\rfloor^{-1}, & t \in [-1,1]\backslash\{0\}, \\ 0 & t = 0. \end{cases}$$

f is right continuous. Furthermore, it is clear that if $t \in [-1,1]\backslash\{0\}$, $f_g' = 0$, so $f_g' = 0$ μ_g-a.e.

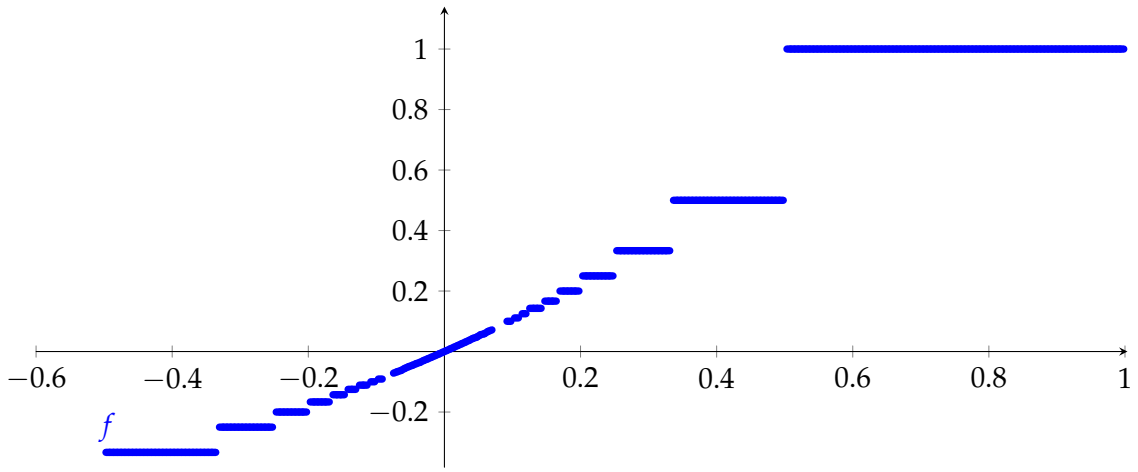

Figure 4.3: Representation of the function f.

—see Figure 4.3. Taking into account that, for $t \in [-1,1)\backslash\{0\}$,

$$t \leqslant \left\lfloor \frac{1}{t} \right\rfloor^{-1} < \frac{t}{1-t},$$

for $t \in (0,1)$,

$$\frac{f(t)-f(0)}{g(t)-g(0)} - 1 \leqslant \frac{\frac{t}{1-t}}{t + \sum\limits_{\substack{0<s<t \\ \frac{1}{s}\in\mathbb{Z}}} 2^{-s}} - 1 \leqslant \frac{\frac{t}{1-t}}{t} - 1 = \frac{1}{1-t} - 1 = \frac{t}{1-t},$$

and

$$\frac{f(t)-f(0)}{g(t)-g(0)} - 1 \geqslant \frac{t}{t + \sum\limits_{\substack{0<s<t \\ \frac{1}{s}\in\mathbb{Z}}} 2^{-s}} - 1 = \frac{t}{t} - 1 = 0,$$

whereas, for $t \in (-1/2, 0)$, given that $f(t) - f(0)$ and $g(t) - g(0)$ are negative,

$$\frac{f(t)-f(0)}{g(t)-g(0)} - 1 \leqslant \frac{t}{t + \sum_{\substack{t \leqslant s < 0 \\ \frac{1}{s} \in \mathbb{Z}}} 2^{-s} - 1} - 1 = \frac{-t}{1 - t - \sum_{\substack{t \leqslant s < 0 \\ \frac{1}{s} \in \mathbb{Z}}} 2^{-s}} - 1 \leqslant \frac{-t}{1-t},$$

and

$$\begin{aligned}\frac{f(t)-f(0)}{g(t)-g(0)} - 1 &\geqslant \frac{\frac{t}{1-t}}{t + \sum_{\substack{t \leqslant s < 0 \\ \frac{1}{s} \in \mathbb{Z}}} 2^{-s} - 1} - 1 = \frac{-\frac{t}{1-t}}{1 - t - \sum_{\substack{t \leqslant s < 0 \\ \frac{1}{s} \in \mathbb{Z}}} 2^{-s}} - 1 \geqslant \frac{\frac{-t}{1-t}}{-t} - 1 = \frac{t}{t} - 1 \\ &= \frac{t}{1-t}.\end{aligned}$$

In any case, we have that

$$f_g'(0) = \lim_{t \to 0} \frac{f(t)-f(0)}{g(t)-g(0)} = 1.$$

Thus, f is g-differentiable, $f_g' = 0$ μ_g-a.e. and

$$f_g'(x) := \begin{cases} 0, & x \neq 0, \\ 1, & x = 0. \end{cases}$$

Theorem 4.33. *Let $n \in \mathbb{N}$. $f \in \mathcal{BD}_g^n([a,b],\mathbb{F})$ if and only if $f = h + \sum_{k=1}^n \rho_k$, where $h \in W_g^{n,1}([a,b],\mathbb{F}) \cap \mathcal{BD}_g^n([a,b];\mathbb{F})$ and $\rho_k \in W^{k-1,1}([a,b];\mathbb{F}) \cap \mathcal{BD}_g^n([a,b],\mathbb{F})$ is such that $\rho_g^{(k)} = 0$, for all $k = 1, \ldots, n$.*

Proof. Given that $W_g^{n,1}([a,b],\mathbb{F}) \cap \mathcal{BD}_g^n([a,b];\mathbb{F}) \subset \mathcal{BD}_g^n([a,b];\mathbb{F})$, the sufficient condition is immediate. Let us now examine the necessary condition.

For $n = 1$, given an element $f \in \mathcal{BD}_g^1([a,b];\mathbb{F})$, we have that $f_g' \in \mathcal{BD}([a,b];\mathbb{F}) \subset \mathcal{L}_g^1([a,b];\mathbb{F})$. We can then consider $h(t) := \int_{[a,t)} f_g' \,\mathrm{d}\,\mu_g$, which is clearly $h \in W^{1,1}([a,b];\mathbb{F}) \cap \mathcal{BD}_g^1([a,b];\mathbb{F})$. Moreover, thanks to Lemma 4.14, we have $h_g' = (f_g')^* = f_g' \in \mathcal{BD}_g([a,b];\mathbb{F})$. Now, let us define $\rho_1 := f - h \in \mathcal{BD}_g^1([a,b],\mathbb{F})$. By Lemmas 4.14 and 4.31, we obtain $\rho_g' = f_g' - h_g' = 0$.

Now, let $n \in \mathbb{N}$, $n \geq 2$, and assume the result holds for $n-1$. Since $f \in \mathcal{BD}_g^n([a,b];\mathbb{F})$, we have that $f_g' \in \mathcal{BD}_g^{n-1}([a,b];\mathbb{F})$. Therefore, there exist elements $\widetilde{h} \in W^{n-1,1}([a,b];\mathbb{F}) \cap \mathcal{BD}_g^{n-1}([a,b];\mathbb{F})$ and $\widetilde{\rho}_k \in W^{k-1,1}([a,b];\mathbb{F}) \cap \mathcal{BD}_g^{n-1}([a,b];\mathbb{F})$, with $(\widetilde{\rho}_k)_g^{k)} = 0$ for all $k = 1, \ldots, n-1$, such that $f_g' = \widetilde{h} + \sum_{k=1}^{n-1} \widetilde{\rho}_k$. Define:

$$\begin{aligned} h(t) &:= \int_{[a,t)} \widetilde{h} \,\mathrm{d}\,\mu_g, \ t \in [a,b], \\ \rho_k(t) &:= \int_{[a,t)} \widetilde{\rho}_{k-1} \,\mathrm{d}\,\mu_g, \ t \in [a,b], \ k = 2, \ldots, n, \\ \rho_1 &:= f - h - \sum_{k=2}^n \rho_k. \end{aligned}$$

It follows that $h \in W^{n,1}([a,b];\mathbb{F}) \cap \mathcal{BD}_g^n([a,b];\mathbb{F})$, $\rho_k \in W^{k-1,1}([a,b];\mathbb{F}) \cap \mathcal{BD}_g^n([a,b];\mathbb{F})$ for $k = 1, \ldots, n$. Furthermore, thanks to Lemmas 4.14 and 4.31 and [6, Proposition 4.1 and Remark 4.3]

(that if φ is g-differentiable, φ^* is g-differentiable and the derivatives coincide), we obtain:

$$(\rho_k)_g^{k)} = (\widetilde{\rho}_{k-1}^*)_g^{k-1)} = (\widetilde{\rho}_{k-1})^{k-1)} = 0, \quad \forall k = 2, \dots, n,$$
$$(\rho_1)_g' = f_g' - h_g' - \sum_{k=2}^{n} (\rho_k)_g' = f_g' - \widetilde{h}^* - \sum_{k=1}^{n-1} (\widetilde{\rho}_k^*)_g = f_g' - (f_g')^* = 0. \qquad \square$$

Remark 4.34. The decomposition is unique if we impose $\rho_k(a) = 0$ for all $k = 1, \dots, n$.

Theorem 4.35. *Let $f : [a,b] \to \mathbb{F}$ a be such that $f_g'/f^* \in \mathcal{L}_g^1([a,b);\mathbb{F})$ is g-regressive. Then $f \in \mathcal{BD}_g^1([a,b],\mathbb{F})$ if and only if $f = \rho \cdot u$, where $u \in W_g^{1,1}([a,b],\mathbb{F}) \cap \mathcal{BD}_g^1([a,b];\mathbb{F})$ and $\rho \in \mathcal{BD}_g^1([a,b],\mathbb{F})$ is such that $\rho_g' = 0$.*

Furthermore, in that case, $u \in W_g^{1,1}([a,b],\mathbb{F}) \cap \mathcal{BD}_g^1([a,b];\mathbb{F})$ is a solution of equation

$$u_g'(t) = \frac{f_g'(t)}{f(t^*)} u(t), \quad \forall t \in [a,b]. \tag{4.5}$$

Proof. Since $W_g^{1,1}([a,b],\mathbb{F}) \cap \mathcal{BD}_g^1([a,b];\mathbb{F}) \subset \mathcal{BD}_g^1([a,b];\mathbb{F})$ and the product of two elements of $\mathcal{BD}_g^1([a,b];\mathbb{F})$ is in $\mathcal{BD}_g^1([a,b];\mathbb{F})$ (see Lemma 4.6), the sufficient condition is immediate. Let us now examine the necessary condition.

Let us consider the following initial value problem:

$$\begin{cases} u_g'(t) = \dfrac{f_g'(t)}{f(t^*)} u(t), \ g\text{-a.a. } t \in [a,b), \\ u(a) = 1. \end{cases}$$

Thanks to [5, Theorem 4.2 and Remark 4.4], we know that the above problem admits a unique solution in the space $\mathcal{AC}_g([a,b];\mathbb{F})$, which is also nonzero in $[a,b]$. Now, since $\frac{f_g'(t)}{f(t^*)} u(t) \in \mathcal{BD}_g([a,b];\mathbb{F})$, thanks to Lemma 4.14 and the fact that $(f_g')^* = f_g'$ and $u = u^*$ (since u is g-continuous), we can ensure that (4.5) holds at every point of the interval $[a,b]$. Consequently, we have $u \in \mathcal{AC}_g([a,b];\mathbb{F}) \cap \mathcal{BD}_g^1([a,b];\mathbb{F})$.

Now, let us define $\rho = f/u \in \mathcal{BD}_g^1([a,b];\mathbb{F})$. Clearly, we have $f = \rho \cdot u$. Moreover, given any element $t \in [a,b]$, we obtain:

$$\begin{aligned} \rho_g'(t) &= \left(\frac{f}{u}\right)_g'(t) \\ &= \frac{f_g'(t)u(t) - u_g'(t)f(t^*)}{u(t^*)\left(u(t^*) + u_g'(t)\,\Delta g(t^*)\right)} = 0, \end{aligned}$$

since (4.5) holds for all elements in the interval $[a,b]$. $\square$

5 Applications to Stieltjes differential equations

Although we have so far considered an arbitrary interval $[a,b]$, in this section, we will focus on the interval $[0,T]$ as it is a more natural choice for the study of initial value problems. In any case, the generalization to generic intervals of the form $[a,b]$ is possible. Thus, throughout this section we will assume that $[0,T] \subset \mathbb{R}$ and $g : \mathbb{R} \to \mathbb{R}$ is a derivator such that $0 \notin N_g^-$ and $T \notin N_g^+ \cup D_g \cup C_g$.

Definition 5.1 (Kernel of the operator ∂_g)**.** We define $\ker(\partial_g) \subset \mathcal{BD}^1_g([0,T];\mathbb{F})$ as the kernel of the following operator:

$$\begin{aligned} \partial_g : \mathcal{BD}^1_g([0,T];\mathbb{F}) &\to \mathcal{BD}_g([0,T];\mathbb{F}) \\ h &\to \partial_g(h) = h'_g. \end{aligned}$$

In the following proposition, we will show that $\ker(\partial_g)$ is a non-empty set.

Proposition 5.2. *Assume $D'_g \subset D_g$ and let $h : [0,T] \to \mathbb{F}$ be bounded, right continuous at $[0,T] \cap D_g$ and constant on each connected component of $[0,T]\backslash D_g$. Then $h \in \ker(\partial_g)$.*

Proof. Given an element $t \in D_g$, we have that $h(t^+) = h(t)$, so $h'_g(t) = 0$. Now, given $t \in [0,T]\backslash D_g$, since D_g is closed, there exists $\delta > 0$ such that h is constant at $(t-\delta, t+\delta)$, therefore $h'_g(t) = 0$. □

Let us now examine the relationship between $\ker(\partial_g) \subset \mathcal{BD}^1_g([0,T];\mathbb{F})$ and the solutions of the homogeneous Stieltjes linear differential equation in the space $\mathcal{BD}^1_g([0,T];\mathbb{F})$.

Proposition 5.3. *Let $\beta \in \mathcal{BD}_g([0,T];\mathbb{F})$ be g-regressive. The solutions in $\mathcal{BD}^1_g([0,T];\mathbb{F})$ of problem*

$$\begin{cases} v'_g(t) - \beta(t)\, v(t) = 0, \ t \in [0,T), \\ v(0) = 1, \end{cases} \tag{5.1}$$

are the functions of the form $h \cdot v$ where $h \in \ker(\partial_g)$ with $h(0) = 1$ and $v \in \mathcal{BD}^1_g([0,T];\mathbb{F})$ is the unique g-absolutely continuous solution of problem (5.1).

Proof. We start by observing that the uniqueness of the g-absolutely continuous solution v of problem (5.1) was proven in [5, Theorem 4.2 and Remark 4.4]. Moreover, since v is g-absolutely continuous, it is bounded and g-continuous by [9, Proposition 5.5] and, therefore, by definition of $\mathcal{BD}_g([0,T];\mathbb{F})$, we have that $v \in \mathcal{BD}_g([0,T];\mathbb{F})$. Given that $\beta \in \mathcal{BD}_g([0,T];\mathbb{F})$, we have, by Lemma 4.6, that $\beta \cdot v \in \mathcal{BD}_g([0,T];\mathbb{F})$. Furthermore, since $v'_g = \beta \cdot v \ \mu_g$-a.e. and v is g-absolutely continuous, by Theorem 2.10 we have that $v(t) = v(0) + \int_{[0,t)} \beta \cdot v \, \mathrm{d}\, \mu_g$ for every $t \in [0,T]$. Thanks to Lemma 4.14, we have that $v'_g = \beta^* v \in \mathcal{BD}_g([0,T];\mathbb{F})$ and $v'_g(t) - \beta(t^*)\, v(t) = 0$ for all $t \in [0,T)$. Hence, $v \in \mathcal{AC}_g([0,T];\mathbb{F}) \cap \mathcal{BD}^1_g([0,T];\mathbb{F})$.

We now show that a function of the form $\widetilde{v} = h\, v$ is a solution of problem (5.1) in $\mathcal{BD}^1_g([0,T];\mathbb{F})$. Indeed, observe that, thanks to Lemma 4.6 and the fact that $h \in \mathcal{BD}^1_g([0,T];\mathbb{F})$, we have that $\widetilde{v} = h\, v \in \mathcal{BD}^1_g([0,T];\mathbb{F})$. Moreover, $\widetilde{v}(0) = h(0)\, v(0) = 1$.

Furthermore, for a given element $t \in [0,T)\backslash C_g$, $t^* = t$. If t is such that $v'_g(t) = \beta(t)\, v(t)$, it follows, thanks to Lemma 3.21, that $\widetilde{v}'_g(t) = h(t)\, v'_g(t) = h(t)\, \beta(t)\, v(t) = \beta(t)\, \widetilde{v}(t)$. We conclude that $\widetilde{v}'_g(t) = \beta(t)\, \widetilde{v}(t)$, g-a.e. $t \in [0,T)$ and, thus, $\widetilde{v}$ is a solution of problem (5.1) in $\mathcal{BD}^1_g([0,T];\mathbb{F})$.

Finally we show that if $w \in \mathcal{BD}^1_g([0,T];\mathbb{F})$ is a solution of problem (5.1), it has to be of the form $h \cdot v$ where $h \in \ker(\partial_g)$ with $h(0) = 1$. Indeed, given that $\beta = w'/w^* \in \mathcal{L}^1_g([0,T);\mathbb{F})$ is g-regressive, we can apply the construction in Theorem 4.35 to conclude that $w = h \cdot u$, for some $h \in \mathcal{BD}^1_g([0,T],\mathbb{F})$ such that $h'_g = 0$ and $u \in \mathcal{AC}_g([0,T];\mathbb{F}) \cap \mathcal{BC}^1_g([0,T];\mathbb{F})$ satisfying

$$\begin{cases} u'_g(t) = \dfrac{w'(t)}{w(t^*)}\, u(t) = \beta(t)\, u(t), \forall t \in [0,T], \\ u(0) = 1. \end{cases}$$

Hence, u is a g-absolutely continuous function that is a solution of problem (5.1). Since the g-absolutely continuous solution is unique, $u = v$, so $w = h \cdot v$, as we wanted to show. □

Proposition 5.4. *Let $\beta \in \mathcal{BD}_g([0,T];\mathbb{F})$ be g-regressive. Given $v \in \mathcal{AC}_g([0,T];\mathbb{F}) \cap \mathcal{BC}^1_g([0,T];\mathbb{F})$ the solution of (5.1) we have that a function $h \in \mathcal{BD}^1_g([0,T];\mathbb{F})$, with $h(0) = 1$, belongs to $\ker(\partial_g)$ if and only if $\widetilde{v} = h\,v \in \mathcal{BD}^1_g([0,T];\mathbb{F})$ is a solution of problem (5.1) and it satisfies that $\widetilde{v}'_g(t) - \beta(t)\,\widetilde{v}(t) = 0,\ \forall t \in [0,T] \setminus C_g$.*

Proof. Before starting the proof, it is worth remembering that the unique solution v of (5.1) in the space $\mathcal{AC}_g([0,T];\mathbb{F}) \cap \mathcal{BD}^1_g([0,T];\mathbb{F})$ is such that $v(t) \neq 0$, for all $t \in [0,T]$ —see [5, Theorem 4.2 and Remark 4.4]. Moreover, $v'_g(t) - \beta(t)\,v(t) = 0$, for all $t \in [0,T] \setminus C_g$.

Now, on the one hand, given an element $h \in \ker(\partial_g)$, by Proposition 5.3, it follows that $\widetilde{v} = h\,v \in \mathcal{BD}^1_g([0,T];\mathbb{F})$ is also a solution of (5.1). Moreover, $\widetilde{v}'_g(t) = h(t)\,v'_g(t) = h(t)\,\beta(t)\,v(t) = \beta(t)\,\widetilde{v}(t)$, for all $t \in [0,T] \setminus C_g$.

On the other hand, assume that $\widetilde{v} \in \mathcal{BD}^1_g([0,T];\mathbb{F})$ is a solution of (5.1) which also satisfies $\widetilde{v}'_g(t) - \beta(t)\,\widetilde{v}(t) = 0$, for all $t \in [0,T] \setminus C_g$. We have that:

$$\begin{aligned}\beta(t)\,\widetilde{v}(t) &= \widetilde{v}'_g(t)\\ &= (h\,v)'_g(t)\\ &= h'_g(t)\,v(t) + h(t)\,v'_g(t) + h'_g(t)\,v'_g(t)\,\Delta g(t),\ \forall t \in [0,T] \setminus C_g.\end{aligned}$$

Taking into account that $\widetilde{v} = hv$ and that $v'_g = \beta v$,

$$\beta(t)\,h(t)\,v(t) = h'_g(t)\,v(t) + \beta(t)\,h(t)\,v(t) + \beta(t)\,h'_g(t)\,v(t)\,\Delta g(t),\ \forall t \in [0,T] \setminus C_g.$$

Therefore,

$$h'_g(t)\,v(t)\,(1 + \beta(t)\,\Delta g(t)) = 0,\ \forall t \in [0,T] \setminus C_g.$$

Since $1 + \beta(t)\,\Delta g(t) \neq 0$ and $v(t) \neq 0$ for all $t \in [0,T]$, we conclude that $h'_g(t) = 0$ for all $t \in [0,T] \setminus C_g$, and thus, $h'_g(t) = 0$ for all $t \in [0,T]$. □

Remark 5.5. From Proposition 5.4 it follows that, given an element $\beta \in \mathcal{BD}_g([0,T];\mathbb{F})$ such that $1 + \beta(t)\Delta g(t) \neq 0$ for all $t \in [0,T] \cap D_g$, the dimension of the space of solutions in $\mathcal{BD}^1_g([0,T];\mathbb{F})$ of problem (5.1) is equal to the dimension of $\ker(\partial_g)$.

Example 5.6. Let be $\beta \in \mathcal{BD}_g([0,T];\mathbb{F})$ be g-regressive. Let $v = \exp_g(\beta,\cdot)$, see Definition 2.11.

Now, let us define the function $h : t \in [0,T] \to h(t) \in \mathbb{F}$, where

$$\begin{aligned}h(t) &= \exp\left(-\int_{[0,t]\cap D_g} \widetilde{\beta}(s)\ \mathrm{d}\,\mu_g(s)\right)\\ &= \exp\left(-\sum_{s\in[0,t]\cap D_g} \ln\left(1+\beta(s)\Delta g(s)\right)\right)\\ &= \left[\prod_{s\in[0,t]\cap D_g} (1+\beta(s)\,\Delta g(s))\right]^{-1}.\end{aligned}$$

The above function is well-defined since $\beta \in \mathcal{L}^1_g([0,T);\mathbb{F})$ and $T \notin D_g$. Furthermore, h is bounded, right-continuous in $[0,T] \cap D_g$, constant in the connected components of $[0,T] \setminus D_g$,

and satisfies $h(0) = 1$. Therefore, thanks to Proposition 5.2, $h \in \ker(\partial_g)$, and, by Proposition 5.3, the function $\widetilde{v} : t \in [0,T] \to \mathbb{F}$, defined by

$$\begin{aligned}\widetilde{v}(t) &= h(t)\, v(t)\\ &= \frac{\left[\prod_{s\in[0,t)\cap D_g}(1+\beta(s)\,\Delta g(s))\right]}{\left[\prod_{s\in[0,t]\cap D_g}(1+\beta(s)\,\Delta g(s))\right]}\exp\left(\int_{[0,t)\setminus D_g}\beta(s)\ \mathrm{d}\,\mu_g(s)\right)\\ &= \frac{1}{(1+\beta(t)\,\Delta g(t))}\exp\left(\int_{[0,t)\setminus D_g}\beta(s)\ \mathrm{d}\,\mu_g(s)\right)\end{aligned}$$

is another solution in the space $\mathcal{BD}^1_g([0,T];\mathbb{F})$ of the initial value problem (5.1).

For example, let $T > 2$ and consider the following generator:

$$g : t \in \mathbb{R} \to g(t) := \begin{cases} t, & t \le 1,\\ t+\delta_1, & t \in (1,2],\\ t+\delta_1+\delta_2, & t > 2,\end{cases}$$

where $\delta_k > 0$, for $k = 1,2$. In this case, $D_g = \{1,2\}$ and $N_g = \emptyset$, thus it is clear that $N_g' \setminus N_g \subset D_g$ and $D_g' \subset D_g$. Now, let $\beta : t \in [0,T] \to \beta(t) = 1$. It follows that β is g-regressive on $[0,T]$ for all $\delta_k > 0$, with $k = 1,2$. Therefore,

$$\begin{aligned}v(t) &= \exp_g(\beta,t)\\ &= \left[\prod_{s\in[0,t)\cap D_g}(1+\Delta g(s))\right]\exp\left(\mu_g([0,t)\setminus D_g\right) = \begin{cases}\exp(t), & t \le 1,\\ (1+\delta_1)\exp(t), & t \in (1,2],\\ (1+\delta_1)(1+\delta_2)\exp(t), & t > 2\end{cases}\end{aligned}$$

and

$$\begin{aligned}\widetilde{v}(t) &= h(t)\, v(t)\\ &= \frac{\prod_{s\in[0,t)\cap D_g}(1+\Delta g(s))}{\prod_{s\in[0,t]\cap D_g}(1+\Delta g(s))}\exp\left(\mu_g([0,t)\setminus D_g\right) = \begin{cases}\exp(t), & t < 1,\\ (1+\delta_1)^{-1}\exp(t), & t = 1,\\ \exp(t), & t \in (1,2),\\ (1+\delta_2)^{-1}\exp(t), & t = 2,\\ \exp(t), & t > 2.\end{cases}\end{aligned}$$

are two solutions in the space $\mathcal{BD}^1_g([0,T];\mathbb{R})$ of the initial value problem (5.1). Observe that both solutions converge to $\exp(t)$ as δ_1 and δ_2 tends to zero.

In Figure 5.1, we can observe the behavior of $v(t) = \exp_g(\beta,t)$, while in Figure 5.2, we see that of $\widetilde{v}(t) = h(t)\, v(t)$. Observe that, in both cases, the solutions exhibit discontinuities at the points of D_g. However, while v is left-continuous, $\widetilde{v}$ is not.

The significance of this example is crucial in the sense that the g-exponential function associated to β under the given conditions is unique in the space $\mathcal{AC}_g([0,T];\mathbb{F})$, while if we consider the space $\mathcal{BD}^1_g([0,T];\mathbb{F})$, the g-exponential function is not uniquely determined.

We end this work with the following corollaries of Theorem 5.3.

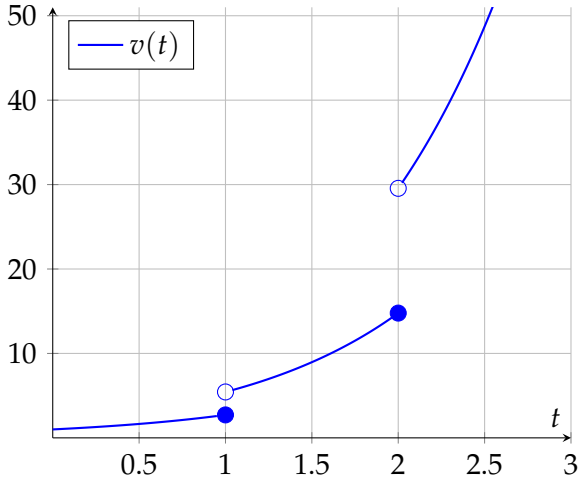

Figure 5.1: $v(t) = \exp_g(\beta, t)$.

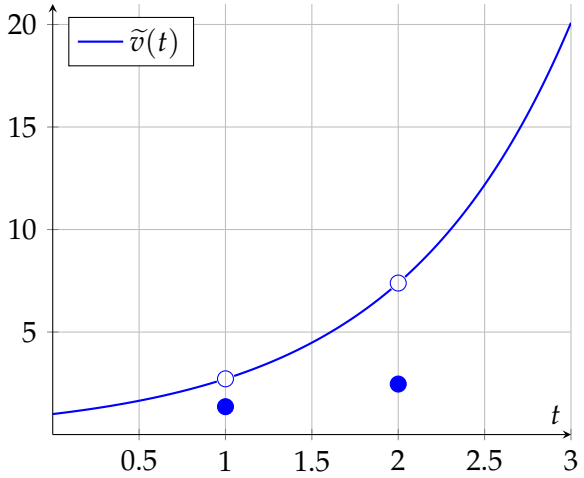

Figure 5.2: $\widetilde{v}(t) = h(t)\, v(t)$.

Corollary 5.7. *Let $n \in \mathbb{N}$, $\beta \in \mathcal{BD}_g^n([0,T];\mathbb{F})$ g-regressive. The solutions in $\mathcal{BD}_g^{n+1}([0,T];\mathbb{F})$ of problem*

$$\begin{cases} v_g'(t) - \beta(t)\, v(t) = 0, \ t \in [0,T), \\ v(0) = 1, \end{cases} \tag{5.2}$$

are the functions of the form $h \cdot v$ where $h \in \ker(\partial_g)$ with $h(0) = 1$ and $v \in \mathcal{BD}_g^{n+1}([0,T];\mathbb{F})$ is the unique g-absolutely continuous solution of problem (5.2).

Proof. We will assume $n \geqslant 2$, as the case $n = 1$ is covered by Proposition 5.3. We start by observing that $v \in \mathcal{BD}_g^n([0,T];\mathbb{F})$, where v is the unique g-absolutely continuous solution of problem (5.2). Indeed, as we reasoned in Proposition 5.3, $v \in \mathcal{BD}_g^1([0,T];\mathbb{F})$ and, given that $\beta \in \mathcal{BD}_g^n([0,T];\mathbb{F})$, we have, by Lemma 4.6, that $\beta \cdot v \in \mathcal{BD}_g^1([0,T];\mathbb{F})$. Furthermore, since $v_g' = \beta \cdot v$ μ_g-a.e. and v is g-absolutely continuous, by Theorem 2.10 we have that $v(t) = v(0) + \int_{[0,t)} \beta\, v \,\mathrm{d}\,\mu_g$ for every $t \in [0,T]$. Thanks to Lemma 4.14, we have that $v_g' = \beta\, v \in \mathcal{BD}_g^2([0,T];\mathbb{F})$ and $v_g'(t) - \beta(t^*)\, v(t) = 0$ for all $t \in [0,T]$. Hence, $v \in \mathcal{BD}_g^2([0,T];\mathbb{F})$. Repeating this argument inductively, we conclude that $v \in \mathcal{BD}_g^{n+1}([0,T];\mathbb{F})$.

Now take $\widetilde{v} = h \cdot v$ where $h \in \ker(\partial_g)$ with $h(0) = 1$ and we will show that $\widetilde{v}$ is a solution in $\mathcal{BD}_g^n([0,T];\mathbb{F})$ of problem (5.2). We already know from Proposition 5.3 that $\widetilde{v}$ is a solution in $\mathcal{BD}_g^1([0,T];\mathbb{F})$ of problem (5.2), so it is enough to show that $\widetilde{v} \in \mathcal{BD}_g^n([0,T];\mathbb{F})$, but this is evident given that, since $h_g' = 0$, and $v \in \mathcal{BD}_g^n([0,T];\mathbb{F})$, we have that $\widetilde{v}_g^{k)} = hv^{k)}$ for $k = 1, \dots, n$ and, thus, $\widetilde{v} \in \mathcal{BD}_g^n([0,T];\mathbb{F})$.

On the other hand, if $u \in \mathcal{BD}_g^n([0,T];\mathbb{F})$ is a solution of problem (5.2), by Proposition 5.3, $u = h\,v$ for some $h \in \ker \partial_g$ with $h(0) = 1$. □

The next corollary is proven following the same steps as in Proposition 5.3 and Corollary 5.7.

Corollary 5.8. *Let $n \in \mathbb{N}$, $\beta, f \in \mathcal{BD}_g^n([0,T];\mathbb{F})$ g-regressive. The solutions in $\mathcal{BD}_g^{n+1}([0,T];\mathbb{F})$ of problem*

$$\begin{cases} v_g'(t) - \beta(t)\, v(t) = f(t),\ t \in [0,T), \\ v(0) = 1, \end{cases} \tag{5.3}$$

are the functions of the form $h \cdot v$ where $h \in \ker(\partial_g)$ with $h(0) = 1$ and $v \in \mathcal{BD}_g^{n+1}([0,T];\mathbb{F})$ is the unique g-absolutely continuous solution of problem (5.3).

Abstract. We present a detailed study of a scalar differential equation with threshold state-dependent delayed feedback. This equation arises as a simplification of a gene regulatory model. There are two monotone nonlinearities in the model: one describes the dependence of delay on state, and the other is the feedback nonlinearity. Both increasing and decreasing nonlinearities are considered. Our analysis is exhaustive both analytically and numerically as we examine the bifurcations of the system for various combinations of increasing and decreasing nonlinearities. We identify rich bifurcation patterns including Bautin, Bogdanov–Takens, cusp, fold, homoclinic, and Hopf bifurcations whose existence depend on the derivative signs of nonlinearities. Our analysis confirms many of these patterns in the limit where the nonlinearities are switch-like and change their value abruptly at a threshold. Perhaps one of the most surprising findings is the existence of a Hopf bifurcation to a periodic solution when the nonlinearity is monotone increasing and the time delay is a decreasing function of the state variable.

Keywords: state dependent delay, threshold delay, negative feedback, positive feedback, bifurcation (Bautin, Bogdanov–Takens, cusp, fold, homoclinic, Hopf).

1 Introduction

In considering mathematical models for the dynamics of biological feedback systems, the occurrence of delays is almost ubiquitous and this leads to very interesting biological, mathematical, and modeling problems. These delays arise because of the time required to propagate feedback signals in biological systems. For physiological examples one need only think of the

✉Corresponding author. Email: tgedeon@montana.edu

conduction time of action potentials in a neural feedback circuit [2,38], the time required to complete DNA synthesis, mitosis and cytokinesis in cell replication [12], the significant time required to produce mature cells in the hematopoietic system [10,16], as well as a myriad of others [19]. Examples in engineering and physical settings are rich and abundant ranging from control of ships [44], vibration control [45], and the delays due to the relativistic propagation of signals at the speed of light [11,66,67].

In this paper we study the dynamics of the positive solutions of the scalar state-dependent delay differential equation (DDE)

$$x'(t) = \beta e^{-\mu\tau(t)} \frac{v(x(t)))}{v(x(t-\tau(t)))} g(x(t-\tau(t))) - \gamma x(t) \tag{1.1}$$

where for $t \geq 0$ the delay $\tau(t)$ is defined by the threshold condition

$$a = \int_{-\tau(t)}^{0} v(x(t+s))ds = \int_{t-\tau(t)}^{t} v(x(s))ds. \tag{1.2}$$

We assume that the constants β, μ, γ and a are all positive.

We will consider the system (1.1),(1.2) with both smooth and piecewise constant functions $v(x)$ and $g(x)$. In the smooth case, we take the functions to be Hill functions

$$g(x) = \frac{g^- \theta_g^n + g^+ x^n}{\theta_g^n + x^n}, \qquad v(x) = \frac{v^- \theta_v^m + v^+ x^m}{\theta_v^m + x^m}, \tag{1.3}$$

where the exponents m and n are strictly positive real numbers. We also assume that $v(x)$ is strictly positive and bounded away from zero:

$$0 < v_0 \leq v(x) \leq v_U, \qquad \text{where} \quad v_0 = \min\{v^-, v^+\}, \quad v_U = \max\{v^-, v^+\}. \tag{1.4}$$

This ensures that the delay defined by (1.2) satisfies $\tau(t) \in [a/v_U, a/v_0]$, and is thus both bounded and bounded away from zero. Moreover, applying Leibnitz's rule to (1.2) with $v(x) \geq v_0 > 0$ shows that $\frac{d}{dt}(t-\tau(t)) \geq v_0/v_U > 0$ so $t - \tau(t)$ is a strictly monotonically increasing function of t. Consequently to pose (1.1)–(1.2) as an initial value problem (IVP) it is sufficient to provide an initial function $x(t) = \phi(t)$ for $t \in [-\tau(0), 0]$ where $\tau(0)$ is defined by (1.2). We will take the function g to be non-negative and bounded with

$$0 < g_0 \leq g(x) \leq g_U, \qquad \text{where} \quad g_0 = \min\{g^-, g^+\}, \quad g_U = \max\{g^-, g^+\}. \tag{1.5}$$

We are interested in the dynamics when the Hill coefficients m, n are small or large, and also consider the case of piecewise constant functions obtained by taking the limits of $v(x)$ and $g(x)$ as m and $n \to \infty$. In that case we take the limiting functions to be set-valued at the threshold points with

$$g(x) = \begin{cases} g^-, & x < \theta_g \\ [g_0, g_U], & x = \theta_g \\ g^+, & x > \theta_g \end{cases} \tag{1.6}$$

$$v(x) = \begin{cases} v^-, & x < \theta_v \\ [v_0, v_U], & x = \theta_v \\ v^+, & x > \theta_v \end{cases} \tag{1.7}$$

Equation (1.6) is derived from (1.3) by regarding the curve $\{x, g(x)\}$ as a subset of $\mathbb{R}^2$ and taking the limit as $n \to \infty$ using the Hausdorff metric, and (1.7) is derived similarly. There is a long history of incorporating set-valued functions into differential equations, resulting in differential inclusions for ordinary differential equations [3,4], and in DDEs. Mallet-Paret and Nussbaum ([40,41]) consider set-valued limiting solutions in their study of slowly oscillating periodic solutions.

As shown in Appendix A, the system (1.1)–(1.2) arises as a quasi-steady state reduction of the state-dependent delayed extension of the Goodwin [21] operon model studied in [18,63, 65]. Thus the model is taken to describe the regulation of a bacterial operon in which the cells are growing exponentially at a rate μ and have finite transcriptional and translational velocities that are potentially dependent on the state of the system. Then the function g denotes the production flux of messenger RNA (mRNA) while v is the velocity of translation/transcription of the mRNA strand to produce the end product (protein). x represents the dimensionless effector concentration.

The function $g(x)$ in (1.3) is monotone increasing when $g^- < g^+$, which we refer to as a positive feedback case. In the operon context ([21]) this corresponds to an *inducible* operon. The classical example would be the *lac* operon regulating bacterial utilization of lactose as an energy source. Conversely, when $g^- > g^+$ the function $g(x)$ is monotone decreasing, which we refer to as a negative feedback case, and in the operon setting it would correspond to a *repressible* operon. The immediate example that comes to mind is the *tryp* operon regulating the production of the amino acid tryptophan.

In [18] it is argued that the transcription velocity for an operon should be an increasing function when g is a decreasing function, and vice versa, while the translation velocity should always be monotonically decreasing. In the current study, we do not make this assumption and instead consider the different possible combinations of increasing/decreasing/constant g and v to explore potential dynamics. To avoid confusion we use $g \uparrow$ to indicate that the function g is monotonically increasing or equivalently that $g^- < g^+$. Then $g \downarrow$ denotes that g is monotonically decreasing or equivalently that $g^- > g^+$, while we use $g \leftrightarrow$ to denote that $g^- = g^+$ and so g is a constant function. With analogous definitions for the function v we denote different cases of these pairs of functions by $(g \uparrow, v \uparrow)$, $(g \uparrow, v \downarrow)$, $(g \uparrow, v \leftrightarrow)$, etc.

Smith [55, 56] showed that a DDE with a threshold delay can be converted through a time transformation to a distributed delay DDE with a constant delay, so the theory of those equations is applicable to this model. Some authors have used this transformation to study threshold models as distributed constant delay DDEs (see for example [33,58]), but other times the existence of the time transformation to constant delay DDE has been used as an excuse to just ignore the threshold delay and treat the delay as if constant. We will demonstrate that the model (1.1) with the threshold delay (1.2) can display very different dynamics than the same model (1.1) with a constant discrete delay.

In this work we will tackle (1.1) with the threshold delay (1.2) directly without transforming to a constant delay DDE. We do this because we are also interested in problems with multiple delays. For a problem with multiple threshold delays defined by different integrands, or even for a problem with a single threshold delay and a single constant delay, it is not possible to use a time transformation to convert it to a constant delay DDE. We also point out that when $\mu \neq 0$, the term $e^{-\mu\tau}$ in (1.1) would cause the time transformed equation to be a distributed DDE with constant delay, and not a discrete delay DDE (see [64]). Finally, we believe it is interesting that the analysis and numerics of these problems can be tackled directly for the problem as originally formulated.

The outline of this paper is as follows. Section 2 discusses the semiflow generated by (1.1)–(1.2). The following Section 3 considers issues related to the positivity of solutions and the existence of a global attractor, and then Section 4 examines the linearization of the system at one of the steady states and the stability of the steady state.

Sections 5 and 6 contain a detailed investigation of the rich dynamics generated by the system (1.1)–(1.2). We combine the verification of essential necessary conditions for local bifurcations from stationary points with numerical studies of one- and two-parameter bifurcations. Our numerical techniques are extensively documented in [18,63,65], and summarised in Appendix C. Concerning Theorems 5.3, 5.4, 5.6 and 5.9 about fold- and Hopf-bifurcations the reader should be aware that for most statements we limit ourselves to proving only those parts which make the result plausible and serve as a basis for numerical investigation. In particular, we do not verify non-degeneracy conditions for the bifurcations. Theorems on Hopf bifurcation for differential equations with state-dependent delay can be found in [14,30,53].

We begin in Section 5 by examining the simpler situation in which there is only one nonlinearity, with one of g or v being constant. In Sections 5.1 and 5.2 we consider the constant delay cases $(g\downarrow, v\leftrightarrow)$ and $(g\uparrow, v\leftrightarrow)$ respectively. Then in Sections 5.3 and 5.4 we consider $(g\leftrightarrow, v\downarrow)$ and $(g\leftrightarrow, v\uparrow)$. In these two cases v and thus τ are varying, resulting in state-dependent delays. We find that the dynamics are considerably richer and more surprising in the state-dependent delay cases, with qualitative differences in the dynamics depending on whether the growth rate, μ, or the decay rate, γ, is larger.

We continue in this vein in Section 6 but considering both nonlinearities, g and v. In Section 6.1 we begin by considering the case where $\theta_g \neq \theta_v$. In principle there should be four cases to consider: $(g\uparrow, v\uparrow)$, $(g\uparrow, v\downarrow)$,$(g\downarrow, v\uparrow)$ and $(g\downarrow, v\downarrow)$, but in practice we find that the dynamics is determined by the cases studied in Section 5. For example with $(g\uparrow, v\uparrow, \theta_g \neq \theta_v)$ we find that the dynamics and bifurcations from the steady state ξ are given by the previously studied cases $(g\uparrow, v\leftrightarrow)$ for $\xi \approx \theta_g$ and by $(g\leftrightarrow, v\uparrow)$ for $\xi \approx \theta_v$. Consequently, we illustrate just two of these cases, $(g\downarrow, v\uparrow, \theta_g \neq \theta_v)$ and $(g\uparrow, v\uparrow, \theta_g \neq \theta_v)$ to show how the dynamics relates to the previous examples of Section 5. The case $(g\uparrow, v\uparrow, \theta_g \neq \theta_v)$ is interesting as it can result in up to five co-existing steady states, three of which are stable.

If $|\theta_g - \theta_v| \ll 1$ then both functions g and v influence the dynamics, so in Section 6.2 we consider the dynamics when $\theta_g = \theta_v$. In the cases $(g\uparrow, v\uparrow)$ and $(g\downarrow, v\downarrow)$ both functions are increasing or decreasing, and no new dynamics arise, beyond what was already seen in Section 5. However, the cases $(g\uparrow, v\downarrow, \theta_g = \theta_v)$ and $(g\downarrow, v\uparrow, \theta_g = \theta_v)$ reveal surprising dynamics in limiting cases.

Section 7 contains summary remarks as well as comments on possible extensions of this work.

Finally, as noted above the appendices contain the reduction of the model of [18] to the situation we consider here (Appendix A) as well as a brief elaboration in Appendix B of five previously published models that fall within the context of this paper, along with a summary and references for our numerical techniques (Appendix C).

2 The semiflow of differentiable solution operators generated by the system (1.1)–(1.2)

For delay differential equations a familiar state space is given by the space of continuous functions on a compact interval, see e.g. [13,28]. In case of variable, state-dependent delays,

however, there is a specific lack of smoothness which means that in general the initial value problem is not well-posed for only continuous initial data, not to speak of, say, smoothness of solutions with respect to initial data and linearization ([29, 59]).

Recall the definition of the segment x_t of a map $x : I \to \mathbb{R}$ for which the domain I contains the interval $[t-r, t]$ with $t \in \mathbb{R}$ and $r > 0$: x_t is the map $[-r, 0] \to \mathbb{R}$ given by $x_t(s) = x(t+s)$ for $-r \le s \le 0$. In other words, the restriction of x to $[t-r, t]$ is shifted to the interval $[-r, 0]$. In this section we reformulate the system (1.1), (1.2) as a delay differential equation

$$x'(t) = G(x_t) \tag{2.1}$$

with a functional $G : C^1 \to \mathbb{R}$ on the Banach space $C^1 = C^1([-r, 0], \mathbb{R})$ of continuously differentiable maps $[-r, 0] \to \mathbb{R}$, for some $r > 0$ which is to be determined. The norm on C^1 is given by

$$|\phi|_1 = \max_{-r \le t \le 0} |\phi(t)| + \max_{-r \le t \le 0} |\phi'(t)|,$$

We will also need the Banach space $C \supset C^1$ of continuous maps $[-r, 0] \to \mathbb{R}$, with the norm given by

$$|\phi| = \max_{-r \le t \le 0} |\phi(t)|.$$

We shall verify the hypotheses from [29, 59, 60] which guarantee the existence, uniqueness, and differentiability, with respect to initial data, of solutions to an initial value problem which is associated with (2.1) in a submanifold of the space C^1.

We make the following assumptions. The function $g : \mathbb{R} \to (0, \infty)$ is continuously differentiable with

$$0 < \inf g(\mathbb{R}) \le \sup g(\mathbb{R}) = g_U.$$

The function $v : \mathbb{R} \to [v_0, \infty)$, with $v_0 > 0$, is continuously differentiable. We fix a number $r > a/v_0$ and notice that r is an a priori bound for $\tau(t)$ in Eq. (1.2).

Next we rewrite the system Eq. (1.1), (1.2) in a form which is more convenient for our purpose. Using segment notation, Eq. (1.2) becomes

$$a = \int_{-\tau(t)}^{0} v(x_t(s))ds \tag{2.2}$$

with the segment $x_t \in C$. More generally, we consider the equation

$$a = \int_{-u}^{0} v(\phi(s))ds \tag{2.3}$$

for $u \in [0, r]$ and $\phi \in C$. Using positivity of the function v and the Intermediate Value Theorem we infer that for every $\phi \in C$ there is a uniquely determined solution $u = \delta(\phi) \in (0, r)$ of Eq. (2.3). This yields a map $\delta : C \to (0, r)$.

Proposition 2.1. *The map $\delta : C \to (0, r)$ is continuously differentiable with*

$$D\delta(\phi)\chi = -\frac{\int_{-\delta(\phi)}^{0} v'(\phi(s))\chi(s)ds}{v(\phi(-\delta(\phi)))}.$$

In case $\phi(s) = \xi$ for all $s \in [-r, 0]$,

$$\delta(\phi) = \frac{a}{v(\xi)}$$

and

$$D\delta(\phi)\chi = -\frac{v'(\xi)}{v(\xi)} \int_{-a/v(\xi)}^{0} \chi(s)ds.$$

Before giving the proof recall from [59, page 47] or [29, page 466] that the evaluation map

$$ev_C : C \times [-r, 0] \ni (\chi, u) \mapsto \chi(u) \in \mathbb{R}.$$

is continuous (but not locally Lipschitz continuous, let alone differentiable), and that the restricted evaluation map

$$ev : C^1 \times (-r, 0) \ni (\phi, u) \mapsto \phi(u) \in \mathbb{R}$$

is continuously differentiable with

$$D\,ev(\phi, u)(\hat{\phi}, \hat{u}) = D_1 ev(\phi, u)\hat{\phi} + D_2 ev(\phi, u)\hat{u} = \hat{\phi}(u) + \phi'(u)\hat{u}, \tag{2.4}$$

where D_1 and D_2 denote partial derivatives with respect to the argument in C^1 and in $(-r, 0)$, respectively. The substitution operator

$$V : C \ni \phi \mapsto v \circ \phi \in C$$

is continuously differentiable with

$$(DV(\phi)\hat{\phi})(s) = v'(\phi(s))\hat{\phi}(s) \quad \text{for all} \quad \hat{\phi} \in C, \quad s \in [-r, 0],$$

see for example [13, Appendix IV, Lemma 1.5].

Proof of Proposition 2.1. For every $\phi \in C$ the value $u = \delta(\phi)$ is the unique solution of the equation $h(u, \phi) = 0$, where $h : (0, r) \times C \to \mathbb{R}$ is given by

$$h(u, \phi) = a - \int_{-u}^{0} v(\phi(s))ds = a - ev(I(V(\phi))), -u)$$

with the continuous linear integration operator $I : C \to C^1$ defined by

$$(I\psi)(t) = \int_t^0 \psi(s)ds.$$

The map h is continuously differentiable with

$$D_1 h(u, \phi)1 = -v(\phi(-u)) < 0$$

and

$$\begin{aligned} D_2 h(u, \phi)\chi = -D_1 ev(I(V(\phi)), -u)DI(V(\phi))DV(\phi)\chi = -(DI(V(\phi))DV(\phi)\chi)(-u) \\ = -(I(DV(\phi)\chi))(-u) = -\int_{-u}^{0} v'(\phi(s))\chi(s)ds. \end{aligned}$$

The Implicit Function Theorem applies at every $(\delta(\phi), \phi) \in (-r, 0) \times C$ and yields that locally, δ is given by a continuously differentiable map. Differentiation of the equation $h(\delta(\phi), \phi) = 0$ gives

$$D\delta(\phi)\chi = -\frac{D_2 h(\delta(\phi), \phi)\chi}{D_1 h(\delta(\phi), \phi)1} = -\frac{\int_{-\delta(\phi)}^{0} v'(\phi(s))\chi(s)ds}{v(\phi(-\delta(\phi)))}.$$

In the case ϕ is constant with value $\xi \in \mathbb{R}$, Eq. (2.3) gives $a = \delta(\phi)v(\xi)$, and by the previous formula,

$$D\delta(\phi)\chi = -\frac{v'(\xi)}{v(\xi)} \int_{-a/v(\xi)}^{0} \chi(s)ds.$$

□

Using the delay functional $\delta : C \to (0, r)$ the system (1.1),(2.2) is reduced to the equation

$$x'(t) = \beta\, e^{-\mu\,\delta(x_t)}\frac{v(x(t))}{v(x(t-\delta(x_t)))}g(x(t-\delta(x_t))) - \gamma\, x(t) \tag{2.5}$$

with segments $x_t \in C$. Eq. (2.5) is of the form $x'(t) = G_C(x_t) \in \mathbb{R}$ with the map $G_C : C \to \mathbb{R}$ given by

$$G_C(\phi) = \beta\, e^{-\mu\,\delta(\phi)}\frac{v(\phi(0))}{v(\phi(-\delta(\phi)))}g(\phi(-\delta(\phi))) - \gamma\,\phi(0) \tag{2.6}$$

We observe that G_C is continuous. The restriction G of G_C to C^1 is continuously differentiable because, for $\phi \in C^1 \subset C$, we have $ev_C(\phi, -\delta(\phi)) = ev(\phi, -\delta(\phi))$. Here $ev : C^1 \times (0, r) \to \mathbb{R}$ is continuously differentiable, the map δ is continuously differentiable, and the evaluation map $ev_0 : C \ni \chi \mapsto \chi(0) \in \mathbb{R}$ is linear and continuous.

To simplify the calculations below we now introduce the continuous map

$$E_C : C \to \mathbb{R}, \quad E_C(\phi) = ev_C(\phi, -\delta(\phi)),$$

and the continuously differentiable map

$$E : C^1 \to \mathbb{R}, \quad E(\phi) = ev(\phi, -\delta(\phi)),$$

with the derivative at $\phi \in C^1$ given by

$$\begin{aligned} DE(\phi)\hat{\phi} &= D_1 ev(\phi, -\delta(\phi))\hat{\phi} + D_2 ev(\phi, -\delta(\phi))D(-\delta)(\phi)\hat{\phi} \\ &= \hat{\phi}(-\delta(\phi)) - \phi'(-\delta(\phi))D\delta(\phi)\hat{\phi} \end{aligned}$$

for all $\hat{\phi} \in C^1$. Notice that the right hand side of the previous equation makes sense also for arguments $\chi \in C$ instead of $\hat{\phi} \in C^1$. Thus they define linear extensions $D_e E(\phi) : C \to \mathbb{R}$ of $DE(\phi) : C^1 \to \mathbb{R}$. Using the continuity of the map ev_C, and the fact that differentiation $C^1 \ni \phi \mapsto \phi' \in C$ is linear and continuous we obtain the next result.

Proposition 2.2. *The map $C^1 \times C \ni (\phi, \chi) \mapsto D_e E(\phi)\chi \in \mathbb{R}$ is continuous.*

Incidentally, in the case $\phi \in C^1$ is constant with value $\xi \in \mathbb{R}$ we have

$$E(\phi) = \xi, \quad DE(\phi)\hat{\phi} = \hat{\phi}(-a/v(\xi)).$$

With the linear continuous evaluation map $ev_0 : C \ni \phi \mapsto \phi(0) \in \mathbb{R}$ we obtain for the restriction G of G_C

$$G(\phi) = \beta\, e^{-\mu\delta(\phi)}\frac{v(ev_0\phi)}{v(E(\phi))}g(E(\phi)) - \gamma\, ev_0\phi. \tag{2.7}$$

In the sequel we will show that the initial value problem

$$x'(t) = G(x_t) \quad \text{for} \quad t > 0, \quad x_0 = \phi \tag{2.8}$$

is well-posed on the set

$$X_G = \{\phi \in C^1 : \phi'(0) = G(\phi)\},$$

which is a continuously differentiable submanifold of codimension 1 in the space C^1. This result follows from results in [29,59,60] provided that the following two assertions are verified:

1. $X_G \neq \emptyset$; and
2. G has the property that

   each derivative $DG(\phi) : C^1 \to \mathbb{R}$, $\phi \in C^1$, *has a linear extension* $D_eG(\phi) : C \to \mathbb{R}$, *and the map*

   $$C^1 \times C \ni (\phi, \hat{\phi}) \mapsto D_eG(\phi)\hat{\phi} \in \mathbb{R}$$

   is continuous.

Property (2) is a version of being *almost Fréchet differentiable* from [42]. In case the delay functional $\delta : C \to (0, r)$ is bounded away from zero, which happens to be true for v bounded also from above as in the subsequent sections, the manifold X_G is simply a graph in the space C^1, given by a continuously differentiable map from an open subset of the closed hyperplane $\{\phi \in C^1 : \phi'(0) = 0\}$ into a complementary line in C^1, see [62, Theorem 2.4].

We now proceed to the proof of properties (1) and (2). We first show that $X_G \neq \emptyset$. The continuous map

$$[0, \infty) \ni \xi \mapsto \beta\, e^{-\mu\, a/v(\xi)} - \gamma\, \xi \in \mathbb{R}$$

is positive at $\xi = 0$ and tends to $-\infty$ for $\xi \to \infty$. Therefore the Intermediate Value Theorem yields a zero $\zeta > 0$ of this map. The constant function $\phi \in C^1$ with value ζ satisfies $\phi'(0) = 0 = G(\phi)$, so it belongs to the set X_G. This finishes the proof of property (1).

To prepare for the proof of the extension property (2) we compute the derivatives $DG(\phi)$, $\phi \in C^1$. For $\delta : C \to \mathbb{R}$ we use the fact that restrictions of differentiable maps $m : C \to \mathbb{R}$ to C^1 remain differentiable, with derivatives $D(m|C^1)(\phi) : C^1 \to \mathbb{R}$ being restrictions of the derivatives $Dm(\phi) : C \to \mathbb{R}$, $\phi \in C^1 \subset C$. It follows that

$$\begin{aligned} DG(\phi)\hat{\phi} = {} & -\gamma\, \hat{\phi}(0) + \\ & \beta \Bigg\{ \frac{1}{[v(E(\phi))]^2} \left[v'(\phi(0))\hat{\phi}(0) \cdot v(E(\phi)) - v(\phi(0))v'(E(\phi))DE(\phi)\hat{\phi} \right] e^{-\mu\delta(\phi)} g(E(\phi)) \\ & \quad + \frac{v(\phi(0))}{v(E(\phi))} \left[-\mu\, e^{-\mu\delta(\phi)} D\delta(\phi)\hat{\phi} \cdot g(E(\phi)) + e^{-\mu\delta(\phi)} g'(E(\phi))DE(\phi)\hat{\phi} \right] \Bigg\}. \end{aligned} \tag{2.9}$$

Now we are ready to verify property (2). In the formula for $DG(\phi)\hat{\phi}$, replace the real number $DE(\phi)\hat{\phi}$ by $D_eE(\phi)\chi$ with $\chi \in C$, replace the function $\hat{\phi}$ by χ, and replace $\hat{\phi}(0)$ by $\chi(0)$. This defines $D_eG(\phi)\chi \in \mathbb{R}$ for $\phi \in C^1$ and $\chi \in C$ so that the maps $D_eG(\phi) : C \to \mathbb{R}$, $\phi \in C^1$, are linear. Using the continuous differentiability of $\delta : C \to \mathbb{R}$ and Proposition 2.1 one shows that the map $C^1 \times C \ni (\phi, \chi) \mapsto D_eG(\phi)\chi \in \mathbb{R}$ is continuous. This finishes the proof of property (2).

With (1) and (2) verified, results from [29, 59, 60] apply and yield the following.

The set X_G is a continuously differentiable submanifold of the Banach space C^1, with codimension 1. Each $\phi \in X_G$ uniquely determines a maximal continuously differentiable solution $x : [-r, t_x) \to \mathbb{R}$, $0 < t_x \leq \infty$, of the initial value problem (2.8). That is, x is continuously differentiable and satisfies $x_0 = \phi$ and $x'(t) = G(x_t)$ for all $t \in (0, t_x)$, and any other continuously differentiable function $y : [-r, t_y) \to \mathbb{R}$, $0 < t_y \leq \infty$, which satisfies $y_0 = \phi$ and $y'(t) = G(y_t)$ for all $t \in (0, t_y)$ is a restriction of x. All segments x_t, $0 \leq t < \infty$, belong to X_G (because of Eq. (2.8)). Write $x^\phi = x$ and $t_\phi = t_x$. Let

$$\Omega_G = \{(t, \phi) \in [0, \infty) \times X_G : 0 \leq t < t_\phi\}.$$

The equation

$$S_G(t,\phi) = x_t^\phi,$$

defines a continuous semiflow $S_G : \Omega_G \to X_G$. For each $t \geq 0$ the set

$$\Omega_{G,t} = \{\phi \in X_G : t < t_\phi\}$$

is an open subset of X_G (possibly empty), $\Omega_{G,0} = X_G$, and each map

$$S_{G,t} : \Omega_{G,t} \ni \phi \mapsto S_G(t,\phi) \in X_G, \quad t \geq 0,$$

on a non-empty domain is continuously differentiable.

Moreover, the restriction of the semiflow S_G to the open subset $\{(t,\phi) \in \Omega_G : r < t\}$ of the manifold $\mathbb{R} \times X_G$ is continuously differentiable [60].

3 Positivity, dissipativity, global attractor

In addition to the assumptions made in Section 2, we assume in this section that the function v is also bounded from above by a real number $v_U \geq v_0$. Using Eq. (2.3) we infer

$$\frac{a}{v_U} \leq \delta(\phi) \leq \frac{a}{v_0}$$

for all $\phi \in C$.

Proposition 3.1. *For every $c > 0$ there exists $c' > 0$ such that for all $\phi \in X_G$ with $|\phi(t)| \leq c$ on $[-r,0]$ and for all $t \in [-r, t_\phi)$ we have $|x^\phi(t)| \leq c'$.*

Proof. Let $\phi \in X_G$ with $|\phi(t)| \leq c$ on $[-r,0]$ be given, and set $x = x^\phi$. The first term on the right hand side of Eq. (2.5) is positive and bounded by the constant

$$d^U = \beta\, g_U\, \frac{v_U}{v_0}.$$

The variation-of-constants formula yields

$$\begin{aligned} |x(t)| &= \left| x(0)e^{-\gamma t} + \int_0^t e^{-\gamma(t-s)} \left[\frac{\beta v(x(s))}{v(x(s-\delta(x_s)))} e^{-\mu\,\delta(x_s)} g(x(s-\delta(x_s))) \right] ds \right| \\ &\leq c + e^{-\gamma t} \frac{d^U}{\gamma} \left(e^{\gamma t} - 1\right) \leq c + \frac{d^U}{\gamma} \quad \text{for} \quad 0 \leq t < t_\phi. \end{aligned}$$

Set $c' = c + \frac{d^U}{\gamma}$. With $|x(t)| = |\phi(t)| \leq c$ on $[-r,0]$ we obtain $|x(t)| \leq c'$ for all $t \in [-r, t_\phi)$. □

Observe that for any (continuously differentiable) solution $x : [-r, t_x) \to \mathbb{R}$ of Eq. (2.5) and for any $t \in [0, t_x)$ the first term on the right hand side of Eq. (2.5) belongs to the interval

$$[d^L, d^U] = \left[\beta \frac{v_0}{v_U} e^{-\mu\, a/v_0} g_0, \beta\, g_U\, \frac{v_U}{v_0} \right],$$

and in the case

$$x(t) > \frac{d^U}{\gamma} \quad \text{we have} \quad x'(t) \leq d^U - \gamma\, x(t) < 0,$$

while for

$$x(t) < \frac{d^L}{\gamma} \quad \text{we have} \quad x'(t) \geq d^L - \gamma\, x(t) > 0.$$

Set

$$Q = \left[\frac{d^L}{\gamma}, \frac{d^U}{\gamma}\right] \subset \mathbb{R}$$

and

$$R = \{\phi \in C^1 : \phi([-r, 0]) \subset Q\}.$$

Proposition 3.2 (Global existence, absorption and positive invariance, positivity)**.**

(i) For all $\phi \in X_G$, $t_\phi = \infty$.

(ii) For every neighbourhood N of Q in $\mathbb{R}$ and for each $\phi \in X_G$ there exists $t(\phi, N) \in [0, \infty)$ with $x^\phi(t) \in N$ for all $t \geq t(\phi, N)$.

(iii) If $\phi \in X_G \cap R$ then $x^\phi(t) \in Q$ for all $t \geq 0$.

(iv) If $\phi \in X_G$ is strictly positive then $x^\phi(t) > 0$ for all $t \geq -r$.

Proof. 1. On (i). Let $\phi \in X_G$ be given. From Proposition 3.1 the solution $x = x^\phi$ is bounded. Using this and Eq. (2.5) we infer that x' is bounded. It follows that x is Lipschitz continuous. Assume now $t_\phi < \infty$. Then Lipschitz continuity yields that x has a limit $\xi \in \mathbb{R}$ at $t = t_\phi$ and x extends to a continuous map $\hat{x} : [-r, t_\phi] \to \mathbb{R}$. From uniform continuity on the compact interval $[-r, t_\phi]$ it follows that the curve $[0, t_\phi] \ni t \mapsto \hat{x}_t \in C$ is continuous. Using this and the equation

$$x'(t) = G(x_t) = G_C(\hat{x}_t) \quad \text{for} \quad 0 \leq t < t_\phi$$

with the continuous map $G_C : C \to \mathbb{R}$, we also conclude that x' has a limit $\eta \in \mathbb{R}$ at $t = t_\phi$. It follows that $\hat{x}$ is continuously differentiable (with $\hat{x}'(t_\phi) = \eta$), and $\hat{x}'(t_\phi) = G_C(\hat{x}_{t_\phi}) = G(\hat{x}_{t_\phi})$. In particular, $\psi = \hat{x}_{t_\phi}$ belongs to X_G, and defines a maximal solution $x^\psi : [0, t_\psi) \to \mathbb{R}$ of Eq. (2.1), with $0 < t_\psi \leq \infty$. From the semiflow properties, it follows that when $t_\psi = \infty$ we have $t_\phi = \infty$, in contradiction to the assumption above, while in the case $t_\psi < \infty$ we get $t_\phi \geq t_\phi + t_\psi$, which contradicts $t_\psi > 0$.

2. On (ii). Let a neighbourhood N of Q in $\mathbb{R}$ and $\phi \in X_G$ be given. Set $x = x^\phi$. There exists $\epsilon > 0$ so that for

$$d_{-\epsilon} = \frac{d^L}{\gamma} - \epsilon \quad \text{and} \quad d_{+\epsilon} = \frac{d^U}{\gamma} + \epsilon$$

we have $d_{-\epsilon} > 0$ and $N \supset [d_{-\epsilon}, d_{+\epsilon}]$.

2.1. Proof that when $x(t) \leq d_{+\epsilon}$ for some $t \geq 0$ we have

$$x(s) \leq d_{+\epsilon} \quad \text{for all} \quad s \geq t.$$

Otherwise $x(s) > d_{+\epsilon} = \frac{d^U}{\gamma} + \epsilon$ for some $s > t$. For the smallest $u \in [t, s]$ with $x(u) = x(s)$ we have $0 \leq x'(u)$ and, on the other hand,

$$x'(u) < d^U - \gamma\, x(u) = d^U - \gamma\, x(s) < -\epsilon\, \gamma < 0.$$

2.2. Proof that when $x(s) > d_{+\epsilon}$ for some $s \geq 0$ there exists $t > s$ with

$$x(t) \leq d_{+\epsilon}.$$

Otherwise $x(t) > d_{+\epsilon} = \frac{d^U}{\gamma} + \epsilon$ on $[s, \infty)$. Hence

$$x'(t) < d^U - \gamma\, x(t) < -\epsilon\, \gamma < 0 \quad \text{on} \quad [s, \infty),$$

and consequently $x(t) \to -\infty$ as $t \to \infty$, in contradiction to the assumption.

2.3. It follows that there exists $t^* \geq 0$ with

$$x(t) \leq d_{+\epsilon} \quad \text{for all} \quad t \geq t^*.$$

Similarly one finds $t(\phi, N) \geq t^*$ with

$$x(t) \geq d_{-\epsilon} \quad \text{for all} \quad t \geq t(\phi, N).$$

Hence

$$x(t) \in [d_{-\epsilon}, d_{+\epsilon}] \subset N \quad \text{for all} \quad t \geq t(\phi, N).$$

3. The proof of assertion (iii) begins with the assumption that for a given $\phi \in X_G \cap R$ there exists $s > 0$ with $x^\phi(s) > \frac{d^U}{\gamma}$, and is then accomplished by a simplified version of arguments as in Part 2.1.

4. On (iv). Let $\phi \in X_G$ be given with $\phi(t) > 0$ for all $t \in [-r, 0]$. Set $x = x^\phi$. The assumption $x(t) \leq 0$ for some $t > 0$ leads to a smallest $t > 0$ with $x(t) = 0$. Necessarily, $x'(t) \leq 0$ while Eq. (2.5) yields $x'(t) > 0$. It follows that $x(t) > 0$ for all $t \geq -r$. □

The solution manifold X_G is a closed subset of the space C^1, and thereby a complete metric space with respect to the metric given by the norm on C^1. The next result implies that the semiflow S_G on the complete metric space X_G is point dissipative as defined in [27].

Corollary 3.3. *There is a bounded open subset B_G of the submanifold $X_G \subset C^1$, with*

$$\phi(t) > 0 \quad \textit{for all} \quad \phi \in B_G, \quad t \in [-r, 0],$$

such that for every $\phi \in X_G$ there exists $t(\phi) \geq 0$ with

$$S_G(t, \phi) \in B_G \quad \textit{for all} \quad t \geq t(\phi).$$

Proof. Choose $c > 0$ so that $N = (0, c)$ is a neighbourhood of Q. Set $\tilde{R} = \{\phi \in C^1 : \phi([-r, 0]) \subset N\}$. Let $\phi \in X_G$ be given. Choose $t(\phi, N)$ according to Proposition 3.2 (ii). From Eq. (2.5) we see that the map G sends the set $\tilde{R}$ (which is not a bounded subset of C^1) into a bounded subset of $\mathbb{R}$, say, into $(-b, b)$ for some $b > 0$. It follows that for all $t \geq t(\phi, N) + r$ we have $|(x^\phi)'(t)| < b$. For $t \geq t(\phi, N) + 2r$ we obtain $x_t^\phi \in \{\psi \in X_G \cap \tilde{R} : |\psi'| < b\} = B_G$. The set B_G is an open and bounded subset of X_G, with $0 < \phi(t)$ for all $\phi \in B_G$, $t \in [-r, 0]$. Set $t(\phi) = t(\phi, N) + 2r$. □

Recall from [27] the definition of a global attractor of a semiflow, which in the case of our semiflow S_G is equivalent to saying that a subset $A_G \subset X_G$ is a global attractor if it is

- compact,
- invariant in the sense that for every $\phi \in A_G$ there exists an entire flowline[1] $\xi : \mathbb{R} \to X_G$ with $\xi(0) = \phi$ and $\xi(\mathbb{R}) \subset A_G$, and

[1] An entire flowline is a curve $\xi : \mathbb{R} \to X_G$ with $\xi(t + s) = S_G(t, \xi(s))$ for all $t \geq 0$ and $s \in \mathbb{R}$

- if A_G attracts every bounded set $B \subset X_G$ in the sense that given an open neighbourhood $U \supset A_G$ of A_G in X_G there exists $t_{B,U} \geq 0$ such that

$$S_G([t_{B,U}, \infty) \times B) \subset U.$$

Theorem 3.4.8 of [27] guarantees the existence of such a global attractor provided the semiflow is point-dissipative and there exists $t_1 \geq 0$ so that the semiflow S_G is *completely continuous for* $t \geq t_1$. The property of being completely continuous (for $t \geq t_1$) is explained after Lemma 3.2.1 in [27]. It means that for every $t \geq t_1$ and for every bounded set B with $S_G([0,t] \times B)$ bounded the set $S_G(\{t\} \times B)$ is precompact.

To prove the latter property, it is sufficient to verify the slightly stronger property that for every bounded set $B \subset X_G$

(i) there exists $t_1 \geq 0$ so that for every $t \geq t_1$ the set $S_G(\{t\} \times B)$ is precompact.

Theorem 3.4. *The semiflow S_G has a global attractor $A_G \subset X_G$, with $\phi(t) > 0$ for all $\phi \in A_G$, $t \in [-r, 0]$.*

Proof. 1. We first show that for every bounded subset $B \subset X_G$ there exists $c_B > 0$ with

$$|x^\phi(t)| \leq c_B \quad \text{and} \quad |(x^\phi)'(t)| \leq c_B \quad \text{for all} \quad \phi \in B \quad \text{and} \quad t \geq -r.$$

Let $B \subset X_G$ be bounded (with respect to the norm of the space C^1). Proposition 3.1 guarantees the existence of a constant $c_{B,0}$ with $|x^\phi(t)| \leq c_{B,0}$ for all $\phi \in B$, $t \geq -r$. Then (2.7) shows that the set $\{G(x_t^\phi) \in \mathbb{R} : \phi \in B, t \geq 0\}$ is bounded, and Eq. (2.1) gives that the set $\{(x^\phi)'(t) \in \mathbb{R} : \phi \in B, t \geq 0\}$ is bounded. Also the set $\{\phi'(t) \in \mathbb{R} : \phi \in B, -r \leq t \leq 0\}$ is bounded.

2. Claim: For every bounded subset $B \subset X_G$ the set $S_G(\{r\} \times B) \subset X_G$ has compact closure in C^1.

Proof: (a) Let $B \subset X_G$ be a bounded subset of C^1. Due to Part 1 the sets $\{x^\phi(t) \in \mathbb{R} : \phi \in B, -r \leq t \leq r\}$ and $\{(x^\phi)'(t) \in \mathbb{R} : \phi \in B, -r \leq t \leq r\}$ are bounded. Using the Mean Value Theorem we see that in particular the set $S_G(\{r\} \times B)$ is equicontinuous. As it also is bounded in C, the Ascoli–Arzelà Theorem implies that its closure in C is compact.

(b) We turn to the set $\{S_G(r, \phi)' \in C : \phi \in B\}$ of derivatives, which is bounded in C, and proceed to show that it is also equicontinuous. As in Part (a) one sees that the closure K of the set

$$\{S_G(t, \phi) \in C : \phi \in B, 0 \leq t \leq r\}$$

in the space C is compact. The map $G : C^1 \to \mathbb{R}$ is the restriction of the continuous map $G_C : C \to \mathbb{R}$ which is uniformly continuous on the compact set $K \subset C$. Using the boundedness of the set $\{(x^\phi)'(t) \in \mathbb{R} : \phi \in B, -r \leq t \leq r\}$ and the Mean Value Theorem one finds that the curves

$$[0, r] \ni t \mapsto S_G(t, \phi) \in C, \quad \phi \in B,$$

are uniformly Lipschitz continuous, hence equicontinuous. Now let $t_0 \in [0, r]$ and $\epsilon > 0$ be given. There exists $\delta' > 0$ with

$$|G_C(\phi) - G_C(\psi)| \leq \epsilon \quad \text{for all} \quad \phi, \psi \quad \text{in} \quad S_G([0, r] \times B) \quad \text{with} \quad |\phi - \psi| \leq \delta',$$

due to uniform continuity of G_C on K. Due to equicontinuity there exists $\eta > 0$ with

$$|S_G(t, \phi) - S_G(t_0, \phi)| \leq \delta' \quad \text{for all } \phi \in B \text{ and } t \in [0, r] \text{ with } |t - t_0| < \eta.$$

Hence

$$\begin{aligned}|(x^\phi)'(t) - (x^\phi)'(t_0)| &= |G(S_G(t,\phi)) - G(S_G(t_0,\phi))| \\ &= |G_C(S_G(t,\phi)) - G_C(S_G(t_0,\phi))| < \epsilon\end{aligned}$$

for all $\phi \in B$ and $t \in [0,r]$ with $|t - t_0| < \eta$.

(c) The Ascoli–Arzelà Theorem implies that the closure of $\{S_G(r,\phi)' \in C : \phi \in B\}$ in C is compact. For the closure of $S_G(\{r\} \times B)$ in C^1 to be compact it is sufficient to show that every sequence of points $\phi_j \in S_G(\{r\} \times B)$, $j \in \mathbb{N}$, has a subsequence which converges in C^1. Let a sequence $(\phi_j)_1^\infty$ in $S_G(\{r\} \times B)$ be given. Part a) implies that there is a subsequence which converges in C to some $\phi \in C$. Part b) shows that the subsequence has a secondary subsequence so that the derivatives of the latter subsequence converge in C to some $\psi \in C$. It follows that $\phi \in C^1$ with $\phi' = \psi$, which in turn yields convergence of the secondary subsequence to $\phi \in C^1$ as $k \to \infty$.

3. We now show that for every bounded subset $B \subset X_G$ and for every $t \geq r$ the set $S_G(\{t\} \times B) \subset X_G$ has compact closure in C^1. Let $B \subset X_G$ be bounded and let $t \geq r$. For every $\phi \in B$,

$$S_G(t,\phi) = S_G(t-r, S_G(r,\phi)),$$

hence

$$S_G(\{t\} \times B) = S_G(t-r,\cdot)(S_G(\{r\} \times B)).$$

Use that the closure of $S_G(\{r\} \times B)$ in C^1 is compact and belongs to X_G (since X_G is a closed subset of C^1), and that the map $S_G(t-r,\cdot)$ is continuous, and conclude that the closure of $S_G(\{t\} \times B)$ in C^1 is contained in a compact subset of $X_G \subset C^1$.

4. Point dissipativity from Corollary 3.3 in combination with condition (i) from the previous Part 3 of the proof yield existence of a global attractor, see the remarks preceding Theorem 3.4.

5. Finally we show that for all $\phi \in A_G$ and $t \in [-r,0]$ we have $\phi(t) > 0$. Let $\phi \in A_G$ be given. There exists a solution $x : \mathbb{R} \to \mathbb{R}$ of Eq. (2.5) with $x_0 = \phi$ and all segments x_s, $s \in \mathbb{R}$, in the compact set A_G. It suffices to deduce $x(t) > 0$ for all $t \in \mathbb{R}$. Proof of this: First, observe that x is bounded. Assume $x(t) \leq 0$ for some $t \in \mathbb{R}$. In case $x(t) = 0$ Eq. (2.5) yields $x'(t) > 0 - \gamma\, x(t) = 0$. It follows that $x(u) < 0$ for some $u \in (-\infty, t)$. In case $x(t) < 0$ set $u = t$. For every $s \leq u$ the variation-of-constants formula yields

$$x(u) \geq x(s)e^{-\gamma(u-s)} + 0,$$

hence

$$x(s) \leq x(u)e^{\gamma(u-s)} \qquad (\to -\infty \quad \text{as} \quad s \to -\infty),$$

and we arrive at a contradiction to the boundedness of x. □

4 Linearization

We now turn to linearization. At a point $\phi \in X_G$ the tangent space of the manifold X_G is given by

$$T_\phi X_G = \{\chi \in C^1 : \chi'(0) = DG(\phi)\chi\}.$$

For $\phi \in \Omega_{G,t}$ the derivative

$$DS_{G,t}(\phi) : T_\phi X_G \to T_{S_{G,t}(\phi)} X_G$$

is given by

$$DS_{G,t}(\phi)\chi = w_t^{\phi,\chi}$$

where $w^{\phi,\chi} = w$ is the unique continuously differentiable solution $[-r, t_\phi) \to \mathbb{R}$ of the IVP

$$w'(t) = DG(S_G(t,\phi))w_t \quad \text{for} \quad t > 0, \tag{4.1}$$

$$w_0 = \chi \in T_\phi X_G. \tag{4.2}$$

Equation (4.1) is called the linear variational equation along the solution x^ϕ or along the flowline

$$S_G(\cdot,\phi) : [0, t_\phi) \ni t \mapsto S_G(t,\phi) \in X_G.$$

Suppose that $\phi \in X_G$ is a stationary point of the semiflow S_G, that is, $t_\phi = \infty$ and $S_G(t,\phi) = \phi$ for all $t \geq 0$. Then ϕ is constant since for every $t \geq 0$, $x^\phi(t) = x_t^\phi(0) = S_G(t,\phi)(0) = \phi(0)$, hence

$$\phi(s) = S_G(r,\phi)(s) = x_r^\phi(s) = x^\phi(r+s) = \phi(0) \quad \text{for each } s \in [-r, 0].$$

Let $\xi \in \mathbb{R}$ denote the value of ϕ. Then $x^\phi(t) = \xi$ for all $t \geq -r$. To obtain the linear variational equation along this constant solution in terms of $g, v, a, \beta, \mu, \gamma$ we compute the values $DG(\phi)\hat{\phi}$, $\hat{\phi} \in C^1$ from the formula (2.9). Using Proposition 2.1 (for the values and for the derivatives of the map δ in case of constant arguments) and the calculation of $DE(\phi)\hat{\phi}$ right after Proposition 2.1 (in case of constant arguments), we find

$$\begin{aligned} DG(\phi)\hat{\phi} &= -\gamma\hat{\phi}(0) + \beta\Bigg\{ \frac{1}{[v(\xi)]^2}\left[v'(\xi)\hat{\phi}(0)v(\xi) - v(\xi)v'(\xi)\hat{\phi}(-a/v(\xi))\right] e^{-\mu a/v(\xi)} g(\xi) \\ &\quad + \left[-\mu e^{-\mu a/v(\xi)}\left(-\frac{v'(\xi)}{v(\xi)}\int_{-a/v(\xi)}^0 \hat{\phi}(s)ds\right) g(\xi) + e^{-\mu a/v(\xi)} g'(\xi)\hat{\phi}(-a/v(\xi))\right]\Bigg\} \\ &= -\gamma\hat{\phi}(0) + A\hat{\phi}(0) + \mu A\int_{-a/v(\xi)}^0 \hat{\phi}(s)ds + \left(\beta e^{-\mu a/v(\xi)} g'(\xi) - A\right)\hat{\phi}(-a/v(\xi)) \end{aligned} \tag{4.3}$$

with

$$A = \beta\frac{v'(\xi)}{v(\xi)} e^{-\mu a/v(\xi)} g(\xi). \tag{4.4}$$

The variational equation (4.1) along the constant solution $x^\phi : [-r, \infty) \ni t \mapsto \xi \in \mathbb{R}$ becomes

$$\begin{aligned} w'(t) = &-\gamma w(t) + Aw(t) + \left(\beta e^{-\mu a/v(\xi)} g'(\xi) - A\right) w(t - a/v(\xi)) \\ &+ \mu A\int_{-a/v(\xi)}^0 w(t+s)ds \end{aligned} \tag{4.5}$$

The derivatives $T_{G,t} = DS_{G,t}(\phi)$, $t \geq 0$, form a strongly continuous semigroup on the closed hyperplane $T_\phi X_G$ of the space C^1. This semigroup is given by $T_{G,t}\chi = T_{G,e,t}\chi$, where $T_{G,e,t} : C \to C$ is the solution operator associated with the *classical* initial value problem

$$w'(t) = D_e G(\phi)w_t \quad \text{for} \quad t > 0, \tag{4.6}$$

$$w_0 = \chi \in C, \tag{4.7}$$

with the continuous linear functional $L : C \to \mathbb{R}$, $L = D_e G(\phi)$, as in the monographs, e.g., [13,28]. Recall that by definition the solution $w : [-r, \infty) \to \mathbb{R}$ of the initial value problem (4.6), (4.7) is only continuous, with the restriction $w|_{[0,\infty)}$ continuously differentiable and satisfying Eq. (4.6).

The extended derivative $D_e G(\phi) : C \to \mathbb{R}$ in the case just considered (where $\phi \in X_G$ is a stationary point with value ξ) is given by (4.3), now for $\hat{\phi} \in C$. Therefore the equation (4.6) coincides with Eq. (4.5), considered for continuous maps $[-r, \infty) \to \mathbb{R}$ whose restrictions to $[0, \infty)$ are differentiable and satisfy Eq. (4.5) for all $t \geq 0$.

The stability of the zero solution of the linear variational equation (4.5) is determined by the spectrum $\sigma \subset \mathbb{C}$ of the generator of the semigroup $(T_{G,t})_{t\geq 0}$ on $T_\phi X_G \subset C^1$, which coincides with the spectrum $\sigma_e \subset \mathbb{C}$ of the generator of the semigroup on C.

The spectrum σ_e consists of the solutions $\lambda \in \mathbb{C}$ of the *characteristic equation*, which is obtained from the ansatz $\mathbb{R} \ni t \mapsto e^{\lambda t} \in \mathbb{C}$ for a complex-valued solution of Eq. (4.5) as follows. We write down Eq. (4.5) for $w : t \mapsto e^{\lambda t}$, multiply by $e^{-\lambda t}$, and obtain the equation

$$\lambda = -\gamma + A + \left(\beta\, e^{-\mu\, a/v(\xi)} g'(\xi) - A\right) e^{-\lambda\, a/v(\xi)} + \mu\, A \int_{-a/v(\xi)}^{0} e^{\lambda\, s} ds,$$

or equivalently,

$$0 = \lambda + \gamma - A - \left(\beta\, e^{-\mu\, a/v(\xi)} g'(\xi) - A\right) e^{-\lambda\, a/v(\xi)} - \mu\, A \int_{-a/v(\xi)}^{0} e^{\lambda\, s} ds. \tag{4.8}$$

To investigate the stability of steady states in different special cases, we make explicit various forms of (4.8).

If we study the case with a constant delay, i.e. v is a constant function with $v(\xi) = v^- = v^+$ in (1.3) and (1.7), then $v' = 0$ and hence $A = 0$. The characteristic equation reduces to

$$\lambda = -\gamma + \beta\, e^{-\mu\, a/v} g'(\xi) e^{-\lambda\, a/v}. \tag{4.9}$$

Similarly, if we study the case with g constant by setting $g^- = g^+$ in (1.3) and (1.6), then $g'(\xi) = 0$ and the characteristic equation is of the form

$$\lambda = -\gamma + A - A e^{-\lambda a/v(\xi)} + \mu A \int_{-a/v(\xi)}^{0} e^{\lambda s} ds = -\gamma + A(1 - e^{-\lambda a/v(\xi)}) \left(1 + \frac{\mu}{\lambda}\right). \tag{4.10}$$

We remark that when $\mu A \neq 0$ in (4.8), the integration of the solution $e^{\lambda t}$ over the delay interval results in a term μ/λ term as appears in (4.10). Division by λ does not arise in the characteristic functions of discrete delay DDEs, and so even if (1.1) looks at first glance like a discrete delay DDE, when combined with the threshold delay condition (1.2) it is a distributed delay DDE. This accords with the results of Smith [55,56] who showed that a DDE with a single threshold delay can be converted through a time transformation to a distributed delay DDE with a constant delay.

When we study the limiting case where both g and v are piecewise constant as defined in (1.6) and (1.7), then there are intervals where $A = v'(\xi) = 0$. For a steady state ξ in such an interval, the characteristic equation simplifies to

$$\lambda = -\gamma, \tag{4.11}$$

where there is a unique negative real characteristic root and the steady state is stable.

5 Dynamics with one Hill function

At a steady state $x(t) \equiv \xi \in \mathbb{R}$, equation (1.2) reduces to

$$\tau(\xi) = \frac{a}{v(\xi)}, \tag{5.1}$$

so the delay is still state-dependent. Equation (1.1) becomes

$$0 = h(\xi) := \beta e^{-\mu\tau(\xi)} g(\xi) - \gamma\xi \tag{5.2}$$

at a steady state. With $g(x)$ and $v(x)$ defined by (1.3) we have that

$$\beta g^- \geq h(0) = \beta e^{-\mu a/v^-} g^- \geq 0, \qquad h(x) \leq \beta e^{-\mu a/v_U} g_U - \gamma x \leq \beta g_U - \gamma x.$$

Consequently any steady state satisfies $\xi \in [0, \beta g_U/\gamma]$, and there is always at least one such steady state.

The steady states occur at the zeros of $h(\xi)$, which from (5.2) occur at the intersections of $\beta e^{-\mu\tau(\xi)} g(\xi)$ and $\gamma\xi$. Thus the number of steady states depends on the behavior of the term $e^{-\mu\tau(\xi)} g(\xi)$ in (5.2).

We begin by considering the simplified setting where either g or v is a constant function, while the other one is either a Hill function defined in (1.3), or a piecewise constant function (1.6) or (1.7). This leads to the four cases discussed below.

With $v^\pm := v^- = v^+$ in (1.3) and (1.7) we obtain $v(\xi) = v^\pm$ independent of the value of ξ and consequently a constant delay $\tau = a/v^\pm$, and equation (1.1) reduces to

$$x'(t) = \beta e^{-\mu\tau} g(x(t-\tau)) - \gamma x(t), \tag{5.3}$$

which is a constant delay DDE with a monotone feedback nonlinearity. We consider this case first for decreasing and increasing g in Sections 5.1 and 5.2, respectively. The results which we obtain correspond to semi-local properties of equilibria which are familiar for the constant delay equation (5.3) with a sufficiently smooth nonlinearity g. If g is strictly decreasing then there is a single equilibrium solution, from which periodic solutions bifurcate off in a sequence of Hopf bifurcations when a parameter multiplying g grows to infinity. These periodic solutions can be distinguished by their oscillation frequencies. Stable periodic orbits occur only at the lowest possible frequency, for so-called *slowly oscillating periodic solutions* [31]. If g is increasing then multiple equilibria are possible. Hopf bifurcations from these equilibria yield periodic orbits which are all unstable. For more detailed information about the numerous local and global results on solutions of autonomous delay differential equations which were achieved during the past decades see, for example, the survey [61].

Sections 5.1 and 5.2 contain results which are not covered by the existing theory. We consider the limiting cases as the smooth function g approaches a piecewise constant function, as these help to understand better the changes which occur in the dynamics when certain parameters grow to infinity. This also affords us the opportunity to present, in the simpler setting of constant delays, the methods we will subsequently use when the delays are state-dependent in Sections 5.3 and 5.4.

With $g^- = g^+$ in (1.3) and (1.6), g is a constant function, while $v^- \neq v^+$ results in a state-dependent delay. We consider the two cases of v decreasing or increasing in Sections 5.3 and 5.4, respectively. The general case where g and v are both non-constant is studied in Section 6.

5.1 Constant delay with decreasing g $(g\downarrow, v\leftrightarrow)$

In this section we study (1.1)–(1.2) with a constant delay τ and decreasing g. The DDE reduces to (5.3) with $\tau = a/v^{\pm}$ on setting $v^{\pm} = v^{-} = v^{+}$ in (1.3) or (1.7). We require $g^{-} > g^{+}$ in (1.3) or (1.6) to ensure that g is decreasing.

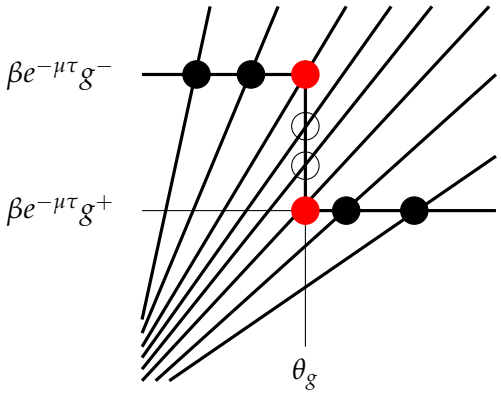

Figure 5.1: Steady states of (1.1), given by (5.2), occur at the intersections of $\xi \mapsto \beta e^{-\mu\tau} g(\xi)$ and $\xi \mapsto \gamma\xi$. These are illustrated for various γ in the limiting case of (1.6) and (1.7) with $v^{\pm} = v^{-} = v^{+}$, so the delay $\tau = a/v^{\pm}$ is constant, and $g^{-} > g^{+}$, so g is monotonically decreasing: $(g\downarrow, v\leftrightarrow)$.

As noted above, if $h(0) \geq 0$ with g decreasing we have $h'(\xi) = \beta e^{-\mu\tau} g'(\xi) - \gamma < 0$. Therefore, with smooth g defined in (1.3), for any fixed values of the parameters there is always exactly one steady state ξ. We note for later use that rearranging (5.2), for any fixed value of $\xi > 0$, there is also a unique value of γ for which ξ is a steady state.

Figure 5.1 illustrates the uniqueness of the steady state with a piecewise constant g defined by (1.6) as γ varies. At the 'corners', the steady state $\xi = \theta_g$ satisfies (5.2) with $g = g^{+}$ and $g = g^{-}$ respectively, which gives rise to

$$\gamma_1 = \frac{\beta e^{-\mu\tau} g^{+}}{\theta_g} \quad \text{and} \quad \gamma_2 = \frac{\beta e^{-\mu\tau} g^{-}}{\theta_g}. \tag{5.4}$$

We refer to the steady state where $e^{-\mu\tau} g(\xi)$ and $\gamma\xi$ intersect on the vertical line segment of the curve as a *singular steady state*. The singular steady state exists for $\gamma \in (\gamma_1, \gamma_2)$, where the bounds on γ are given by (5.4).

Next, we consider the stability of the steady state for the piecewise constant function g defined in (1.6). If $\gamma \in (0, \gamma_1) \cup (\gamma_2, +\infty)$, the intersection occurs on the horizontal line segments. Then $A = g'(\xi) = 0$ and the characteristic equation (4.8) reduces to (4.11), and hence the steady state must be stable. This implies that in the limiting case only a singular steady state may be unstable. However, the characteristic equation is not defined in this situation and we therefore consider the smooth nonlinearity g defined in (1.3) for large n. As a consequence of the choices made in this section, $A = 0$ and $g'(\xi) < 0$ with $n > 0$.

It follows immediately from (4.9) that there are no real non-negative characteristic values when $g'(\xi) < 0$. So, suppose $\lambda = \alpha \pm i\omega$, $\omega > 0$ is a solution of the characteristic equation (4.9). Then for $\lambda = \alpha + i\omega$ we have

$$\alpha + i\omega = -\gamma + \beta e^{-\mu\tau} g'(\xi) e^{-(\alpha+i\omega)\tau} = -\gamma + \beta e^{-\mu\tau} g'(\xi) e^{-\alpha\tau} \left[\cos(\omega\tau) - i\sin(\omega\tau)\right].$$

Equating real and imaginary parts respectively, we obtain

$$\alpha + \gamma = \beta e^{-\mu\tau} g'(\xi) e^{-\alpha\tau} \cos(\omega\tau), \tag{5.5}$$

$$\omega = -\beta e^{-\mu\tau} g'(\xi) e^{-\alpha\tau} \sin(\omega\tau). \tag{5.6}$$

Now suppose that $\lambda = \alpha + i\omega$ is a root of the characteristic equation with $\alpha \geq 0$. Then

$$\gamma \leq \alpha + \gamma \leq \beta e^{-\mu\tau} e^{-\alpha\tau} |g'(\xi)\cos(\omega\tau)| \leq \beta e^{-\mu\tau} |g'(\xi)|.$$

Consequently, if

$$\gamma > \beta e^{-\mu\tau} |g'(\xi)| \tag{5.7}$$

then $\alpha < 0$ for all the characteristic values and the steady state is asymptotically stable. Notice, that since (5.2) is also satisfied at a steady state, equation (5.7) is equivalent to

$$\left| \frac{\xi g'(\xi)}{g(\xi)} \right| < 1. \tag{5.8}$$

We arrive at a sufficient condition for stability of the unique steady state: when (5.8) is satisfied at a steady state, the steady state is asymptotically stable.

The function $\xi \mapsto \xi g'(\xi)/g(\xi)$ plays a central role in the analysis, so we study its properties here. Differentiating g in (1.3) gives

$$g'(\xi) = \frac{n\theta_g^n (g^+ - g^-)\xi^{n-1}}{(\theta_g^n + \xi^n)^2} \tag{5.9}$$

and hence

$$\frac{\xi g'(\xi)}{g(\xi)} = \frac{n(g^+ - g^-)(\xi/\theta_g)^n}{(1 + (\xi/\theta_g)^n)(g^- + g^+(\xi/\theta_g)^n)}. \tag{5.10}$$

Now, let

$$f(x, p, r) = \frac{p(1-r)x^p}{(1+x^p)(r+x^p)} \tag{5.11}$$

and note from (5.10) that $f(\xi/\theta_g, n, g^-/g^+) = \xi g'(\xi)/g(\xi)$. The following proposition will be essential in this and following sections.

Proposition 5.1. *Let $f(x,p,r) : \mathbb{R}^3_{>0} \to \mathbb{R}$ be defined by (5.11) then*

1. *For fixed $p > 0$, $r > 0$,*
$$\lim_{x\to 0} f(x,p,r) = \lim_{x\to\infty} f(x,p,r) = 0.$$
2. *For fixed $r > 0$ with $r \neq 1$ we have $\lim_{p\to\infty} |f(1,p,r)| = \infty$, with*
$$f(1,p,r) = \frac{p(1-r)}{2(1+r)},$$
and $|f(1,p,r)| \leq p/2$.
3. *For fixed $r > 0$ and fixed $x > 0$ with $x \neq 1$,*
$$\lim_{p\to\infty} f(x,p,r) = 0.$$
Moreover, for fixed $r > 0$ and any fixed $x^- \in (0,1)$ and $x^+ > 1$
$$\lim_{p\to\infty} \left(\max_{x\in[0,x^-]} |f(x,p,r)| \right) = \lim_{p\to\infty} \left(\max_{x\in[x^+,\infty)} |f(x,p,r)| \right) = 0.$$

4. *For fixed $r > 0$ with $r \neq 1$ and fixed $p > 0$, regarding $|f(x,p,r)|$ as a function of x only, $|f(x,p,r)|$ has a unique global maximum at $x = r^{1/2p}$ with*

$$f(r^{1/2p},p,r) = \frac{p(1-r^{1/2})}{1+r^{1/2}},$$

and $|f(r^{1/2p},p,r)| \leq p$.

Proof. Follows using elementary differentiation and algebra. □

Proposition 5.1 shows that $\xi \mapsto \xi g'(\xi)/g(\xi)$ is a unimodal function which approaches zero uniformly as $n \to 0$, but which resembles a delta-function with its peak at $\xi = \theta_g(g^-/g^+)^{1/2n} \to \theta_g$ as $n \to \infty$.

Now (5.8) and Proposition 5.1(1) show that if $\xi \ll \theta_g$ or for $\xi \gg \theta_g$ the steady state must be asymptotically stable. From (5.8), a necessary condition for the steady state to be unstable is that $|\xi g'(\xi)/g(\xi)| \geq 1$, but from Proposition 5.1(4) we have

$$\left|\frac{\xi g'(\xi)}{g(\xi)}\right| \leq |f(r^{1/2n},n,r)| = \frac{n|1-r^{1/2}|}{1+r^{1/2}}$$

where $r = r_g = g^-/g^+$. Thus a necessary condition for the steady state to be unstable is that $|f(r^{1/2n},n,r)| \geq 1$. For g decreasing, the value $r_g = g^-/g^+ > 1$, and this necessary condition for instability becomes $n > 1$ and

$$r_g = \frac{g^-}{g^+} \geq \left(1+\frac{2}{n-1}\right)^2. \tag{5.12}$$

Since the steady state is unique, a steady state bifurcation cannot occur, and we therefore investigate the existence of Hopf bifurcations. At a Hopf bifurcation, $\lambda = \pm i\omega$, and (5.5) and (5.6) reduce to

$$\gamma = \beta e^{-\mu\tau} g'(\xi)\cos(\omega\tau), \tag{5.13}$$
$$\omega = -\beta e^{-\mu\tau} g'(\xi)\sin(\omega\tau). \tag{5.14}$$

As $\beta, \gamma, \omega, e^{-\mu\tau} > 0$ and $g'(\xi) < 0$, we must have $\cos(\omega\tau) < 0 < \sin(\omega\tau)$, and hence $\omega\tau \in (\pi/2 + 2k\pi, \pi + 2k\pi)$ for $k \in \mathbb{N}$. We denote by ω_k any solution of (5.13) and (5.14) with the property that $\omega_k\tau \in (\pi/2 + 2k\pi, \pi + 2k\pi)$ for $k \in \mathbb{N}$.

Note that at a Hopf bifurcation, in addition to (5.13) and (5.14), equation (5.2) must also be satisfied. These three equations can be rearranged as

$$\gamma = \frac{\beta}{\xi} e^{-\mu\tau} g(\xi), \tag{5.15}$$
$$\omega\cot(\omega\tau) = -\gamma, \tag{5.16}$$
$$|g'(\xi)| = \frac{\sqrt{\gamma^2+\omega^2}}{\beta e^{-\mu\tau}}. \tag{5.17}$$

We will consider these equations sequentially to show that γ and ω can be regarded as functions of ξ, resulting in a single equation to solve for ξ. First note that for a smooth nonlinearity $g(\xi)$, and for arbitrary $\xi > 0$, equation (5.15) gives a unique value of $\gamma = \gamma(\xi) > 0$. Moreover, since g is monotonically decreasing, we also obtain that $\xi \mapsto \gamma(\xi)$ is monotonically decreasing. Because of the remarks following Proposition 5.1 we will be particularly interested

in the cases where $\xi = \theta_g$ and $\xi = \theta_g(g^-/g^+)^{1/2n}$. Using (5.15), (5.4) and (1.3) it is easy to see that $\gamma(\theta_g) = (\gamma_1 + \gamma_2)/2$ and $\gamma(\theta_g(g^-/g^+)^{1/2n}) = \sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n}$. This shows that the γ value corresponding to the extremum of $\xi g'(\xi)/g(\xi)$ converges to the geometric mean of γ_1 and γ_2 as $n \to \infty$, while the γ value corresponding to $\xi = \theta_g$ is equal to the arithmetic mean of γ_1 and γ_2 independent of the value of n.

Next, for a given $\gamma > 0$, it follows from the properties of the cotangent function that the equation (5.16) gives a sequence of solutions $\{\omega_k\}_{k\geq 0}$ with $\omega_k\tau \in (\pi/2 + 2k\pi, \pi + 2k\pi)$ for $k = 0, 1, 2, \ldots$, with each ω_k uniquely defined as a function of γ. Recall that τ is constant because we are considering $v^- = v^+ = v$. Thus the values $\omega_k \to \infty$ as $k \to \infty$. It follows that solutions ω_k of the equation (5.16) for fixed γ must satisfy $\cot(\omega_k\tau) \to 0$ and hence $\omega_k\tau \to \pi/2 + 2k\pi$ as $k \to \infty$.

Since g is decreasing, the last equation (5.17) then becomes

$$g'(\xi) = -\frac{\sqrt{\gamma^2 + \omega_k^2}}{\beta e^{-\mu\tau}}. \tag{5.18}$$

Notice here that through (5.15) we have γ as a function of ξ, while from (5.16) we can regard each ω_k as an implicitly defined function of γ and hence of ξ. Thus it remains only to solve (5.18) for ξ, or more precisely, we need to solve for a ξ_k for every ω_k.

Combining (5.13) and (5.15) we see that at a Hopf bifurcation

$$\frac{\xi g'(\xi)}{g(\xi)}\cos(\omega\tau) = 1. \tag{5.19}$$

Thus, the function $\xi \mapsto \xi g'(\xi)/g(\xi)$ also plays a role for Hopf bifurcations. Consequently, instead of solving (5.18) directly for ξ, we proceed by combining (5.15) and (5.18) which leads to

$$\beta e^{-\mu\tau} = \frac{\gamma\xi}{g(\xi)} = -\frac{\sqrt{\gamma^2 + \omega_k^2}}{g'(\xi)},$$

and hence

$$\frac{\xi g'(\xi)}{g(\xi)} = -\sqrt{1 + (\omega_k/\gamma)^2}. \tag{5.20}$$

Combining (5.20) and (5.10), it remains to find ξ that solves

$$\frac{n(g^+ - g^-)(\xi/\theta_g)^n}{(1 + (\xi/\theta_g)^n)(g^- + g^+(\xi/\theta_g)^n)} = -\sqrt{1 + (\omega_k/\gamma)^2}. \tag{5.21}$$

We already considered the behaviour of the left-hand side of (5.21) in Proposition 5.1. The behaviour of the right-hand side is considered in the following proposition.

Proposition 5.2. *Let $s_k(\xi) = \sqrt{1 + (\omega_k/\gamma)^2}$ where $\gamma = \gamma(\xi)$ is defined by (5.15) and ω_k satisfies $\omega_k\tau \in (\pi/2 + 2k\pi, \pi + 2k\pi)$ and is a function of γ and hence of ξ through (5.16). Then*

1. $\left(1 + \left(\frac{\pi(2k+1/2)}{\beta\tau e^{-\mu\tau} g_U}\right)^2 \xi^2\right)^{\frac{1}{2}} = m_k(\xi) \leq s_k(\xi) \leq M_k(\xi) = \left(1 + \left(\frac{\pi(2k+1)}{\beta\tau e^{-\mu\tau} g_0}\right)^2 \xi^2\right)^{\frac{1}{2}}$.
2. $1 < s_k(\xi) < 1 + \frac{\pi(2k+1)}{\beta\tau e^{-\mu\tau} g_0}\xi$ *for all* $\xi > 0$.

Proof. Using (5.15)

$$s_k(\xi) = \left(1 + \left(\frac{\omega_k}{\beta e^{-\mu\tau} g(\xi)}\right)^2 \xi^2\right)^{\frac{1}{2}}.$$

Recalling (1.5) and also using the bounds on $\omega_k\tau$, the inequalities in Proposition 5.2(1), and the expressions for the bounds $m_k(\xi)$ and $M_k(\xi)$ follow easily, while Proposition 5.2(2) is weaker than Proposition 5.2(1). □

Recall that for a Hopf bifurcation, we need to solve (5.20) for ξ, but this is the same as solving $f(\xi/\theta_g, n, g^-/g^+) = -s_k(\xi)$, where the relevant properties of f and s_k are stated in Propositions 5.1 and 5.2. Propositions 5.2(1) defines bands $[m_k(\xi), M_k(\xi)]$ within which each $s_k(\xi)$ lies. Since $|s_k(\xi)| > 1$ and $\lim_{\xi\to 0} f(\xi/\theta_g, n, g^-/g^+) = \lim_{\xi\to\infty} f(\xi/\theta_g, n, g^-/g^+) = 0$, for all ξ sufficiently large or small we have $f(\xi/\theta_g, n, g^-/g^+) > -s_k(\xi)$. On the other hand, considering $\xi = \theta_g$, by Proposition 5.1(2), $f(1, n, g^-/g^+) \to -\infty$ as $n \to \infty$ while $s_k(\theta_g) \le M_k(\theta_g)$ is bounded. Consequently, for n sufficiently large $f(1, n, g^-/g^+) < -s_k(\xi)$. It follows that there are at least two points $\xi_k^- < \theta_g < \xi_k^+$ for which $f(\xi_k^\pm/\theta_g, n, g^-/g^+) = -s_k(\xi_k^\pm)$, and hence which solve (5.21). With the corresponding values of γ and ω_k defined by (5.15) and (5.16) this defines two solutions of (5.15)–(5.17).

We already noted that the steady state must be stable, and hence cannot undergo a Hopf bifurcation for ξ sufficiently small or large. On the other hand, Hopf bifurcations must occur for n sufficiently large, as for large enough n the function f will pierce through the band $s_k(\xi) \in [m_k(\xi), M_k(\xi)]$ for $\xi \approx 1$. In particular, a sufficient (but not necessary) condition for this to occur is that $M_k(\theta_g) < -f(1, n, g^-/g^+)$, or equivalently that

$$n > 2\frac{(g^-/g^+)+1}{(g^-/g^+)-1}\left(1 + \left(\frac{\pi\theta_g(2k+1)}{\beta\tau e^{-\mu\tau} g_0}\right)^2\right)^{\frac{1}{2}}. \tag{5.22}$$

This condition follows from evaluation of the function f at $x = 1$. A more complicated but tighter bound can be derived using the maximum of f. Therefore another sufficient condition to ensure that the k-th Hopf bifurcation occurs is that

$$M_k(\theta_g(g^-/g^+)^{1/(2n)}) < -f((g^-/g^+)^{1/(2n)}, n, g^-/g^+).$$

While there is a unique steady state ξ for the case of decreasing g with constant τ, the location and properties of this steady state will depend on the values of the other parameters. The following theorem collects together our results for this case.

Theorem 5.3. *Let ξ be the steady state of the DDE (1.1), (1.2) with constant delay τ and nonlinearity g defined by (1.3) with g monotonically decreasing (so $g^- > g^+$). Then:*

1. *If $|\frac{\xi g'(\xi)}{g(\xi)}| < 1$, then the steady state ξ is asymptotically stable.*
2. *If $n \le 1$, or $n > 1$ and $r_g = \frac{g^-}{g^+} < \left(1 + \frac{2}{n-1}\right)^2$, then the steady state ξ is asymptotically stable.*
3. *For any fixed $n > 1$, and for $0 < \xi \ll \theta_g$ or $\xi \gg \theta_g$, or equivalently for $\gamma \gg \gamma_2$ or $0 < \gamma \ll \gamma_1$, the steady state is asymptotically stable.*
4. *For any fixed $\xi \neq \theta_g$, let $\gamma = \gamma(n, \xi)$ be the value of γ such that (5.2) is satisfied and hence ξ is a steady state. Or, for any fixed γ with $0 < \gamma < \gamma_1$ or $\gamma > \gamma_2$ let $\xi = \xi(n, \gamma)$ satisfy (5.2) and hence be a steady state. Then ξ is asymptotically stable for all n sufficiently large.*

5. *Let (5.22) be satisfied for fixed $n \geq 2$ and fixed $k \geq 0$. Then as γ is varied*

   (a) *There are two families of (at least) $k+1$ Hopf bifurcations. One exists for $\gamma < \sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n}$ and the other for $\gamma > (\gamma_1+\gamma_2)/2$. In the first family, the characteristic values $\lambda_j = i\omega_j$ satisfy $\omega_j\tau \in (\pi/2+2j\pi, \pi+2j\pi)$ for $j = 0,1,\ldots,k$ and cross the imaginary axis from left to right as γ is increased, while in the second family they cross the imaginary axis from right to left.*

   (b) *For $\xi \in [\theta_g, \theta_g(g^-/g^+)^{1/(2n)}]$ or equivalently for $\gamma \in [\sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n}, (\gamma_1+\gamma_2)/2]$ the steady state is unstable with at least $k+1$ pairs of complex conjugate characteristic values $\lambda_j = \alpha_j \pm i\omega_j$ with $\alpha_j > 0$ and $\omega_j\tau \in (\pi/2+2j\pi, \pi+2j\pi)$ for $j = 0,1,\ldots,k$.*

6. *Let $\gamma \in (\gamma_1,\gamma_2)$ be fixed. Then as n is increased there is an infinite sequence of Hopf bifurcations where the real part of $\lambda_k = \alpha_k \pm i\omega_k$ becomes positive with $\omega_k\tau \in (\pi/2+2k\pi, \pi+2k\pi)$ for $k = 0,1,2,\ldots$*

Proof. (1) and (2) were already shown immediately after the proof of Proposition 5.1.

The first part of (3) then follows from Proposition 5.1(1), since $\lim_{\xi\to 0} f(\xi/\theta_g, n, g^-/g^+) = \lim_{\xi\to\infty} f(\xi/\theta_g, n, g^-/g^+) = 0$ implies $|\xi g'(\xi)/g(\xi)| < 1 < s_k(\xi)$ and $\xi g'(\xi)/g(\xi) = -s_k(\xi)$ cannot hold for ξ sufficiently small ($0 < \xi \ll \theta_g$) or large ($\xi \gg \theta_g$). The second part follows from (5.15) on noting that g monotonically decreasing implies that $\gamma(\xi)$ is monotonically decreasing with $\lim_{\xi\to 0}\gamma(\xi) = +\infty$ and $\lim_{\xi\to\infty}\gamma(\xi) = 0$.

For the first part of (4), consider a steady state at a fixed value of ξ as n is varied, with the other parameters fixed except for $\gamma = \gamma(n,\xi)$ which is determined by (5.2). The result then follows directly from the first part of Proposition 5.1(3). To prove the second part of (4) note that when $g^- > g^+$ from (1.3) we have $g^- > g(\xi) > g^+$ which using (5.4) is equivalent to

$$\gamma_2 > \frac{\beta e^{-\mu\tau} g(\xi)}{\theta_g} > \gamma_1.$$

Fix $\gamma > 0$ and using (5.15), we further rewrite this as

$$\frac{\gamma_2}{\gamma} > \frac{\xi}{\theta_g} > \frac{\gamma_1}{\gamma}. \tag{5.23}$$

Consequently, for $\xi = \xi(n,\gamma)$ satisfying (5.2), if $\gamma < \gamma_1$ then we have $\xi > \theta_g\gamma_1/\gamma > \theta_g$ while $\gamma > \gamma_2$ implies $\xi < \theta_g\gamma_2/\gamma < \theta_g$. The result then follows from the second part of Proposition 5.1(3).

For (5), equation (5.22) implies that

$$-f(1,n,g^-/g^+) > M_k(\theta_g) > M_{k-1}(\theta_g) > \ldots > M_0(\theta_g).$$

However, $s_j(\xi) \geq 1$ for all $\xi \in \mathbb{R}$ and $\lim_{x\to 0} f(x,n,g^-/g^+) = \lim_{x\to\infty} f(x,n,g^-/g^+) = 0$. Consequently for each $j \in \{0,1,\ldots,k\}$ there are at least two values of ξ which solve $-f(\xi/\theta_g, n, g^-/g^+) = s_j(\xi)$. The largest such ξ with $\xi > \theta_g(g^-/g^+)^{1/(2n)}$ and the smallest with $\xi < \theta_g$ define the required Hopf bifurcations. Since, as already noted, $\gamma(\xi)$ defined by (5.15) is a monotonically decreasing function of ξ with $\gamma(\theta_g) = (\gamma_1+\gamma_2)/2$ and $\gamma(\theta_g(g^-/g^+)^{1/(2n)}) = \sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n}$, the result follows.

For (6) we consider the behaviour of the Hopf bifurcation points as $n \to \infty$. Applying Proposition 5.1 (and recalling that $g_- > g_+$ because g is decreasing), the function $|\xi g'(\xi)/g(\xi)|$ takes its maximum at $\xi = \theta_g(g^-/g^+)^{1/2n} > \theta_g$, while also $|\theta_g g'(\theta_g)/g(\theta_g)| =$

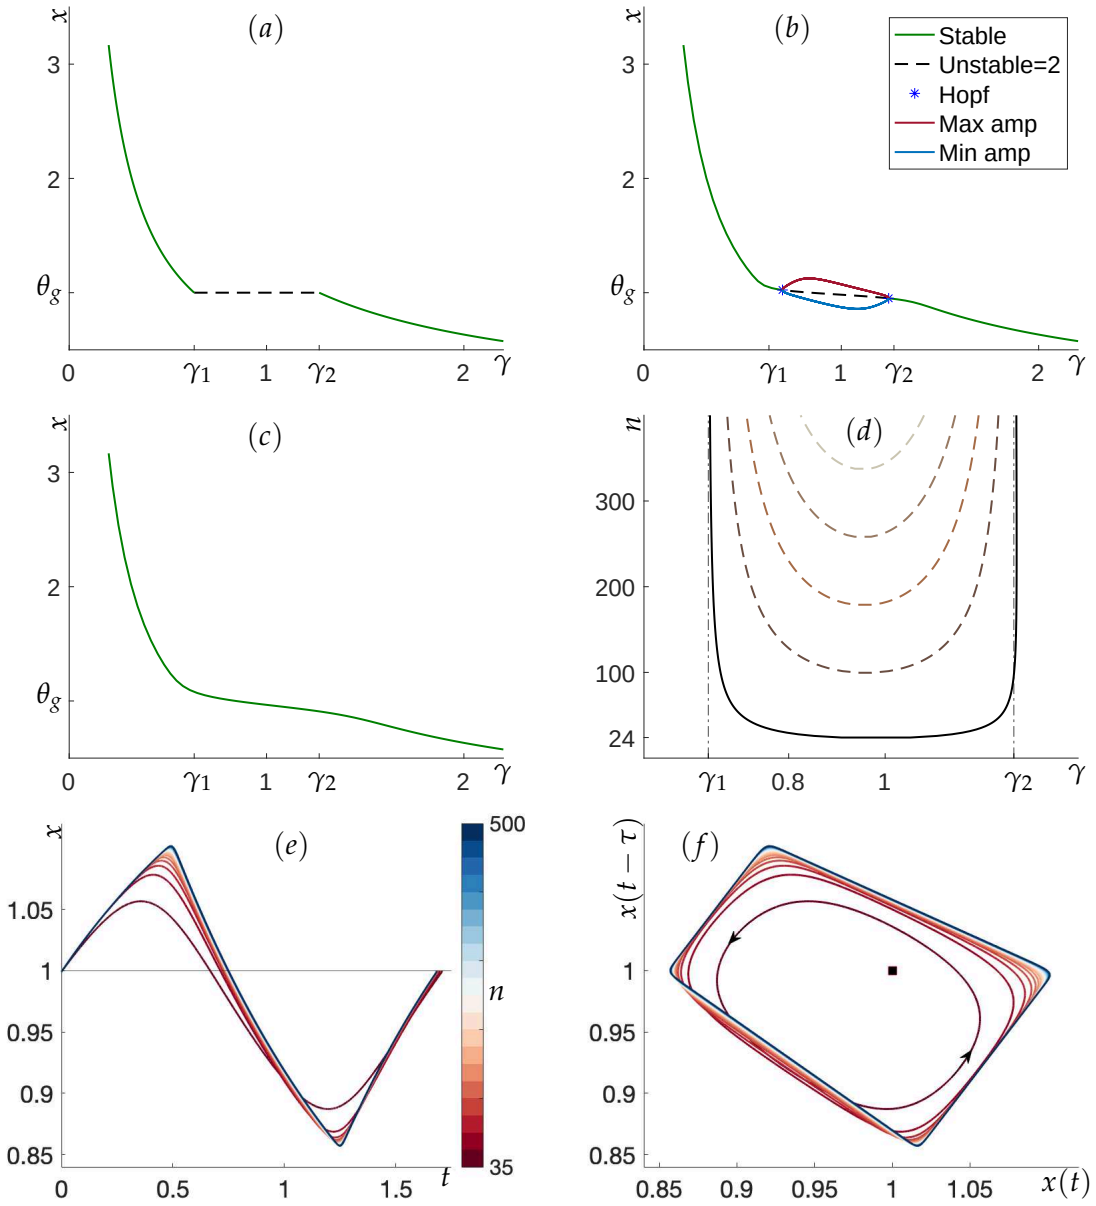

Figure 5.2: Bifurcations of (1.1)–(1.2) for $(g\downarrow, v\leftrightarrow)$ with parameters $\beta = 1.4$, $\mu = 0.2$, $g^- = 1$, $g^+ = 1/2$, $\theta_g = 1$, $\gamma = a = 1$, and $v = v^- = v^+ = 2$. (a) The limiting case with g defined by (1.6) showing the stable (green solid line) and singular (black dashed line) steady states. (b) With smooth nonlinearity g defined by (1.3) and $n = 50$. Solid lines denote stable objects including the stable steady state (green) and a stable limit cycle (represented by maximum and minimum of $x(t)$ on the periodic solution). Dashed lines represent unstable steady states which have two eigenvalues with positive real part (in black). (c) As in (b) but with $n = 23$. (d) Two-parameter continuations in n and γ of the Hopf bifurcations defined by (5.15)–(5.17) with the other parameters as above. Solid curves indicate the parts of the branch where there are no characteristic values with positive real part (and hence a stability change at the bifurcation), and dashed lines indicate the parts of the branch where there are already unstable characteristic values. The outermost curve of Hopf bifurcations is associated with the stability change seen in (b). The dash-dotted vertical black lines denote $\gamma = \gamma_1$ and $\gamma = \gamma_2$, the locations of the Hopf bifurcations in the limiting case as $n \to \infty$. (e) Profiles of the stable periodic orbits from the outermost curve of Hopf bifurcations in (d) at $\gamma = 1$ for different values of the continuation parameter n. (f) The same periodic orbits as in (e), but now shown as a projection onto the plane $(x(t), x(t-\tau))$ where $\tau = 0.5$. The arrow indicates the direction of the flow. The square denotes the singular steady state in the limiting case.

$|f(1, n, g^-/g^+)| \gg 1$. Consequently for fixed k the two Hopf bifurcation points, ξ_k^- and ξ_k^+ satisfy $\xi_k^- < \theta_g < \theta_g(g^-/g^+)^{1/2n} < \xi_k^+$. Using Proposition 5.1(3) we conclude that $\xi_k^\pm \to \theta_g$ as $n \to \infty$.

Also for fixed k, as $n \to \infty$, the value of $\omega_k \leq (2k+1)\pi/\tau$ remains bounded, as does γ by (4). Consequently for (5.18) to be satisfied it follows that $g'(\xi_k)$ must also remain bounded as $n \to \infty$. Then in the limit as $n \to \infty$ the Hopf bifurcations must converge to the "corners" of $g(\xi)$ where $\xi = \theta_g$ and $\gamma = \gamma_1$ or $\gamma = \gamma_2$. Consequently for any fixed $\gamma \in (\gamma_1, \gamma_2)$ as $n \to \infty$ there is an infinite sequence of Hopf bifurcations. □

Figure 5.2 illustrates the behaviour of (1.1)–(1.2) for $(g\downarrow, v\leftrightarrow)$. Panels (b)–(f) were computed numerically using `ddebiftool` as described in Appendix C.

Figure 5.2(a) and (b) show the similarities between the dynamics with the piecewise continuous nonlinearity (1.6) and the smooth Hill function g defined in (1.3) with $n = 50$. The singular steady state in (a) becomes an unstable steady state in the smooth case, with a bubble of stable periodic orbits existing between the pair of Hopf bifurcations where the steady state changes stability. The stable periodic orbits at $\gamma = 1$ for increasing values of n are shown as profiles in Figure 5.2(e) and projected onto the $(x(t), x(t-\tau))$-plane in Figure 5.2(f). The apparent limiting behaviour that is revealed is the topic of [31].

When the value of n is decreased, the interval of γ values between the Hopf bifurcations shrinks, until for n sufficiently small the steady state is always stable, as seen in Figure 5.2(c). Interestingly, even though there is no bifurcation in this case, the graph in Figure 5.2(c) still has a plateau around where the singular steady states exist in Figure 5.2(a).

Figure 5.2(d) shows two-parameter continuations in the (γ, n) plane of the Hopf bifurcations. This reveals the Hopf bifurcations associated with ω_k for $k = 0, 1, \ldots, 4$, with each successive Hopf bifurcation only existing for progressively larger values of n, as implied by (5.22). In particular there is no Hopf bifurcation for $n < 24$ and a second Hopf bifurcation is only seen if $n > 100$. This is why no Hopf bifurcation is seen in Figure 5.2(c) with $n = 23$, and only one pair of Hopf bifurcations is seen in Figure 5.2(b) with $n = 50$.

Figure 5.2(d) also illustrates Theorem 5.3 (points 5 and 6) where the additional Hopf bifurcations occurring as n increases approach the vertical asymptotes $\gamma = \gamma_1$ and $\gamma = \gamma_2$ in the limit as $n \to \infty$. Notice also the existence of Hopf bifurcations with $\gamma > \gamma_2$ in Figure 5.2(d); so it *is* possible for the steady state to be unstable outside the interval $\gamma \in [\gamma_1, \gamma_2]$, albeit only for a finite range of values n by Theorem 5.3 (point 3).

5.2 Constant delay with g increasing $(g\uparrow, v\leftrightarrow)$

In this section we study (1.1)–(1.2) with constant delay again, but in contrast to the previous section we assume that g is increasing. We thus assume $g^- < g^+$ in (1.3) and (1.6), with $v^- = v^+ = v^\pm$ so the delay $\tau = a/v^\pm$ is constant, independent of ξ.

When g is increasing, it is possible for multiple steady states to coexist. For example, considering the limiting case where g is given by (1.6), as shown in Figure 5.3, there are up to three coexisting steady states, including a singular steady state, as the slope of the line $\gamma\xi$ changes. The corners defined by (5.4) give rise to fold bifurcations due to a change in the number of steady states. Since these bifurcations involve a singular steady state they are not truly fold bifurcations but we use this term since, as we show below, they reflect the presence of true fold bifurcations for the smooth nonlinearity g defined by (1.3) with $g'(\xi) \gg 0$. This is illustrated in Figure 5.4(a) where there are two fold bifurcations between stable and singular steady states, with the outer steady states stable, and the middle steady state is singular.

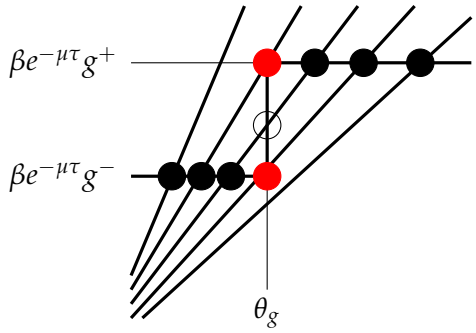

Figure 5.3: Illustration of how the number of steady states of (1.1) given by (5.2) changes with the intersections of $\xi \mapsto \beta e^{-\mu\tau} g(\xi)$ and $\xi \mapsto \gamma\xi$. These are shown in the limiting case with $v^\pm = v^- = v^+$ so $\tau = a/v^\pm$ is constant, and $g^- < g^+$ in (1.6) so g is piecewise constant and monotonically increasing: $(g \uparrow, v \leftrightarrow)$.

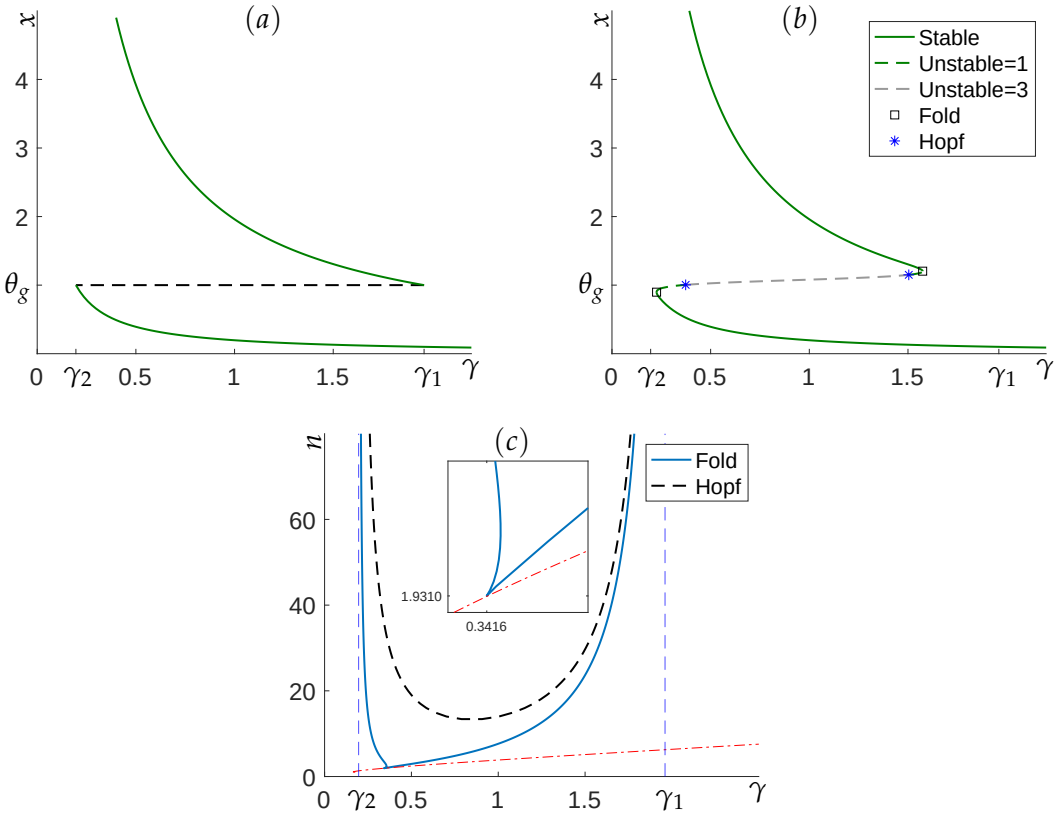

Figure 5.4: Bifurcations of (1.1)–(1.2) with $(g \uparrow, v \leftrightarrow)$ and parameters $\beta = 2$, $\mu = 0.02$, $g^- = 0.1$, $g^+ = 1$, $\theta_g = 1$, $\gamma = 1$, $a = 2$ and $v = v^- = v^+ = 2$. (a) The limiting case with g defined by (1.6). Stable steady states are shown as green solid lines, and the singular steady state as a black dashed line. (b) With a smooth nonlinearity g defined by (1.3) with $n = 30$. (c) Two-parameter continuations in n and γ of the fold (blue) and the Hopf (black) bifurcations with the other parameters as above. The dashed vertical lines denote $\gamma = \gamma_1$ and $\gamma = \gamma_2$, the location of the fold bifurcations in the limiting case as $n \to \infty$. The red dash-dotted curve denotes the bound on the fold bifurcations given by (5.28).

With g defined by the piecewise constant function (1.6), as in Section 5.1, for the non-singular steady states we have $A = g'(\xi) = 0$. The characteristic equation is again of the form (4.11), so these steady states must be stable. Only the singular steady state may be unstable, and since it coexists with two stable steady states, it is natural to regard it as unstable even though the dynamical system is infinite dimensional and the characteristic equation is not defined at the singular steady state. The bifurcation diagram for this case is illustrated in Figure 5.4(a).

For the smooth nonlinearity $g(\xi)$ defined by (1.3), from (4.9) the characteristic function is given by

$$\Delta(\lambda) = \lambda + \gamma - \beta e^{-\mu\tau} g'(\xi) e^{-\lambda\tau}. \tag{5.24}$$

Considering $\lambda \in \mathbb{R}$ first, note that $\Delta(\lambda)$ is asymptotic to $\lambda + \gamma$ for $\lambda \gg 0$. On the other hand, using (5.2) we find

$$\Delta(0) = \gamma \left(1 - \frac{\xi g'(\xi)}{g(\xi)}\right). \tag{5.25}$$

Consequently when

$$\frac{\xi g'(\xi)}{g(\xi)} > 1 \tag{5.26}$$

there is always a real characteristic value $\lambda > 0$ and the steady state is unstable. Moreover there is a characteristic value $\lambda = 0$ if and only if

$$\frac{\xi g'(\xi)}{g(\xi)} = 1, \tag{5.27}$$

and the results developed in Section 5.1, and in particular Proposition 5.1, can be applied to the fold bifurcations. Thus for $n \gg 0$ there will be two fold bifurcations $\xi^{\pm} \approx \theta_g$: one with $\gamma \approx \gamma_1$ and the other with $\gamma \approx \gamma_2$, where γ_1 and γ_2 are defined by (5.4) with $\gamma_2 < \gamma_1$ since g is increasing.

To find the fold bifurcations, equations (5.27) and (5.15) must be solved together. We first do this numerically. Figure 5.4(b) shows the resulting bifurcation diagram for the smooth nonlinearity $g(\xi)$ defined by (1.3) with $n = 30$, revealing, as expected, two smooth fold bifurcations, with an intermediate branch of unstable steady states between the stable steady states.

To further investigate when multiple steady states arise for smoothly increasing g, note that a necessary condition for multiple coexisting steady states is that $\max_{\xi \geq 0}\{h'(\xi)\} \geq 0$. This imposes a constraint on the parameters as follows. The function g has a single point of inflection $\bar{x}$ with $g''(\bar{x}) = 0$, which can be computed by differentiating g twice to find

$$\bar{x} = \theta_g \left(\frac{n-1}{n+1}\right)^{1/n}.$$

Note that $\bar{x} > 0$ requires the restriction $n > 1$. With $\bar{x}$, we can compute the maximal value of the derivative

$$\max_{\xi \geq 0}\{h'(\xi)\} = h'(\bar{x}) = \beta e^{-\mu\tau} g'(\bar{x}) - \gamma = \beta e^{-\mu\tau}(g^+ - g^-)\frac{(n+1)^{1+1/n}(1-n)^{1-1/n}}{4n\theta_g} - \gamma.$$

Therefore, if there are multiple steady states, the parameters must satisfy

$$\gamma \leq \beta e^{-\mu\tau}(g^+ - g^-)\frac{(n+1)^{1+1/n}(n-1)^{1-1/n}}{4n\theta_g}. \tag{5.28}$$

Figure 5.4(c) shows a two-parameter continuation of the fold bifurcations for increasing g. For large n the folds approach the asymptotes $\gamma = \gamma_1$ and $\gamma = \gamma_2$ defined by the limiting case. As n decreases the two fold bifurcations move closer together until they collide in a cusp bifurcation. At the cusp, the three steady states coincide, and at this point $h(\xi)$ is a monotonically decreasing function of ξ with a zero of multiplicity three at the steady state $\bar{\xi}$. Consequently not only is $h(\bar{\xi}) = h'(\bar{\xi}) = 0$ at this point, but also the function $h'(\xi)$ attains its maximum at $\bar{\xi}$ and the cusp point lies on the bounding curve defined by (5.28), as seen in Figure 5.4(c).

The analysis of Hopf bifurcations from Section 5.1 can be repeated with only minor changes for the case of increasing g. Characteristic values again satisfy (5.5) and (5.6), and at a Hopf bifurcation (5.13) and (5.14). Since $g'(\xi) > 0$, we require $\sin(\omega\tau) < 0 < \cos(\omega\tau)$ and hence

$$\omega\tau \in (2k + 3/2)\pi, (2k + 2)\pi), \quad k \in \mathbb{N}.$$

Equations (5.15), (5.16) and (5.17) can again be considered sequentially, and reduced to a single equation to solve for ξ, where for increasing g, equation (5.17) becomes

$$g'(\xi) = \frac{\sqrt{\gamma^2 + \omega_k^2}}{\beta e^{-\mu\tau}}. \tag{5.29}$$

This last equation is most easily considered by combining it with (5.15) to obtain

$$\frac{\xi g'(\xi)}{g(\xi)} = \sqrt{1 + (\omega_k/\gamma)^2}, \tag{5.30}$$

where $\xi g'(\xi)/g(\xi)$ is still given by (5.10) and Propositions 5.1 and 5.2 both apply.

We conclude that as γ is varied there is a sequence of Hopf bifurcations parameterized by a frequency $\omega_k \to \infty$ satisfying $\omega_k\tau \in ((2k+3/2)\pi, (2k+2)\pi)$ for $k \in \mathbb{N}$, where for each fixed k there is a minimal n at which this bifurcation exists. Furthermore, this minimal n grows with k. Additionally, for any fixed k as $n \to \infty$ the bifurcation points satisfy $\gamma \to \gamma_1$ and $\gamma \to \gamma_2$. Figure 5.4(b) shows that the steady states lose stability at the fold bifurcation and the resulting unstable steady state undergoes a Hopf bifurcation. This indicates that the resulting periodic orbits are unstable and thus not consequential for the asymptotic dynamics in contrast to the case of decreasing g. The two-parameter continuation of the first Hopf bifurcation is shown in Figure 5.4(c).

We collect our results from this section together in the following theorem. While there are many similarities between Theorems 5.3 and 5.4, the presence of fold bifurcations introduces some important differences. Note also that since g is increasing, in this section we have $r_g = g^-/g^+ < 1$ and also $\gamma_1 > \gamma_2$.

Theorem 5.4. *Let ξ be a steady state of the DDE (1.1), (1.2) with constant delay τ and nonlinearity g defined by (1.3) with g monotonically increasing (so $g^- < g^+$). Then*

1. *The steady state ξ is asymptotically stable if $\frac{\xi g'(\xi)}{g(\xi)} < 1$, and unstable if $\frac{\xi g'(\xi)}{g(\xi)} > 1$.*
2. *For any fixed $\xi \neq \theta_g$ let $\gamma = \gamma(n, \xi)$ be the value of γ such that (5.2) is satisfied and hence ξ is a steady state. Or, for any fixed γ with $0 < \gamma < \gamma_2$ or $\gamma > \gamma_1$ let $\xi = \xi(n, \gamma)$ satisfy (5.2) and hence be a steady state. Then ξ is asymptotically stable for all n sufficiently large.*
3. *If $n \leq 1$, or $n > 1$ and $r_g = \frac{g^-}{g^+} > \left(1 - \frac{2}{n+1}\right)^2$, then the steady state ξ is asymptotically stable.*

4. *If* $n > 1$ *and* $r = \frac{g^-}{g^+} < \left(1 - \frac{2}{n+1}\right)^2$, *then there exists* $\xi^- < \theta_g (g^-/g^+)^{1/2n} < \xi^+$ *and* $\gamma(\xi^-) < \sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n} < \gamma(\xi^+)$ *such that as* γ *is varied, there is one branch of stable steady states with* $\xi < \xi^-$ *and* $\gamma > \gamma(\xi^-)$ *and another stable branch with* $\xi > \xi^+$ *and* $\gamma < \gamma(\xi^+)$. *For* $\gamma \in (\gamma(\xi^-), \gamma(\xi^+))$ *the two stable branches of steady states co-exist with a branch of unstable steady states which exists between fold bifurcations at* $(\xi, \gamma) = (\xi^-, \gamma(\xi^-))$ *and* $(\xi, \gamma) = (\xi^+, \gamma(\xi^+))$.

5. *Let fixed* $n \geq 2$ *and fixed* $k \geq 0$ *satisfy*

$$n > 2\frac{1 + (g^-/g^+)}{1 - (g^-/g^+)} \left(1 + \left(\frac{2\pi\theta_g(k+1)}{\beta\tau e^{-\mu\tau} g_0}\right)^2\right)^{\frac{1}{2}}. \tag{5.31}$$

Then as γ *is varied*

   (a) *There are two families of (at least)* $k+1$ *Hopf bifurcations from the unstable steady-state. One exists for* $\gamma < \sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n}$ *and the other for* $\gamma > (\gamma_1 + \gamma_2)/2$. *In the first family, the characteristic values* $\lambda_j = \alpha_j \pm i\omega_j$ *with* $\omega_j\tau \in (3\pi/2 + 2j\pi, 2\pi + 2j\pi)$ *for* $j = 0, 1, \ldots, k$ *cross the imaginary axis from left to right as* γ *is increased, while in the second family they cross the imaginary axis from right to left.*

   (b) *For* $\xi \in [\theta_g(g^-/g^+)^{1/(2n)}, \theta_g]$, *or equivalently for* $\gamma \in (\sqrt{\gamma_1\gamma_2}/(g^-/g^+)^{1/2n}, (\gamma_1 + \gamma_2)/2)$, *the unstable steady state has one positive real characteristic value and at least* $k+1$ *pairs of complex conjugate characteristic values* $\lambda_j = \alpha_j \pm i\omega_j$ *with* $\alpha_j > 0$ *and* $\omega_j\tau \in (3\pi/2 + 2j\pi, 2\pi + 2j\pi)$ *for* $j = 0, 1, \ldots, k$.

6. *Let* $\gamma \in (\gamma_2, \gamma_1)$ *be fixed. Then as* n *is increased there is an infinite sequence of Hopf bifurcations on the branch of unstable equilibria where the real part of* $\lambda_k = \alpha_k \pm i\omega_k$ *becomes positive with* $\omega_k\tau \in (3\pi/2 + 2k\pi, 2\pi + 2k\pi)$.

Proof. The first part of (1) follows from (5.8), while the second part follows from (5.24)–(5.26).

The proof of the first part of (2) is identical to the proof of the first part of (4) of Theorem 5.3. To show the second part of (2), note that when $g^+ > g^-$ from (1.3) we have $g^+ > g(\xi) > g^-$ which, using (5.4), is equivalent to

$$\gamma_1 > \frac{\beta e^{-\mu\tau} g(\xi)}{\theta_g} > \gamma_2.$$

Fix $\gamma > 0$ and using (5.15), we further rewrite this as

$$\frac{\gamma_1}{\gamma} > \frac{\xi}{\theta_g} > \frac{\gamma_2}{\gamma}.$$

Hence, for $\xi = \xi(n, \gamma)$ satisfying (5.2) if $\gamma > \gamma_1$ then $\xi < \theta_g\gamma_1/\gamma < \theta_g$. On the other hand, if $\gamma < \gamma_2$ then $\xi > \theta_g\gamma_2/\gamma > \theta_g$. The result follows from (1) and the second part of Proposition 5.1(3)

Statement (3) is shown similarly to the corresponding result in Theorem 5.3, noting that since g is increasing $r_g = g^-/g^+ < 1$, which results in a different inequality than the one found in (5.12).

To show (4) consider the curve of steady states $(\xi, \gamma(\xi))$ for $\xi > 0$ where $\gamma(\xi)$ is defined by (5.15). Using Proposition 5.1, the conditions of (4) imply that $\xi g'(\xi)/g(\xi)$ has a maximum value larger than 1 at $\xi = \theta_g(g^-/g^+)^{1/2n}$. Let $\xi^- < \theta_g(g^-/g^+)^{1/2n} < \xi^+$ be the points where

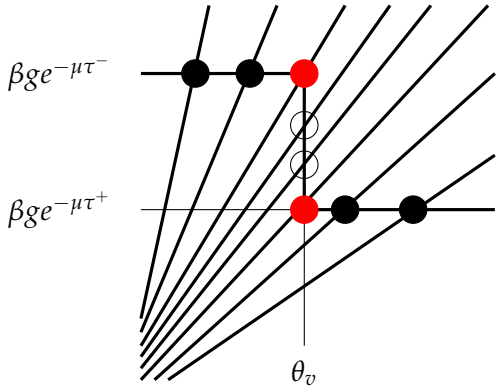

Figure 5.5: Steady states of (1.1) are given by (5.2), and hence occur at the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g$ and $\xi \mapsto \gamma\xi$. These are illustrated for various $\gamma > 0$ in the limiting case of (1.6) and (1.7) with $g^\pm = g^- = g^+$, so $g(\xi) = g^\pm$ is a constant function, and $v^- > v^+$, so v is piecewise constant and monotonically decreasing : $(g \leftrightarrow, v \downarrow)$. Then $\tau(\xi) = a/v(\xi)$ is state-dependent; $\tau(\xi) = \tau^- = a/v^-$ for $\xi < \theta_v$, $\tau(\xi) = \tau^+ = a/v^+$ for $\xi > \theta_v$ and $\tau(\xi)$ is set-valued when $\xi = \theta_v$.

$\xi^- g'(\xi^-)/g(\xi^-) = \xi^+ g'(\xi^+)/g(\xi^+) = 1$. Then the steady state is stable for $\xi < \xi^-$ and $\xi > \xi^+$, and unstable for $\xi \in (\xi^-, \xi^+)$. Now differentiating (5.15) we find that

$$\gamma'(\xi) = -\frac{\beta}{\xi^2} e^{-\mu\tau} g(\xi) + \frac{\beta}{\xi} e^{-\mu\tau} g'(\xi) = \frac{\beta}{\xi^2} e^{-\mu\tau} g(\xi) \left[\frac{\xi g'(\xi)}{g(\xi)} - 1\right] = \frac{\gamma(\xi)}{\xi} \left[\frac{\xi g'(\xi)}{g(\xi)} - 1\right]. \quad (5.32)$$

Thus $\gamma(\xi)$ is a decreasing function of ξ when the steady state is stable, and an increasing function when it is unstable. From this (4) follows.

The proofs of (5) and (6) are similar to the proof of Theorem 5.3, with the main difference being that for a Hopf bifurcation from the unstable steady state we require $\omega_k \tau \in (3\pi/2 + 2k\pi, 2\pi + 2k\pi)$, while for g increasing a sufficient condition to obtain a solution of (5.30) is that $M_k(\theta_g) < f(1, n, g^-/g^+)$. □

It would be interesting if the Hopf and fold bifurcations could exchange positions on the branch, so that the steady state lost stability in a Hopf bifurcation instead of a fold bifurcation. However, this cannot happen with a constant delay because, as the theorem shows, stability is always lost when $\xi g'(\xi)/g(\xi) = 1$ at which point there is a zero characteristic value giving rise to a fold bifurcation.

5.3 State-dependent delay with v decreasing and g constant $(g \leftrightarrow, v \downarrow)$

To understand the dynamics of (1.1)–(1.2) with a state-dependent delay, we impose $g^\pm := g^- = g^+$ in (1.3) and (1.6), so $g(\xi) = g^\pm$ is a constant function. We first consider a decreasing function v with $v^- > v^+$ in (1.3) and (1.7).

It is convenient to let $\tau^+ := a/v^+$ and $\tau^- := a/v^-$. Then at a steady state ξ with $v^- > v^+$, equation (5.1) implies $\tau(\xi)$ is an increasing function of ξ with $\tau^- < \tau(\xi) < \tau^+$, so $e^{-\mu\tau(\xi)}$ is a decreasing function of ξ. Under these circumstances, $h(\xi)$ is monotonically decreasing and equation (5.2) has exactly one solution, and so there is always a unique steady state.

Figure 5.5 illustrates the uniqueness of the steady state in the limiting case when v defined

by (1.7) is piecewise constant. The steady states at the corners are associated with

$$\gamma_3 = \frac{\beta g^{\pm} e^{-\mu\tau^+}}{\theta_v} \quad \text{and} \quad \gamma_4 = \frac{\beta g^{\pm} e^{-\mu\tau^-}}{\theta_v}. \tag{5.33}$$

As discussed in Section 5.1, the steady state is stable if $\gamma \in (0,\gamma_3) \cup (\gamma_4,\infty)$ as then $A = g'(\xi) = 0$ and the characteristic equation (4.8) reduces to (4.11) with exactly one negative real characteristic value. Consequently, the steady state may only be unstable in the singular case for $\gamma \in (\gamma_3,\gamma_4)$.

Since A, which is given by (4.4), is undefined for singular steady states, the characteristic equation (4.10) cannot be used to study the stability of the singular steady states. So, instead we consider the stability of the steady states for the smooth velocity nonlinearity v defined in (1.3). There will be some similarities to the analysis in Section 5.1, but the problem studied in this section with state-dependent delay is significantly more complicated than the constant delay problem considered before.

With g constant and v defined by (1.3) the characteristic equation is of the form (4.10). Recalling the definition of A from (4.4) and using (5.2), we obtain at a steady state ξ

$$A = \beta \frac{v'(\xi)}{v(\xi)} e^{-\mu\tau(\xi)} g^{\pm} = \gamma \frac{\xi v'(\xi)}{v(\xi)} < 0, \tag{5.34}$$

since $v^- > v^+$ implies $v'(\xi) < 0$. It follows that the right-hand side of (4.10) is negative when $\lambda \geq 0$, and so there are no non-negative real characteristic values. This is not surprising since we already know that the steady state is unique, and therefore there are no steady-state bifurcations.

Furthermore, since $v(\xi)$ is a Hill function, it follows that

$$\frac{\xi v'(\xi)}{v(\xi)} = f(\xi/\theta_v, m, v^-/v^+), \tag{5.35}$$

where f is defined by (5.11). Thus Proposition 5.1 will be relevant in what follows.

To investigate the stability of the steady state we consider complex characteristic values. Let $\lambda = \alpha + i\omega$, $\omega > 0$ then (4.10) implies

$$\begin{aligned}
\alpha + i\omega &= -\gamma + A(1 - e^{-(\alpha+i\omega)\tau(\xi)})\left(1 + \frac{\mu}{\alpha + i\omega}\right), \\
&= -\gamma + \frac{A}{\alpha^2+\omega^2}\left[(1 - e^{-\alpha\tau(\xi)}\cos\omega\tau(\xi))(\alpha^2+\omega^2+\mu\alpha) + e^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)\mu\omega\right] \\
&\quad + i\frac{A}{\alpha^2+\omega^2}\left[e^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)(\alpha^2+\omega^2+\mu\alpha) - (1 - e^{-\alpha\tau(\xi)}\cos\omega\tau(\xi))\mu\omega\right].
\end{aligned}$$

Equating the real and imaginary parts yields

$$\begin{aligned}
\alpha + \gamma &= \frac{A}{\alpha^2+\omega^2}\left[(1 - e^{-\alpha\tau(\xi)}\cos\omega\tau(\xi))(\alpha^2+\omega^2+\mu\alpha) + e^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)\mu\omega\right], \\
\omega &= \frac{A}{\alpha^2+\omega^2}\left[e^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)(\alpha^2+\omega^2+\mu\alpha) - (1 - e^{-\alpha\tau(\xi)}\cos\omega\tau(\xi))\mu\omega\right].
\end{aligned}$$

Isolating $e^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)$ and $1 - e^{-\alpha\tau(\xi)}\cos\omega\tau(\xi)$ respectively gives

$$A\left(1 - e^{-\alpha\tau(\xi)}\cos\omega\tau(\xi)\right)\left[(\alpha+\mu)^2+\omega^2\right] = (\alpha+\gamma)(\alpha^2+\omega^2+\mu\alpha) - \mu\omega^2, \tag{5.36}$$

$$Ae^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)\left[(\alpha+\mu)^2+\omega^2\right] = \omega\Big((2\alpha+\gamma)\mu + \alpha^2 + \omega^2\Big). \tag{5.37}$$

Notice that since $A < 0$, for $\alpha \geq 0$ the left-hand side of (5.36) is non-positive. On the other hand, when

$$\gamma > \mu \tag{5.38}$$

and $\alpha \geq 0$ then the right-hand side of (5.36) is strictly positive. Consequently if (5.38) holds, then all the characteristic values must have $\alpha < 0$ and the steady state is asymptotically stable.

Next we show that the steady state is also stable if $\gamma \leq \mu$ and

$$\left|\frac{\xi v'(\xi)}{v(\xi)}\right| < \frac{1}{\mu\tau(\xi)}. \tag{5.39}$$

To do so, for contradiction suppose that $\lambda = \alpha + i\omega$ is a characteristic value with $\alpha \geq 0$ and $\omega > 0$ where $\gamma \leq \mu$ and (5.39) holds. Then $|\sin\omega\tau(\xi)| \leq |\omega\tau(\xi)|$ and (5.39) implies

$$\left|\frac{\xi v'(\xi)}{v(\xi)}\sin\omega\tau(\xi)\right| < \frac{\omega}{\mu}. \tag{5.40}$$

Consequently, using (5.34),

$$\begin{aligned}\left|Ae^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)\left[(\alpha+\mu)^2+\omega^2\right]\right| &< \frac{\gamma\omega}{\mu}\left((\alpha+\mu)^2+\omega^2\right)\\ &= \omega\Big((2\alpha+\mu)\gamma + \frac{\gamma}{\mu}(\alpha^2+\omega^2)\Big)\\ &\leq \omega\big((2\alpha+\gamma)\mu + (\alpha^2+\omega^2)\big).\end{aligned}$$

However, this contradicts the assumption that $\lambda = \alpha + i\omega$ satisfies (5.37). We thus conclude that the steady state is asymptotically stable whenever (5.38) or (5.39) is satisfied.

Since the right-hand side of (5.39) is bounded below by $1/\mu\tau^+$, it follows from Proposition 5.1(1) that the steady state is stable for $0 < \xi \ll \theta_v$ and for $\xi \gg \theta_v$.

To determine when the steady state may be unstable we investigate the basic spectral condition for Hopf bifurcation, namely, the existence of a pair of complex conjugate eigenvalues on the imaginary axis. A proof that Hopf bifurcations actually occur for our equations would, of course, require in addition that a pair of eigenvalues crosses the imaginary axis at nonzero speed, that a nonresonance condition is satisfied, and furthermore that the right hand side of the delay differential equation has certain higher order smoothness properties, see [14, 30, 53] for the case of state-dependent delays.

Assume that $\lambda = \pm i\omega$, $\omega > 0$ solves equation (4.10). Then with $\alpha = 0$ equations (5.36) and (5.37) reduce to

$$A(1-\cos(\omega\tau))(\omega^2+\mu^2) = \omega^2(\gamma-\mu), \tag{5.41}$$

$$A\sin(\omega\tau)(\omega^2+\mu^2) = \omega(\omega^2+\gamma\mu). \tag{5.42}$$

Since $A < 0$ and the right-hand side of (5.42) is positive, at any Hopf bifurcation we must have $\sin(\omega\tau) < 0$ to satisfy (5.42). Moreover, the left-hand side of (5.41) is negative, and so a Hopf bifurcation is only possible if the right-hand side is also negative, that is if

$$\gamma < \mu. \tag{5.43}$$

In Section 5.1 it was so simple to rewrite (5.5) and (5.6) as (5.16) and (5.17) that we did so without comment. Equation (5.17) involves the derivative $g'(\xi)$; here the analogous term is $v'(\xi)$ which is part of A. We want to rewrite (5.41) and (5.42) as one equation for ω which is

independent of $v'(\xi)$ and one equation for $v'(\xi)$ which contains no trigonometric functions. To accomplish this we make use of half-angle formulae.

Let $U = \omega\tau/2$ then

$$\tan\frac{\omega\tau}{2} = \tan U = \frac{2\sin^2 U}{2\sin U\cos U} = \frac{1-\cos(\omega\tau)}{\sin(\omega\tau)},$$

and hence using (5.42) and (5.41)

$$\tan\frac{\omega\tau}{2} = \frac{\omega(\gamma-\mu)}{\omega^2+\gamma\mu}. \tag{5.44}$$

We next simplify (5.42) using another half-angle formula. Still with $U = \omega\tau/2$, from the standard formula

$$\sin\omega\tau = \frac{2\tan U}{1+\tan^2 U},$$

on substituting for $\tan U$ from (5.44) we obtain

$$\sin\omega\tau = \frac{2\omega(\gamma-\mu)(\omega^2+\gamma\mu)}{(\omega^2+\gamma^2)(\omega^2+\mu^2)}.$$

Substituting this into (5.42), rearranging and using (5.34) gives

$$\frac{\xi v'(\xi)}{v(\xi)} = \frac{\omega^2+\gamma^2}{2\gamma(\gamma-\mu)}. \tag{5.45}$$

At a Hopf bifurcation equations (5.2), (5.41) and (5.42) must all be satisfied. This is equivalent to solving

$$\gamma = \frac{\beta g^{\pm}}{\xi}e^{-\mu\tau(\xi)}, \tag{5.46}$$

along with (5.44) and (5.45).

We will follow similar steps as in Section 5.1, and consider (5.46), (5.44) and (5.45) sequentially, using the first two equations to define γ and ω_k as functions of ξ, so that it only remains to solve (5.45) for ξ. But because of the state-dependent delay and the constraint (5.43) the situation is not as simple as in the constant delay case considered in the previous two sections.

Note first that for any $\xi > 0$ equation (5.46) gives a unique value of $\gamma = \gamma(\xi)$. Moreover, since as already noted, τ is monotonically increasing it follows that γ is a monotonically decreasing function of ξ.

For γ satisfying (5.43), the right-hand side of (5.44) is negative. Then because of the properties of the tan function in (5.44) there will be at least one solution $\omega\tau$ to (5.44) satisfying $\omega\tau \in ((2k+1)\pi, (2k+2)\pi)$ for $k = 0, 1, 2, \ldots$. We denote by ω_k any solution of (5.44) for which $\omega_k\tau(\xi) \in ((2k+1)\pi, (2k+2)\pi)$.

At this point, we have defined γ and ω_k as functions of ξ. We still need to solve for ξ, or ξ_k from (5.45). We already considered the behaviour of the left-hand side of (5.45) in Proposition 5.1, so we now consider the behaviour of the right-hand side. Let

$$r_k(\gamma) = \frac{\omega_k^2+\gamma^2}{2\gamma(\gamma-\mu)}. \tag{5.47}$$

Usually we will take $\gamma = \gamma(\xi)$, defined by (5.46), but in the proposition below we consider $r_k(\gamma)$ for general γ. Note that a solution of (5.45) corresponds to a solution of $f(\xi/\theta_v, m, v^-/v^+) = r_k(\gamma(\xi))$, and since v is decreasing both f and r_k will be negative at such a solution, thus from (5.47) we require $\gamma < \mu$.

Proposition 5.5. *Let $r_k(\gamma)$ be defined by (5.47) and ω_k satisfy $\omega_k\tau \in ((2k+1)\pi, (2k+2)\pi)$ for integer $k \geq 0$. Then for $\gamma \in (0, \mu)$ it holds that*

1. $$|r_k(\gamma)| \geq 2\left(\frac{\omega_k}{\mu}\right)^2.$$
2. *$r_k(\gamma) \to -\infty$ as $\gamma \to 0$ or $\gamma \to \mu$,*
3. $$|r_k(\gamma)| \leq \frac{(2k+2)^2(\pi/\tau^-)^2 + \gamma^2}{2\gamma(\mu - \gamma)}.$$

Proof. The proof is elementary. □

While there is a unique steady state ξ for the case of decreasing v with constant g, just as in Section 5.1 the location and properties of this steady state will depend on the values of the other parameters. The following theorem collects together our results for this case.

Theorem 5.6. *Let ξ be the steady state of the DDE (1.1), (1.2) with $g(\xi) = g^{\pm}$ constant, and v monotonically decreasing, so $v^- > v^+$ and the state-dependent delay τ defined by (1.3) evaluated at the steady state is $\tau(\xi) = a/v(\xi)$. Then*

1. *If $\left|\frac{\xi v'(\xi)}{v(\xi)}\right| < \frac{1}{\mu\tau(\xi)}$ then the steady state ξ is asymptotically stable.*
2. *The steady state ξ is asymptotically stable if $m \leq 1/(\mu\tau(\xi))$, or if both $m > 1/(\mu\tau(\xi))$ and $r = r_v = \frac{v^-}{v^+} < \left(1 + \frac{2}{m\mu\tau(\xi) - 1}\right)^2$.*
3. *For any fixed $m > 0$, and for $0 < \xi \ll \theta_v$ or $\xi \gg \theta_v$, or equivalently for $\gamma \gg \gamma_4$ or $0 < \gamma \ll \gamma_3$, the steady state is asymptotically stable.*
4. *If $\gamma > \mu$ the steady state is asymptotically stable.*
5. *For any fixed $\xi \neq \theta_v$ let $\gamma = \gamma(m, \xi)$ be the value of γ such that (5.2) is satisfied and hence ξ is a steady state. Or, for any fixed γ with $0 < \gamma < \gamma_3$ or $\gamma > \gamma_4$ let $\xi = \xi(m, \gamma)$ satisfy (5.2) and hence be a steady state. Then ξ is asymptotically stable for all m sufficiently large.*
6. *Let $\mu > \gamma_3$.*
   (a) *For any $k > 0$, for all $m = m(k)$ sufficiently large there are two families of (at least) $k+1$ Hopf bifurcations as γ is varied. In the first family, the characteristic values $\lambda_j = \alpha_j \pm i\omega_j$ with $\omega_j\tau \in ((2j+1)\pi, (2j+2)\pi)$ for $j = 0, 1, \ldots, k$ cross the imaginary axis from left to right as γ increases, while in the second family they cross the imaginary axis from right to left.*
   (b) *Let $\gamma \in (\gamma_3, \min\{\gamma_4, \mu\})$ be fixed. Then as m is increased there is an infinite sequence of Hopf bifurcations where the real part of $\lambda_k = \alpha_k \pm i\omega_k$ becomes positive with $\omega_k\tau \in ((2k+1)\pi, (2k+2)\pi)$.*

Proof. Statements (1) and (4) were already shown; see equations (5.34), (5.39) and (5.38).

Claim (2) follows from (1) using Proposition 5.1, since

$$\left|\frac{\xi v'(\xi)}{v(\xi)}\right| \leq |f(r_v^{1/2m}, m, r_v)| = \frac{m|1 - r_v^{1/2}|}{1 + r_v^{1/2}}$$

where $r_v = v^-/v^+ > 1$.

Claim (3) also follows from (1), similarly to the proof of Theorem 5.3(3).

Statement (5) is derived similarly to Theorem 5.3 (4), by using (5.46) and (5.33) to show that $e^{-\mu\tau^+} < e^{-\mu\tau(\xi)} < e^{-\mu\tau^-}$ implies that $\gamma_3/\gamma < \xi/\theta_v < \gamma_4/\gamma$.

Finally, (6) is more delicate to prove. As noted before Proposition 5.5, to find a Hopf bifurcation we need to solve $f(\xi/\theta_v, m, v^-/v^+) = r_k(\gamma(\xi))$. Since for $\xi \neq \theta_v$ the function $f(\xi/\theta_v, m, v^-/v^+) \to 0$ as $m \to \infty$, we begin by considering $\xi = \theta_v$. Recall that $\gamma(\xi)$ defined by (5.46) is a monotonically decreasing function of ξ. Moreover, using (1.3) we see that $\tau(\theta_v) = 2a/(v^- + v^+) \in (\tau^-, \tau^+)$, which is independent of the value of m. Then

$$\gamma(\theta_v) = \frac{\beta g^{\pm}}{\theta_v} e^{-\mu\tau(\theta_v)} \in (\gamma_3, \gamma_4), \tag{5.48}$$

and $\gamma(\theta_v)$ is also independent of the value of m.

Now there are two cases to consider. First consider the case where $\gamma(\theta_v) < \mu$. If

$$m > 2\frac{(v^-/v^+)+1}{(v^-/v^+)-1}\left(\frac{(2k+2)^2(\pi/\tau(\theta_v))^2 + \gamma(\theta_v)^2}{2\gamma(\theta_v)(\mu - \gamma(\theta_v))}\right), \tag{5.49}$$

then

$$\begin{aligned} f(1, m, v^-/v^+) = -\frac{m(v^-/v^+ - 1)}{2(v^-/v^+ + 1)} &< \left(\frac{(2k+2)^2(\pi/\tau(\theta_v))^2 + \gamma(\theta_v)^2}{2\gamma(\theta_v)(\gamma(\theta_v) - \mu)}\right) \\ &\leq r_j(\gamma(\theta_v)), \quad j = 0, 1, \ldots, k. \end{aligned}$$

Here the equality comes from definition of f, the strict inequality from (5.49) and the last inequality follows from a similar argument that proves Proposition 5.5(3), the only difference being that here we use the actual value of $\tau(\theta_v)$ in the inequality, rather than the bound τ^-.

With this inequality as the starting point, we examine what happens when we increase ξ away from θ_v. If ξ is increased then $\gamma(\xi)$ decreases with $\lim_{\xi\to\infty}\gamma(\xi) = 0$. But $r_j(\gamma(\xi))$ and $f(\xi/\theta_v, m, v^-/v^+)$ are both continuous functions of ξ with $\lim_{\xi\to\infty} r_j(\gamma(\xi)) = -\infty$ and $\lim_{\xi\to\infty} f(\xi/\theta_v, m, v^-/v^+) = 0$. Consequently for each $j = 0, 1, \ldots, k$ there exists a ξ such that $f(\xi/\theta_v, m, v^-/v^+) = r_j(\gamma(\xi))$.

If instead ξ is decreased from θ_v then $\lim_{\xi\to 0}\gamma(\xi) = +\infty$, so $\gamma(\xi) > \mu$ for ξ sufficiently small. However, for $\gamma(\xi) < \mu$ we have $\lim_{\gamma\nearrow\mu} r_j(\gamma) = -\infty$, while $f(\xi/\theta_v, m, v^-/v^+)$ is bounded, so again for each $j = 0, 1, \ldots, k$ there exists a ξ such that $f(\xi/\theta_v, m, v^-/v^+) = r_j(\gamma(\xi))$.

Solutions of this equation define the Hopf bifurcation points, which gives the required Hopf bifurcations when $\gamma(\theta_v) < \mu$. To summarize the argument up to this point, for a fixed k and any large enough $m = m(k)$ satisfying (5.49), we found two families of $k+1$ Hopf bifurcations, one for $\xi_j < \theta_v$ and one for $\xi_j > \theta_v$, by finding appropriate $\gamma(\xi_j)$ that satisfy $f(\xi_j/\theta_v, m, v^-/v^+) = r_j(\gamma(\xi_j))$ for each $j = 0, \ldots, k$. See Figure 5.7(d) for illustration of these families as functions of the parameters m and γ.

Now consider the more delicate case where $\gamma_3 < \mu \leq \gamma(\theta_v) < \gamma_4$. The above argument fails in that case as $|f(\xi/\theta_v, m, v^-/v^+)| \gg 0$ for $\xi = \theta_v$ but the corresponding γ is $\gamma(\theta_v)$, with $\gamma(\theta_v) > \mu$, and by (4) the steady state would be asymptotically stable. Instead, noting that $\gamma(\xi)$ defined by (5.46) is monotonically decreasing, this function is invertible and we can instead consider $\xi = \xi(\gamma)$ as a function of γ. Fix $\gamma \in (\gamma_3, \mu)$, and consider the behaviour as $m \to \infty$. In this case the function $v(\xi)$ defined by (1.3) approaches the piecewise constant function (1.7), and the steady-state function $h(\xi)$ (recall (5.2)) approaches the case illustrated in Figure 5.5.

Since γ is fixed with $\gamma \in (\gamma_3, \mu) \subset (\gamma_3, \gamma_4)$, we find $\xi \to \theta_v$ and $v'(\xi) \to -\infty$ while $v(\xi)$ and ξ remain bounded and bounded away from zero. Consequently, for m sufficiently large $\frac{\xi v'(\xi)}{v(\xi)} < r_j(\gamma)$ for $j = 0, 1, \ldots, k$. From here the argument proceeds as in the case $\gamma(\theta_v) < \mu$. Statement (6)b also follows trivially in the case that $\gamma_3 < \mu \leq \gamma(\theta_v) < \gamma_4$. □

Although Theorem 5.6(6) is stated for one-parameter continuation in m or γ, we can also draw conclusions for two-parameter continuation of the Hopf bifurcations in the (γ, m)-parameter plane.

The argument used in the proof of Theorem 5.6(6) in the case when $\mu \in (\gamma_3, \gamma_4)$ shows that for any $\gamma_- > \gamma_3$ the k-th Hopf bifurcation occurs for $\gamma \in (\gamma_3, \gamma_-)$ for all m sufficiently large. Then because of Theorem 5.6(5) the k-th Hopf bifurcation approaches $\gamma = \gamma_3$ as $m \to \infty$, and in the (γ, m)-parameter plane the left side of the Hopf bifurcation curves asymptote to $\gamma = \gamma_3$ as $m \to \infty$. Similarly for any $\gamma_+ < \mu$ the other instance of the k-th Hopf bifurcation occurs for $\gamma \in (\gamma_+, \mu)$ for all m sufficiently large, and the right side of the Hopf bifurcation curves asymptote to $\gamma = \mu$ as $m \to \infty$.

In the case that $\mu > \gamma_4$, a similar argument can be applied to show that the k-th Hopf bifurcation curve asymptotes to $\gamma = \gamma_3$ and $\gamma = \gamma_4$ in the (γ, m)-parameter plane.

There are nevertheless differences between the cases where γ converges to γ_3 or γ_4 as $m \to \infty$ and the case where $\gamma \to \mu$ as $m \to \infty$. To see this consider for fixed k the limit as $m \to \infty$ when v approaches the piecewise constant function (1.7). Then from Theorem 5.6, we have $\xi \to \theta_v$, and $\gamma \in [\gamma_3, \min\{\gamma_4, \mu\}]$. Since $\tau(\xi) \in [a/v_U, a/v_L]$ and $\omega_k \tau(\xi) \leq (2k+2)\pi$ it also follows that ω_k is bounded. Thus the numerator of the right-hand side of (5.45) also remains bounded. Now there are two cases to consider.

First suppose that as $m \to \infty$ and $\xi \to \theta_v$ that $v'(\xi)$ becomes unbounded, that is $v'(\xi) \to -\infty$, or equivalently that $A \to -\infty$. Then the left-hand side of (5.45) becomes unbounded in the limit as $m \to \infty$. Since the numerator of the right-hand side is bounded, we must have $\gamma - \mu = \mathcal{O}(1/A) \to 0$ to satisfy equation (5.45). To summarize, if $v'(\xi) \to -\infty$ as $m \to \infty$ we must have that $\gamma \to \mu$ in this limit.

On the other hand, if $A < 0$ remains finite as $m \to \infty$, because γ, ξ and $v(\xi)$ are bounded and bounded away from zero in the limit, the only possibility in (5.34) is that $v'(\xi)$ also remains finite. But as $m \to \infty$ the function $v(\xi)$ approaches a step function, and the only places where $v'(\xi)$ is non-zero and finite are near the corners of the limiting velocity nonlinearity. Consequently, the only possibility for a Hopf bifurcation to exist for arbitrary m is that the steady state at which this Hopf bifurcation happens converges to the corners of the limiting velocity nonlinearity. That is, in the limit as $m \to \infty$ with $A < 0$ finite, we must have that $\gamma \to \gamma_3$ or $\gamma \to \gamma_4$ with $\xi \to \theta_v$, where γ_3 and γ_4 are defined by (5.33).

Below we illustrate the different possible behaviours allowed by Theorem 5.6 in the three cases: $\mu < \gamma_3$, $\mu \in (\gamma_3, \gamma_4)$ and $\mu > \gamma_4$.

Case 1: We begin with the case $\mu < \gamma_3$. By Theorem 5.6 (point 4) the steady state must be stable whenever $\gamma > \mu$, while for $\gamma \leq \mu$ we have $\gamma \leq \mu < \gamma_3$ so by Theorem 5.6(point 5) the steady state is stable for all m sufficiently large, or by Theorem 5.6 (point 3) it is stable for all γ sufficiently small.

Figure 5.6 shows an example of the behaviour of (1.1)–(1.2) for $(g \leftrightarrow, v \downarrow)$ with $\mu < \gamma_3 < \gamma_4$. Panel (b) shows the smooth case for several different values of m, which reveals that the steady state is always stable. Panel (a) shows the behavior in the limiting case with (1.7). In this case the singular steady state can only become a stable steady state for large finite m.

In the model (1.1)–(1.2) we consider the parameters γ and μ to be independent, but de-

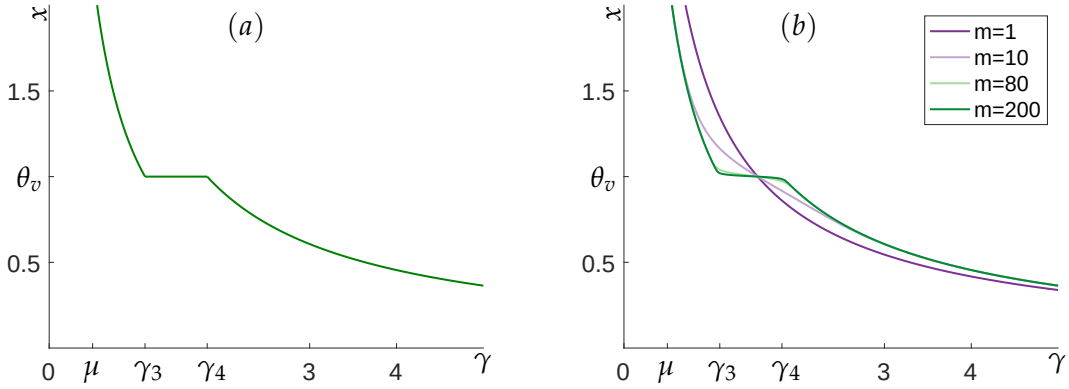

Figure 5.6: Bifurcation diagram of (1.1)–(1.2) with $(g \leftrightarrow, v \downarrow)$ and parameters $\beta = 3, \mu = 0.5, g^- = g^+ = 1, \gamma = 1, \theta_v = 1, a = 2, v^- = 2$ and $v^+ = 1$. (a) The limiting case with v defined by (1.7). The stable steady state is shown as a green solid line. (b) With smooth velocity nonlinearity v defined by (1.3) with $m = 1$, 10, 80, 200 as indicated by color. The steady state is always stable.

pending on how the model is derived, that may not be the case. For example, the current model (1.1)–(1.2) can be derived as a reduction of the operon model in [18]. In the model in [18] the parameter equivalent to γ is an effective removal rate which is the sum of the actual degradation rate with the dilution because of the growth rate μ. Consequently, in the model of [18], and in similar systems modelling gene regulatory dynamics in a growing cell, we obtain the natural parameter constraint $\gamma > \mu$, and expect dynamics corresponding to Figure 5.6.

Case 2: Next, in Figure 5.7, we illustrate the behavior of (1.1)–(1.2) for $(g \leftrightarrow, v \downarrow)$ with $\mu \in (\gamma_3, \gamma_4)$. Panel (a) depicts the behavior of the limiting case with piecewise constant v defined by (1.7). Panel (b) shows the case of the smooth velocity nonlinearity (1.3) with $m = 100$. The steady state close to $x = \theta_v$ undergoes a pair of Hopf bifurcations creating a bubble of stable periodic orbits which coexist with the unstable steady state for an interval of values of γ which is a subinterval of (γ_3, μ). As required by Theorem 5.6(4) the steady state is asymptotically stable for $\gamma > \mu$. Thus, in contrast to the previous case, the singular steady state may become either a stable or unstable steady state for very large finite values of m. Panel (c) is similar to panel (b) but for $m = 32$. In this case the steady state is always stable, and no Hopf bifurcations are seen.

Figure 5.7(d) shows a two-parameter continuation of the first three Hopf bifurcations illustrating Theorem 5.6(4-6). The steady state is stable below and outside the outermost Hopf curve and unstable otherwise, and Hopf bifurcations appear sequentially for increasing values of m. The bifurcation curve of first Hopf bifurcation (corresponding to $k = 0$ in the analysis above) is clearly seen to asymptote to $\gamma = \gamma_3$ and $\gamma = \mu$ as $m \to \infty$. The subsequent Hopf bifurcations also approach these limits as m becomes larger, but do so more slowly.

For the parameter values shown in Figure 5.7 the inequalities $\gamma_3 < \gamma(\theta_v) < \mu < \gamma_4$ hold. Consequently, (5.49) applies and gives a sufficient condition on m to ensure that the k-th Hopf bifurcation arises. For the given parameters (see the caption of Figure 5.7) these sufficient conditions are approximately $m > 84$, 316 and 703 for $k = 0, 1, 2$ respectively, whereas in Figure 5.7 the corresponding Hopf bifurcation curves have minimal m values of approximately $m = 34$, 147, and 336. Therefore, at least in this case, the sufficient condition is not tight. No Hopf bifurcations are seen for $m < 34$ in panel (d), which explains why no Hopf bifurcations

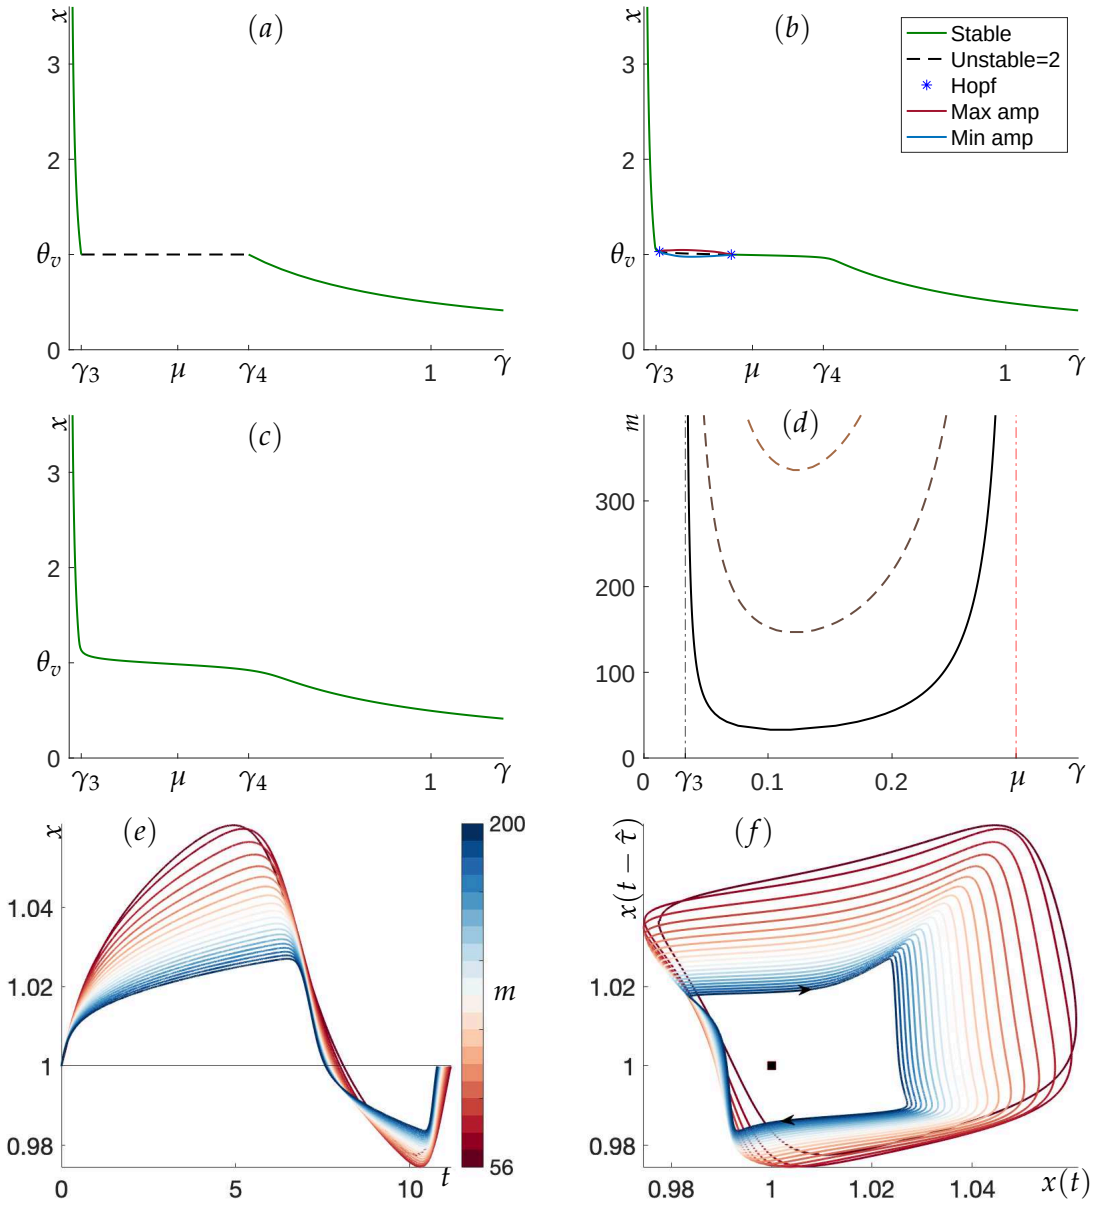

Figure 5.7: Bifurcation diagram of (1.1)–(1.2) with $(g \leftrightarrow, v \downarrow)$ and parameters $\beta = 3, \mu = 0.3, g^- = g^+ = 1, \gamma = 1, \theta_v = 1, a = 3, v^- = 0.5$ and $v^+ = 0.2$. (a) The limiting case with v defined by (1.7). The stable steady state is shown as a green solid line, and the singular steady state as a black dashed line. (b) With a smooth velocity nonlinearity v defined by (1.3) with $m = 100$. Solid lines represent stable objects including the stable steady state (in green), and envelope of the periodic orbit (in red and blue). Dashed lines represent unstable steady states which have two eigenvalues with positive real part (in black). (c) As in (b) but with $m = 32$. (d) Two-parameter continuations in m and γ of the Hopf bifurcations (shown as solid curves) with the other parameters as above. The outermost curve of Hopf bifurcations is associated with the stability change seen in (b). The black dash-dotted line denotes $\gamma = \gamma_3 = 0.0333$ and the red dash-dotted line denotes $\gamma = \mu = 0.3$, the location of the Hopf bifurcations in the limiting case as $m \to \infty$. Note that $\gamma(\theta_v) = 0.2293 < \mu < \gamma_4 = 0.4959$. (e) Profiles of the stable periodic orbits from the Hopf bifurcations in (b) at $\gamma = 0.13$ and $m \in [56, 200]$ as indicated by the color map. (f) Projection of the phase space dynamics into the $(x(t), x(t-\hat{\tau}))$ plane at $\gamma = 0.13$ where $\hat{\tau} = \tau(\theta_v) = 60/7$. The arrow indicates the direction of the flow. The square marks the unstable steady state in the limiting case at the threshold.

were detected for $m = 32$ in (c).

As m increases, the stable periodic orbits created in the Hopf bifurcation at $\gamma = 0.13 \in (\gamma_3, \mu)$ are shown in Figure 5.7(e) and (f). Panel (e) shows the profiles of these orbits, while in (f) we show their projection into the $(x(t), x(t-\hat{\tau}))$ plane. Note that since the delay τ is state-dependent we do not use the actual delay for this projection, but we took $\hat{\tau} = \tau(\theta_v)$. The limiting behaviour as $m \to \infty$ is quite different from the constant delay case considered in Section 5.1. Not only is the shape of the profile different, but comparing Figure 5.7(f) and Figure 5.2(f) we see that the direction of rotation of the orbits, as indicated by the arrows, is reversed in the two examples.

Case 3: The final case to consider for (1.1)–(1.2) with $(g \leftrightarrow, v \downarrow)$ is when $\gamma_3 < \gamma_4 < \mu$, and this is illustrated in Figure 5.8. Panels (a)–(c) show the dynamics for the limiting case with the piecewise constant velocity nonlinearity (1.7) and for the smooth case with the Hill function from (1.3) with $m = 250$ and $m = 100$ respectively. For the limiting case in (a) the singular steady state with $x = \theta_v$ appears as a straight line segment for $\gamma \in (\gamma_3, \gamma_4)$. The singular steady states become unstable steady states in the smooth case as shown in (b), and there is a bubble of stable periodic orbits between the pair of Hopf bifurcations.

Figure 5.8(d) shows the locus of the principal Hopf bifurcation for a two-parameter continuation in m and γ. Below and outside the curve of Hopf bifurcations the steady state is stable, while between the Hopf bifurcations it is unstable. We see that the Hopf bifurcation curves approach γ_3 and γ_4 as $m \to \infty$, as follows from Theorem 5.6. Since $\gamma_4 < \mu$ and necessarily $\gamma(\theta_v) \in (\gamma_3, \gamma_4)$ we are guaranteed that $\gamma(\theta_v) < \mu$, so for all such examples Theorem 5.6 guarantees that there are infinitely many Hopf bifurcations. However, they may occur for very large values of m. For the example depicted in Figure 5.8, only one Hopf bifurcation is observed with $m \geq 117$. For the parameter values of this example the sufficient condition (5.49) (with $k = 0, 1$) ensures a first Hopf bifurcation for $m > 152$, while a second one is ensured for $m > 602$, which is outside the parameter range considered in Figure 5.8.

If the value of the Hill coefficient m is reduced sufficiently then there are no longer any Hopf bifurcations and the steady state remains stable, as seen in Figure 5.8(c). Interestingly, even though there are no longer any Hopf bifurcations in this case, the dependence of the steady state x on γ is still very similar to (a) and (b), with an obvious plateau visible in the graph of x in Figure 5.8(c) for $\gamma \in (\gamma_3, \gamma_4)$.

Figure 5.8(e) and (f) respectively show the profiles and the $(x(t), x(t-\hat{\tau}))$-space projections of the stable periodic orbits at $\gamma = 0.4$ as m increases, where we choose $\hat{\tau} = \tau(\theta_v)$. The periodic orbits approach a certain structure as $m \to \infty$. Note that the direction of rotation in both Figure 5.8(f) and Figure 5.7(f) is clockwise, while in Figure 5.2(f) it is counterclockwise.

5.4 State-dependent delay with v increasing and g constant $(g \leftrightarrow, v \uparrow)$

Here we again consider the model (1.1)–(1.2) with a constant function $g(\xi) = g^{\pm}$ and state-dependent delay, but now we consider the case of increasing v, so $v^- < v^+$ in (1.3) and (1.7): $(g \leftrightarrow, v \uparrow)$.

As illustrated in Figure 5.9, it is possible for up to three steady states to coexist due to the fold bifurcations at the corners associated with $\gamma = \gamma_3$ and $\gamma = \gamma_4$. Note that in Section 5.3 we had $\gamma_3 < \gamma_4$. Since the function v is increasing in this section, it follows from the definition (5.33) that now $\gamma_4 < \gamma_3$. In the limiting case where v is defined in (1.7), at the non-singular steady states the characteristic equation is of the form (4.11), and hence these steady states are stable. For $\gamma \in (\gamma_4, \gamma_3)$ the two stable steady states co-exist with a singular steady state, at

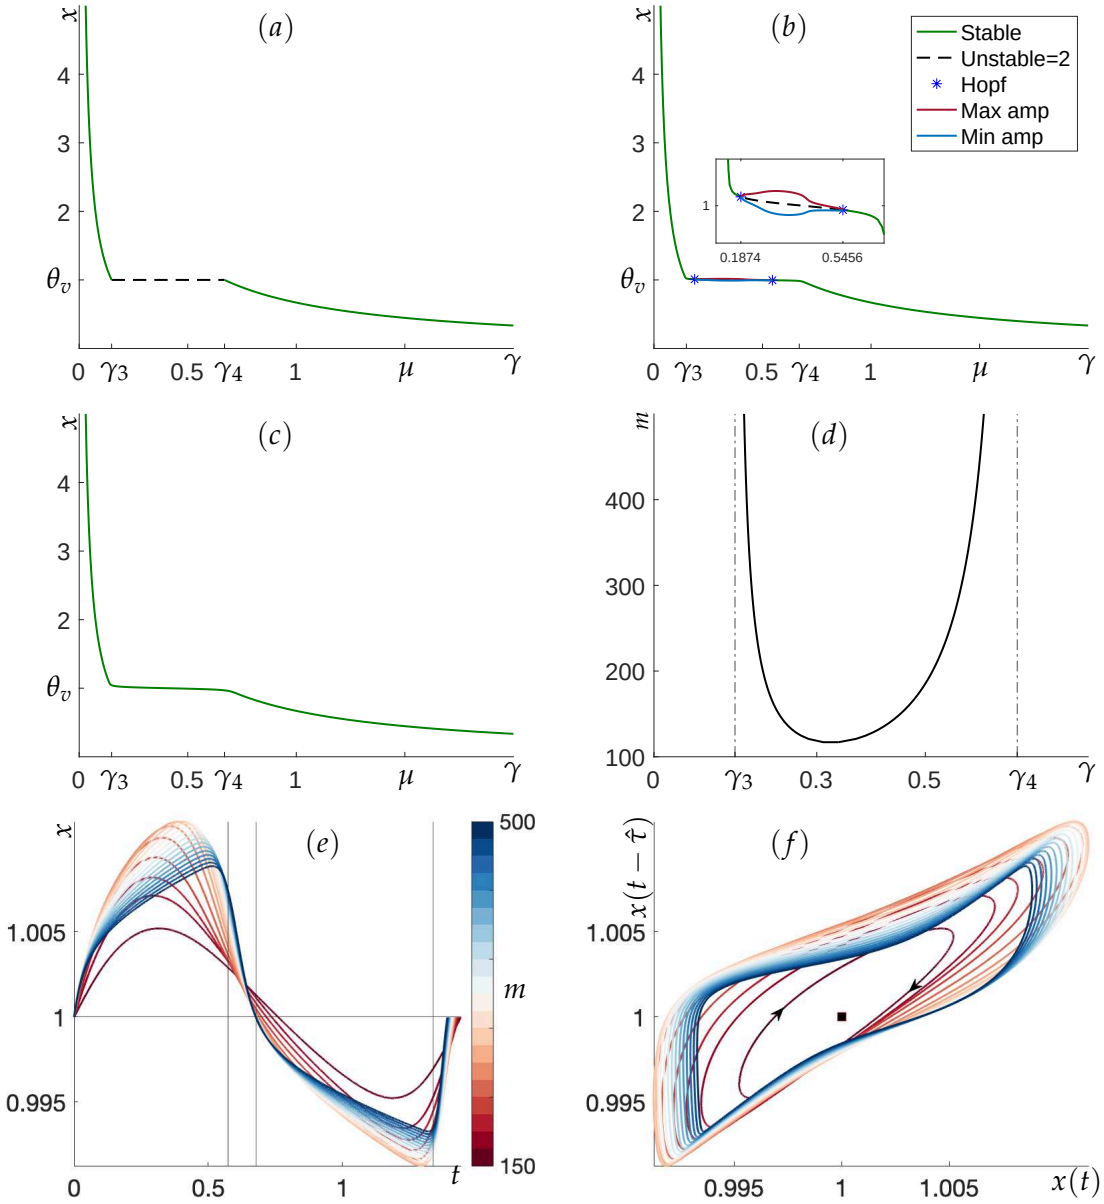

Figure 5.8: Bifurcation diagram of (1.1)–(1.2) with $(g \leftrightarrow, v \downarrow)$ and parameters $\beta = 3, \mu = 1.5, g^- = g^+ = 1, \gamma = 1, \theta_v = 1, a = 2, v^- = 2$ and $v^+ = 1$. (a) The limiting case with v defined by (1.7). The stable steady state is shown as a green solid line, and the singular steady state as a black dashed line. (b) With a smooth velocity nonlinearity v defined by (1.3) with $m = 250$. Solid lines represent stable objects including the stable steady state (in green) and a stable limit cycle (represented by maximum and minimum of $x(t)$ on the periodic solution). Dashed lines represent unstable steady states which have two eigenvalues with positive real part (in black). (c) As in (b) but with $m = 100$. (d) Two-parameter continuations in m and γ of the Hopf bifurcations seen in (b). The dash-dotted lines denote $\gamma = \gamma_3 = 0.1494$ and $\gamma = \gamma_4 = 0.6694$, the location of the Hopf bifurcations in the limiting case as $m \to \infty$. (e) Profile of the stable periodic orbits from the Hopf bifurcations in (b) at $\gamma = 0.4$. The color map indicates values of the continuation parameter m. (f) Projection of the phase space dynamics into the $(x(t), x(t-\hat{\tau}))$ plane at $\gamma = 0.4$ where $\hat{\tau} = \tau(\theta_v) = 4/3$. The arrow indicates the direction of the flow. The square marks the unstable steady state in the limiting case at the threshold.

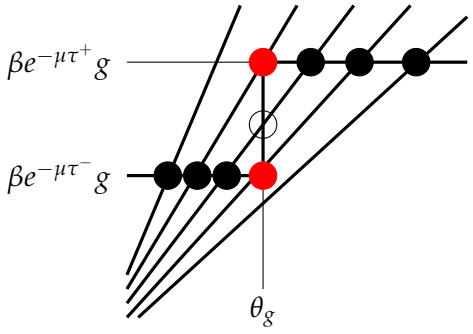

Figure 5.9: Illustration of how the number of steady states of (1.1), which are given by (5.2), changes with the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g$ and $\xi \mapsto \gamma\xi$. These are shown in the limiting case of (1.6) and (1.7) with $g^{\pm} = g^- = g^+$, so $g(\xi) = g^{\pm}$ is a constant function, and $v^- < v^+$ so v is piecewise constant and monotonically increasing: $(g \leftrightarrow , v \uparrow)$. Then $\tau(\xi) = a/v(\xi)$ is state-dependent; $\tau(\xi) = \tau^- = a/v^-$ for $\xi < \theta_v$, $\tau(\xi) = \tau^+ = a/v^+$ for $\xi > \theta_v$ and $\tau(\xi)$ is set-valued when $\xi = \theta_v$.

which the characteristic function is not defined. This leads us to consider the smooth velocity nonlinearity (1.3).

Because the smooth velocity nonlinearity approaches the step function shown in Figure 5.9 as $m \to \infty$, it follows that for all m sufficiently large there will be a pair of fold bifurcations at $(\xi, \gamma) = (\xi^-, \gamma(\xi^-))$ and $(\xi, \gamma) = (\xi^+, \gamma(\xi^+))$, with $(\xi^-, \gamma(\xi^-)) \to (\theta_v, \gamma_4)$ and $(\xi^+, \gamma(\xi^+)) \to (\theta_v, \gamma_3)$ as $m \to \infty$. To study the associated bifurcations consider the characteristic equation which has the form (4.10). Writing the characteristic function $\Delta(\lambda)$ as

$$\Delta(\lambda) = \lambda + \gamma - A + Ae^{-\lambda\tau(\xi)} - \mu A \int_{-a/v(\xi)}^{0} e^{\lambda s} ds, \tag{5.50}$$

it follows from (5.2) that at a steady state

$$\begin{aligned} \Delta(0) &= \gamma - \mu A \int_{-a/v(\xi)}^{0} 1 ds = \gamma - \mu\tau(\xi)A = \gamma - \mu\tau(\xi)\gamma\frac{\xi v'(\xi)}{v(\xi)} \\ &= \gamma\mu\tau(\xi)\Big(\frac{1}{\mu\tau(\xi)} - \frac{\xi v'(\xi)}{v(\xi)}\Big). \end{aligned} \tag{5.51}$$

Hence, $\lambda = 0$ is a characteristic value if and only if

$$\frac{\xi v'(\xi)}{v(\xi)} - \frac{1}{\mu\tau(\xi)} = 0. \tag{5.52}$$

In addition, note that

$$\frac{\xi v'(\xi)}{v(\xi)} > \frac{1}{\mu\tau(\xi)} \tag{5.53}$$

implies that $\Delta(0) < 0$. At the same time, it is easily seen that for real λ the characteristic function satisfies $\Delta(\lambda) \to +\infty$ as $\lambda \to +\infty$. We conclude that when (5.53) is satisfied there is a real positive characteristic value and hence the steady state is unstable.

We now show that fold bifurcations occur when (5.52) is satisfied. To that end, consider the curve of solutions $(\gamma(\xi), \xi)$ where $\gamma(\xi)$ is defined by (5.46), which by (5.2) is the locus of steady states in (γ, ξ)-plane. Differentiating this relationship with respect to ξ we find

$$\gamma'(\xi) = -\frac{\gamma(\xi)}{\xi}\Big(1 + \mu\xi\tau'(\xi)\Big).$$

However, $\tau(\xi) = a/v(\xi)$ implies that

$$\tau'(\xi) = -\frac{av'(\xi)}{v(\xi)^2} = -\frac{v'(\xi)\tau(\xi)}{v(\xi)}. \tag{5.54}$$

Thus

$$\gamma'(\xi) = -\frac{\gamma(\xi)}{\xi}\Big(1 - \mu\xi\frac{v'(\xi)\tau(\xi)}{v(\xi)}\Big) = \frac{\mu\tau(\xi)\gamma(\xi)}{\xi}\Big(\frac{\xi v'(\xi)}{v(\xi)} - \frac{1}{\mu\tau(\xi)}\Big). \tag{5.55}$$

Hence $\operatorname{sgn}(\gamma'(\xi)) = \operatorname{sgn}\left(\frac{\xi v'(\xi)}{v(\xi)} - \frac{1}{\mu\tau(\xi)}\right)$, and $\gamma'(\xi)$ changes sign when the left-hand side of (5.52) changes sign, which ensures that fold bifurcations occur at these points in the (γ, ξ)-plane.

While the above analysis appears similar to the constant delay case considered in Section 5.2, the state-dependency of the delay introduces two significant differences.

First, with a state-dependent delay and increasing v, fold bifurcations occur when (5.52) is satisfied, whereas in Section 5.2 with increasing g we found fold bifurcations when (5.27) is satisfied. Thus for the constant delay case the fold bifurcations occur when the unimodal function $\xi \mapsto f(\xi/\theta_g, n, g^-/g^+) = \xi g'(\xi)/g(\xi)$ is equal to 1, and so there is at most one pair of fold bifurcations. In contrast, for the state-dependent delay case, fold bifurcations occur when the unimodal function (5.35) is equal to $1/\mu\tau(\xi)$. For increasing v, the function $\xi \mapsto 1/\mu\tau(\xi)$ is also an increasing function, thus the fold bifurcation occurs at the intersections of a unimodal function with an increasing function. Clearly, such functions may have multiple pairs of intersections and hence multiple pairs of fold bifurcations. From Proposition 5.1, for the Hill function $v(\xi)$ defined by (1.3) we have that $\xi \mapsto \xi v'(\xi)/v(\xi)$ is monotonically decreasing for $\xi > \theta_v(v^-/v^+)^{1/2m}$, so there will be at most one intersection with the increasing function $\xi \mapsto 1/\mu\tau(\xi)$ on this interval. Thus if there are additional fold bifurcations they must occur for $\xi < \theta_v(v^-/v^+)^{1/2m} < \theta_v$. In the current work, we will not look for these additional fold bifurcations, nor will we show that they cannot exist. Even if it were possible to show that they cannot exist when v is defined by (1.3), we would expect that additional fold bifurcations could be induced by suitable modifications to the velocity nonlinearity.

A second difference between the state-dependent and constant delay cases concerns the stability of the steady state near the fold bifurcation. Note that the argument after (5.39) in Section 5.3 still applies to show that the steady state is stable if $\gamma \leq \mu$ and (5.39) holds. Consequently, a fold bifurcation which occurs for $\gamma < \mu$ must involve a stable steady state which loses stability at the fold bifurcation. However, this argument does not apply when $\gamma > \mu$, and we will see examples where stable steady states lose stability in a Hopf bifurcation with $\gamma > \mu$, and also fold bifurcations where the steady state is unstable on both sides of the bifurcation (with different numbers of unstable characteristic values). This contrasts with the constant delay case in Section 5.2 where we showed that a stable steady state can only lose stability at a fold bifurcation.

As was the case when v was decreasing, Hopf bifurcations are governed by equations (5.41) and (5.42). However, since v is increasing we now have $A > 0$. At a Hopf bifurcation the right-hand side of (5.42) is strictly positive, and hence $\sin(\omega\tau) > 0$. Since $\sin(\omega\tau) > 0$ implies $\cos(\omega\tau) < 1$, it then follows that the left-hand side of (5.41) is also strictly positive, and a Hopf bifurcation is only possible if the right-hand side is also strictly positive, that is if

$$\gamma > \mu. \tag{5.56}$$

As in Section 5.3, we find Hopf bifurcations by sequentially solving (5.46), (5.44) and (5.45). Equation (5.44) has infinitely many solutions $\omega_k(\gamma(\xi))$ for $k = 0, 1, \ldots$ with $\omega_k\tau \in$

$(2k\pi, (2k+1)\pi)$. Finally, to solve (5.45) with $v'(\xi) > 0$, we need to determine ξ that satisfies $f(\xi/\theta_v, m, v^-/v^+) = r_k(\gamma(\xi)) > 0$ (defined in (5.47)). Usually we will take $\gamma = \gamma(\xi)$, defined by (5.46), but in the proposition below we consider $r_k(\gamma)$ for general γ.

Proposition 5.7. *Let $r_k(\gamma)$ be defined by (5.47) and ω_k satisfy $\omega_k\tau \in (2k\pi, (2k+1)\pi)$ for integer $k \geq 0$. Then for $\gamma > \mu$ it holds that $r_k(\gamma) > 0$ and*

1. *$r_k(\gamma)$ is monotonically decreasing,*
2. *$r_k(\gamma) \to +\infty$ as $\gamma \to \mu$ and $r_k(\gamma) \to 1/2$ as $\gamma \to +\infty$,*
3. $$r_k(\gamma) \leq \frac{(2k+1)^2(\pi/\tau^+)^2 + \gamma^2}{2\gamma(\gamma - \mu)}.$$

Proof. The proof is elementary. □

The following lemma will be needed in the proof of Theorem 5.9.

Lemma 5.8. *For $x > 0$ let $f(x) = \frac{1}{x}(1 - e^{-x})$ then $f(x)$ is strictly monotonically decreasing for $x > 0$ with*

$$1 = \lim_{x\to 0} f(x) > \lim_{x\to+\infty} f(x) = 0. \tag{5.57}$$

Proof. The two limits in (5.57) are easily verified. To show the monotonicity of $f(x)$ first differentiate to obtain

$$f'(x) = -\frac{1}{x^2}\left[1 - (x+1)e^{-x}\right].$$

The assumption $f'(x) = 0$ for some $x > 0$ yields $e^x = 1 + x$ which is impossible for $x \neq 0$. Using continuity we infer that on $(0, \infty)$ there is no sign change of $f'(x)$, and that $f'(x)$ is strictly monotonic for $x > 0$. Because of (5.57) f is decreasing. □

The following theorem collects our results for the case of increasing v with constant g.

Theorem 5.9. *Let ξ be a steady state of the DDE (1.1), (1.2) with $g(\xi) = g^{\pm}$ constant, and v monotonically increasing, so $v^- < v^+$, and the state-dependent delay τ defined by (1.3) evaluated at the steady state is $\tau(\xi) = a/v(\xi)$. Then*

1. *If $\frac{\xi v'(\xi)}{v(\xi)} < \frac{1}{\tau(\xi)\max\{\mu,\gamma\}}$ then the steady state ξ is asymptotically stable, while if $\frac{\xi v'(\xi)}{v(\xi)} > \frac{1}{\mu\tau(\xi)}$ it is unstable.*
2. *For any fixed $\xi \neq \theta_v$ let $\gamma = \gamma(m, \xi)$ be the value of γ such that (5.2) is satisfied and hence ξ is a steady state. Or, for any fixed γ with $0 < \gamma < \gamma_4$ or $\gamma > \gamma_3$ let $\xi = \xi(m, \gamma)$ satisfy (5.2) and hence be a steady state. Then ξ is asymptotically stable for all m sufficiently large.*
3. *The steady state ξ is asymptotically stable if $m \leq 1/(\tau(\xi)\max\{\mu, \gamma\})$, or both $m > 1/(\tau(\xi)\max\{\mu, \gamma\})$ and $1 \geq \frac{v^-}{v^+} > \left(1 - \frac{2}{m\tau(\xi)\max\{\mu,\gamma\}+1}\right)^2$.*
4. *For any fixed $m > 0$, and for $\xi \gg \theta_v$, or equivalently for $0 < \gamma \ll \gamma_4$, the steady state is asymptotically stable. For any fixed $m > 1$, and for $0 < \xi \ll \theta_v$ or equivalently for $\gamma \gg \gamma_3$ the steady state is asymptotically stable.*

5. *If* $m > 1/(\mu\tau^+)$ *and* $\frac{v^-}{v^+} < \left(1 - \frac{2}{1+m\mu\tau^+}\right)^2$ *then there exist* $\xi^- < \theta_v(v^-/v^+)^{1/2m} < \xi^+$ *with* $\gamma(\xi^-) < \gamma(\xi^+)$ *such that as* γ *is varied there is a branch of steady states with* $\xi < \xi^-$ *and* $\gamma > \gamma(\xi^-)$ *and another branch with* $\xi > \xi^+$ *and* $\gamma < \gamma(\xi^+)$*. For* $\gamma \in (\gamma(\xi^-), \gamma(\xi^+))$ *these two branches of steady states co-exist with a branch of unstable steady states which exists between fold bifurcations at* $(\xi, \gamma) = (\xi^-, \gamma(\xi^-))$ *and* $(\xi, \gamma) = (\xi^+, \gamma(\xi^+))$*.*

6. *Let* $\mu < \gamma_3$*.*

   (a) *For any* $k > 0$*, for all* $m = m(k)$ *sufficiently large there are two families of (at least)* $k+1$ *Hopf bifurcations as* γ *is varied. In the first family, the characteristic values* $\lambda_j = \alpha_j \pm i\omega_j$ *with* $\omega_j\tau \in (2j\pi, (2j+1)\pi)$ *for* $j = 0, 1, \ldots, k$ *cross the imaginary axis from left to right as* γ *is increased, while in the second family they cross the imaginary axis from right to left. For all* j *sufficiently large these bifurcations occur on the branch of unstable steady states between the fold bifurcations identified in (5).*

   (b) *Let* $\gamma \in (\max\{\gamma_4, \mu\}, \gamma_3)$ *be fixed. Then as* m *is increased there is an infinite sequence of Hopf bifurcations where the real part of* $\lambda_k = \alpha_k \pm i\omega_k$ *becomes positive with* $\omega_k\tau \in ((2k\pi, (2k+1)\pi)$*. All but finitely many of these bifurcations are located on the branch of unstable steady states between the fold bifurcations.*

Proof. The last part of (1) is shown after (5.53). To establish asymptotic stability we show that $Re(\lambda) < 0$ for all of the characteristic values that solve (4.10). From $\xi v'(\xi)/v(\xi) < 1/\mu\tau(\xi)$ and (5.51) it follows immediately that $\lambda = 0$ is not a characteristic value. To show that $\lambda > 0$ is not a characteristic value, evaluating the integral in (5.50) we obtain

$$\Delta(\lambda) = \lambda + \gamma - (1 - e^{-\lambda\tau(\xi)})\frac{A}{\lambda}(\lambda + \mu).$$

But

$$A = \gamma\frac{\xi v'(\xi)}{v(\xi)} < \frac{\gamma}{\tau(\xi)\max\{\mu, \gamma\}},$$

hence

$$\Delta(\lambda) > \lambda + \gamma - \frac{1}{\lambda\tau(\xi)}(1 - e^{-\lambda\tau(\xi)})\frac{\gamma}{\max\{\mu, \gamma\}}(\lambda + \mu) > \lambda + \gamma - \frac{\gamma}{\max\{\mu, \gamma\}}(\lambda + \mu),$$

where the last inequality follows from Lemma 5.8. Now there are two cases to consider. If $\gamma > \mu$ then

$$\Delta(\lambda) > \lambda + \gamma - (\lambda + \mu) = \gamma - \mu > 0.$$

On the other hand, if $\gamma \le \mu$ then

$$\Delta(\lambda) > \lambda + \gamma - \frac{\gamma}{\mu}(\lambda + \mu) = \lambda\left(1 - \frac{\gamma}{\mu}\right) \ge 0.$$

In both cases the characteristic function satisfies $\Delta(\lambda) > 0$ for all $\lambda > 0$ so there are no real positive characteristic values.

To complete the proof of (1) it remains to show that there are no complex characteristic values $\lambda = \alpha + i\omega$ with $\alpha \ge 0$ and $\omega > 0$. For the case $\gamma \le \mu$ the proof is the same as in Section 5.3 (where (5.39) holds independent of the sign of $v'(\xi)$). For the remaining case, if

$\gamma > \mu$ the assumption of the theorem reads $\frac{\xi v'(\xi)}{v(\xi)} < \frac{1}{\gamma\tau(\xi)}$. Let $\lambda = \alpha + i\omega$ be a characteristic value with $\alpha \geq 0$ and $\omega > 0$ then

$$\begin{aligned}|Ae^{-\alpha\tau(\xi)}\sin\omega\tau(\xi)\left[(\alpha+\mu)^2+\omega^2\right]| &\leq A\omega\tau(\xi)\left[(\alpha+\mu)^2+\omega^2\right]\\ &= \gamma\frac{\xi v'(\xi)}{v(\xi)}\omega\tau(\xi)\left[(\alpha+\mu)^2+\omega^2\right]\\ &< \omega\left[(\alpha+\mu)^2+\omega^2\right]\\ &< \omega\Big((2\alpha+\gamma)\mu+\alpha^2+\omega^2\Big).\end{aligned}$$

Consequently (5.37) is violated, and so there is no such characteristic value. Thus $\alpha < 0$ for all characteristic values and the steady state is asymptotically stable.

Statement (2) is derived similarly to Theorem 5.3(4), by first using (5.46) and (5.33) to show that $e^{-\mu\tau^-} < e^{-\mu\tau(\xi)} < e^{-\mu\tau^+}$ implies that $\gamma_4/\gamma < \xi/\theta_v < \gamma_3/\gamma$, then applying Proposition 5.1 and (1).

Statement (3) follows from (1) using Proposition 5.1 (point 4), since

$$\frac{\xi v'(\xi)}{v(\xi)} \leq f(r_v^{1/2m}, m, r_v) = \frac{m(1-r_v^{1/2})}{1+r_v^{1/2}},$$

where $r_v = v^-/v^+ \in (0,1)$. Statement (4) also follows from (1), using Proposition 5.1 (point 1), similar to Theorem 5.3 and Theorem 5.6, where for the second part of (4), $m > 1$ ensures that

$$f(\xi/\theta_v, m, v^-/v^+)\gamma(\xi) = \frac{m(1-v^-/v^+)(\xi/\theta_v)^m}{\left(1+(\xi/\theta_v)^m\right)\left(v^-/v^+ + (\xi/\theta_v)^m\right)}\frac{\beta g^{\pm}}{\xi}e^{-\mu\tau(\xi)} \to 0 \quad \text{as } \xi \to 0.$$

To show (5), note that the parameter constraints ensure that $f(\xi/\theta_v, m, v^-/v^+) = \frac{\xi v'(\xi)}{v(\xi)} > \frac{1}{\mu\tau(\xi)}$ when $\xi = \theta_v(v^-/v^+)^{1/2m}$. Then since $f(\xi/\theta_v, m, v^-/v^+) \to 0$ as $\xi \to 0$ and as $\xi \to \infty$ it follows that there exists $\xi^+ > \theta_v(v^-/v^+)^{1/2m}$ and $\xi^- < \theta_v(v^-/v^+)^{1/2m}$ which both solve (5.52). We take ξ^- to be the largest ξ which solves (5.52) with $\xi^- < \theta_v(v^-/v^+)^{1/2m}$, while as discussed after (5.55), ξ^+ is unique. Then it follows from (5.52), (5.55) and the adjacent arguments that there is a pair of fold bifurcations at $(\xi,\gamma) = (\xi^-, \gamma(\xi^-))$ and $(\xi,\gamma) = (\xi^+, \gamma(\xi^+))$, which are connected by a branch of unstable steady states, and no other fold bifurcation (besides $\xi = \xi^+$) with $\xi > \xi^-$. For $\xi > \xi^+$, it follows from (5.55) that $\gamma'(\xi) < 0$ and hence this branch exists for $\xi \in (\xi^+, \infty)$ and $\gamma \in (0, \gamma(\xi^+))$. If $\gamma(\xi^+) < \mu$ then the whole of this branch of steady states is stable, otherwise by (1) it is stable for all ξ sufficiently large, given by condition $\gamma(\xi) < \mu$.

For the branch which exists for $\xi \in (0, \xi^-)$, it follows from (5.46) that $\gamma(\xi) \to +\infty$ as $\xi \to 0$. Hence $\gamma(\xi)$ takes all values in $[\gamma(\xi^-), +\infty)$ for $\xi \in (0, \xi^-)$. However, as discussed after (5.55), it is possible for this branch to have additional fold bifurcations. If there are no additional fold bifurcations and $\gamma(\xi^-) < \mu$ then the branch of steady states is stable for $\gamma \in (\gamma(\xi^-), \mu)$. Also, if $m > 1$ by (4) it is stable for all ξ sufficiently small, or, equivalently, for all $\gamma(\xi)$ sufficiently large.

To show (6), first consider the case when $\gamma(\theta_v)$ defined by (5.48) satisfies $\gamma(\theta_v) > \mu$. If

$$m > 2\frac{1+(v^-/v^+)}{1-(v^-/v^+)}\left(\frac{(2k+1)^2(\pi/\tau(\theta_v))^2+\gamma(\theta_v)^2}{2\gamma(\theta_v)(\gamma(\theta_v)-\mu)}\right), \tag{5.58}$$

then

$$f(1, m, v^-/v^+) = \frac{m(1 - v^-/v^+)}{2(1 + v^-/v^+)} > \left(\frac{(2k+1)^2(\pi/\tau(\theta_v))^2 + \gamma(\theta_v)^2}{2\gamma(\theta_v)(\gamma(\theta_v) - \mu)} \right)$$
$$\geq r_j(\gamma(\theta_v)), \quad j = 0, 1, \ldots, k.$$

Here the equality comes from the definition of f, the strict inequality from (5.58) and the last inequality follows from a similar argument as in the proof of Proposition 5.7 (point 3), but using the actual value of $\tau(\theta_v)$ in the inequality, rather than the bound τ^+.

With this inequality as the starting point, increasing ξ away from θ_v we have $\lim_{\xi\to\infty} \gamma(\xi) = 0$. But $r_j(\gamma(\xi))$ and $f(\xi/\theta_v, m, v^-/v^+)$ are both continuous functions of ξ with $\lim_{\xi\to\infty} r_j(\gamma(\xi)) = \infty$ and $\lim_{\xi\to\infty} f(\xi/\theta_v, m, v^-/v^+) = 0$. Consequently for each $j = 0, 1, \ldots, k$ there exists a ξ such that $f(\xi/\theta_v, m, v^-/v^+) = r_j(\gamma(\xi))$.

Similarly, for ξ decreasing from θ_v (see also the proof of Theorem 5.6) it follows for each $j = 0, 1, \ldots, k$ that there exists a ξ such that $f(\xi/\theta_v, m, v^-/v^+) = r_j(\gamma(\xi))$. As in the proof of Theorem 5.6 this defines the required Hopf points for the two families of $k+1$ Hopf bifurcations.

This argument fails in the more delicate case where $\gamma_4 < \gamma(\theta_v) \leq \mu < \gamma_3$. In this case fix $\gamma \in (\mu, \gamma_3)$, and consider the behaviour as $m \to \infty$. Since $\gamma(\xi^+) \to \gamma_4$ and $\gamma(\xi^-) \to \gamma_3$, it follows that $\gamma \in (\gamma(\xi^+), \gamma(\xi^-))$ for all m sufficiently large. Then since $\gamma(\xi)$ defined by (5.46) is monotonically increasing for $\xi \in (\xi^-, \xi^+)$, this function is locally invertible and we can instead consider $\xi = \xi(\gamma)$ as a function of γ. From here the argument proceeds as in the proof of Theorem 5.6(6). □

We now present several examples to illustrate the complex dynamics allowed by Theorem 5.9. There are essentially three main cases to consider depending on whether μ falls above, below or within the interval (γ_4, γ_3). As in Section 5.3 we start with the simplest case where there are no Hopf bifurcations.

Case 1: $\gamma_4 < \gamma_3 < \mu$. This is illustrated in Figure 5.10. Panel (a) shows one-parameter continuations of the steady-states in γ for several fixed values of m, along with the limiting case (1.7), while panel (b) shows the two-parameter continuation of fold bifurcations of steady-states in the (γ, m) plane. We see that for all m sufficiently large there is a pair of fold bifurcations at $(\xi, \gamma) = (\xi^-, \gamma(\xi^-))$ and $(\xi, \gamma) = (\xi^+, \gamma(\xi^+))$, with $(\xi^-, \gamma(\xi^-)) \to (\theta_v, \gamma_4)$ and $(\xi^+, \gamma(\xi^+)) \to (\theta_v, \gamma_3)$ as $m \to \infty$. As required by Theorem 5.9, the steady state is always unstable between the fold bifurcations, while we observe it to always be stable otherwise.

Similar to the analysis in Section 5.2 that led to (5.28), imposing $\max\{h'(x)\} \geq 0$ leads to the necessary condition

$$\gamma \leq -\beta\mu\tau'(\xi)e^{-\mu\tau(\xi)}g^{\pm} \tag{5.59}$$

for the coexistence of three steady states. However, the algebra to turn this into an explicit condition (compare (5.59) with (5.28)) is challenging with a state-dependent delay (5.1), so instead we apply this condition numerically. The red dash-dotted curve in Figure 5.10(b) depicts the condition (5.59). For any fixed m, this curve provides an upper bound on γ for the existence of fold bifurcations and hence multiple coexisting steady states. By the same argument as in Section 5.2 the cusp bifurcation must lie on this curve. This can be seen in Figure 5.10(b) where the cusp point $(\gamma, m) = (0.4844, 5.0002)$ lies on this bounding curve.

Because of (5.56), there can be no Hopf bifurcations for $\gamma < \mu$, and since the fold bifurcations all occur for $\gamma < \mu$, there can be no Hopf bifurcations between the folds, as seen

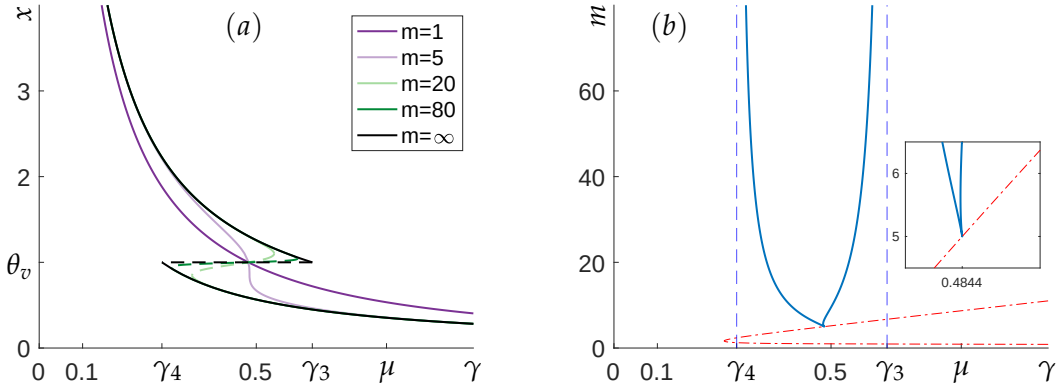

Figure 5.10: Bifurcation diagram of (1.1)–(1.2) with $(g \leftrightarrow, v \uparrow)$ and parameters $\beta = 1.4$, $\mu = 0.8$, $g^- = g^+ = 1$, $\gamma = \theta_v = a = 1$, $v^- = 0.5$ and $v^+ = 1$. By (5.33) this implies $\gamma_4 = 0.2827 < \gamma_3 = 0.6291 < \mu$ (Case 1). (a) One parameter continuation of the steady state in γ for the velocity functions in (1.7) and in (1.3) with different fixed values of m. For $m < 5$ the steady state is always stable. For $m > 5$ it is unstable between two fold bifurcations, and for large m approaches the limiting case (1.7) (denoted by $m = \infty$ in the figure). (b) Two-parameter continuation of the fold bifurcations in the (γ, m)-plane, with a cusp point at $(\gamma, m) = (0.4844, 5.0002)$. The red dash-dotted curve denotes the bound on the fold bifurcations given by (5.59).

in Figure 5.10. For $\gamma > \mu$, Theorem 5.9 ensures that the steady state is stable for γ sufficiently large or for m sufficiently large. In Figure 5.10 we see that actually there are no Hopf bifurcations at all and the steady state is stable for all values of $\gamma > \mu$ and for all $m > 0$.

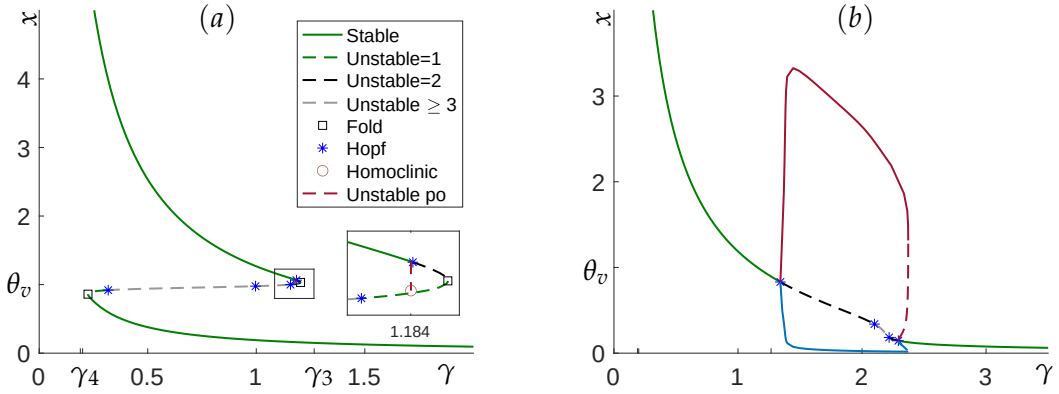

Figure 5.11: One parameter bifurcation diagrams of (1.1)–(1.2) with $(g \leftrightarrow, v \uparrow)$ for varying γ and smooth increasing v defined by (1.3), with the exponent m in the velocity nonlinearity defined by (a) $m = 50$ and (b) $m = 2$. The other parameters are taken to be $\beta = 1.4$, $\mu = 0.2$, $g^- = g^+ = 1$, $\theta_v = 1$, $a = 1$, $v^- = 0.1$ and $v^+ = 2$. By (5.33) this implies $\gamma_4 = 0.1895 < \mu < \gamma_3 = 1.2668$ (Case 2). Solid lines represent stable objects (with stable steady states shown in green), and dashed lines represent unstable objects (with unstable steady states shown in green, black or grey depending on the number of unstable characteristic values). In (a) a branch of unstable periodic orbits is represented by the 2-norm (5.60) of the periodic solution (red dashed line in inset), while in (b) red and blue lines represent the maximum and minimum values of $x(t)$ on the periodic orbit.

Case 2. The case $\mu \in (\gamma_4, \gamma_3)$ is illustrated in Figures 5.11–5.14. Figure 5.11 shows two one-parameter continuations in γ for different values of m. At first glance, Figure 5.11(a) for which $m \gg 0$, looks much like the corresponding constant delay case with increasing g illustrated in Figure 5.4(b) in Section 5.2. In both of these examples there are two fold bifurcations, leading to an interval of bi-stability of steady states, and Hopf bifurcations between the fold bifurcations leading to unstable periodic orbits. However, as shown in the inset of Figure 5.11(a), for the state-dependent delay with $\mu < \gamma_3$ the upper branch of stable steady states, which exists for $x > \theta_v$, loses stability in a (subcritical) Hopf bifurcation, and not at the fold bifurcation. Recall that for the constant delay case considered in Section 5.2 we showed that the steady-state could only lose stability in a fold bifurcation.

Figure 5.11(b) illustrates the dynamics for a much smaller value of m, but with the other parameters unchanged. In this case m is too small for fold bifurcations to occur, but we still find a pair of Hopf bifurcations, one supercritical and one subcritical, leading to a stable periodic orbit, and also a very narrow interval of bistability of this periodic orbit and a stable steady state between the subcritical Hopf bifurcation and a saddle-node of periodic orbits bifurcation. This is quite different from the dynamics seen before where, for decreasing g or v respectively in Sections 5.1 and 5.3, only supercritical Hopf bifurcations were observed, and for increasing g in Section 5.3 where Hopf bifurcations only occur between the pair of fold bifurcations.

The branches of periodic orbits in Figure 5.11(a) and (b) are represented differently. In Figure 5.11(a) we plot the L_2 norm of the periodic solution of period T, defined as

$$\|x\|_2 = \left(\frac{1}{T} \int_{t=0}^{T} |x(t)|^2 dt \right)^{1/2}. \tag{5.60}$$

In contrast, in Figure 5.11(b) we display the branch of periodic orbits by plotting both $\max x(t)$ and $\min x(t)$ over the periodic orbit, which clearly shows the amplitude of the periodic solution. Both representations can be useful on bifurcation diagrams since at a Hopf bifurcation all three expressions are equal to the steady state value and therefore the periodic orbits emanate from the steady states at Hopf bifurcations. However, the representation (5.60) has the additional property that $\|x\|_2 \to x_s$ as the solution approaches a homoclinic orbit to a saddle steady state x_s. An example of this is seen in Figure 5.11(a) where the branch of unstable periodic orbits emanating from the subcritical Hopf bifurcation appears to terminate in a homoclinic bifurcation at the middle steady state. We will investigate homoclinic bifurcations below, and so we will mainly use the L_2 norm (5.60) to represent periodic orbits.

To investigate this example further in Figure 5.12 we present two-parameter continuations of the bifurcations in γ and m, with all the other parameter values the same as in Figure 5.11.

Figure 5.12(a) shows how the γ-m parameter plane is divided into regions where there are 0, 1 or 2 stable steady states. These regions are partly bounded by a curve of fold bifurcations, but mainly by a curve of Hopf bifurcations, with the two bifurcation curves meeting at a Bogdanov–Takens (BT) bifurcation point, at which the characteristic equation has a double zero characteristic value.

Figure 5.12(b) shows the locus of the fold bifurcations, along with codimension-two bifurcations which occur on this branch. Different line types/colours are used to indicate the number of unstable characteristic values (not counting the zero characteristic value associated with the fold bifurcation itself). Since $(\xi^+, \gamma(\xi^+)) \to (\theta_v, \gamma_4)$ as $m \to \infty$, and $\mu > \gamma_4$, it follows that $\gamma(\xi^+) < \mu$ for all m sufficiently large. As explained before Proposition 5.7, these fold bifurcations which occur for $\gamma < \mu$ always involve a stable steady state. The fold bifurcations

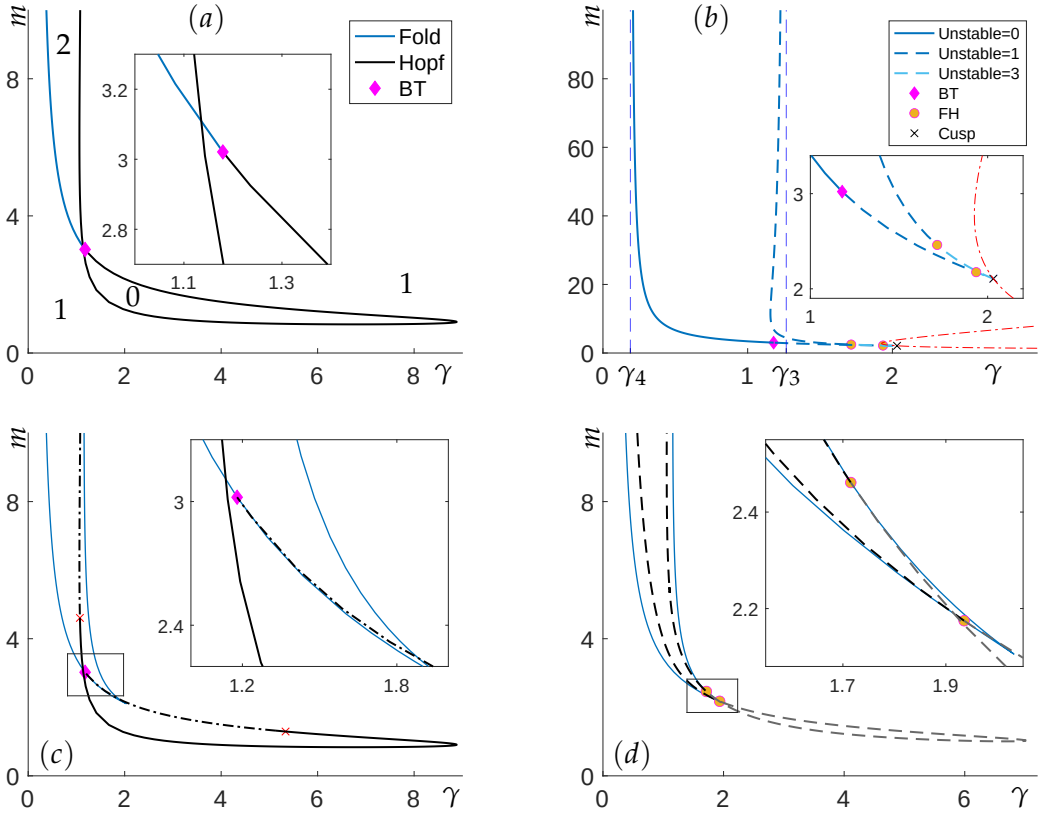

Figure 5.12: Two parameter (Case 2) bifurcation diagrams of (1.1)–(1.2) with $(g \leftrightarrow, v \uparrow)$ and smooth increasing v defined by (1.3). The bifurcation parameters are γ and m, with the other parameters for all the panels taken as stated in the caption to Figure 5.11. (a) The parameter space is divided into regions where there are 0, 1 or 2 stable steady states as indicated. These regions are partly bounded by a curve of Hopf bifurcations (black), and partly by a curve of fold bifurcations (blue). These two curves meet in a Bogdanov–Takens (BT) bifurcation point at $(\gamma, m) = (1.1795, 3.0209)$. (b) Two-parameter continuation of the fold bifurcations only. The fold curve is drawn according to the number of characteristic values with positive real part; solid blue for zero, dashed blue for one, and dashed light blue for three. The dashed vertical blue lines denote $\gamma = \gamma_3$ and $\gamma = \gamma_4$, given by (5.33), the location of the fold bifurcations in the limiting case as $m \to \infty$. The red dash-dotted curve denotes the bound on the fold bifurcations given by (5.59). There is a cusp point at $(\gamma, m) = (2.0321, 2.1058)$. The same BT point is detected again as well as two fold-Hopf points at $(\gamma, m) = (1.7153, 2.4612)$ and $(\gamma, m) = (1.9354, 2.1748)$. (c) Continuation of the branch of Hopf bifurcations emanating from the BT point (in black), with the branch of fold bifurcations shown in blue for scale. These Hopf bifurcations always involve a stable steady state that loses stability, either in a supercritical Hopf bifurcation to a stable periodic orbit (the solid black curve), or in a subcritical Hopf bifurcation to an unstable periodic orbit (the dotted-dashed black curve). Two Bautin bifurcations at $(\gamma, m) = (1.0721, 4.6069)$ and $(5.3352, 1.2929)$ where the criticality of the Hopf bifurcation changes are denoted by red stars. (d) Continuation of the branch of Hopf bifurcations which passes through both fold-Hopf points. This bifurcation curve only involves unstable steady states. The dashed black curve represents Hopf bifurcations with one unstable eigenvalue, and the dashed gray curve with two unstable eigenvalues. The change in number of eigenvalues with positive real part occurs at the fold-Hopf points.

where a stable steady state is created/destroyed are shown as the solid blue segment of the curve of fold bifurcations which is asymptotic to $\gamma = \gamma_4$ in Figure 5.12(b). In contrast, the part of the branch asymptotic to $\gamma = \gamma_3$ as $m \to \infty$ consists of fold bifurcations of two unstable steady states (with different numbers of unstable characteristic values). The BT point, already seen in Figure 5.12(a), separates these two parts of the branch of fold bifurcations. Consequently, only part of the branch of fold bifurcations delineates the boundary between regions of parameter space with different numbers of stable steady states. This contrasts starkly with the constant delay case considered in Section 5.2 and the state-dependent case with $\mu > \gamma_3$ (shown in Figure 5.10), for both of which steady states only lose stability in a fold bifurcation.

Figure 5.12(c) shows the Hopf curve which terminates at the BT point. We verified numerically that at all points on this curve the Hopf bifurcation is from a stable steady state that loses stability. Close to the BT point, and at the other end of this branch as $m \to \infty$, the Hopf bifurcation is subcritical leading to an unstable periodic orbit. But on a large segment of this curve (and in particular for the smallest values of m on the curve) the Hopf bifurcation is supercritical leading to a stable periodic orbit. Two Bautin bifurcation points, where the Hopf bifurcation changes criticality, separate the sub and supercritical segments of the curve. Figure 5.12(a) shows the number of stable steady states in the γ-m parameter plane, and just the parts of the bifurcation curves that delineate these regions. The region with no stable steady states contains a stable periodic orbit (because of the supercritical Hopf bifurcation on the left-side of this region).

Figure 5.12(d) shows another curve of Hopf bifurcations for the same problem. This curve passes through the two fold-Hopf bifurcation points seen on the curve of fold bifurcations in Figure 5.12(b). We notice that while these points are close together on the branch of fold bifurcations (they are both close to, but on different sides of, the cusp point), as the inset shows, they are on different legs of the branch of Hopf points, and hence far from each other on this branch of Hopf bifurcations. The codimension-two fold-Hopf bifurcation points are of interest, as such bifurcations are impossible for the constant delay model of Section 5.2. However the Hopf bifurcations seen in this example all generate unstable periodic orbits bifurcating from unstable steady states, and we will not study them further.

In Figure 5.13 we continue our study of the dynamics seen in Figures 5.11 and 5.12 by showing one-parameter continuations of the dynamics and bifurcations as γ is varied for different fixed values of the steepness parameter m in the Hill function (1.3). For m small there is a unique stable steady state for each value of γ and no bifurcations occur. For $m > 0.8355$ there is still a unique steady state, but it is unstable between a pair of super-critical Hopf bifurcations, where a branch of stable periodic orbits exists. This is illustrated in Figure 5.13(a) for $m = 1.2$, where we see that the period of the periodic orbits is monotonically increasing from the left Hopf point to the right Hopf point.

Increasing m further for $m > 1.2929$ we pass the lower Bautin bifurcation seen in Figure 5.12(c) and the right Hopf point becomes subcritical. The branch of periodic orbits is still contiguous, but a fold bifurcation of periodic orbits born in the Bautin bifurcation divides the branch of periodic orbits into an upper stable branch and a lower unstable branch. The period is no longer monotonically increasing on the branch of periodic orbits, but attains a maximum period near to the fold bifurcation of periodic orbits, but on the unstable branch of periodic orbits (as illustrated for $m = 2$ in Figure 5.13(b)).

For $m > 2.1058$ the cusp bifurcation seen in Figure 5.12(b) introduces two fold bifurcations of steady states (seen for $m = 2.15$ in Figure 5.13(c)). As m is increased further the maximum period seen on the branch of periodic orbits increases dramatically and the point where the

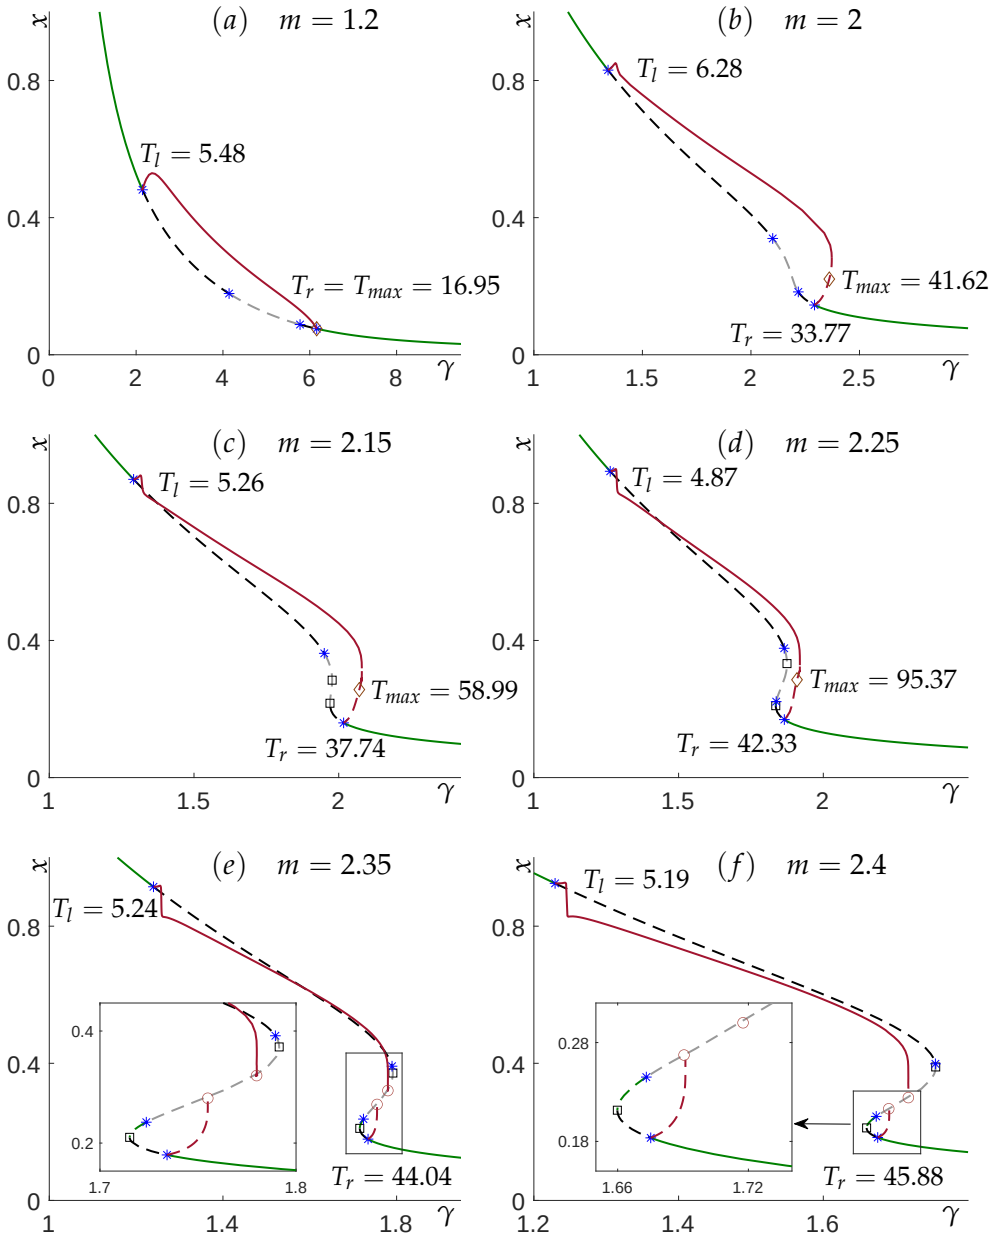

Figure 5.13: Case 2 one-parameter bifurcation diagrams for $(g \leftrightarrow, v \uparrow)$ with varying γ and different fixed values of m, with the other parameters the same as in Figures 5.11 and 5.12. Solid lines represent stable objects including stable steady states (in green) and stable periodic orbits (represented by the 2-norm (5.60)). Dashed lines represent unstable objects including unstable steady states (depending on the number of eigenvalues with positive real part, green for one, black for two and gray for three and more) and unstable periodic orbits (represented by 2-norm (5.60)). Hopf bifurcations are marked by blue stars, fold bifurcations of steady states by black squares, and homoclinic bifurcations by red circles. For the branch of periodic orbits, T_l is the period at the left Hopf bifurcation, and T_r at the right Hopf bifurcation. The point on the branch where the largest period, T_{max}, occurs is marked by a brown diamond.

maximum period occurs approaches the intermediate steady state (see Figure 5.13(d)).

Comparing panels (d) and (e) of Figure 5.13 suggests that (1.1) undergoes a codimension-two global bifurcation between these panels. The branches of periodic orbits emanating from the Hopf bifurcations where the steady states lose stability no longer join up in panels (e) and (f). Instead, each branch ends at a homoclinic bifurcation to the intermediate steady state (at different values of the parameter γ). The panels shown suggest, but do not prove, that as m is increased the branch of periodic orbits approaches the fold point with $T_{max} \to \infty$ at the first point where a homoclinic bifurcation occurs. Further evidence is presented in the two-parameter continuation of Figure 5.14(a) where the homoclinic curves seem to approach the curve of folds. For larger values of $m > 2.3$, codimension-one homoclinic bifurcations to the intermediate saddle steady state are found. Examples of dynamical systems with a single branch of homoclinic bifurcations terminating at a fold bifurcation of steady states can be found in [1, 35]. Our example is somewhat different from those, as we have two branches of homoclinic bifurcations.

The homoclinic bifurcation on the branch emanating from the lower Hopf point in Figures 5.13(e) and (f) does not persist for large m, but instead the homoclinic bifurcation and the Hopf bifurcation itself move towards the fold bifurcation and terminate at the BT-point found previously. This is illustrated in a two-parameter continuation in Figure 5.14(a), which shows the branch of fold bifurcations of steady states passing through the BT point, next to a branch of Hopf bifurcations, then a branch of homoclinic bifurcations, the latter two branches both terminating at the BT point tangential to the branch of fold bifurcations at that point. This is well-known behaviour for Bogdanov–Takens bifurcations, and can be seen in the normal form diagram for this bifurcation in Section 8.4 of [35]. Bogdanov–Takens bifurcations have recently been analysed for constant delay DDEs in [6] (where Figures 5 and S8 resemble the part of Figure 5.14(a) close to the BT point), but we are not aware of any systematic study of them in state-dependent DDE problems.

While in the classical unfolding the bifurcation curves extend arbitrarily far from the BT point, in our example in Figure 5.14(a) both the branch of homoclinic orbits and the branch of fold bifurcations terminate. The branch of fold bifurcations terminates at a cusp bifurcation with the other branch of fold bifurcations. The proximity of the cusp point to the BT point suggests that our system may be close to a codimension-three Bogdanov–Takens–cusp (BTC) point. While we are not aware of a systematic study of this bifurcation, they have been observed in a neuron model in [1], and some of the bifurcation structures that we find resemble those in [1].

The homoclinic bifurcation on the branch emanating from the upper Hopf point in Figures 5.13(e) and (f) is also shown in Figure 5.14(a) and persists for arbitrary large values of m (it was already seen with $m = 50$ in Figure 5.11(a)), but there is a change in stability on this branch for $m > 4.6069$ due to the Bautin bifurcation seen in Figure 5.12(c).

The maximum period of orbits from the one-parameter continuations described in Figure 5.13 are also shown as a curve in two-parameter space in Figure 5.12(a). This curve approaches the right most curve of fold bifurcations with the period becoming unbounded as it does so. Our computations of the two branches of homoclinic bifurcations also terminate close to this point. We conjecture that the co-dimension two of the homoclinic orbits already described in Figure 5.13 that occurs where the branch of maximum period orbits terminates will occur on the branch of fold bifurcations. This would be consistent with the previously mentioned examples of curves of homoclinic bifurcations which terminate at fold bifurcations [1, 35].

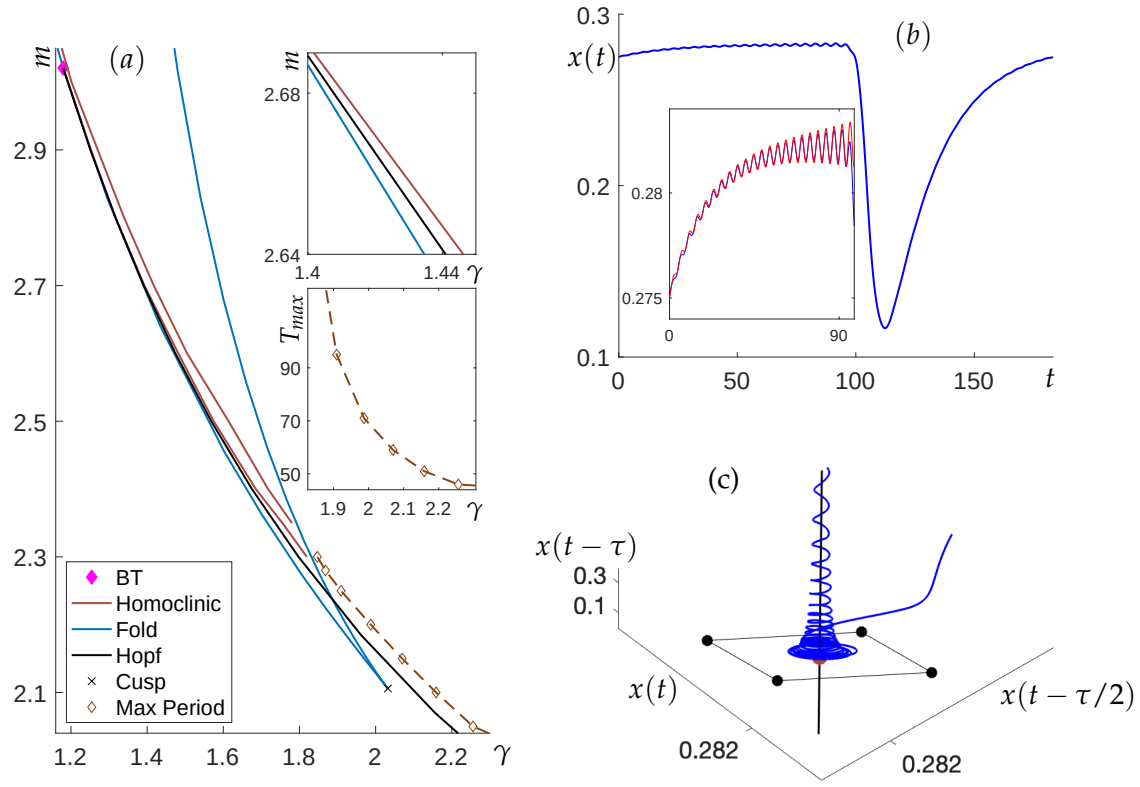

Figure 5.14: (a) Bifurcation diagram near the Bogdanov–Takens point shown in Figure 5.12 for $(g \leftrightarrow, v \uparrow)$ shows a branch of Hopf bifurcations and a branch of homoclinic bifurcations emerging from the BT point. The dashed brown line denotes the point in parameter space where the largest period was encountered on the branches of periodic orbits shown in Figure 5.13, with the period shown in the lower inset. The upper inset shows the ordering of the curves emerging from the BT point. (b) Profile of the unstable periodic orbit with parameters $\beta = 1.4$, $\mu = 0.2$, $g^- = g^+ = 1$, $m = 2.35$, $\gamma = 1.7550$, $\theta_v = 1$, $a = 1$, $v^- = 0.1$, and $v^+ = 2$. The blue curve shows the periodic orbit with period $T = 183$. In the inset the part of the periodic orbit (in blue) near to the intermediate steady state is overlayed by a linear approximation to the dynamics in red (see text for details). (c) Projection of the periodic orbit from (b) onto the space $(x(t), x(t - \tau/2), x(t - \tau))$ where $\tau = 5.1926$ is chosen to be the delay at the intermediate steady state represented by the orange dot. The solid black line represents the dominant one-dimensional linear stable manifold associated with the characteristic value -0.045. The parallelogram denotes the plane associated with the dominant unstable characteristic values $\lambda = 0.0184 \pm 1.4738i$.

In Figure 5.14(b) and (c) we display one of the periodic orbits for $m = 2.35$ from the lower branch of periodic orbits shown in Figure 5.13(e). The orbit is shown close to the homoclinic bifurcation at the end of the branch, for which the period is large. Figure 5.14(c) shows a phase space projection of the part of the orbit close to the intermediate steady state. In this projection the orbit approaches the saddle steady state from above close to the dominant stable direction (associated with the characteristic value with negative real part closest to zero which is $\lambda = -0.045$), but with a growing oscillation about this point in the plane defined by the dominant unstable direction (associated with the characteristic value with positive real part closest to zero which is $\lambda = 0.0184 \pm 1.4738i$). To further confirm that this linear

behaviour is determining the dynamics near to the intermediate steady state x^*, in the inset of Figure 5.14(b) we plot in red the curve

$$x(t) = x^* + k_1 e^{-0.045t} + k_2 e^{0.0184t} \cos(1.4738t),$$

for suitably chosen coefficients k_j, and observe that it overlays the periodic solution over most of the time interval shown. This behavior is similar to that associated with Shilnikov type complex dynamics, but in contrast with the construction of a chaotic attractor of Shilnikov type, the periodic orbit pictured in Figure 5.14(b) and (c) is unstable.

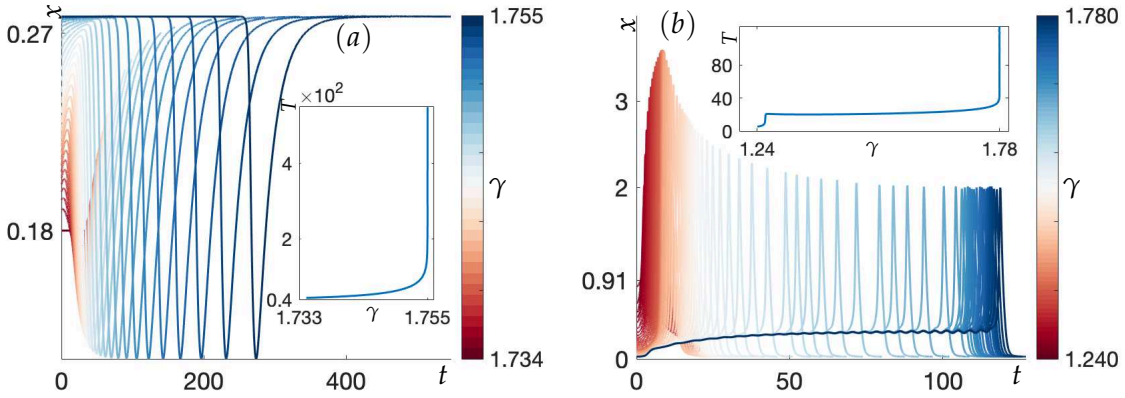

Figure 5.15: Profiles and periods of periodic orbits on the branches that approach homoclinic bifurcations in Figure 5.13(e) with $m = 2.35$ for (a) the unstable periodic orbits on the branch emanating from the subcritical Hopf bifurcation at $\gamma = 1.734$, and (b) the stable periodic orbits on the branch emanating from the supercritical Hopf bifurcation at $\gamma = 1.240$.

Figure 5.15(a) and (b) shows the profiles and periods on the two branches of periodic solutions seen in Figure 5.13(e). Comparing these two panels we see that the periodic orbits on the two branches are very different, with the unstable orbit in Figure 5.15(a) having a small amplitude and with $x(t)$ below the steady state value along the whole orbit on the entire branch. In contrast stable periodic orbits shown in panel (b) have much larger amplitude.

Case 3: It remains to consider the case where $\mu < \gamma_4 < \gamma_3$. Making a small change to the parameters considered in the example in Figures 5.11 to 5.15 by changing the value of β from $\beta = 1.4$ to $\beta = 2$ but leaving the values of the other parameters unchanged, results in $\mu = 0.2 < \gamma_4 = 0.2707 < \gamma_3 = 1.8097$. However, although $\mu < \gamma_4$ in this case μ is close to γ_4 and the dynamics and bifurcations are very similar to those shown in Figure 5.11, so we do not show them here. Instead in Figure 5.16 we consider an example with $\mu \ll \gamma_4 < \gamma_3$.

Theorem 5.9 suggests that stability may be lost in either a Hopf or a fold bifurcation, but for the example in Figure 5.16 with $\mu \ll \gamma_4$ we see that the steady state always loses stability at a Hopf bifurcation. Unlike the previous example, there is no longer a BT point, and for all m sufficiently large the steady state loses stability in a subcritical Hopf bifurcation close to the fold bifurcation, resulting in a short branch of periodic orbits that terminates in a homoclinic bifurcation to the intermediate steady state created at the fold bifurcation, as illustrated for $m = 50$ in Figure 5.16(b)–(d). For m small, below the cusp bifurcation at $m = 5.0007, \gamma = 0.7572$, the Hopf bifurcations are supercritical leading to a branch of stable periodic orbits between the Hopf bifurcations, similar to Figure 5.13(a). As seen in Figure 5.16(b) the Hopf bifurcations and homoclinic points are very close to the fold bifurcations. This makes

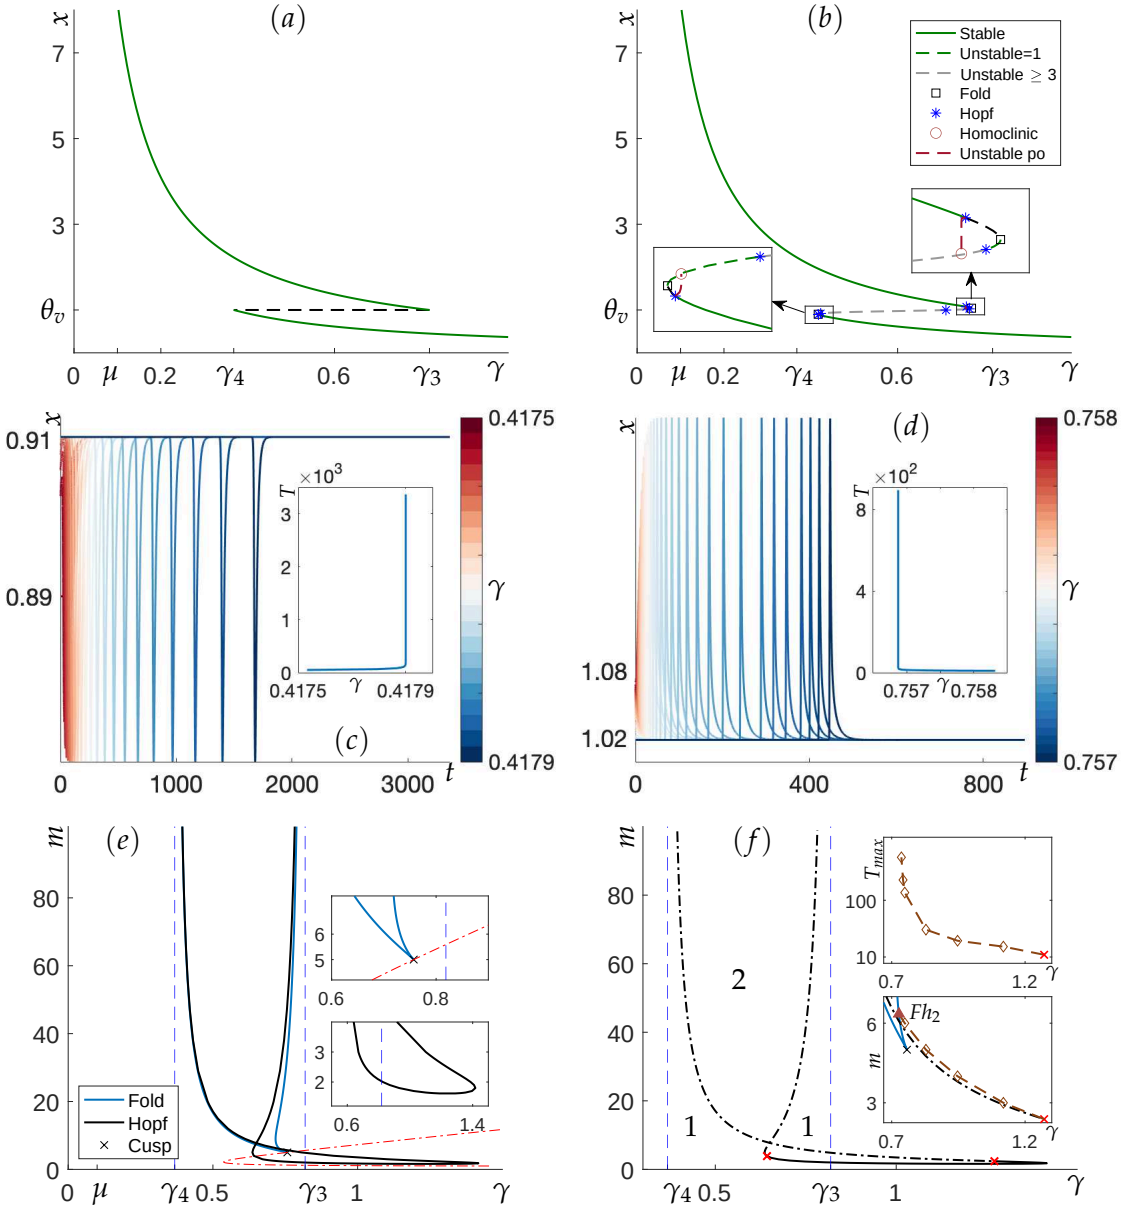

Figure 5.16: Bifurcation diagrams of (1.1)–(1.2) with $(g \leftrightarrow, v \uparrow)$ and parameters $\beta = 1$, $\mu = 0.1$, $g^- = g^+ = 1$, $\theta_v = 1$, $a = 2$, $v^- = 0.2$ and $v^+ = 1$. By (5.33) this implies $\mu < \gamma_4 = 0.3679 < \gamma_3 = 0.8187$ (Case 3). (a) The limiting case with v defined by (1.7). The stable steady state is shown as a green solid line, and the singular steady state as a black dashed line. (b) With smooth velocity nonlinearity v defined by (1.3) with $m = 50$. Solid lines represent stable steady states (in green). Dashed lines represent unstable objects including unstable steady states (depending on the number of eigenvalues with positive real part, green for one, and gray for three and more) and unstable periodic orbits (represented by 2-norm (5.60)). (c) and (d) Profiles and periods of the periodic orbits on the branches shown in (b) that terminate at homoclinic bifurcations and emanate from the subcritical Hopf bifurcations at (c) $\gamma = 0.4175$ and (d) $\gamma = 0.758$. (e) Two-parameter continuations in m and γ of the fold and the Hopf bifurcations with other parameters as above. The dashed vertical blue lines denote $\gamma = \gamma_3$ and $\gamma = \gamma_4$ the location of the fold bifurcations in the limiting case as $m \to \infty$. The red dash-dotted curve denotes the bound on the fold bifurcations. (f) Two parameter continuation of the curve of Hopf bifurcations, with the two Bautin bifurcation points and the criticality of the Hopf bifurcation indicated. The Hopf bifurcations delineate the parameter space into regions where there is 0, 1 or two stable steady states, as indicated. Also shown in the insets is the maximum period curve (similar to Figures 5.13 and 5.14), which terminates at the point marked Fh_2 with infinite period.

numerical continuation of the branches of homoclinic bifurcations very delicate, and so we do not show the curves of homoclinic bifurcations in the two parameter continuations in Figure 5.16(e) and (f). Instead in the insets in Figure 5.16(f) we show the curve formed by the periodic orbits of maximum periods from the one-parameter continuations in γ; as was done in case (b) in Figures 5.13 and 5.14. This curve is born from the Bautin bifurcation point and terminates at the point labelled Fh_2 on the curve of fold bifurcations, where the period becomes infinite. We expect two curves of homoclinic bifurcations to be born at this point, and to persist for arbitrarily large m (as seen in (b) for $m = 50$).

5.5 Summary

We briefly summarize the results of Section 5. We have separately studied cases with constant delay and decreasing (Section 5.1) and increasing (Section 5.2) function g, and then the cases with constant g but with state dependent delay with velocity v decreasing (Section 5.3) or increasing (Section 5.4). These results can be compared between constant and state-dependent cases but with the same type of nonlinearity (Section 5.1 and 5.3, and Section 5.2 and 5.4), or between the two types of nonlinearity with the same type of delay (Section 5.1 and 5.2, and Section 5.3 and 5.4), as we will do below.

In general, the dynamics with state-dependent delay is significantly richer than that of the corresponding constant delay case. For decreasing non-linearity (Section 5.1 vs Section 5.3) in the constant delay case there is a range (γ_1, γ_2) of the parameter γ where the unique equilibrium undergoes a series of Hopf bifurcations as the Hill coefficient $n \to \infty$ (Figure 5.2). In contrast, in the state dependent case a new constraint becomes important as we show that Hopf bifurcations can only occur for $\gamma < \mu$. Therefore, if the μ is below the range (γ_3, γ_4) the unique equilibrium is always stable (Figure 5.6), when it is above (γ_3, γ_4) we recover the result from Section 5.1 (Figure 5.8), and when $\mu \in (\gamma_3, \gamma_4)$, the result of Section 5.1 is confined to values of $\gamma \in (\gamma_3, \gamma_4) \cap \{\gamma < \mu\} = (\gamma_3, \mu)$; see Figure 5.7.

When the feedback nonlinearity is increasing with constant delay (Section 5.2) the system has multiple equilibria for γ in an interval which approaches (γ_2, γ_1) in the limit as the feedback nonlinearity approaches a piecewise constant function. The stable equilibria always lose stability at fold bifurcations at the ends of the interval, leading to bistability of steady states for this interval of γ values. Hopf bifurcations can only occur on the middle branch of unstable equilibria.

As documented in Section 5.4, this scenario changes dramatically for state dependent delays. For increasing v there is again a constraint and we show that Hopf bifurcations can only occur for $\gamma > \mu$. Consequently if $\mu > \gamma_3$ there are no Hopf bifurcations. On the other hand, when $\mu < \gamma_3$ new dynamics are observed. In this case stable equilibria can now lose stability in a Hopf bifurcation and the interaction of the Hopf and fold bifurcation curves in two-parameter continuation in γ and the Hill coefficient leads to existence of Bogdanov–Takens points, fold-Hopf points and a possible double homoclinic bifurcation. This last scenario, documented in Figure 5.13, suggests that a curve of periodic orbits connecting subcritical and supercritical Hopf bifurcations of the stable equilibria, collides with a fold bifurcation where the equilibrium also admits a homoclinic orbit. Continuation of the curve of periodic orbits in two-parameter space suggests that the curve splits into two curves of periodic orbits each terminating at a homoclinic bifurcation at the middle equilibrium branch, but at different values of parameter γ. A less dramatic result, but perhaps more important for applications, is the observation of bistability between a stable fixed point and a stable periodic orbit in Fig-

ure 5.13(b), a scenario that is impossible in the constant delay case of the Goodwin operon model considered in Sections 5.1 and 5.2.

6 Dynamics with two Hill functions

We now consider the model (1.1), (1.2) with both the functions g and v non-constant at the same time. In the limiting case these functions are defined by (1.6) and (1.7), and when $\theta_v \neq \theta_g$, the steps in the functions occur for different values of x, so they reduce to the cases considered in Section 5 with v constant for x in a neighbourhood of θ_g, and g constant for x in a neighbourhood of θ_v. With smooth nonlinearities defined by (1.3) and large exponents $m \gg 0$, $n \gg 0$, when $\theta_v \neq \theta_g$ we will see dynamics and bifurcations near $x = \theta_g$ similar to those observed in Sections 5.1 and 5.2, and similar to Sections 5.3 and 5.4 near $x = \theta_v$. On the other hand, when $\theta_v = \theta_g$ new dynamics are observed.

Recall the notation $(g \downarrow, v \downarrow)$ that indicates the monotonicity type of functions g and v, introduced in Section 1. Note that if $v^- > v^+$ then $v(x)$ is a decreasing function of x, then $\tau(x)$ given by (5.1) is an increasing function of x, and therefore $e^{-\mu\tau(x)}$ is a decreasing function of x. It follows immediately that for $(g \downarrow, v \downarrow)$ the function $h(x)$ (see (5.2)) is strictly monotonically decreasing and hence for g and v both monotonically decreasing there is exactly one steady state.

If either or both of g or v is increasing then it is possible to have fold bifurcations and additional steady states. To see this, consider a steady state ξ with both v and g given by (1.3), in which case the characteristic equation has the form (4.8), which can be written as $\Delta(\lambda) = 0$ with

$$\Delta(\lambda) = \lambda + \gamma(\xi) - A(\xi) - (Q(\xi) - A(\xi))e^{-\lambda\tau(\xi)} - \mu A(\xi)\int_{-\tau(\xi)}^{0} e^{\lambda s} ds \tag{6.1}$$

where (recalling (4.4) and (5.15))

$$Q(\xi) := \beta e^{-\mu\tau(\xi)} g'(\xi) = \gamma \frac{\xi g'(\xi)}{g(\xi)}, \qquad A(\xi) = \beta \frac{v'(\xi)}{v(\xi)} e^{-\mu\tau(\xi)} g(\xi) = \gamma \frac{\xi v'(\xi)}{v(\xi)}.$$

The properties of $A(\xi)$ and $Q(\xi)$ were already described in Proposition 5.1. Now

$$\begin{aligned}\Delta(0) &= \gamma(\xi) - Q(\xi) - \mu A(\xi)\int_{-\tau(\xi)}^{0} 1 ds = \gamma(\xi) - Q(\xi) - \mu\tau(\xi)A(\xi) \\ &= \gamma(\xi)\Big(1 - \frac{\xi g'(\xi)}{g(\xi)} - \mu\tau(\xi)\frac{\xi v'(\xi)}{v(\xi)}\Big).\end{aligned}$$

Hence, $\lambda = 0$ is a characteristic value if and only if

$$M(\xi) := \frac{\xi g'(\xi)}{g(\xi)} + \mu\tau(\xi)\frac{\xi v'(\xi)}{v(\xi)} - 1 = 0. \tag{6.2}$$

In addition, we note that $M(\xi) > 0$ implies that $\Delta(0) < 0$. At the same time, for real λ the characteristic function satisfies $\Delta(\lambda) \to +\infty$ as $\lambda \to +\infty$. We conclude that when $M(\xi) > 0$ there is a real positive characteristic value and hence the steady state is unstable.

We now show that fold bifurcations occur when (6.2) is satisfied. To that end, consider the curve of solutions $(\gamma(\xi), \xi)$ where $\gamma(\xi)$ is defined by

$$\gamma(\xi) = \frac{\beta g(\xi)}{\xi} e^{-\mu\tau(\xi)}, \tag{6.3}$$

which by (5.2) is the locus of steady states in the (γ, ξ)-plane. Differentiating this relationship with respect to ξ we find

$$\gamma'(\xi) = -\frac{\gamma(\xi)}{\xi} + \frac{\gamma(\xi)g'(\xi)}{g(\xi)} - \gamma(\xi)\mu\tau'(\xi).$$

Using (5.54) we obtain

$$\xi\gamma'(\xi) = \gamma(\xi)\left(\frac{\xi g'(\xi)}{g(\xi)} + \mu\tau(\xi)\frac{\xi v'(\xi)}{v(\xi)} - 1\right) = \gamma(\xi)M(\xi). \tag{6.4}$$

Hence $\operatorname{sgn}(\gamma'(\xi)) = \operatorname{sgn}(M(\xi))$, and $\gamma'(\xi)$ changes sign when $M(\xi)$ does, which ensures that fold bifurcations occur at these points in the (γ, ξ)-plane.

Note that this is a direct generalisation of the fold bifurcations found in Section 5 as (6.2) reduces to (5.27) when v is a constant function, and to (5.52) when g is constant.

Next we determine when Hopf bifurcations may arise for the general case where both g and v are non-constant. For $\lambda \neq 0$, using (6.1) we can rewrite the characteristic equation $\Delta(\lambda) = 0$ as

$$\lambda = -\gamma + A(\xi)(1 - e^{-\lambda\tau(\xi)})\left(1 + \frac{\mu}{\lambda}\right) + Q(\xi)e^{-\lambda\tau(\xi)}. \tag{6.5}$$

At a Hopf bifurcation we set $\lambda = i\omega$, with $\omega \neq 0$, and from (6.5) obtain

$$\begin{aligned} i\omega &= -\gamma + A(\xi)(1 - e^{-i\omega\tau})\left(1 + \frac{\mu}{i\omega}\right) + Q(\xi)e^{-i\omega\tau} \\ &= -\gamma + A(\xi)(1 - \cos\omega\tau + i\sin\omega\tau)\left(\frac{\omega^2 - i\omega\mu}{\omega^2}\right) + Q(\xi)(\cos\omega\tau - i\sin\omega\tau). \end{aligned}$$

Taking real and imaginary parts, this reduces to

$$\gamma = A(\xi)\left(1 - \cos\omega\tau + \frac{\mu}{\omega}\sin\omega\tau\right) + Q(\xi)\cos\omega\tau, \tag{6.6}$$

$$\omega = A(\xi)\left(\sin\omega\tau - \frac{\mu}{\omega}(1 - \cos\omega\tau)\right) - Q(\xi)\sin\omega\tau. \tag{6.7}$$

Note that when $\omega\tau = 2k\pi$ for $k \in \mathbb{Z}$ the last equation reads $\omega = 0$, which contradicts the requirement that $\omega \neq 0$ for a Hopf bifurcation. It follows that at a Hopf bifurcation

$$|\cos(\omega\tau)| < 1. \tag{6.8}$$

The equations (6.6) and (6.7) can each be rearranged in two ways: first, as $A(\xi)(1 - \cos\omega\tau) = \textit{other terms}$, or, second, as $A(\xi)\sin\omega\tau = \textit{other terms}$. Doing so, then equating the same expressions from the two equations gives

$$A(\xi)\sin\omega\tau(\omega^2 + \mu^2) = \omega(\gamma\mu + \omega^2) + Q(\xi)(\omega\sin\omega\tau - \mu\cos\omega\tau), \tag{6.9}$$

$$A(\xi)(1 - \cos\omega\tau)(\omega^2 + \mu^2) = \omega^2(\gamma - \mu) - Q(\xi)(\omega^2\cos\omega\tau + \mu\omega\sin\omega\tau). \tag{6.10}$$

Note that when $g^+ = g^-$ so g is constant and $Q(\xi) = 0$ these equations reduce to (5.41) and (5.42). On the other hand when $v^+ = v^-$ so $v'(\xi) = 0$ and hence $A(\xi) = 0$, equations (6.9) and (6.10) can be shown to reduce to (5.13) and (5.14).

Using (6.8), the left-hand side of (6.10) has the sign of $A(\xi)$ (recall also (5.41) which has an identical left-hand side).

When $Q(\xi) = 0$, the right-hand side of (6.10) has the sign of $\gamma - \mu$. For the general case with $Q(\xi) \neq 0$, since $|\cos \omega\tau| \leq 1$ and $|\sin \omega\tau| \leq \omega\tau$, we obtain

$$|Q(\xi)(\omega^2 \cos \omega\tau + \mu\omega \sin \omega\tau)| \leq |Q(\xi)|(\omega^2|\cos \omega\tau| + \mu\omega|\sin \omega\tau|) \leq |Q(\xi)|\omega^2(1 + \mu\tau).$$

Then, when $A(\xi) < 0$, and hence v is a decreasing function, the left-hand side of (6.10) is negative, while the right-hand side satisfies

$$\begin{aligned} \omega^2(\gamma - \mu) - Q(\xi)(\omega^2 \cos \omega\tau + \mu\omega \sin \omega\tau) &\geq \omega^2(\gamma - \mu) - |Q(\xi)|\omega^2(1 + \mu\tau) \\ &= \omega^2(\gamma - \mu - |Q(\xi)|(1 + \mu\tau)). \end{aligned} \tag{6.11}$$

Consequently, there can be no Hopf bifurcations if $\gamma > \mu + |Q(\xi)|(1 + \mu\tau)$.

Similarly for the case that $A(\xi) > 0$ (and hence v is an increasing function), the left-hand side of (6.10) is positive, while the right-hand side satisfies

$$\begin{aligned} \omega^2(\gamma - \mu) - Q(\xi)(\omega^2 \cos \omega\tau + \mu\omega \sin \omega\tau) &\leq \omega^2(\gamma - \mu) + |Q(\xi)|\omega^2(1 + \mu\tau) \\ &= \omega^2(\gamma - \mu + |Q(\xi)|(1 + \mu\tau)). \end{aligned} \tag{6.12}$$

Thus, when $A(\xi) > 0$ there can be no Hopf bifurcations if $\gamma < \mu - |Q(\xi)|(1 + \mu\tau)$.

Note that both the conditions here reduce to the previous ones in the limit as $Q(\xi) \to 0$, or equivalently as $g'(\xi) \to 0$. As in Section 5, we will deal with this by considering the different combinations of increasing and decreasing functions v and g separately.

6.1 Two Hill functions with $\theta_g \neq \theta_v$

With g and v both varying and $\theta_g \neq \theta_v$, the dynamics will be comparable to a combination of the four simplified cases as discussed in Section 5.1–5.4. In particular, if both g and v are decreasing functions, there is always exactly one steady state. The dynamics in the case $(g \downarrow, v \downarrow)$ will be similar to the case in Section 5.1 near to $x = \theta_g$ and similar to the case in Section 5.3 near to $x = \theta_v$. The singular steady states in the limiting case give rise to steady states in the smooth case which may undergo Hopf bifurcations where the stability of steady state changes, as illustrated in Sections 5.1 and 5.3.

For the cases when g and v have opposite monotonicity, there are up to three coexisting steady states. The bifurcations occurring near the two respective thresholds agree with the examples in Section 5. Since the dynamics can be explained using the results of Section 5 we only briefly consider the dynamics with $\theta_g \neq \theta_v$ and present two examples, one with $(g \downarrow, v \uparrow)$ in Section 6.1.1, and another for $(g \uparrow, v \uparrow)$ in Section 6.1.2. In this last example, it is possible for up to five steady states to coexist with sufficiently steep nonlinearity.

The constants γ_j for $j = 1, 2, 3, 4$ introduced in (5.4) and (5.33) in Section 5 will also play a role here. When $\theta_v \neq \theta_g$ we again define these using (5.4) and (5.33). However, since both the functions g and v are non-constant we need to define a value for τ in (5.4) and for g in (5.33). We proceed as follows. For γ_1 and γ_2 given by (5.4), the required value of τ is $\tau(\theta_g)$ and hence we take $\tau = \tau^-$ if $\theta_v > \theta_g$ and $\tau = \tau^+$ if $\theta_v < \theta_g$. Similarly in (5.33) we take $g = g^-$ if $\theta_g > \theta_v$ and $g = g^+$ if $\theta_g < \theta_v$.

6.1.1 Decreasing g and increasing v $(g \downarrow, v \uparrow, \theta_g \neq \theta_v)$

When g and v have opposite monotonicity, either $(g \downarrow, v \uparrow)$ or $(g \uparrow, v \downarrow)$, and $\theta_g \neq \theta_v$, there are up to three coexisting steady states in the limiting case. Figure 6.1 shows such an example in the case $(g \downarrow, v \uparrow, \theta_v < \theta_g)$.

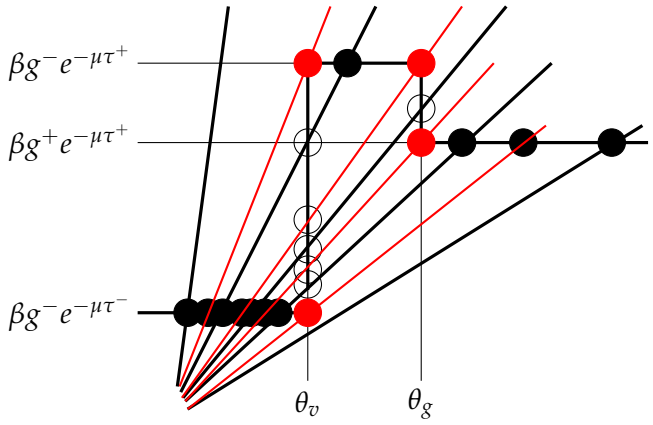

Figure 6.1: Steady states of (1.1), given by (5.2), occur at the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and $\xi \mapsto \gamma\xi$. These are illustrated for various γ in the limiting case of (1.6) and (1.7) for $(g\downarrow, v\uparrow, \theta_v < \theta_g)$. The red lines denote the slopes γ_j, illustrated here with $\gamma_4 < \gamma_1 < \gamma_2 < \gamma_3$. There is a singular steady state at $\xi = \theta_v$ for $\gamma \in (\gamma_4, \gamma_3)$ and at $\xi = \theta_g$ for $\gamma \in (\gamma_1, \gamma_2)$.

Figure 6.1 shows that if $\gamma \in (\gamma_4, \gamma_3)$ then there are three steady states in the limiting case. At most two of these steady states will be stable, with the intermediate steady state at $x = \theta_v$ singular. If the intervals (γ_1, γ_2) and (γ_4, γ_3) overlap then it is possible to have one stable steady state coexisting with two singular steady states. Such a scenario is illustrated in Figure 6.2(a) which has two singular steady states and one stable steady state for $\gamma \in (\gamma_1, \gamma_2)$. The number of steady states changes when $\gamma\xi$ intersects $\beta e^{-\mu\tau(\xi)} g(\xi)$ at the corners along θ_v at parameter values γ_3 and γ_4. The singular 'fold' bifurcations give rise to classical fold bifurcations in the case of smooth nonlinearities defined by (1.3), as seen in Figure 6.2(b) for the case $m = n = 40$. We note from (6.2) that since g' and v' have opposite signs, we require $\xi v'(\xi)/v(\xi) > 1/(\mu\tau(\xi))$ for a fold bifurcation to occur, and so for $m = n$ a somewhat larger value of the steepness parameter m is required to obtain a fold bifurcation than would have been the case with constant g (for which, by (5.52), fold bifurcations occur when $\xi v'(\xi)/v(\xi) = 1/(\mu\tau(\xi))$ is satisfied).

In the example presented in Figure 6.2 the function v is increasing with $\mu < \gamma_4$, and so we expect to see similar behaviour for $x \approx \theta_v$ as in Case 3 of Section 5.4, while since g is decreasing the behaviour for $x \approx \theta_g$ should be similar to that seen in Section 5.1. This is indeed what is observed.

Since v is increasing, from (6.10) and (6.12) it is necessary that $\gamma > \mu - |Q(\xi)|(1+\mu\tau)$ for Hopf bifurcations to occur. However, this does not impose any additional constraints as in this example $\mu - |Q(\xi)|(1+\mu\tau) < \mu < \min_{j=\{1,2,3,4\}} \gamma_j$, and as we already saw in Section 5, Hopf bifurcations typically occur for $\gamma > \min_{j=\{1,2,3,4\}} \gamma_j$. So the steady state can lose stability in a Hopf bifurcation close to the fold point. This is seen in Figure 6.2(b) close to $(\gamma, x) = (\gamma_3, \theta_v)$ and is similar to the behaviour observed in Cases 2 and 3 in Section 5.4. Figure 6.2(c) shows two-parameter continuations of these bifurcations. Apart from the Hopf bifurcations giving rise to a stable periodic orbit for $\gamma \in (\gamma_1, \gamma_2)$ the rest of the dynamics observed are remarkably similar to those seen in Figure 5.12 with v increasing and constant g. In particular, as the steepness of the nonlinearities given by $m = n$ increases, the fold bifurcations approach $\gamma = \gamma_4$ and $\gamma = \gamma_3$ with the steady states at which they happen approaching θ_v, the fold bifurcations disappear at a cusp point (at $\gamma = 2.1535$), while the Hopf

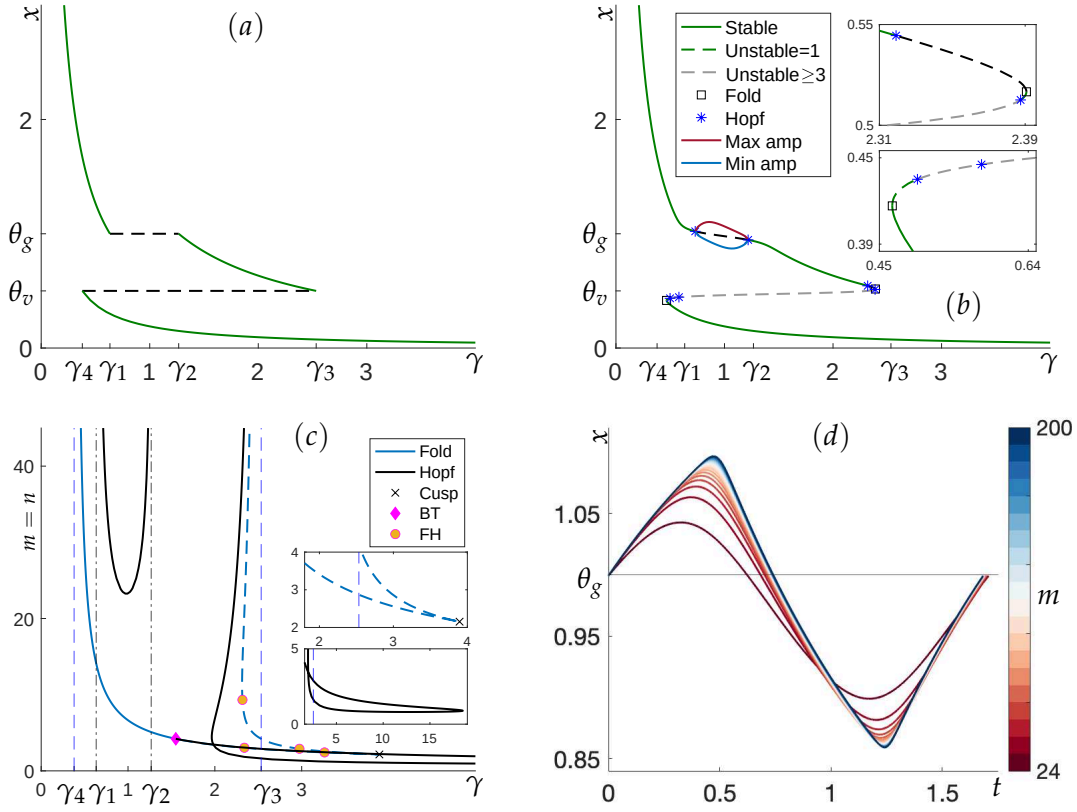

Figure 6.2: Bifurcations of (1.1)–(1.2) in the case $(g\downarrow, v\uparrow, \theta_v < \theta_g)$ with parameters $\beta = 1.4$, $\mu = 0.2$, $g^- = 1 > g^+ = 0.54$, $\theta_v = 0.5 < \theta_g = 1$, $a = 1$, and $v^- = 0.1 < v^+ = 2$. With these parameters $\mu < \gamma_4 = 0.3789 < \gamma_1 = 0.6334 < \gamma_2 = 1.2668 < \gamma_3 = 2.5335$. (a) The limiting case with g defined by (1.6) and v defined by (1.7). The stable steady state is shown as a green solid line, and the singular steady state as a black dashed line. (b) With smooth nonlinearity g and v defined by (1.3) with $m = n = 40$. Periodic solutions are represented by maximum (in red) and minimum (in blue) of x(t) on the solution. (c) Two-parameter continuations in $m = n$ and γ of the fold and the Hopf bifurcations with the other parameters as above. There is a cusp point at $(\gamma, m) = (3.8948, 2.1535)$, a BT point at $(\gamma, m) = (1.5502, 4.2073)$ and fold-Hopf points at $(\gamma, m) = (2.3399, 3.0346), (3.2632, 2.4198), (2.9741, 2.8976)$ and $(2.3178, 9.3191)$. (d) Profile of the stable periodic orbits at $\gamma = 1$ emanating from the Hopf bifurcations in (c). The color map indicates values of the continuation parameter $m = n$.

bifurcations and stable periodic orbits can occur for smaller values of $m > 0.8079$. There is also a Bogdanov–Takens bifurcation, fold-Hopf bifurcations at which Hopf bifurcations cross the fold points, and for the fold close to $\gamma = \gamma_3$ the steady state loses stability in a subcritical Hopf bifurcation for arbitrary large $m = n$, and not at the fold bifurcation.

The most significant difference between the example shown in Figure 6.2 and Cases 2 and 3 from Section 5.4 is the pair of Hopf bifurcations seen for $x \approx \theta_g$ and $\gamma \in (\gamma_1, \gamma_2)$. In Figure 6.2(c) the steady state is seen to lose stability between a pair of Hopf bifurcations for $m > 23$. Since for $m = n \gg 0$ the function v is essentially constant except for $\theta \approx \theta_v$, it follows that v is close to constant for $\theta \approx \theta_g$ and so these Hopf bifurcations and the resulting periodic orbits follow the dynamics explored in Section 5.1. Indeed, the dynamics associated with the Hopf bifurcations and periodic orbits for $x \approx \theta_g$ seen in Figure 6.2 is remarkably similar to

that seen for constant v and decreasing g in Figure 5.2 of Section 5.1. The Hopf bifurcations are supercritical, generating a stable periodic orbit which co-exists with the unstable steady state between the pair of Hopf bifurcations. The amplitude of the periodic orbit is shown for $m = n = 40$ in Figure 6.2(b), from which we see that it is always small and shrinks to zero at the Hopf bifurcations at each end of the interval.

Figure 6.2(d) depicts the profile of such stable periodic orbits for a fixed value of γ in between the two Hopf bifurcations. As $m = n \to \infty$, the periodic orbits appear to approach a limiting profile. Notice that this stable periodic orbit oscillates around θ_g but does not cross the other threshold at $\theta_v = 0.5$. Thus in the limiting case as $m = n \to \infty$ the delay will be constant and equal to τ^+ on this periodic orbit. In [31] we construct slowly oscillating periodic solutions for both constant and threshold delays, and using those constructions it can be seen that the limiting profile in Figure 6.2(d) is a slowly oscillating periodic solution.

6.1.2 Increasing g and increasing v $(g \uparrow, v \uparrow, \theta_g \neq \theta_v)$

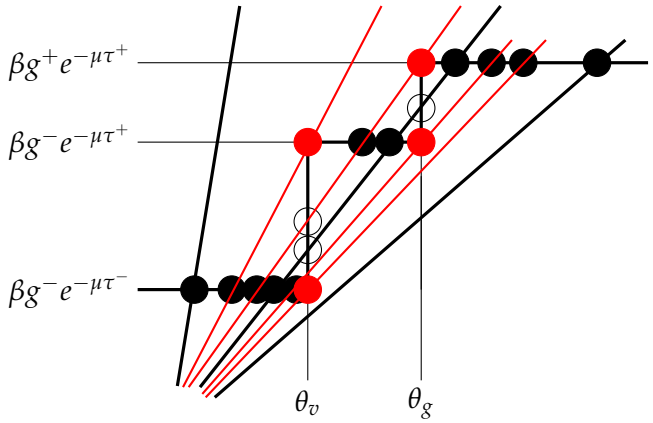

Figure 6.3: Steady states of (1.1), given by (5.2), occur at the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and $\xi \mapsto \gamma\xi$. These are illustrated for various γ in the limiting case of (1.6) and (1.7) for $(g \uparrow, v \uparrow, \theta_v < \theta_g)$. The red lines denote $\gamma = \gamma_4, \gamma_2, \gamma_1, \gamma_3$ in ascending order.

When v and g are both increasing with $\theta_g \neq \theta_v$ there are up to five coexisting steady states in the limiting case as shown in Figure 6.3. The four corners at the respective thresholds θ_g and θ_v are associated with the emergence of fold bifurcations. A necessary and sufficient condition to obtain five coexisting steady states is that $(\gamma_2, \gamma_1) \cap (\gamma_4, \gamma_3) \neq \emptyset$. Note that since g is now increasing the values $\gamma_2 < \gamma_1$ have the opposite order than in previous example, see (5.4).

Figure 6.4(a) shows such an example, with five co-existing steady states in the limiting case when $\gamma \in (\gamma_2, \gamma_1)$. Referring to the discussion in Sections 5.2 and 5.4, in the limiting case the non-singular steady states are always stable, leading to tristability of steady states in this parameter interval. This then leads to tristability of steady states for smooth nonlinearities with $m = n$ sufficiently large, as depicted in Figure 6.4(b).

Following the discussion in Sections 5.2 and 5.4, the intermediate singular steady states become unstable steady states between the fold bifurcations in the smooth case. However, the behaviour is not the same at each of the folds. In the example presented in Figure 6.4 we have $\mu \in (\gamma_4, \gamma_3)$, and so we expect to see similar behaviour for $x \approx \theta_v$ as in Case 2 of Section 5.4,

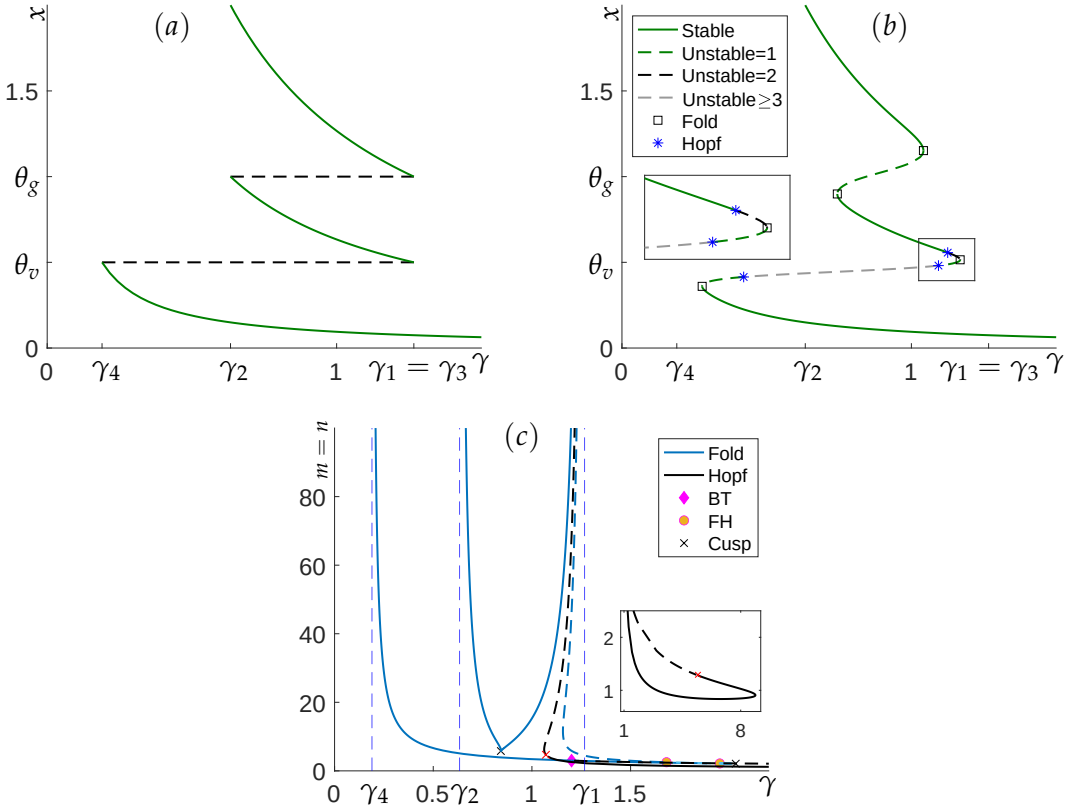

Figure 6.4: Bifurcation diagram of (1.1)–(1.2) for $(g\uparrow, v\uparrow, \theta_v < \theta_g)$ with parameters $\beta = 1.4, \mu = 0.2, g^- = 0.5, g^+ = 1, \gamma = 0.8, \theta_g = 1, \theta_v = 0.5, a = 1, v^- = 0.1$ and $v^+ = 2$. With these parameters $\gamma_4 = 0.1895 < \gamma_2 = 0.6334 < \gamma_1 = \gamma_3 = 1.2668$. (a) The limiting case with g defined by (1.6) and v defined by (1.7). The stable steady state is shown as a green solid line, and the singular steady state as a black dashed line. (b) With smooth nonlinearity g and v defined by (1.3) with $m = n = 20$. (c) Two-parameter continuations in $m = n$ and γ of the fold and the Hopf bifurcations with the other parameters as above. There are two cusp points at $(\gamma, m) = (2.0329, 2.1053)$ and $(0.84265, 5.7871)$, a BT point at $(\gamma, m) = (1.2009, 2.9825)$, two fold-Hopf points at $(\gamma, m) = (1.6820, 2.5172)$ and $(1.9519, 2.1629)$, and two Bautin bifurcations at $(\gamma, m) = (5.4365, 1.2928)$ and $(1.0709, 4.6890)$.

while since g is increasing the behaviour for $x \approx \theta_g$ should be similar to what was observed in Section 5.2, and this is what we observe.

For the fold bifurcation near $(\gamma, \xi) = (\gamma_4, \theta_v)$, the steady state loses stability at the fold for all m sufficiently large (seen for $m = n = 20$ in Figure 6.4(b)). Since v is increasing, from (6.12) there can be no Hopf bifurcations for $\gamma < \mu - |Q(\xi)|(1 + \mu\tau)$. However, $\lim_{m\to\infty} Q(\xi) = 0$ for $\xi \neq \theta_g$, and since $\gamma_4 < \mu$ there can be no Hopf bifurcations near to the fold for m sufficiently large. The same is not true for the fold close to $(\gamma, \xi) = (\gamma_3, \theta_v)$, where since $\gamma_3 > \mu$ the steady state may lose stability in a Hopf bifurcation near to the fold point, which is indeed what is seen for all m sufficiently large. This is similar to the behaviour seen in the previous example in Figure 6.2 and to Cases 2 and 3 in Section 5.4.

Following the theory of Sections 5.2 and 5.4, as $m = n$ is increased there will also be an infinite sequence of Hopf bifurcations on the unstable branches that cross θ_g and θ_v. For the branch that crosses $x = \theta_g$ these Hopf bifurcations will be confined between the fold

bifurcations as $m = n$ is increased. No Hopf bifurcations are seen on this branch in Figure 6.4(b) because the value of m is too small, with the first Hopf bifurcation only occurring for $m = n \approx 61$.

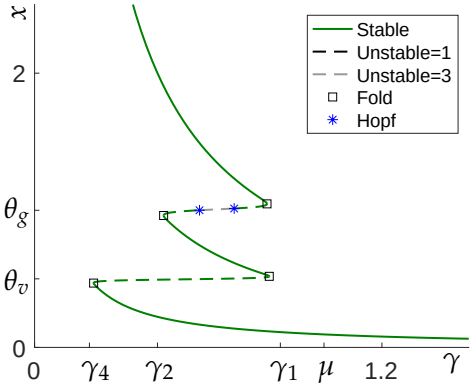

Figure 6.5: Bifurcations of (1.1)–(1.2) in the case $(g\uparrow, v\uparrow, \theta_v < \theta_g)$ with smooth nonlinearities g and v defined by (1.3) with $m = n = 100$, and other parameters $\beta = 1.4$, $\mu = 1$, $g^- = 0.5 > g^+ = 1$, $\theta_v = 0.5 < \theta_g = 1$, $a = 1$, and $v^- = 0.5 < v^+ = 2$. With these parameters $\gamma_4 = 0.1895$, $\gamma_2 = 0.4246$, and $\gamma_1 = \gamma_3 = 0.8491$.

Figure 6.5 shows another example for $(g\uparrow, v\uparrow, \theta_g \neq \theta_v)$, but this time with $\mu > \gamma_3$ which corresponds to Case 1 in Section 5.4. In this example no Hopf bifurcations are observed on the unstable branch that crosses $\xi = \theta_v$. This follows from (6.12) because there can be no Hopf bifurcations for $\gamma < \mu - |Q(\xi)|(1 + \mu\tau)$, and $|Q(\xi)| \to 0$ as $n \to \infty$ for $\xi \neq \theta_g$. On the other hand, a pair of Hopf bifurcations is observed on the branch of unstable steady states that crosses $\xi = \theta_g$. In this case (6.12) does not preclude Hopf bifurcations because Proposition 5.1(2), with $f(x, p, r)$ given by $Q(\xi)$ with parameter $p = n$ from g, shows that $|Q(\xi)|$ can be arbitrarily large for $\xi \approx \theta_g$ as $n \to \infty$.

6.2 Two Hill functions with $\theta_g = \theta_v$

The cases of $(g\uparrow, v\uparrow, \theta_v = \theta_g)$ and $(g\downarrow, v\downarrow, \theta_v = \theta_g)$ where both functions are either increasing or decreasing are reasonably straightforward. However, the two cases for which one function is increasing and the other decreasing, $(g\downarrow, v\uparrow, \theta_v = \theta_g)$ and $(g\downarrow, v\uparrow, \theta_v = \theta_g)$ are altogether more delicate and surprising.

6.2.1 g and v both increasing or decreasing $(g\uparrow, v\uparrow, \theta_g = \theta_v)$ and $(g\downarrow, v\downarrow, \theta_g = \theta_v)$

In both these cases $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ is monotonic, so the existence of steady states is straightforward following the theory in Section 5. Writing θ_{gv} for the value of θ when $\theta_g = \theta_v$, and defining

$$\gamma_{13} = \frac{\beta e^{-\mu\tau^+} g^+}{\theta_{gv}} \quad \text{and} \quad \gamma_{24} = \frac{\beta e^{-\mu\tau^-} g^-}{\theta_{gv}}, \tag{6.13}$$

with g and v both decreasing, there is always a unique steady state. In the limiting case of piecewise constant nonlinearities (1.6)–(1.7), this steady state is stable for $\gamma < \gamma_{13}$ and $\gamma > \gamma_{24}$, and is singular for $\gamma \in (\gamma_{13}, \gamma_{24})$. In the smooth case, this gives rise to a unique stable steady state for very small or very large γ. The question then arises as to when the steady state may

lose stability in a Hopf bifurcation for γ in or near the interval $(\gamma_{13}, \gamma_{24})$. From (6.11) when g and v are both decreasing Hopf bifurcations cannot occur if

$$\gamma > \mu + |Q(\xi)|(1+\mu\tau) = \mu + \gamma(1+\mu\tau)\left|\frac{\xi g'(\xi)}{g(\xi)}\right|. \tag{6.14}$$

Thus when g is a constant function, which implies that $Q = 0$, there can only be Hopf bifurcations when $\gamma < \mu$ as seen in Section 5.3. In contrast, by Proposition 5.1, we have $|\theta_{gv} g'(\theta_{gv})/g(\theta_{gv})| \to \infty$ as $n \to \infty$ while (6.14) cannot be satisfied when $|\xi g'(\xi)/g(\xi)| > 1$. Consequently for n large there is no constraint preventing Hopf bifurcations, and we expect to see Hopf bifurcations for $\xi \approx \theta_{gv}$ for n sufficiently large, just as we did in Section 5.1.

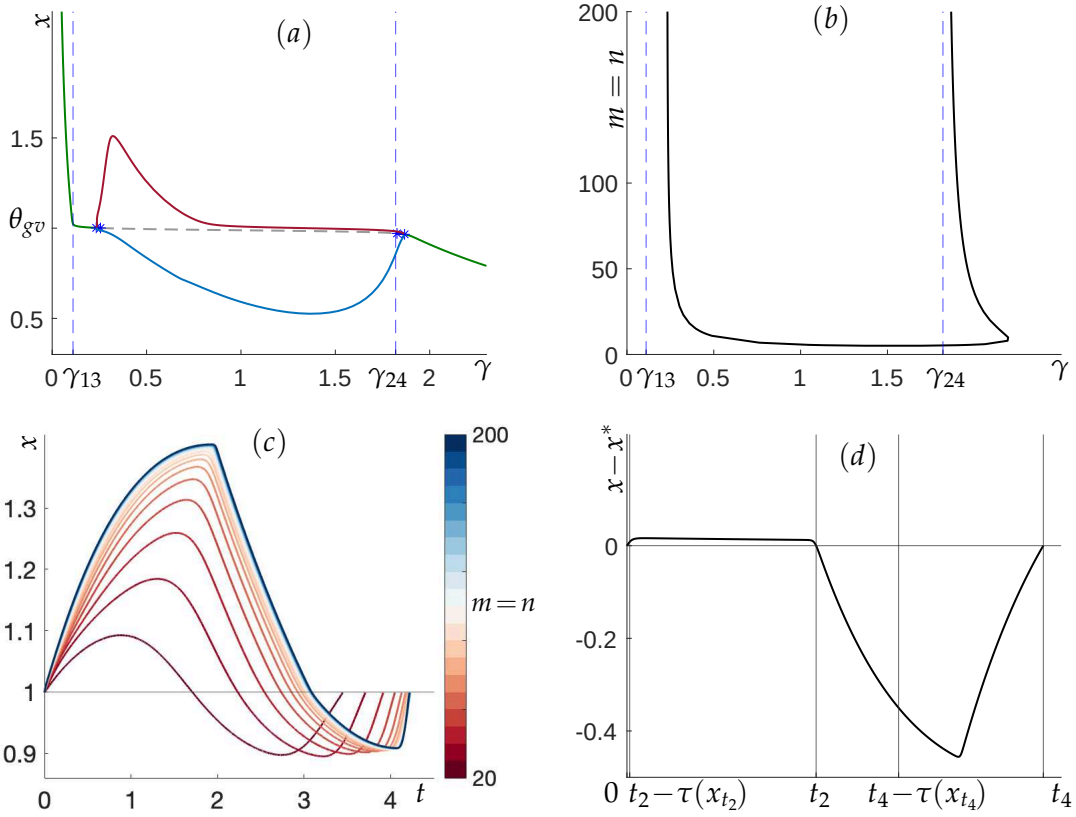

Figure 6.6: Bifurcation diagram of (1.1)–(1.2) for $(g\downarrow, v\downarrow, \theta_g = \theta_v)$ with parameters $\beta = 3$, $\mu = 0.5$, $\gamma = 1$, $\theta_g = \theta_v = \theta_{vg} = 1$, $a = 1$, $g^- = 1 > g^+ = 0.1$, and $v^- = 1 > v^+ = 0.5$. With these parameters $\gamma_{13} = 0.1104$ and $\gamma_{24} = 1.8196$. (a) With nonlinearities g and v defined by (1.3) with $m = n = 200$. The Hopf bifurcations associated with stability change occur at $(\gamma, x) = (0.2333, 1.0018)$ with $\omega = 2.3128$ and $(\gamma, x) = (1.8669, 0.9659)$ with $\omega = 2.3155$. Stable periodic orbits are represented by maximum (in red) and minimum (in blue) of $x(t)$ on the periodic solution. (b) Two-parameter continuations in $m = n$ and γ of the Hopf bifurcations with the other parameters as above. (c) Profile of the stable periodic orbits with $\gamma = 0.4$. The color map indicates values of the continuation parameter $m = n$. (d) Profile of the stable periodic orbit with $m = 200$ and $\gamma = 1.3$ and the other parameters as above. The associated steady state is at $x^* = 0.9848$. The period of the periodic orbit $T = t_4 = 2.8772$.

Figure 6.6 illustrates the case of g and v both decreasing with $\theta_v = \theta_g = \theta_{gv}$. Panel (a) shows the dynamics for smooth nonlinearities g defined by (1.3) with $m = n = 200$. In this

case the steady state is unstable between two supercritical Hopf bifurcations. These Hopf bifurcations occur close to but slightly to the right of the limiting values γ_{13} and γ_{24}. The resulting periodic orbit is stable on the whole of the interval between the Hopf bifurcations.

Figure 6.6(b) shows a two-parameter continuation of the curve of Hopf bifurcations at which the stable periodic orbit is created. The amplitude plot of the periodic orbits in panel (a) of Figure 6.6 suggests that different behavior is seen near the two Hopf points, and this is illustrated in the periodic solution profiles shown in panels (c) and (d). In (c) with $\gamma = 0.4$, as $m = n$ is increased the profile of the periodic orbit converges to a limiting profile (which we construct in [31]). The situation is different with $\gamma > 1$ as shown in panel (d) with $\gamma = 1.3$ and $m = n = 200$. While there is again a large period periodic orbit, the profile is quite different, with $x(t)$ never much greater than x^* even though there is a large segment $t \in (t_0, t_2)$ of the periodic orbit for which $x(t) > x^*$. This large subinterval of the periodic orbit on which the solution is nearly constant looks quite different to the periodic orbits seen in (c).

The case of $(g \uparrow, v \uparrow, \theta_v = \theta_g)$ is analogous to the scenarios considered in Sections 5.2 and 5.4 which lead to a pair of fold bifurcations when (6.2) is satisfied, and an interval of γ values for which two stable steady states coexist with an unstable steady state. Because v and g are both increasing, the functions $\xi \mapsto \xi g'(\xi)/g(\xi)$ and $\xi \mapsto \mu\tau(\xi)\xi v'(\xi)/v(\xi)$ are both positive, and moreover $\theta_{gv} g'(\theta_{gv})/g(\theta_{gv})$ and $\mu\tau(\theta_{gv})\theta_{gv} v'(\theta_{gv})/v(\theta_{gv})$ are increasing functions of n and m, respectively. Since the condition (6.2) is more easily satisfied in this case than when one of these functions is zero or decreasing, fold bifurcations can occur for smaller values of m or n for $(g \uparrow, v \uparrow, \theta_v = \theta_g)$ than was seen for $(g \uparrow, v \leftrightarrow)$ or $(g \leftrightarrow, v \uparrow)$. As $m = n \to \infty$ the interval of bistability converges to $(\gamma_{24}, \gamma_{13})$. Equation (6.12) imposes a constraint on Hopf bifurcations to occur when g and v are both increasing. However, since $Q(\theta_g) \to \infty$ as $n \to \infty$, Hopf bifurcations can occur for all n sufficiently large.

6.2.2 g and v with opposing monotonicity $(g \uparrow, v \downarrow, \theta_g = \theta_v)$ and $(g \downarrow, v \uparrow, \theta_g = \theta_v)$

These cases are altogether more delicate and surprising, and need explaining in some detail. For the smooth nonlinearities when the power m or n is large, and the function $g(x)$ or $v(x)$ is close to a step function, we will informally refer to the part of the function with large gradient as the interface. When $m \gg n$ the $v(x)$ function will have a much narrower interface than the function $g(x)$, while $g(x)$ will have a narrower interface when $n \gg m$. These interfaces are centred at $x = \theta_v$ and $x = \theta_g$, so when $\theta_g = \theta_v$ they will overlap or if $m \gg n$ or $m \ll n$ the interval on which one interface occurs will be inside the interval on which the other interface occurs. When g and v have opposing monotonicity the dynamics of (1.1)–(1.2) will be very different depending on which interface is narrower.

From (6.2) there will be a fold bifurcation when

$$0 = M(\xi) = \frac{\xi g'(\xi)}{g(\xi)} + \mu\tau(\xi)\frac{\xi v'(\xi)}{v(\xi)} - 1.$$

When v is increasing by Proposition 5.1

$$\lim_{m\to\infty} \frac{\theta_v v'(\theta_v)}{v(\theta_v)} = +\infty, \qquad \text{and} \qquad \lim_{\xi\to 0} \frac{\xi v'(\xi)}{v(\xi)} = \lim_{\xi\to+\infty} \frac{\xi v'(\xi)}{v(\xi)} = 0, \tag{6.15}$$

which ensures that a fold bifurcation must occur for m sufficiently large when n is held constant. If g is decreasing then $\xi g'(\xi)/g(\xi) < 0$ and the value of m required for a fold bifurcation to occur will be larger than when this term is non-negative, that is, when g is constant or increasing. Those cases were considered in Sections 5.4 and 6.2.1. An analogous argument to

(6.15) shows that when g is increasing a fold bifurcation will occur for n sufficiently large when m is held constant.

A more delicate question is, what happens when $m \to \infty$ and $n \to \infty$ with g and v having opposite monotonicities. In that case one could expect that whichever of the terms $\xi g'(\xi)/g(\xi)$ or $\xi v'(\xi)/v(\xi)$ grows faster as $m, n \to \infty$ will determine where and whether fold bifurcations occur, however, as we will see, the behaviour is more nuanced than that.

We will now consider the case $(g \downarrow, v \uparrow, \theta_g = \theta_v = \theta_{gv})$ for which $0 < r_v < 1 < r_g$, where $r_g = g^-/g^+$ and $r_v = v^-/v^+$. Evaluating $M(\theta_{gv})$ using Proposition 5.1(2) we obtain

$$M(\theta_{gv}) = \frac{\theta_{gv} g'(\theta_{gv})}{g(\theta_{gv})} + \mu\tau(\theta_{gv}) \frac{\theta_{gv} v'(\theta_{gv})}{v(\theta_{gv})} - 1 = \frac{n(1-r_g)}{2(1+r_g)} + \mu\tau(\theta_{gv}) \frac{m(1-r_v)}{2(1+r_v)} - 1. \tag{6.16}$$

Then if

$$\mu\tau(\theta_{gv}) \frac{(1-r_v)}{(1+r_v)} > \frac{(r_g-1)}{(1+r_g)}, \tag{6.17}$$

it follows that $M(\theta_{gv}) \to +\infty$ as $m = n \to \infty$, and in particular $M(\theta_{gv}) > 0$ for all $m = n$ sufficiently large. This ensures that there is a pair of fold bifurcations as γ is varied with $m = n$ sufficiently large.

Of course, since m and n appear in the different nonlinearities v and g modelling different processes, there is no reason beyond mathematical convenience to assume that $m = n$. So, it is interesting to consider whether fold bifurcations still occur as $m \to \infty$ and $n \to \infty$ independently.

The condition (6.17) was arrived at by evaluating $M(\theta_{gv})$, which has a convenient form because of Proposition 5.1(2). However, we will show below that it is not a necessary condition for existence of fold bifurcations. To see this, note that for the case we consider we have $0 < r_v < 1 < r_g$, and hence

$$r_v^{1/2m} \theta_{gv} < \theta_{gv} < r_g^{1/2n} \theta_{gv}. \tag{6.18}$$

From Proposition 5.1(4) the positive function $\xi v'(\xi)/v(\xi)$ achieves its maximum at $\xi = r_v^{1/2m}\theta_{gv} < \theta_{gv}$ and the negative function $\xi g'(\xi)/g(\xi)$ achieves its minimum at $\xi = r_g^{1/2n}\theta_{gv} > \theta_{gv}$. Thus, for $\xi \in (r_v^{1/2m}\theta_{gv}, r_g^{1/2n}\theta_{gv})$ we have $\xi v'(\xi)/v(\xi)$ and $\xi g'(\xi)/g(\xi)$ as well as $\tau(\xi)$ all decreasing functions of ξ and it follows that $M(\xi)$ is decreasing for $\xi \in (r_v^{1/2m}\theta_{gv}, r_g^{1/2n}\theta_{gv})$ as well as satisfying $\lim_{\xi \to \pm\infty} M(\xi) = -1$. Consequently, we expect $M(\xi)$ to obtain its maximum value for $\xi \lessapprox r_v^{1/2m}\theta_{gv}$. If this maximum value is positive, then (6.2) will have at least two solutions, indicating two fold bifurcations for different ξ values, one on each side of this maximum. While we will not consider the other case of $(g \uparrow, v \downarrow, \theta_g = \theta_v = \theta_{gv})$ in detail, we note that in that case g would be the increasing function, with $r_g = g^-/g^+ < 1 < r_v$, and for $\xi \in (r_g^{1/2n}\theta_{gv}, r_v^{1/2m}\theta_{gv})$ we would have $\xi g'(\xi)/g(\xi)$ positive and decreasing, $\xi v'(\xi)/v(\xi)$ negative and decreasing, and $\tau(\xi)$ increasing, from which it follows that $M(\xi)$ is decreasing for $\xi \in (r_g^{1/2n}\theta_{gv}, r_v^{1/2m}\theta_{gv})$, so $M(\xi)$ would obtain its maximum value for $\xi < \theta_{gv}$.

To study the steady states and fold bifurcations of (1.1)–(1.2) for $(g \downarrow, v \uparrow, \theta_g = \theta_v = \theta_{gv})$ we will work directly with the function $h(\xi)$ defined in (5.2). Suppose the parameters are chosen so that $\beta e^{-\mu\tau^-} g^- > \beta e^{-\mu\tau^+} g^+$. Then

$$\beta e^{-\mu\tau^-} g^- = \lim_{\xi \to 0} \beta e^{-\mu\tau(\xi)} g(\xi) > \lim_{\xi \to +\infty} \beta e^{-\mu\tau(\xi)} g(\xi) = \beta e^{-\mu\tau^+} g^+. \tag{6.19}$$

Figure 6.7 depicts such an example for which $\beta e^{-\mu\tau(\xi)} g(\xi)$ is a monotonically decreasing function of ξ in both the smooth case and the limiting case as $m = n \to \infty$, so that there is

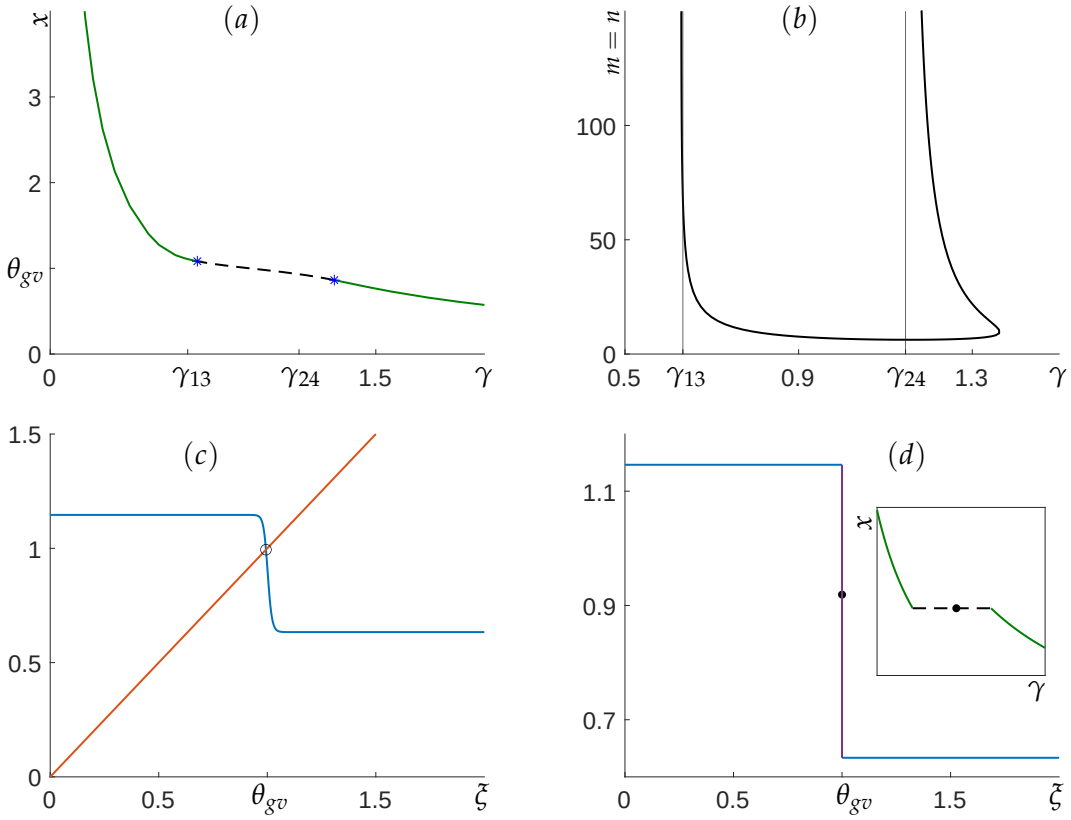

Figure 6.7: Bifurcations of (1.1)–(1.2) for $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ with $\beta = 1.4$, $\mu = 0.2$, $g^- = 1$, $g^+ = 0.5$, $\theta_g = \theta_v = \theta_{gv} = 1$, $a = 1$, $v^- = 1$ and $v^+ = 2$. With these parameters $\beta e^{-\mu\tau^-} g^- > \beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv}) > \beta e^{-\mu\tau^+} g^+$. (a) With smooth nonlinearity g and v defined by (1.3) with $m = n = 100$. (b) Two-parameter continuations in $m = n$ and γ of the Hopf bifurcation at which the steady state loses stability with the other parameters as above. The vertical lines at $\gamma = \gamma_{13} = 0.6334$ and $\gamma = \gamma_{24} = 1.1462$ denote the location of the Hopf bifurcations in the limiting case as $m = n \to \infty$. (c) Graphs of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and $\xi \mapsto \gamma\xi$ with $m = n = 100$ and $\gamma = 1$. Since $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ is monotonically decreasing there is a unique intersection and hence a unique steady state for and $\gamma > 0$. (d) Graph of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ in the limiting case, with the black dot denoting the value of $\beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv})$. The inset depicts the continuation of the steady states in the limiting case with g and v defined by (1.6) and (1.7). Stable steady states are shown as green solid lines, and the singular steady state as a black dashed line.

always a unique steady state. One could easily and incorrectly assume that $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ will be monotonically decreasing whenever (6.19) holds. However, this is not always true, and indeed is never true when (6.17) holds. To show this, recalling the definitions of g and v given by (1.3) in the smooth case, notice that at the threshold, the function values are independent of the nonlinearity m or n, with

$$g(\theta_g) = \frac{g^- + g^+}{2} \quad \text{and} \quad v(\theta_v) = \frac{v^- + v^+}{2}. \tag{6.20}$$

Thus for $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ and $0 < r_v < 1 < r_g$ it holds that

$$g^- > g(\theta_{gv}) > g^+, \tag{6.21}$$

while $v^+ > v(\theta_{gv}) > v^-$ implies

$$\tau^- > \tau(\theta_{gv}) > \tau^+. \tag{6.22}$$

Then (6.17) implies that

$$\mu\tau^-\frac{(1-r_v)}{(1+r_v)} > \mu\tau(\theta_{gv})\frac{(1-r_v)}{(1+r_v)} > \frac{r_g-1}{1+r_g} > \ln\left(1+\frac{r_g-1}{1+r_g}\right) = \ln\left(\frac{2r_g}{1+r_g}\right). \tag{6.23}$$

But

$$\frac{2r_g}{1+r_g} = \frac{2g^-/g^+}{1+g^-/g^+} = \frac{2g^-}{g^++g^-} = \frac{g^-}{g(\theta_{gv})},$$

and

$$\tau^-\frac{(1-r_v)}{(1+r_v)} = \frac{a}{v^-}\left(\frac{v^+-v^-}{v^-+v^+}\right) = \frac{a}{v^-} - \frac{2a}{v^-+v^+} = \tau^- - \tau(\theta_{gv}).$$

Thus

$$\begin{aligned}
\mu\tau^-\frac{(1-r_v)}{(1+r_v)} > \ln\left(\frac{2r_g}{1+r_g}\right) \quad &\iff \quad \mu(\tau^- - \tau(\theta_{gv})) > \ln(g^-/g(\theta_{gv})) \\
&\iff \quad e^{-\mu(\tau(\theta_{gv})-\tau^-)} > g^-/g(\theta_{gv}) \\
&\iff \quad \beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv}) > \beta e^{-\mu\tau^-}g^-.
\end{aligned}$$

Thus if the parameters are chosen so that (6.17) and (6.19) both hold then

$$\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv}) > \beta e^{-\mu\tau^-}g^- > \beta e^{-\mu\tau^+}g^+, \tag{6.24}$$

and the function $\xi \mapsto \beta e^{-\mu\tau(\xi)}g(\xi)$ is not monotonic. This was not the case for the example in Figure 6.7, but below we will demonstrate examples where both (6.17) and (6.24) hold, and more interesting dynamics arise. Moreover, the inequalities in (6.23) are not all tight, and we will also show that it is possible to obtain (6.24) for parameters for which (6.17) does not hold.

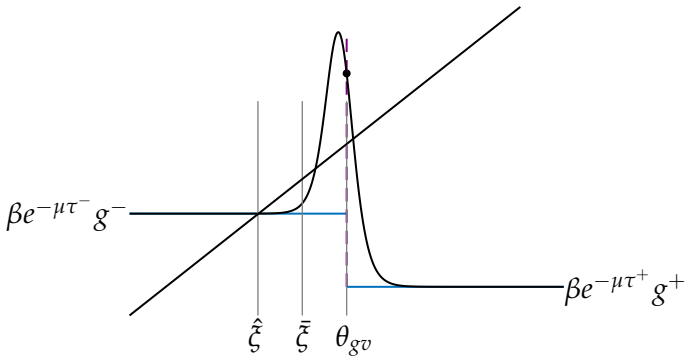

Figure 6.8: An illustration of $\beta e^{-\mu\tau(\xi)}g(\xi)$ and $\hat{\gamma}\xi$ in the case $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ for both smooth nonlinearities and in the limiting case $m = n \to \infty$ when (6.24) holds.

Now suppose that (6.24) holds and consider $h(\xi)$ defined in (5.2). This situation is illustrated in Figure 6.8. Recall (6.13) and also let

$$\gamma_{gv} := \frac{\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv})}{\theta_{gv}}. \tag{6.25}$$

We will now show that when $\gamma \in (\gamma_{24}, \gamma_{gv})$ for all m sufficiently large there are three steady states. From (5.2), we have $h(0) = \beta e^{-\mu\tau^-} g^- > 0$ and $h(\xi) \to -\infty$ as $\xi \to +\infty$. Moreover, (6.25) and $\gamma < \gamma_{gv}$ implies

$$h(\theta_{gv}) = \beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv}) - \gamma\theta_{gv} = \gamma_{gv}\theta_{gv} - \gamma\theta_{gv} = (\gamma_{gv} - \gamma)\theta_{gv} > 0.$$

From $h(\theta_{gv}) > 0$ the intermediate value theorem immediately yields the existence of one steady state $\xi > \theta_{gv}$; to show that there are three steady states it suffices to show that there exists $\bar{\xi} \in (0, \theta_{gv})$ with $h(\bar{\xi}) < 0$.

For any $\hat{\gamma} \in (\gamma_{24}, \gamma_{gv})$ we have $\hat{\gamma}\theta_{gv} \in (\beta e^{-\mu\tau^-} g^-, \beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv}))$ so for some $\varepsilon > 0$ it holds that $\hat{\gamma}\theta_{gv} = \beta e^{-\mu\tau^-} g^- + 2\hat{\gamma}\varepsilon$. This implies that the point $\hat{\xi}$ (shown in Figure 6.8) where the line $\hat{\gamma}\xi$ intersects $\beta e^{-\mu\tau^-} g^-$ satisfies $\hat{\xi} = \beta e^{-\mu\tau^-} g^- / \hat{\gamma} = \theta_{gv} - 2\varepsilon$. Let

$$\bar{\xi} = \theta_{gv} - \varepsilon = \frac{1}{2}(\hat{\xi} + \theta_{gv}) \in (\hat{\xi}, \theta_{gv}).$$

Then

$$\hat{\gamma}\bar{\xi} = \hat{\gamma}(\theta_{gv} - \varepsilon) = \beta e^{-\mu\tau^-} g^- + 2\hat{\gamma}\varepsilon - \hat{\gamma}\varepsilon = \beta e^{-\mu\tau^-} g^- + \hat{\gamma}\varepsilon.$$

We have $g(\bar{\xi}) < g^-$ since g is strictly decreasing, and then

$$h(\bar{\xi}) = \beta e^{-\mu\tau(\bar{\xi})} g(\bar{\xi}) - \hat{\gamma}\bar{\xi} < \beta e^{-\mu\tau(\bar{\xi})} g^- - (\beta e^{-\mu\tau^-} g^- + \hat{\gamma}\varepsilon) = \beta(e^{-\mu\tau(\bar{\xi})} - e^{-\mu\tau^-}) g^- - \hat{\gamma}\varepsilon.$$

Since $\bar{\xi} < \theta_{gv}$, using the pointwise limit of the Hill function to its piecewise constant limit we have $\lim_{m\to\infty} \tau(\bar{\xi}) = \tau^-$. It then follows from the previous equation that there exists $m > 0$ such that $h(\bar{\xi}) < 0$, which shows that $h(\xi)$ has at least three sign changes, and so there are three co-existing steady states.

When $m > 1$ and $n > 1$ it is easy to verify that

$$\lim_{\xi\to 0} \frac{d}{d\xi}\left(\beta e^{-\mu\tau(\xi)} g(\xi)\right) = \lim_{\xi\to+\infty} \frac{d}{d\xi}\left(\beta e^{-\mu\tau(\xi)} g(\xi)\right) = 0,$$

from which it follows that there is a unique steady state for all γ sufficiently small or large. Bifurcations from this steady state will depend on the nonlinearities g and v.

In the case of smooth nonlinearities when one of m or n is held fixed while the other one is increased to infinity the arguments of Sections 5 can be adapted to show that in the limiting case $m \to \infty$ the fold bifurcations occur at

$$\gamma_4 = \frac{\beta e^{-\mu\tau^-} g(\theta_{gv})}{\theta_{gv}} < \gamma_3 = \frac{\beta e^{-\mu\tau^+} g(\theta_{gv})}{\theta_{gv}}. \tag{6.26}$$

with singular solutions for $\gamma \in (\gamma_4, \gamma_3)$. Similarly, with m fixed in the limiting case $n \to \infty$, singular solutions occur for $\gamma \in (\gamma_1, \gamma_2)$ where

$$\gamma_1 = \frac{\beta e^{-\mu\tau(\theta_{gv})} g^+}{\theta_{gv}} < \gamma_2 = \frac{\beta e^{-\mu\tau(\theta_{gv})} g^-}{\theta_{gv}}. \tag{6.27}$$

With g decreasing, whether fold bifurcations occur at the ends of this interval will depend also on the steepness of v. These limiting cases correspond to solutions of $h(\xi) = 0$ where the line $\gamma\xi$ intersects the curve $\beta e^{-\mu\tau(\xi)} g(\xi)$ at its maxima and minima which are illustrated in panels (a) and (c) of Figure 6.9 when one of the values m, n is fixed and the other tends to ∞.

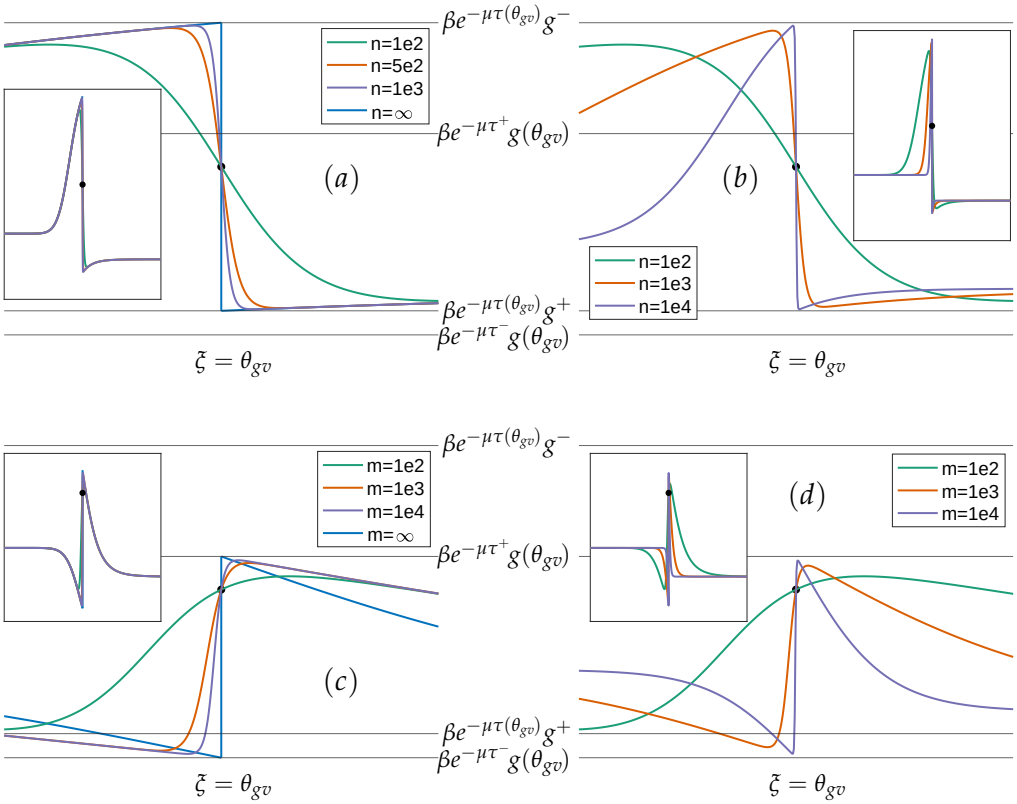

Figure 6.9: Illustrations of the behaviour of the function $\xi \mapsto \beta e^{-\mu\tau(\xi)}g(\xi)$ in the case $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ with $\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv}) > \beta e^{-\mu\tau^-}g^- > \beta e^{-\mu\tau^+}g^+$ as m and/or n tend to infinity, showing that different maxima and minima are possible depending on the limits taken. The insets show the function on the interval $\xi \in [0, 2\theta_{gv}]$ while the main panels show the behaviour for $\xi \approx \theta_{gv}$. The values of m and n are taken to be (a) $m = 10$ fixed and $n \to \infty$, (b) $m^2 = n \to \infty$, (c) $n = 10$ fixed and $m \to \infty$, and, (d) $n = \sqrt{m} \to \infty$. The values of the other parameters are $\beta = 1.4$, $\mu = 0.2$, $g^- = 1$, $g^+ = 0.5$, $\theta_g = \theta_v = \theta_{gv} = 1$, $a = 1$, $v^- = 0.3$ and $v^+ = 2$.

Panels (b) and (d) of Figure 6.9 illustrate what happens when m and n both tend to infinity, but one is increased much faster than the other, showing that the same extrema are observed as when the more slowly increasing exponent is held fixed. Since the maxima and minima of the nonlinearities converge to different values depending on whether m or n is increasing faster, and the limiting locations of the fold bifurcations are determined by the extrema, the location of the fold bifurcations as $m \to \infty$ and $n \to \infty$ will depend on how these limits are approached. We will investigate the dynamics for different relationships between m and n below.

Since the value of $\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv})$ is independent of m and n, the maximum of $\xi \mapsto \beta e^{-\mu\tau(\xi)}g(\xi)$ cannot be smaller than this value, which imposes the bound that the rightmost fold bifurcation must occur for $\gamma \geq \gamma_{gv}$. Using (5.2) and (6.2) it is easy to show that $h'(\xi) = \gamma M(\xi)$ when $h(\xi) = 0$, that is at a steady state. Consequently, if $M(\theta_{gv}) = 0$ the right fold bifurcation will occur at $\xi = \theta_{gv}$ with $\gamma = \gamma_{gv}$, while if $M(\theta_{gv}) < 0$ then $h'(\theta_{gv}) < 0$ so the fold bifurcation occurs for $\xi < \theta_{gv}$ and $\gamma > \gamma_{gv}$. Similarly, if $M(\theta_{gv}) > 0$ the fold bifurcation will occur for $\xi > \theta_{gv}$ and $\gamma > \gamma_{gv}$. These situations are illustrated in Figures 6.10 and 6.11

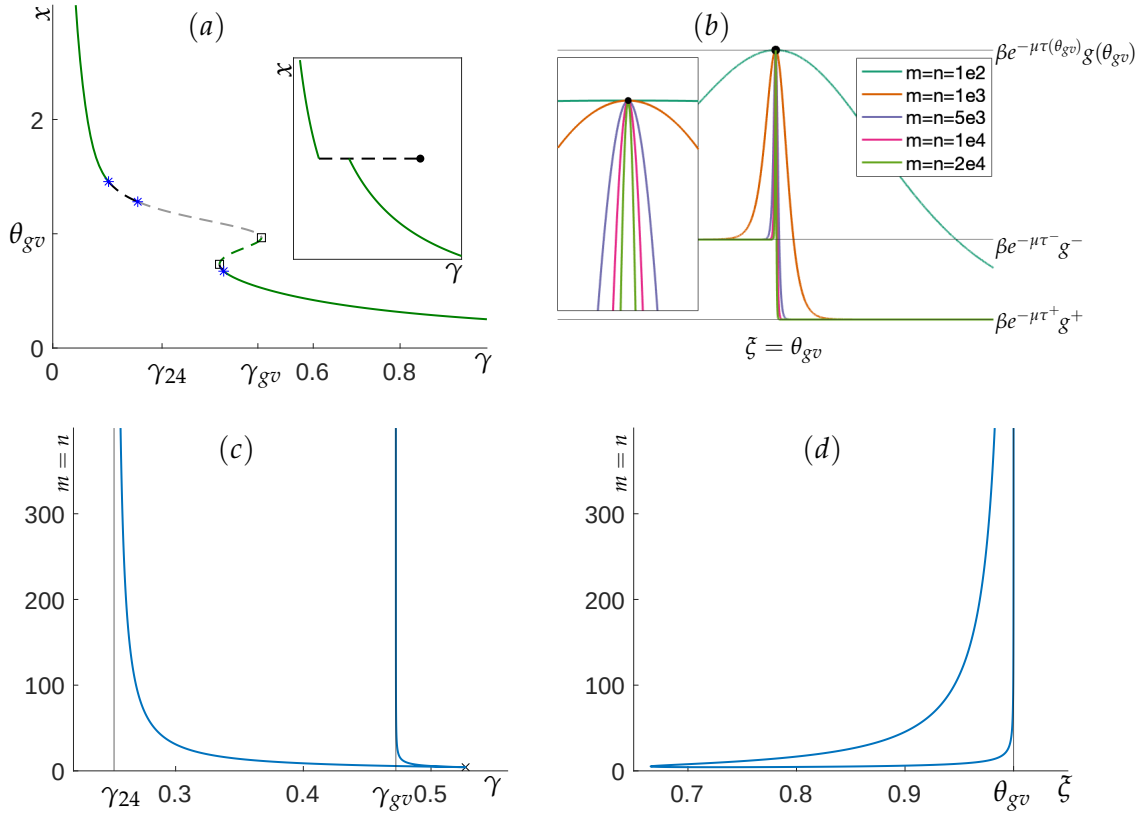

Figure 6.10: Bifurcations of (1.1)–(1.2) in the case $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ with $\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv}) > \beta e^{-\mu\tau^-}g^- > \beta e^{-\mu\tau^+}g^+$ and $m = n$. Parameter values are $\beta = 10$, $\mu = 0.2$, $g^- = 1$, $g^+ = 1/10$, $\theta_{gv} = 1$, $v^- = 1$, $v^+ = 2$ and $a = 18.4091$, for which $M(\theta_{gv}) = -1$ when $m = n$. (a) With smooth nonlinearity g and v defined by (1.3) with $m = n = 10$, and inset showing the limiting case as $m = n \to \infty$. (b) The behaviour of $\xi \mapsto \beta e^{-\mu\tau(\xi)}g(\xi)$ as $m = n \to \infty$ with the inset showing that the maximum of the function is $\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv})$ in the limiting case. (c) Two-parameter continuation in $m = n$ and γ of the fold bifurcation with the other parameters as above. The fold bifurcations are always associated with unstable steady states, and there is a cusp point at $(\gamma, m) = (0.5271, 4.2830)$. In the limiting case as $m = n \to \infty$ the folds occur at $\gamma = \gamma_{24} = 0.2518$ (recall (6.13)) and $\gamma = \gamma_{gv} = 0.4725$. (d) Two-parameter continuation in $m = n$ and ξ of the fold bifurcations with the other parameters as above.

which we now describe in more detail.

From (6.16), for any parameter set with $0 < r_v < 1 < r_g$ taking

$$m = \frac{1}{\mu\tau(\theta_{gv})}\frac{1+r_v}{1-r_v}\left[2 + n\frac{r_g-1}{r_g+1}\right],$$

ensures that $M(\theta_{gv}) = 0$. However, for the example in Figure 6.10, we prefer to set $m = n$ and choose the other parameters to enforce equality in (6.17), which ensures that $M(\theta_{gv}) = -1$ for all $m = n > 0$. This results in a fold bifurcation at $\gamma = \gamma_{gv}$ in the limiting case as $m = n \to \infty$, since as already noted $M(\xi)$ is decreasing at $\xi = \theta_{gv}$ and also both $\xi v'(\xi)/v(\xi)$ and $\xi g'(\xi)/g(\xi)$ become increasingly steep as $m = n \to \infty$ so the point ξ at which $M(\xi) = 0$ approaches θ_{gv} as $m = n \to \infty$. This is illustrated in Figure 6.10 where panel (b) shows that the maximum of $\xi \mapsto \beta e^{-\mu\tau(\xi)}g(\xi)$ tends to $\beta e^{-\mu\tau(\theta_{gv})}g(\theta_{gv})$ as $m = n \to \infty$ while panels (c)

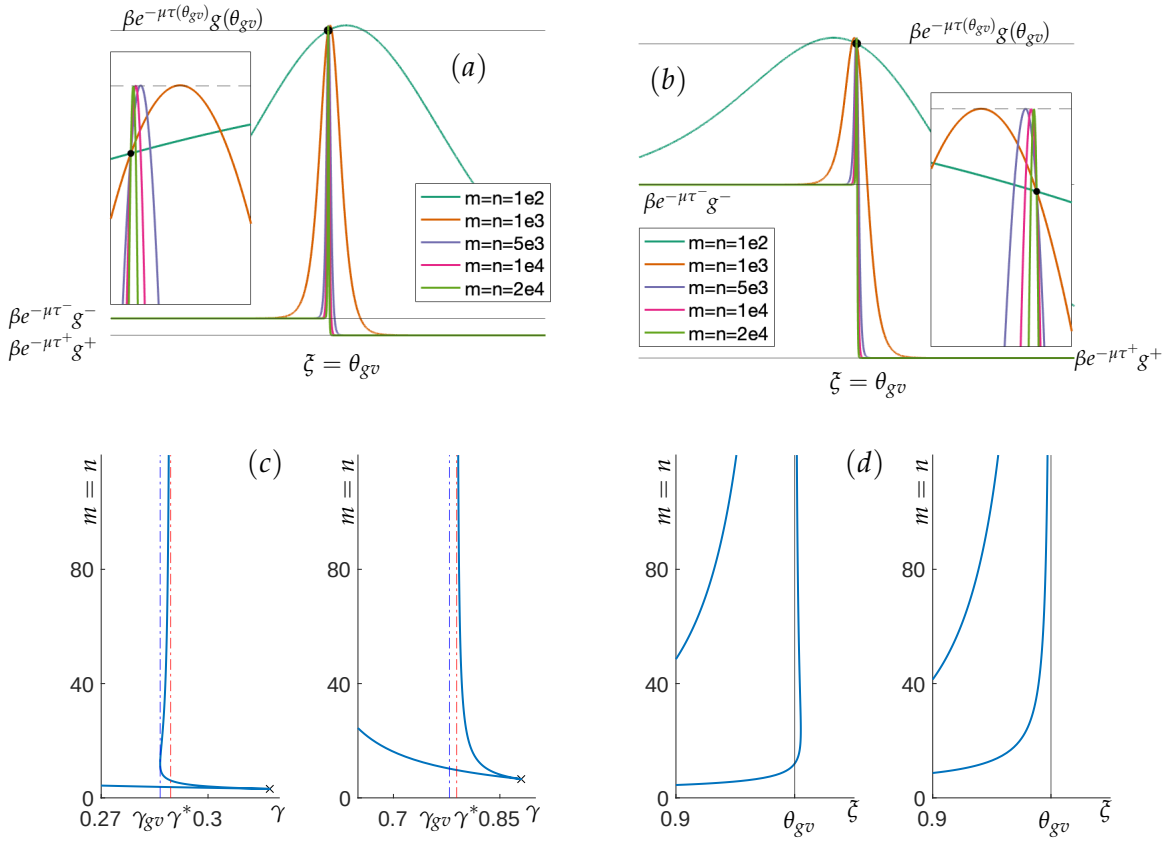

Figure 6.11: (a) and (b) The behaviour of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ as $m = n \to \infty$ in the case $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ with $\beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv}) > \beta e^{-\mu\tau^-} g^- > \beta e^{-\mu\tau^+} g^+$ with the same parameter values as in Figure 6.10 except for the value of a. In (a) $a = 22.1591$ and in (b) $a = 14.6591$. The insets show that $\lim_{m=n\to\infty} \max_\xi \{\beta e^{-\mu\tau(\xi)} g(\xi)\} > \beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv})$, with the maximum indicated by the dashed line in the inset, and the value at θ_{gv} by the black dot. (c) and (d) show the corresponding two-parameter continuations in $m = n$ and either (c) γ or (d) ξ of the fold bifurcations with the left panel showing the case of $a = 22.1591$ and the right panel for $a = 14.6591$. The fold bifurcations are always associated with unstable steady states. In (c) the asymptote denoted γ^* for the fold bifurcation is obtained dividing the maximum value of $\beta e^{-\mu\tau(\xi)} g(\xi)$ from (a) and (b) by θ_{gv} and is seen to be strictly larger than γ_{gv} in both cases.

and (d) show that the corresponding fold bifurcation asymptotes to $\gamma = \gamma_{gv}$ and $\xi = \theta_{gv}$ as $m = n \to \infty$.

Figure 6.11 illustrates two examples with the same parameters as in Figure 6.10, except for the length parameter a. Changing just the length parameter a leaves the ratio r_v unchanged, but changes the value of $\tau(\theta_{gv})$ as well as τ^- and τ^+. With $a = 22.1591$ and $m = n$ it follows that $M(\theta_{gv}) = n/12 - 1$ and $\lim_{m=n\to\infty} M(\theta_{gv}) = +\infty$, while for $a = 14.6591$ we have $M(\theta_{gv}) = -n/12 - 1$ with $\lim_{m=n\to\infty} M(\theta_{gv}) = -\infty$. As Figure 6.11(a) and (b) show, for both of these parameter sets, (6.24) is satisfied and $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ is non-monotone. It is also clear from the insets in these panels that in contrast to Figure 6.10, the maximum of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ is now strictly larger than $\beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv})$ for all $m = n \gg 0$. Consequently, as seen in Figure 6.11(c), the rightmost curve of fold bifurcations asymptotes to a value of γ which is strictly larger than γ_{gv} as $m = n \to \infty$. As Figure 6.11(d) shows in both cases the location of this fold bifurcation converges to θ_{gv} as $m = n \to \infty$. When $M(\theta_{gv}) > 0$

the maximum of $\beta e^{-\mu\tau(\xi)}g(\xi)$ occurs for $\xi > \theta_{gv}$ and consequently for the fold bifurcation as $m = n \to \infty$, $\xi \to \theta_{gv}$ from above and $\gamma \to \gamma^*$ from below for some γ^* strictly larger than γ_{gv}. For $M(\theta_{gv}) < 0$ the convergence is from the other side, but again $\gamma \to \gamma^*$ for some γ^* strictly larger than γ_{gv}.

We remark that for the example with $a = 14.6591$ in Figure 6.11, because $M(\theta_{gv}) < -1$ the condition (6.17) is violated, even though the condition (6.24) is satisfied, demonstrating as we claimed earlier that (6.17) is not a necessary condition to obtain (6.24). This also shows that it is insufficient to just evaluate the value of $M(\theta_{gv})$ to determine whether fold bifurcations occur.

In Figures 6.12 and 6.13 we return to the parameter set first considered in Figure 6.9 for which $\beta e^{-\mu\tau(\theta)}g(\theta) > \beta e^{-\mu\tau^-}g^- > \beta e^{-\mu\tau^+}g^+$. Now, we also consider the Hopf bifurcations and resulting periodic orbits. With these parameters $M(\theta_{gv}) < 0$ when $m = n > 0$ with $M(\theta_{gv}) \to -\infty$ as $m = n \to \infty$ and so the upper fold bifurcation approaches γ^* for some $\gamma^* > \gamma_{gv}$ from above as $m = n \to \infty$, as seen in Figure 6.12(c), similar to the left panel of Figure 6.11(c). The other fold bifurcation is seen in Figure 6.12(c) to approach $\gamma = \gamma_{24}$ as $m = n \to \infty$, as $\xi \mapsto \beta e^{-\mu\tau(\xi)}g(\xi)$ evolves from the smooth function shown in Figure 6.12(b) to its limiting form as in Figure 6.12(d). This agrees with the arguments under Figure 6.8 above.

For the one parameter continuation shown in Figure 6.12(a) the steady state is stable for all γ sufficiently large or sufficiently small, and loses stability in a Hopf bifurcation (and not at the fold bifurcations). A two parameter continuation of these Hopf bifurcations in Figure 6.12(c) shows that they approach γ_{13} and γ_{24} as $m = n \to \infty$, similarly to how we saw the Hopf bifurcations were forced to the ends of the interval of singular steady state solutions in Section 5.1.

In Figure 6.12(a) there are no stable steady states for $\gamma \in (0.624, 0.837)$, so we explored the stable invariant objects in this case using both numerical bifurcation detection and continuation and numerical simulation of the DDE. Using `ddebiftool` we find that the Hopf bifurcation at $\gamma = 0.624$ is supercritical and generates a branch of stable periodic orbits, which is illustrated in Figure 6.13. There is an apparent canard explosion [34] on this branch at $\gamma \approx 0.629$ where the amplitude of the periodic orbit increases dramatically. The continuation of the branch fails in `ddebiftool` at this point, but since the periodic orbits are stable we are able to continue them through the canard explosion using simulation with `ddesd`, and then continue again with `ddebiftool` after the canard explosion, to obtain the continuous branch of periodic solutions for $m = n = 40$ shown in Figure 6.12(a) and Figure 6.13. After the canard explosion for $\gamma \in (0.629, 0.84)$ the periodic orbit is stable with large amplitude and moderate period ($T \approx 13$) and evolves slowly as γ is varied. Then at $\gamma \approx 0.84$ the period of the orbit grows dramatically while the amplitude is roughly constant. In Figure 6.12(a) this branch is represented by its 2-norm as the red curve. This curve appears to terminate on the middle unstable branch of steady states when $\gamma = 0.84$. However, as seen in Figure 6.13(c) and (d) the amplitude of these orbits remains large, so there is not a Hopf bifurcation at this end of the branch.

The large period orbits shown in Figure 6.12(c) and (d) spend a lot of time close to the unstable steady state on the middle branch between the folds, which is itself very close to the threshold $x = \theta_{gv}$, and resemble relaxation oscillations. This branch of periodic orbits most likely ends in a homoclinic orbit to the unstable steady state with an infinite period. There is also bistability between the stable periodic orbit and a stable steady state for a very small range of parameters $\gamma \in [0.837, 0.84]$.

In Figure 6.12 there are two fold bifurcations, as we have seen in many examples when

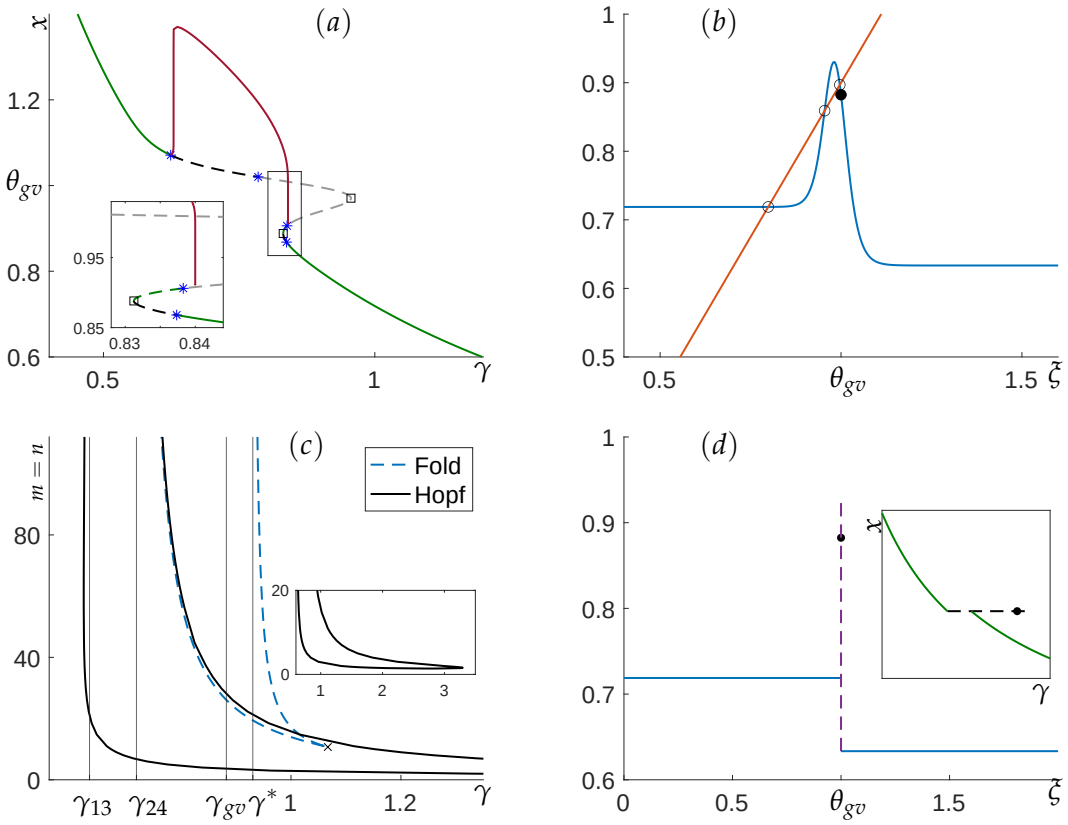

Figure 6.12: Bifurcations of (1.1)–(1.2) when $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ with the same parameters as in Figure 6.9. (a) With smooth nonlinearity g and v defined by (1.3) with $m = n = 40$. The stable periodic orbits are represented by the 2-norm. (b) Steady states occur at the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and $\xi \mapsto \gamma\xi$, with $\gamma\xi$ illustrated here with $\gamma = 0.9$. The black dot marks the value of $\beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv})$. (c) Two-parameter continuation in $m = n$ and γ of the fold bifurcations (in blue) and Hopf bifurcations (black) with the other parameters as above. Solid curves indicate the parts of the bifurcation branch where there are no characteristic values with positive real part (and hence a stability change at the bifurcation), and dashed lines indicate where the parts of the branch where there is at least one unstable characteristic value. In this example the steady state always loses stability in a Hopf bifurcation, and not at the fold. The four vertical lines denote γ_{13} and γ_{24} (recall (6.13)) and γ_{gv} (recall (6.25)), along with $\gamma^* = 0.9305$. (d) Plot of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ in the limiting case with g and v defined by (1.6) and (1.7). The black dot marks the value of $\beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv})$. The dashed line is obtained by taking the Hausdorff limit of the smooth function, and extends above the point-wise limit at θ_{gv} because $\lim_{m=n\to\infty} \max_\xi \beta e^{-\mu\tau(\xi)} g(\xi) > \beta e^{-\mu\tau(\theta_{gv})} g(\theta_{gv})$. The inset panel depicts the continuation of steady states in the limiting case. Stable steady states are shown as green solid lines, and the singular steady state as a black dashed line.

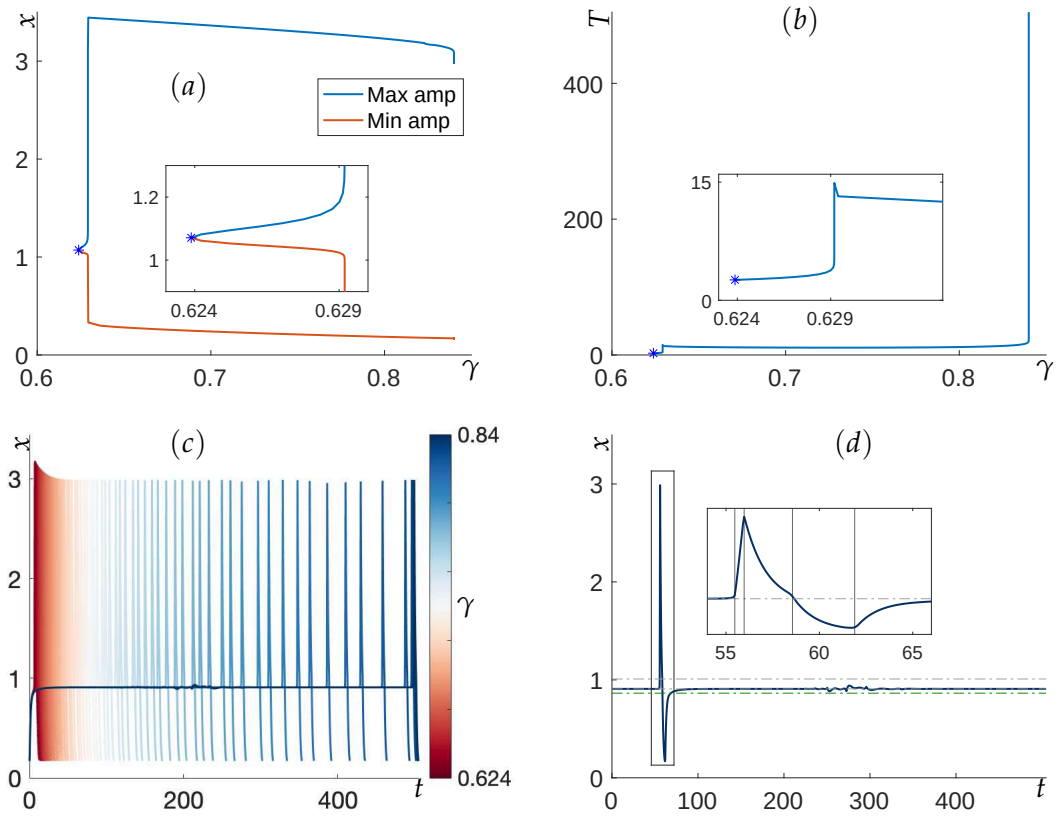

Figure 6.13: The branch of stable periodic orbits for $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ when $\gamma \in [0.624, 0.84]$ from Figure 6.12(a). Panel (a) shows the amplitude of the periodic orbits along the branch. (b) The period of the orbits. (c) Profiles of the periodic solutions show that the large period orbits at the end of the branch are of relaxation oscillator type. Panel (d) depicts the last periodic orbit found by `ddebiftool`, with the inset panel showing a zoom of the dynamics near the spike.

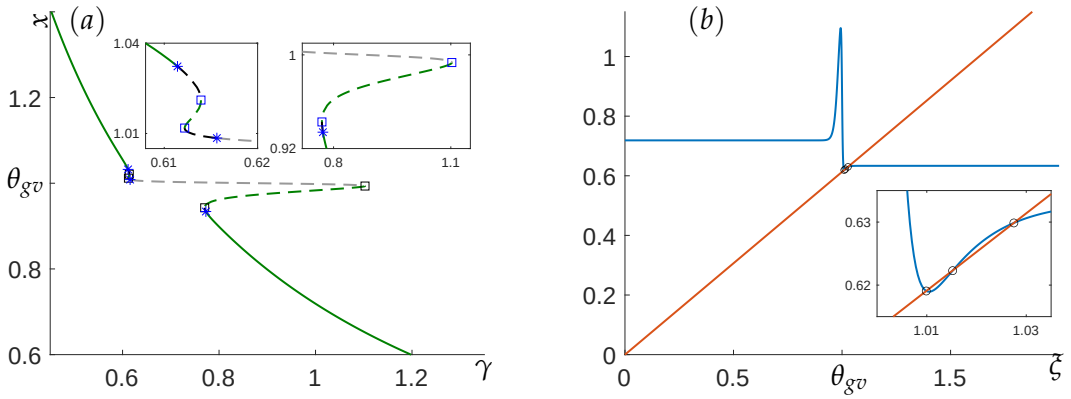

Figure 6.14: (a) One parameter continuation of the steady state when $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ for varying γ with the other parameters the same as in Figure 6.12 except $m = 100$ and $n = 500$ reveals four fold bifurcations. (b) Three steady states are indicated for $\gamma = 0.6130$ at the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and $\gamma\xi$.

one of g and v is increasing. However, as Figure 6.14 shows, it is possible to obtain four fold bifurcations by just changing the steepness of the nonlinearities and resulting width of the interfaces of the nonlinearities. In Figure 6.14 we do this with $n \gg m \gg 0$. Since n is very large the function g has a very sharp interface, and drops from very close to its maximum value g^+ to its minimum value g^- while v is essentially unchanged and equal to $v(\theta_{gv})$. This results in the function $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ having extrema close to $\beta e^{-\mu\tau(\theta_{gv})} g^-$ and $\beta e^{-\mu\tau(\theta_{gv})} g^+$, as shown previously in Figure 6.9(a) and (b). Outside of this narrow interface, g is essentially constant, and therefore $\beta e^{-\mu\tau(\xi)} g(\xi)$ is increasing, since $v(\xi)$ is an increasing function. Thus the function $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ is increasing, then decreasing, then increasing again. For m sufficiently large (so that the derivative of $\beta e^{-\mu\tau(\xi)} g(\xi)$ is larger than γ) this creates two fold bifurcations close to the ends of the inner interface for g in addition to the other two fold bifurcations close to the edges of the outer interface of v.

Figure 6.15(a) shows that with $n = 5m$ the second fold bifurcation exists for all $m \geq 66.39$. As shown in Figure 6.15(b) one pair of fold bifurcations exists for $\xi < \theta_{gv}$ and the other for $\xi > \theta_{gv}$. This happens because θ_{gv} is in the middle of the sharp interface of g, the only (very short) interval on which $\beta e^{-\mu\tau(\xi)} g(\xi)$ is decreasing, with two of the corners giving rise to the fold bifurcations on each side of θ_{gv}. Figure 6.15(b) shows that as $n = 5m \to \infty$ all of the fold bifurcations are squeezed into $\xi = \theta_{gv}$, but in Figure 6.15(a) we see that the limiting γ values of the folds all appear to be different. Because $\beta e^{-\mu\tau(\xi)} g(\xi) \to \beta e^{-\mu\tau^-} g^-$ as $m, n \to \infty$ for all $\xi < \theta_{gv}$ (and to $\beta e^{-\mu\tau^+} g^+$ for $\xi > \theta_{gv}$), two of the fold bifurcations asymptote to $\gamma = \gamma_{24}$ and $\gamma = \gamma_{13}$ as $m, n \to \infty$, as shown in Figure 6.15(a). These are the outer two fold bifurcations for the smallest and largest ξ values in Figure 6.15(b). The asymptotic γ values for the inner pair of fold bifurcations depends on the relative widths of the interfaces of the g and v functions. With $n = 5m$ it appears that the limiting γ values are strictly inside the interval (γ_1, γ_2). Different behaviour is observed if m, n approach infinity with different relationships. For example, if $n = m^2$ (as considered first in Figure 6.9(b)) then the g interface is much narrower than for v and the inner folds asymptote to $\gamma = \gamma_2$ and $\gamma = \gamma_1$ while the outer folds still asymptote to $\gamma = \gamma_{24}$ and $\gamma = \gamma_{13}$ as seen in Figure 6.15(d).

If $n = m^r \to \infty$ for $r \in (0, 1)$ then the behaviour of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and the bifurcations are completely different, as shown in Figure 6.9(d) and Figure 6.15(c). In this case $m \gg n$ so the v interface is much narrower than the g interface. As g is decreasing this results in the function $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ being decreasing for ξ small and large, and increasing only on a small interval about $\xi = \theta_{gv}$ corresponding to the narrow interface of v. In this scenario the limiting form of the function $\beta e^{-\mu\tau(\xi)} g(\xi)$ is still piecewise constant for $\xi < \theta_{gv}$ and $\xi > \theta_{gv}$, but now the function is decreasing rather than increasing at the corners corresponding to γ_{24} and γ_{13}, so these corners no longer result in fold bifurcations. Instead the folds occur close to the local extrema of $\beta e^{-\mu\tau(\xi)} g(\xi)$ seen in Figure 6.9(d), so that, for instance, when $n = m^{2/3} \to \infty$ the fold bifurcations in Figure 6.15(c) approach γ_4 and γ_3 defined by (6.26).

Figure 6.15(b) shows that the locations of the fold bifurcations are squeezed into $\xi = \theta_{gv}$ as $n = 5m \to \infty$ and the nonlinearities in (1.1)–(1.2) become piecewise constant for $\xi \neq \theta_{gv}$. Similar behaviour was observed when $n = m^r \to \infty$ for $r > 0$ but we omit the figures. Notice also that as already observed in the previous example, the outer Hopf bifurcations at which the steady state changes stability approach γ_{24} and γ_{13} as in the limiting case as $n = m^r \to \infty$ in all of these examples.

Although there are four fold bifurcations in the example in Figures 6.14 and 6.15, because of the location of the folds it is not possible to obtain five co-existing steady states.

As a final example we change just the parameters $v^\pm$ in the v function from the previous

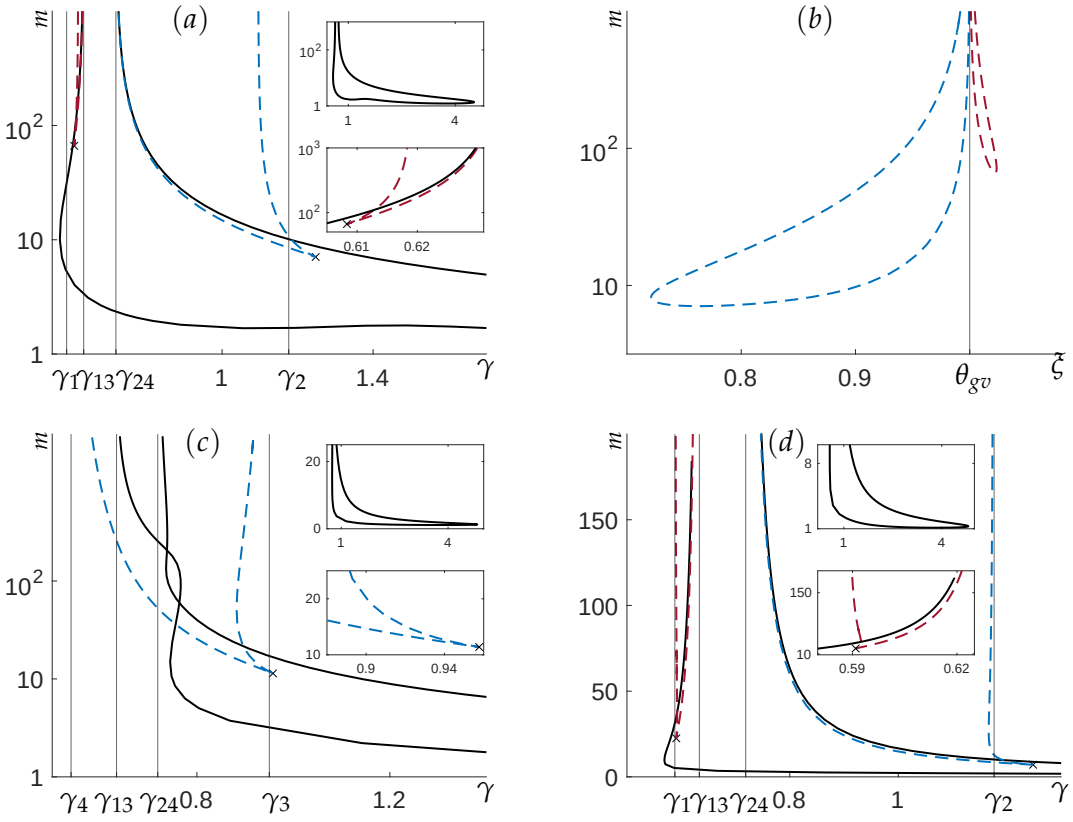

Figure 6.15: Two parameter continuations of the bifurcations of (1.1)–(1.2) when $(g \downarrow, v \uparrow, \theta_g = \theta_v = \theta_{gv})$ with the same parameters as in Figures 6.9, 6.12 and 6.14, except for m and n. The branches of fold bifurcations are shown as blue and red curves and the Hopf bifurcations in black. Solid curves indicate the parts of the bifurcation branch where there are no characteristic values with positive real part (and hence a stability change at the bifurcation), and dashed lines indicate where the parts of the branch where there is at least one unstable characteristic value. In all four examples the steady state always loses stability at a Hopf bifurcation, and not at the fold bifurcation. (a) and (b) Continuation of the fold bifurcations in γ and m with $n = 5m$, showing in (a) the γ values of the fold bifurcations and (b) the value of the steady state ξ at the fold bifurcation. Cusp bifurcations occur at $(\gamma, m) = (0.6083, 66.3853)$ and $(\gamma, m) = (1.2480, 7.0681)$. (c) and (d) are similar to (a), except in (c) $n = m^{2/3}$ and in (d) $n = m^2$. Cusp bifurcations occur in (c) at $(\gamma, m) = (0.9577, 11.3879)$, and in (d) at $(\gamma, m) = (0.5909, 22.4752)$ and $(\gamma, m) = (1.2484, 7.0591)$.

example, to obtain a new example with $\beta e^{-\mu\tau(\theta)} g(\theta) > \beta e^{-\mu\tau^+} g^+ > \beta e^{-\mu\tau^-} g^-$, whose dynamics are explored in Figure 6.16. With $m = n$ the dynamics with one and two parameter continuations is very similar to the earlier case shown in Figure 6.12 with a single pair of fold bifurcations and so we omit the figures here. But different choices of m and n lead to more interesting dynamics shown in Figure 6.16. One-parameter continuation in γ with n and m fixed with $n \gg m \gg 0$, as shown in Figure 6.16(a) reveals four fold bifurcations, a large interval of γ values on which there are three coexisting steady states with two stable, and a small interval for $\gamma \in (0.5352, 0.5513)$ for which there are five co-existing steady states of which one or two are stable. Figure 6.16(b) illustrates how these five steady states arise because for $n \gg m$ the downward g interface is much narrower than the interface for the increasing v

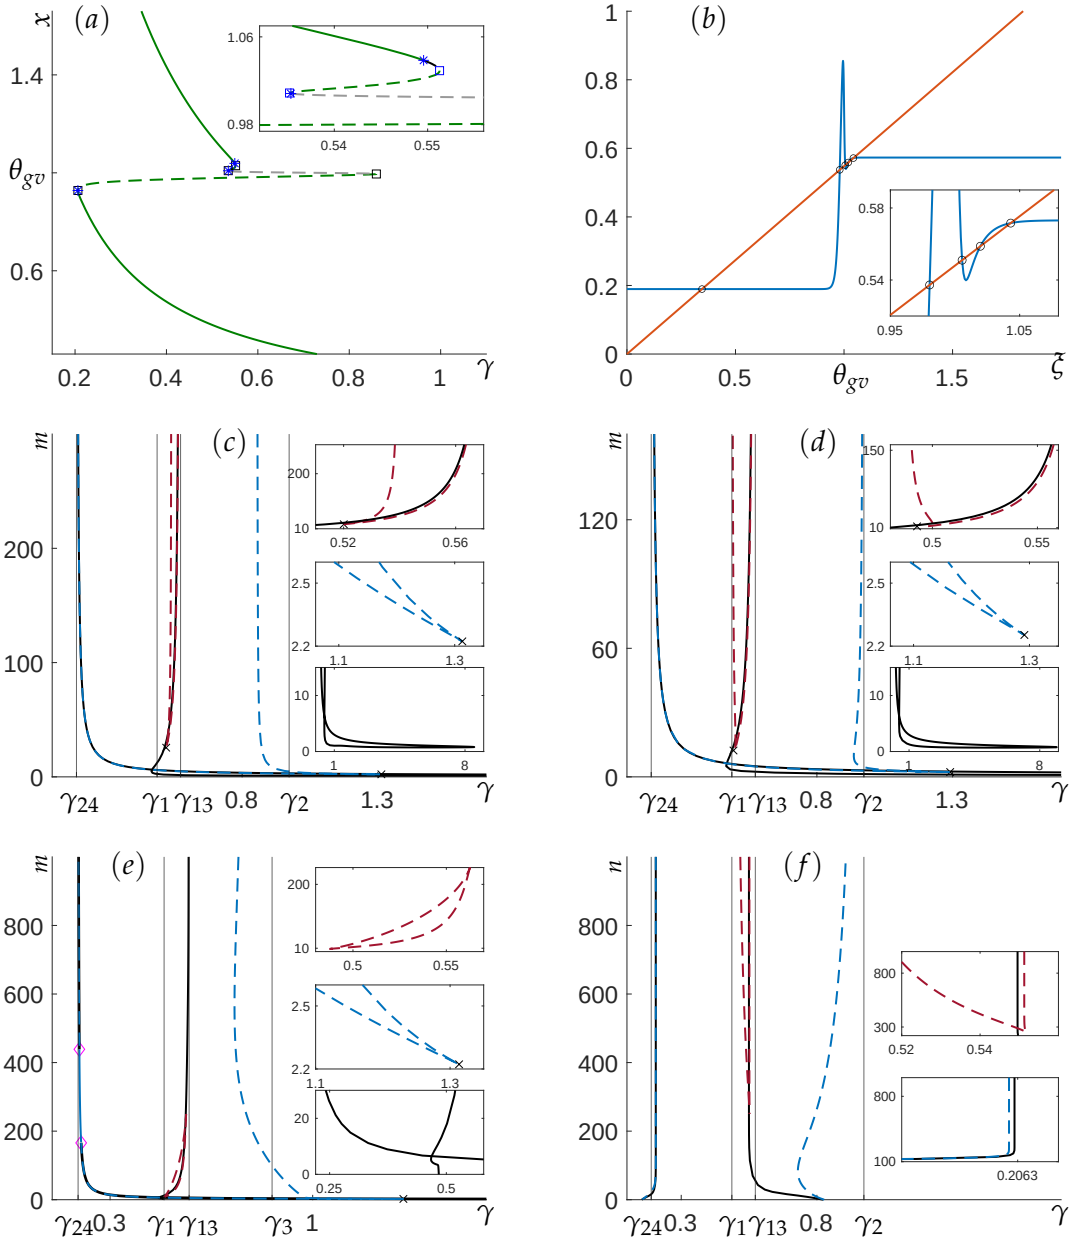

Figure 6.16: Bifurcations of (1.1)–(1.2) when $(g\downarrow, v\uparrow, \theta_g = \theta_v = \theta_{gv})$ with $\beta = 1.4$, $\mu = 0.2$, $g^- = 1$, $g^+ = 0.5$, $\theta_g = \theta_v = \theta_{gv} = 1$, $a = 1$, $v^- = 0.1$ and $v^+ = 1$. Apart from m, n, v^- and v^+, these are the same parameters as in Figures 6.9 and 6.12–6.15. (a) One parameter continuation of steady states in γ with smooth nonlinearities g and v defined by (1.3) with $m = 100$ and $n = 500$. This reveals four fold bifurcations and up to five coexisting steady states (at most two of which are stable). (b) Illustration of the five steady states occurring in (a) at the intersections of $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ and $\xi \mapsto \gamma\xi$ with $\gamma = 0.5480$. (c) to (f) Two parameter continuations of the fold bifurcations (red and blue) and Hopf bifurcations (black) with (c) $n = 5m$ and (d) $n = m^2$ (e) m varying with $n = 500$ fixed and (f) n varying with $m = 100$ fixed. The bifurcation curves are drawn according to the number of characteristic values with positive real part; solid for zero and dashed for one or more. Cusp points are denoted by crosses. In (e) there is a change of stability at the fold bifurcation between two Bogdanov–Takens bifurcations (denoted by pink diamonds) at $(\gamma, m) = (0.2, 165.62)$ and $(\gamma, m) = (0.1938, 438.82)$, otherwise in these examples the stability change is always at the Hopf bifurcation (as was the case in Figure 6.15).

function (compare with Figures 5.3 and 6.14). Panels (c) and (d) of Figure 6.16 show two-parameter continuations with $n = 5m$ and $n = m^2$ which reveal that with these parameter constraints all four fold bifurcations persist to arbitrary large values of m with one pair of fold bifurcations contained in the interval (γ_1, γ_{13}) and the other in the interval (γ_{24}, γ_2) for all m sufficiently large, just as was seen in Figure 6.15. But for the parameters used in Figure 6.16 we have $(\gamma_1, \gamma_{13}) \subset (\gamma_{24}, \gamma_2)$ so there are five coexisting steady states between the red curves in Figure 6.16(c) and (d) for arbitrary large m.

In the examples shown in Figure 6.16(c) and (d) the stable steady states loses stability in a Hopf bifurcation just before the fold bifurcation. As in the previous examples in this section these Hopf bifurcations asymptote to γ_{24} and γ_{13} as $m, n \to \infty$. In Figure 6.16(e) and (f) we explore a different scenario, where we keep one of m or n fixed but much larger than zero, and allow the other one to vary on the positive real line.

The value $m = 0$ in Figure 6.16(e) corresponds to the v function being constant, and since g is decreasing, this corresponds to the scenario considered in Section 5.1. This is why the curves of Hopf bifurcations, but not the folds, extend all the way down to $m = 0$. For $0 < m \ll n$ the g function has a much narrower interface than the v function, so $\beta e^{-\mu\tau(\xi)} g(\xi)$ will be first increasing then decreasing and finally increasing again, similar to many of the examples in this section. However for $m \gg n \gg 0$ the v function will have a narrower interface, so $\beta e^{-\mu\tau(\xi)} g(\xi)$ will be first decreasing, like in Figures 6.9(d) and 6.15(c). Interesting dynamics is observed with $n \gg m > 0$. In particular, in Figure 6.16(e) there is a pair of Bogdanov–Takens bifurcations, and on the curve of fold bifurcations between these points a steady state loses stability at the fold bifurcation, unlike the previous examples in this section, but similar to examples in Section 5.4. In Figure 6.16(f) we explore varying n with $m \gg 0$ fixed. Thus when $n = 0$ we are in the scenario of g fixed and v increasing explored in Section 5.4 which is why fold bifurcations persist down to $n = 0$ in Figure 6.16(f). As n increases, once the interface of the g function becomes narrow enough there is a cusp bifurcation which leads to a second pair of fold bifurcations and five coexisting steady states for all n sufficiently large. For n large the folds are contained in the intervals (γ_{24}, γ_2) and (γ_1, γ_{13}), but do not asymptote to the ends of these intervals as $n \to \infty$ because m is held fixed and finite.

6.3 Summary

In Section 6 we have considered the situation where both functions g and v are non-constant. We first derived formulae for the existence of both fold bifurcations (6.2) and Hopf bifurcations (6.9)–(6.10), which reduce to formulae derived in Section 5 if either v or g is a constant function.

In Section 6.1 we study the case when the thresholds are different; $\theta_g \neq \theta_v$. Not surprisingly, we recover the same dynamics and bifurcation structures as in Section 5 near each threshold when $m \gg 0$, or $n \gg 0$ since in these limits the behavior localizes in the area where the other function is essentially constant. In particular, in the case $(g\downarrow, v\downarrow)$ the dynamics is similar to that observed in Section 5.1 near $x = \theta_g$ and to that in Section 5.3 near $x = \theta_v$. In Section 6.1.1 we consider the example $(g\downarrow, v\uparrow)$ which supports bistability between an equilibrium and periodic orbit and in Section 6.1.2 we examine $(g\uparrow, v\uparrow)$ which can exhibit up to five equilibria and tristability.

In Section 6.2 we look at the situation when $\theta_v = \theta_g$. First in Section 6.2.1 we consider a relatively straightforward situation where both functions g and v are either increasing $(g\uparrow, v\uparrow)$ or both decreasing $(g\downarrow, v\downarrow)$. Both of these cases are similar to their counterparts discussed in

Section 5.

The most interesting case is when $\theta_v = \theta_g$, but the monotonicity of g and v do not agree i.e. $(g\uparrow, v\downarrow)$ and $(g\downarrow, v\uparrow)$. This is discussed in Section 6.2.2. The main result is that which behavior dominates (i.e. the behavior observed for increasing g or v or behavior for decreasing g or v) depends sensitively on the way in which m and n approach infinity. We capture this informally in a concept of "interface width"; if $m \gg n$ then the interface of v is much narrower than the interface of g and vice versa.

Figure 6.9 illustrates that the function $\xi \mapsto \beta e^{-\mu\tau(\xi)} g(\xi)$ converges to different limits as m and n go to infinity at different rates, indicating that the fold bifurcations will occur at different places in these limits. We also observe that additional equilibria may appear when m and n approach infinity at different rates (Figures 6.15 and 6.16). Finally, we observe a canard-like explosion in amplitude of a periodic orbit that emanates from a Hopf bifurcation, see Figure 6.13.

7 Conclusions

This paper is long and complicated, and hence difficult to summarize succinctly. Suffice to say that we have introduced a generalization of a prokaryotic gene regulatory model, in (1.1)–(1.2), originally developed in [18]. The generalization has both nonlinearities in terms of feedback but also nonlinearities appearing in state dependent delays. Moreover the delays are generated by a threshold condition. It is thus somewhat novel for both the mathematical and modeling literature. The first three sections of the paper are concerned with establishing important and relevant mathematical properties of the basic system (1.1)–(1.2). Section 2 establishes properties of the semiflow generated by (1.1)–(1.2), while Section 3 establishes conditions for the existence of a global attractor of the semiflow. Section 4 deals with the linearization of (1.1)–(1.2) which is of significant utility in the following Sections 5 and 6 where we examine the behaviour of (1.1)–(1.2) both numerically and analytically.

At the ends of both Sections 5 and 6 we have offered general synopses of the results of each, which we will not repeat here. As an aid to the reader, in Table 7.1 we have listed all of the figures in this paper illustrating dynamics for various combinations of g and v, along with the types of bifurcations that we observed numerically in each case.

We have studied the threshold model (1.1), (1.2) directly without applying the time transformation of Smith [55,56] to convert the equations to a distributed delay DDE with constant delay. We showed in Sections 5.3–6.2.2 that the dynamics of the model (1.1) with a threshold delay is altogether richer and more surprising than the dynamics of the corresponding constant delay model considered in Sections 5.1–5.1. In so doing we demonstrated that problems with threshold delays can be analysed and studied numerically without time transforming the problems to constant delay problems. Our methods are applicable to problems with multiple delays including one or more threshold delays.

Much of the algebra in this paper is rooted in the use of monotone Hill functions for $g(\xi)$ and $v(\xi)$ which is both relevant and quite justifiable for modeling in the biological realm. Our algebra is helped by the use of the function $\xi \mapsto \xi f'(\xi)/f(\xi)$ which has a tractable form (5.11) when f is a Hill function. Notice that if $f(\xi) = C\xi^p$ then

$$\frac{\xi f'(\xi)}{f(\xi)} = p,$$

so we can think of $\xi f'(\xi)/f(\xi)$ as a description of a local power of a non-polynomial function.

Table 7.1: Summary of various dynamic behaviours seen in Sections 5 and 6. The notation of 'n.m' refers to figure 'm' of Section 'n' and the symbols after indicate the type of continuation explored and the bifurcations observed. $\beta\gamma$ and β refers to a figure in which $\beta e^{-\mu\tau} g(\xi)$ (with or without $\gamma\xi$) is plotted to show qualitatively the number of steady states of the system (1.1)–(1.2). 1 and 2 indicate that 1 and/or 2 parameter numerical continuation was performed. The bifurcations observed are denoted by F (Fold), F_P (Fold of Periodic Orbits), H (Hopf), S (Stable-no bifurcation), and h (homoclinic) and for higher co-dimension bifurcations: Ba (Bautin *or* generalized Hopf), BT (Bogdanov-Takens), Cu (cusp), FH (fold-Hopf), Fh_2 (fold-homoclinic). 4F denotes examples with 4 fold bifurcations, 5SS denotes 5 co-existing steady states, and Ca a canard. Note that 'left clicking' on a number will take you to that figure, while 'Alt ←' will bring you back to this table.

While a similar approach could be adopted for other nonlinearities, the results would likely be quantitatively different, but we expect that for monotone functions they would not show qualitative alterations. However, if non-monotone nonlinearities were considered then we expect that there would be substantial qualitative as well as quantitative differences.

Future directions. In [20] the authors examine the various dynamic patterns (what they term 'multi-synchronization' or 'multi-rhythmicity') that emerge from models of biochemical and cellular oscillators coupled to each other, and illustrate their considerations with examples of the circadian oscillator and the cell cycle. While certainly of interest biologically, perhaps the more interesting question is whether or not one could construct a catalog, or dictionary, of possible dynamical behaviours arising from the coupling of N different dynamics generated by DDEs as we have considered here.

In particular, consider

$$x_i'(t) = \beta_i e^{-\mu_i \tau_i(t)} \frac{v_i(x_i(t)))}{v_i(x_i(t-\tau_i(t)))} g_i(x_i(t-\tau_i(t))) - \gamma_i x_i(t) \tag{7.1}$$

where for $t \geq 0$ the delay $\tau_i(t)$ is defined by the threshold condition

$$a_i = \int_{-\tau_i(t)}^{0} v_i(x_i(t+s))ds = \int_{t-\tau_i(t)}^{t} v_i(x_i(s))ds \tag{7.2}$$

for $i = 1, \ldots, N$. Assuming that these systems are coupled through one or more of the parameters $\beta_i, \mu_i, \gamma_i, a_i$ or through the functions τ_i, v_i, g_i, then what can be said about the resulting

dynamics? The paper [20] considered both 'series' and 'parallel' coupling between their two dynamics, but one would have to precisely define what was meant by this within the context of (7.1)–(7.2).

For $N = 2$ one might consider a system

$$x_1'(t) = \beta_1 x_2 e^{-\mu_1 \tau_1(t)} \frac{v_1(x_1(t)))}{v_1(x_1(t-\tau_1(t)))} g_1(x_1(t-\tau_1(t))) - \gamma_1 x_1(t),$$
$$x_2'(t) = \beta_2 x_1 e^{-\mu_i \tau_2(t)} \frac{v_2(x_2(t)))}{v_2(x_2(t-\tau_2(t)))} g_2(x_2(t-\tau_2(t))) - \gamma_2 x_2(t).$$

One could regulate the strength of the coupling by an additional constant i.e. by considering the term $\beta_1 a_1 x_2$ rather than just $\beta_1 x_2$. This would allow an examination of the strength of coupling while keeping β's the same for comparison with a single DDE oscillator. This seems to be the simplest linear coupling; an alternative might be considering $\beta_1(x_2), \beta_2(x_1)$ where these are Hill functions. This coupling results in a positive mutual feedback in the sense that more x_1 makes $g(x_2)$ bigger and vice versa.

For stable oscillation in a single DDE we need at least one of the functions v or g to be decreasing. Are there differences if we couple same kind oscillators $(-,+)$ with $(-,+)$ or $(+,-)$ with $(+,-)$ on one hand and two different oscillators $(+,-)$ with $(-,+)$? If we mutually couple two DDEs in a way that they form a negative feedback loop, can we identify oscillations that arise due to local negative feedback (i.e. the oscillator type $(-,+)$ and $(+,-)$) and the global negative feedback, that arises from the mutual coupling of the oscillators? In particular, consider two types of mutually coupled equations. First consider the coupling through the nonlinearities g

$$x_1'(t) = \beta_1 e^{-\mu_1 \tau_1(t)} \frac{v_1(x_1(t)))}{v_1(x_1(t-\tau_1(t)))} g_1(x_2(t-\tau_1(t))) - \gamma_1 x_1(t),$$
$$x_2'(t) = \beta_2 e^{-\mu_2 \tau_2(t)} \frac{v_2(x_2(t)))}{v_2(x_2(t-\tau_2(t)))} g_2(x_1(t-\tau_2 t))) - \gamma_2 x_2(t),$$

where both v_1, v_2 are decreasing, so that each equation can support oscillations with constant input from the other oscillator (see Section 5.3). If both g_1, g_2 are also decreasing this represents mutual inhibition between two oscillators and suggests the possible existence of bistability.

Alternatively, one can consider coupling of the equations through the v functions rather than nonlinearities g, with all functions v_1, v_2, g_1, g_2 still decreasing:

$$x_1'(t) = \beta_1 e^{-\mu_1 \tau_1(t)} \frac{v_1(x_2(t)))}{v_1(x_2(t-\tau_1(t)))} g_1(x_1(t-\tau_1(t))) - \gamma_1 x_1(t),$$
$$x_2'(t) = \beta_2 e^{-\mu_2 \tau_2(t)} \frac{v_2(x_1(t)))}{v_2(x_1(t-\tau_2(t)))} g_2(x_2(t-\tau_2 t))) - \gamma_2 x_2(t).$$

Does either system support bistability between periodic solutions? If so, does the shape of the periodic solutions reflect the fact that in mutually repressible coupled systems one component is high while the other is low?

One can also consider larger system of equations that are cyclically coupled

$$x_1'(t) = \beta_1 e^{-\mu_1 \tau_1(t)} \frac{v_1(x_1(t)))}{v_1(x_1(t-\tau_1(t)))} g_1(x_N(t-\tau_1(t))) - \gamma_1 x_1(t), \tag{7.3}$$
$$x_j'(t) = \beta_j e^{-\mu_j \tau_j(t)} \frac{v_j(x_j(t)))}{v_j(x_j(t-\tau_j(t)))} g_j(x_{j-1}(t-\tau_j(t))) - \gamma_j x_j(t), \quad j = 2, \ldots, N. \tag{7.4}$$

We have already tackled a particular problem of this form in [18] where we considered

$$\begin{aligned}
\frac{dM}{dt}(t) &= \beta_M e^{-\mu\tau_M(t)} \frac{v_M(E(t))}{v_M(E(t-\tau_M(t)))} f(E(t-\tau_M(t))) - \bar{\gamma}_M M(t), \\
\frac{dI}{dt}(t) &= \beta_I e^{-\mu\tau_I(t)} \frac{v_I(M(t))}{v_I(M(t-\tau_I(t)))} M(t-\tau_I(t)) - \bar{\gamma}_I I(t), \\
\frac{dE}{dt}(t) &= \beta_E I(t) - \bar{\gamma}_E E(t).
\end{aligned}$$

which is exactly of the form (7.3),(7.4) with $N = 3$ and $g_2(x) = g_3(x) = x$ and $\mu_3 = \tau_3 = 0$.

To conclude, the work presented here opens many interesting questions on how the interplay between the character of the nonlinearity, state dependent delay and coupling affects the local and global dynamics of DDEs.

Appendices

A Relation of (1.1)–(1.2) to the model of Gedeon et al. [18]

The Goodwin model [22] for operon dynamics considers a large population of cells, each of which contains one copy of a particular operon. (M, I, E) respectively denote the mRNA, intermediate protein, and effector protein concentrations. For a generic operon [21, 22, 24, 25, 46, 51] the dynamics are assumed to be given by

$$\frac{dM}{dt} = \beta_M f(E) - \gamma_M M, \tag{A.1}$$

$$\frac{dI}{dt} = \beta_I M - \gamma_I I, \tag{A.2}$$

$$\frac{dE}{dt} = \beta_E I - \gamma_E E. \tag{A.3}$$

The production flux f of mRNA is assumed to be a function of the effector level E. Furthermore, the model assumes that the flux of protein and metabolite production are proportional (at rates β_I, β_E respectively) to the amount of mRNA and intermediate protein respectively. All three of the components (M, I, E) are subject to degradation at rates $\gamma_M, \gamma_I, \gamma_E$. The parameters $\beta_I, \beta_E, \gamma_M, \gamma_I$ and γ_E have dimensions [time^{-1}].

In [18] we extended the classic Goodwin model for the regulation of the bacterial operon to a situation in which the cells are growing exponentially at a rate μ and have finite transcriptional and translational velocities that are potentially dependent on the state of the system. For the full model of [18], retain the notation of the original Goodwin operon model, denote the transcriptional velocity by $v_M(E(t))$ and the translational velocity by $v_I(M(t))$, and let $\bar{\gamma}_i = \gamma_i + \mu$. Then the extension in [18] is

$$\frac{dM}{dt} = \beta_M e^{-\mu\tau_M(t)} \frac{v_M(E)}{v_M(E(t-\tau_M(t)))} f(E(t-\tau_M(t))) - \bar{\gamma}_M M, \tag{A.4}$$

$$\frac{dI}{dt} = \beta_I e^{-\mu\tau_I(t)} \frac{v_I(M)}{v_I(M(t-\tau_I(t)))} M(t-\tau_I(t)) - \bar{\gamma}_I I, \tag{A.5}$$

$$\frac{dE}{dt} = \beta_E I - \bar{\gamma}_E E. \tag{A.6}$$

These equations are supplemented by the two additional equations which implicitly define the delays τ_M and τ_I by threshold conditions, namely

$$a_M = \int_{t-\tau_M(t)}^{t} v_M(E(s))ds = \int_{-\tau_M(t)}^{0} v_M(E(t+s))ds, \tag{A.7}$$

$$a_I = \int_{t-\tau_I(t)}^{t} v_I(M(s))ds = \int_{-\tau_I(t)}^{0} v_I(M(t+s))ds. \tag{A.8}$$

In our extended model [18], as in the original Goodwin [21] formulation, the function f is a monotone increasing function for an inducible operon, and for a repressible operon f is a monotone decreasing function.

To make the transition from the full model (A.4)–(A.6) presented in [18] to the apparently simpler situation of (1.1)–(1.2) considered here is relatively straightforward. We simply need two assumptions:

1. We first assume that the translational velocity v_I is not regulated but is large with respect to the other characteristic times in the system so the translational delay $\tau_I \simeq 0$.
2. Our second assumption involves the existence of fast and slow variables [36, Section 2.3] so there is a clear separation of time scales.

With these assumptions and the substitutions: $E \to x$, $\beta \to \bar{\gamma}_I \frac{\beta_M \beta_I \beta_E}{\bar{\gamma}_M \bar{\gamma}_I \bar{\gamma}_E}$ (or $\beta \to \bar{\gamma}_E \frac{\beta_M \beta_I \beta_E}{\bar{\gamma}_M \bar{\gamma}_I \bar{\gamma}_E}$), $f \to g$, and $\tau_M(t) \to \tau(t)$ we immediately obtain the system (1.1)–(1.2) that we study here.

One might think that (1.1) is somewhat novel but in fact similar formulations are available in different situations. Below, in Appendix B we give several other examples of models in the spirit of (1.1), but which differ in details that may or may not offer significant differences in behaviour.

B Other examples

In this appendix, we mention four different examples of previously published studies which can be thought of as extensions of the considerations in this paper.

A bistable genetic switch

The two types of operon dynamics originally considered were classified as either repressible (in which the production flux function f in (A.1) is a decreasing function of its argument), or inducible (in which f is an increasing function of its argument). In the language of dynamical systems these are negative or positive feedback systems. However, there is a third type of fundamental dynamical entity found in prokaryotes, namely the so called bistable switch in which the effector produced by operon X inhibits the transcription of DNA from operon Y and vice versa (which we might denote as a $(-,-)$ system). The paradigmatic molecular biology example of a bistable switch due to reciprocal negative feedback is the bacteriophage (or phage) λ, which is a virus capable of infecting E. coli bacteria. Originally described in [32] and very nicely treated in [48], it is but one of many examples of mutually inhibitory bistable switches that have been found since. Models of this process are to be found in [26], [50], and [9] among others.

Consider a simple model for this process in which the dynamics of the intermediate of both the X and Y operons is fast relative to the dynamics of the corresponding mRNA M_X

and M_Y, and effectors E_X and E_Y. Then we can write down a reduced version of the model (A.4)–(A.6) in the form

$$\frac{dM_X}{dt} = \beta_{M_X} e^{-\mu\tau_{M_X}(t)} \frac{v_{M_X}(E_Y)}{v_{M_X}(E_Y(t-\tau_{M_X}(t)))} f_X(E_Y(t-\tau_{M_X}(t))) - \bar{\gamma}_{M_X} M_X, \tag{B.1}$$

$$\frac{dE_X}{dt} = \beta_{E_X} M_X - \bar{\gamma}_{E_X} E_X, \tag{B.2}$$

$$\frac{dM_Y}{dt} = \beta_{M_Y} e^{-\mu\tau_{M_Y}(t)} \frac{v_{M_Y}(E_X)}{v_{M_Y}(E_X(t-\tau_{M_Y}(t)))} f(E_X(t-\tau_{M_Y}(t))) - \bar{\gamma}_{M_Y} M_Y, \tag{B.3}$$

$$\frac{dE_Y}{dt} = \beta_{E_Y} M_Y - \bar{\gamma}_{E_Y} E_Y. \tag{B.4}$$

Analysis of the network dynamics of ordinary differential equation systems [23, 47] suggests that the system

$$\begin{aligned}
\frac{dM_X}{dt} &= \beta_{M_X} f_X(E_Y) - \bar{\gamma}_{M_X} M_X,\\
\frac{dE_X}{dt} &= \beta_{E_X} M_X - \bar{\gamma}_{E_X} E_X,\\
\frac{dM_Y}{dt} &= \beta_{M_Y} f(E_X) - \bar{\gamma}_{M_Y},\\
\frac{dE_Y}{dt} &= \beta_{E_Y} M_Y - \bar{\gamma}_{E_Y} E_Y,
\end{aligned}$$

corresponding to (B.1)–(B.4) in both $(++)$ and $(--)$ cases is a positive cyclic feedback system [17] and will display bistability [23, 47]. The recent preprint [49] carefully analyzes the boundary of bistability regions in both $(++)$ and $(--)$ cases.

Based on the results from [18], inclusion of distributed delays could add additional equilibria, resulting in multistability. Adding delays also can change the range of bistability in the parameter space.

System $(+-)$ is a negative feedback system where we expect that the trivial equilibrium will lose stability through Hopf bifurcation if the slope(s) of nonlinearities are sufficiently steep at the equilibrium. Adding delays may result in additional stable equilibria and secondary Hopf bifurcations, as was observed in [18].

A forest growth model

In [39], the authors considered an age structured model for the growth of a single tree species forest. They showed that the dynamics of the number of adult trees A is governed by

$$\frac{dA(t)}{dt} = e^{-\mu\tau(t)} \frac{f(A(t))}{f(A(t-\tau(t)))} rb(A(t-\tau(t))) - \gamma A(t) \tag{B.5}$$

in conjunction with the condition

$$\int_{t-\tau(t)}^{t} f(A(s))ds = \bar{s}. \tag{B.6}$$

In (B.5) μ is the mortality rate of saplings, f is the velocity of maturation of saplings, r is the birth rate, b is the reproduction (birth) function and γ is the mortality rate of adults.

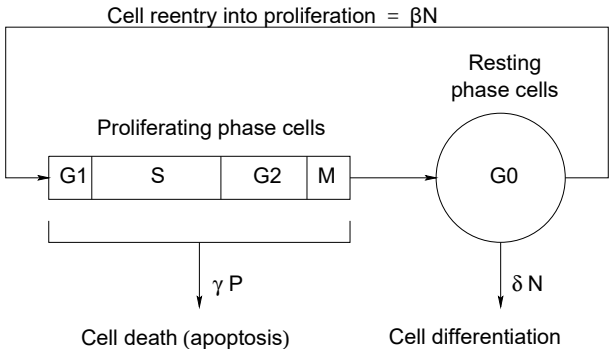

Figure B.1: The Burns and Tannock [7] model for the cell cycle consisting of a resting phase (G_0) and the proliferating phase P with the sub-phases G_1, S (DNA synthesis), G_2, and M (mitosis and cytokinesis). It is assumed that cells can die from the proliferating phase at a rate γ and exit into the differentiation pathway from G_0 at a rate δ. Redrawn from [37].

The G_0 cell cycle model

The original G_0 cell cycle model proposed by Burns and Tannock in [7] is illustrated in Figure B.1, and captures the essence of what is known of the cellular replication process at a intermediate (cellular or non-molecular) level of sophistication and knowledge. The proliferating phase cells are denoted by P while the resting G_0 phase cells are denoted by N.

In the elaboration of [37], it is presumed that cells die from the proliferative phase at a rate γ so the flux of cells to death is γP, and differentiate from G_0 at a rate δ so the differentiation flux is δN. Cells in the G_0 phase can, in addition to differentiating, re-enter the proliferative phase at a rate β so the flux of cells into proliferation is βN. Cells that enter the proliferative phase are assumed to proceed through the stages G_1, S, G_2, and M in a lock step fashion that takes a time τ to complete if death does not intervene. Once mitosis is completed, cytokinesis produces two daughter cells that then enter G_0.

Based on the assumption that the rate β of cell entry from G_0 into P, is a function of the size N of G_0, then it is straightforward to show that the dynamics of the augmented Burns/Tannock cell cycle model are governed by the differential delay equation

$$\frac{dN}{dt} = -[\delta + \beta(N)]N + 2e^{-\gamma\tau}N_\tau\beta(N_\tau), \tag{B.7}$$

where we have used the notation $N \equiv N(t)$ and $N_\tau \equiv N(t-\tau)$. Equation (B.7) has been the subject of an extensive bifurcation analysis in the work of [12].

Now we consider a slightly modified cell cycle model identical to the Burns/Tannock model with the additional wrinkle that the velocity v with which cells move through the proliferative phase of the cell cycle is under the control of the number N of non-proliferative cells.

Remark B.1. One would think that the velocity of movement through the proliferative phase P would be an increasing function of decreased N which would lead to a delay τ that decreases as N decreases. This would lead to cell density dependent inter-division times.

If we take the number of proliferative phase cells at time t and age a to be $p(t,m)$, the maximum age at cytokinesis to be a_m, and the velocity with which they move through the cell

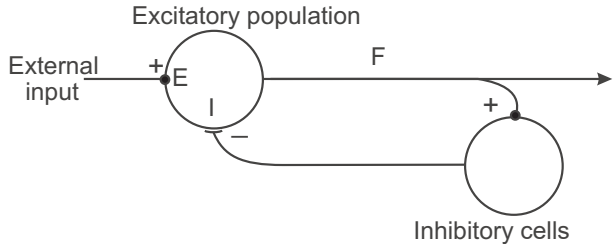

Figure B.2: A schematic representation of the recurrent inhibition circuit considered in [15]. This figure is modified from the original publication.

cycle to be $v(N(t))$, then the evolution equation for $p(t,m)$ is given by

$$\frac{\partial p(t,m)}{\partial t} + v(N(t))\frac{\partial p(t,m)}{\partial m} = -\gamma p(t,m) \tag{B.8}$$

and we have the initial condition

$$p(t,m=0) = N(t)\beta(N(t)). \tag{B.9}$$

Following the same derivation procedure as in [18], the final equation for the dynamics of the non-proliferative cellular population N is given by

$$\frac{dN(t)}{dt} = 2e^{-\gamma\tau(t)}\frac{v(N(t))}{v(N(t-\tau(t)))}N(t-\tau(t))\beta(N(t-\tau(t)) - (\delta+\beta(N(t)))N(t). \tag{B.10}$$

We also have the additional condition that

$$a_m = \int_{t-\tau(t)}^{t} v(N(s))ds. \tag{B.11}$$

Remark B.2. Note that, not unsurprisingly, the augmented cell cycle model is identical in formulation with the forest growth model of [39].

A model for recurrent inhibition

A model for the dynamics of a recurrent inhibitory neural feedback circuit is considered in [15], however the model was incomplete omitting the velocity ratio term which appears in all of the other models here. The term $v(x(t))/v(x(t-\tau(t)))$ in (1.1) is essential as shown in [5, 10, 18] from conservation and flux arguments. Here, we complete the model of [15].

To capture the spirit of the recurrent inhibitory neural circuitry and offer a complete formulation incorporating the ratio term, we consider the situation with dynamics described by

$$\frac{dV(t)}{dt} = \gamma(E - V(t)) - \frac{\Sigma(V(t))}{\Sigma(V(t-\tau(t)))}G(F(V(t-\tau(t)), \tag{B.12}$$

where $V = E - I$ is the net potential in the neuron, $E(I)$ is the excitatory (inhibitory) potential, Σ is the velocity of propagation of the action potentials around the inhibitory loop back to the soma, and G is the response of the neuron to the recurrent inhibitory drive. $F \approx \alpha V$ ($\alpha > 0$) is the firing frequency of the cell, an increasing function of the postsynaptic potential V. In conjunction with (B.12), if the length of the recurrent inhibitory pathway is L we have the ancillary condition

$$L = \int_{t-\tau(t)}^{t} \Sigma(V(s))ds. \tag{B.13}$$

In [15] it was argued that Σ is an increasing function of the postsynaptic potential V so, as a consequence the delay time τ is a decreasing function of V. It was further noted that, on physiological grounds, G is an increasing function of the firing frequency F for small values of F and decreasing with increasing F past a certain maximum.

This model can be further generalized to a state dependent DDE with distributed state dependent delays. This generalization relaxes the assumption that the length L is constant. A more realistic assumption is that the lengths are distributed in population of neurons described by a distribution K_L. Note that this is equivalent to having variable firing threshold at the soma that receives the inhibitory input. The model takes the form

$$\frac{dV(t)}{dt} = \gamma(E - V(t)) - \int_0^\infty \frac{\Sigma(V(t))}{\Sigma(V(t-\phi(t)))} G(F(V(t-\phi(t))) K_L \left(\int_{t-\phi}^{t} \Sigma(V(s)) ds \right) d\phi, \quad \text{(B.14)}$$

where $V = E - I$ is the net potential in the neuron, $E(I)$ is the excitatory (inhibitory) potential, Σ is the velocity of propagation of the action potentials around the inhibitory loop back to the soma, and G is the response of the neuron to the recurrent inhibitory drive. $F \approx \alpha V$ ($\alpha > 0$) is the firing frequency of the cell, an increasing function of the postsynaptic potential V. To derive this equation we note that the distribution of the recurrent loop lengths L is analogous to the distributed maturation times in Kendrick–McCormack age structured models analyzed in [8]. The analog to the Kendrick–McCormack model of the age distributed population is

$$\begin{aligned} &\partial_t E(t,s) + \partial_s(\Sigma(V(t))E(s,t)) = -h(s)E(s,t), \\ &\Sigma(V(t))E(t,0) = G(F(V(t))), \qquad E(t_0,s) = f(s), s \in [0,\infty) \end{aligned}$$

where s is a position along a loop, $E(t,s)$ is the action potential at position s of the loop and the propagation velocity Σ depends on the voltage at time t. The term $h(s)$ is the discharge of the action potential in the soma when the circuit has length s. The function $h(s)$ can be expressed (see [8]) using the distribution K_L of circuit lengths as

$$h(s(t)) = \frac{K_L(s(t))}{1 - \int_0^\sigma K_L(s(\sigma))d\sigma} \frac{d}{dt} s(t).$$

Solving the partial differential equation along the characteristics

$$\frac{d}{d\phi} t(\phi) = 1, \qquad \frac{d}{dt} s(t) = \Sigma(V(t))$$

gives the equation (B.14). For details of the derivation see [8].

C Numerical techniques

Our numerical techniques are documented in detail in [18,63–65], so here we will only briefly summarise them, and note some extensions of the previous methods.

All of our computations are performed using MATLAB [43]. Mainly we perform numerical continuation and bifurcation analyses using the MATLAB package `ddebiftool` [54]. Existing versions of `ddebiftool` are only implemented for discrete delays, and cannot be applied directly to problems with threshold delay. Since the largest possible delay is a/v_0, to implement threshold delay problems in `ddebiftool` we introduce up to 100 dummy constant delays to discretize the time interval $[t - a/v_0, t]$ on a equally spaced mesh. The threshold

delay $\tau(t)$ that satisfies (1.2) can then be computed be applying numerical quadrature. The implementation is explained in detail in [64, 65], and is a refinement of our earlier methods [18, 63].

One of the features that makes `ddebiftool`, and numerical continuation in general, so powerful is its ability to follow stable and unstable branches of solutions equally well. Occasionally we also use numerical simulation of the DDE to find stable solutions. The standard MATLAB solver for state-dependent DDEs is `ddesd` [52], but this is also only implemented for discrete delays. To use it to solve (1.1)–(1.2) as an initial value problem we first differentiate the threshold condition (1.2) to obtain

$$\frac{d\tau(t)}{dt} = 1 - \frac{v(x(t))}{v(x(t-\tau(t)))}, \tag{C.1}$$

and then solve (1.1), (C.1) using `ddesd`. See [18, 63, 65] for implementation details, and also [64] for an investigation of the differences between (1.1), (1.2) and (1.1), (C.1).

The numerical collocation underpinning the `ddebiftool` differential equation solver, is best suited to smooth nonlinearities and solutions. When m or n is large and one of the Hill functions in (1.3) approaches a step function issues may arise in the computations. Here we mention some tricks we applied to compute the figures in those cases.

To circumvent underflow, overflow and division by zero errors in MATLAB when evaluating $\beta e^{-\mu\tau(\xi)} g(\xi)$ near θ_g or θ_v (such as in Figure 6.9), we rewrite the Hill function as

$$g(x) = \begin{cases} \dfrac{g^- + g^+(x/\theta_g)^n}{1+(x/\theta_g)^n}, & x \le \theta_g, \\ \dfrac{g^-(\theta_g/x)^n + g^+}{(\theta_g/x)^n + 1}, & x > \theta_g, \end{cases}$$

and similarly for $v(x)$. It can still be delicate to continue branches of fold bifurcations when m or n are large. In practice, when needed, we apply two different techniques for extending branches of fold bifurcations to very large values of m and/or n. Firstly, the MATLAB nonlinear system solver `fsolve` [57] can be used to solve (6.2) for each fixed value of m or n, to extend the branch to large values of these nonlinearity parameters. Alternatively, since $M(\xi)$ changes sign at the fold bifurcation, these can be revealed by performing a contour plot of $M(\xi)$ in the (ξ, m) or (ξ, n) plane and displaying only the $M(\xi) = 0$ curve. Furthermore, to perform two-parameter continuation of the fold bifurcations in (γ, m) or (γ, n), we evaluate the right hand side of (6.3) to get the corresponding γ for the fold bifurcation at ξ. We apply such tricks extensively in Section 6.2.2.

We were unable to use `ddebiftool` subroutines for detecting codimension-two bifurcations along the fold and the Hopf curves. This was likely due to the complexity of the stability computations with the augmented system `ddebiftool` uses for two-parameter continuation combined with the large number of delays in our implementation. To find the codimension-two bifurcation points we compute the stability of the points on the codimension-one bifurcation branches and track the number of characteristic values with positive real part along the branch. On the fold branch, a fold-Hopf bifurcation occurs when a complex conjugate pair of characteristic values cross the imaginary axis. Fold-Hopf points are also found on a branch of Hopf bifurcations at points where a single real characteristic value changes sign. A Bogdanov–Takens point is characterised by a single real characteristic value changing sign on a fold branch, at a point in parameter space where a branch of Hopf bifurcations also terminates. Note that we do not compute the normal form coefficients of these bifurcations.

Abstract. In this work, we investigate a class of reaction-diffusion system in which both species are influenced by self-diffusion. By introducing two particular functions, we provide a complete characterization of the parameter ranges such that coexisting steady-state solutions of the system do not exist under three boundary conditions. Then based on the maximum principle, a sufficient condition for the existence of constant coexisting solutions of the system under Neumann boundary conditions was derived.

Keywords: reaction-diffusion system, steady-state, existence, boundary condition.

2020 Mathematics Subject Classification: 35B50, 35J57.

1 Introduction

In [14], Shigesada, Kawasaki and Teramoto introduced the following system with cross-diffusions and self-diffusions, when they took a nonlinear dispersive force and an environmental potential function into consideration,

$$\begin{cases} \dfrac{\partial u}{\partial t} = \Delta[(d_1 + a_{11}u + a_{12}v)u] + u(1 - u - a_1 v), & x \in \Omega, t > 0, \\ \dfrac{\partial v}{\partial t} = \Delta[(d_2 + a_{21}u + a_{22}v)v] + v(1 - a_2 u - v), & x \in \Omega, t > 0, \\ \alpha_1 u + \beta_1 \dfrac{\partial u}{\partial \nu} = \alpha_2 v + \beta_2 \dfrac{\partial v}{\partial \nu} = 0, & x \in \partial\Omega, t > 0, \\ u(x,0) = u_0(x) \geq 0,\ v(x,0) = v_0(x) \geq 0, & x \in \Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^n (n \geq 1)$ is a bounded domain with smooth boundary, and satisfies the interior ball condition at any $x \in \partial\Omega$, ν is the outward unit normal vector on $\partial\Omega$. u and v are the densities of two competing species, α_i, β_i and a_{ij} $(i, j = 1, 2)$ are nonnegative constants, $\alpha_i + \beta_i > 0$ $(i = 1, 2)$, a_i and d_i $(i = 1, 2)$ are all positive constants, a_{11} and a_{22} stand for the

✉Corresponding author. Email: bihuili0810@126.com

self-diffusion pressures, while a_{12} and a_{21} are the cross-diffusion pressures, a_1, a_2 describe the inter-specific competitions, and d_1, d_2 are their diffusion rates [19].

In order to analyze and describe the above reaction-diffusion model, it is necessary to clarify the boundary conditions of the region. When $\alpha_i = 0$ $(i = 1, 2)$, we have $\frac{\partial u}{\partial \nu} = \frac{\partial v}{\partial \nu} = 0$, which is called Neumann boundary condition. At this point, individuals who reach the boundary will be reflected back into the region without leaving, meaning that the species is in an isolated environment. When $\beta_i = 0$ $(i = 1, 2)$, we have $u = v = 0$. These indicate that individuals who encounter the boundary cross it immediately and thereby maintain the density on the boundary at zero [1]. This means that the boundary $\partial\Omega$ can effectively absorb all individuals encountering it. Therefore, this boundary is called absorbed, also known as Dirichlet boundary condition. When $\alpha_i, \beta_i > 0$ $(i = 1, 2)$, it is called Robin boundary condition in the mathematical literature.

Since the model, which was abbreviated as SKT model, was proposed, numerous experts and scholars have conducted extensive and in-depth research on it. These results mainly include the existence, boundedness and global convergence of classical solutions, the local and global existence of weak solutions, the existence, nonexistence and stability of steady-state solutions, the existence of traveling wave solutions, and so on.

In fact, the study of standard SKT models is quite difficult. More experts and scholars are turning to the study of certain special forms of SKT model; see [2, 4–8, 12, 15, 16]. Among them, when the spatial dimension is 1 and $d_1 = d_2$, [6] proved the global existence of smooth solutions. Under the same conditions, [15] obtained the uniform boundedness and convergence of smooth solutions. In 2015, Lou and Winkler [12] used the comparison principle and Sobolev regularity theory to obtain the global existence and uniform boundedness of smooth solutions on bounded convex domain when the spatial dimension is less than 3 and $d_1 = d_2$. Taking self-diffusion into consideration, [5] proved the global existence of the unique smooth solution in any spatial dimension; and [8] obtained the global existence of the unique classical solution by using Sobolev embedding theory under the condition $d_1 = d_2$.

For research on steady-state solutions, one can refer to [9–11]. In 1996, Lou and Ni [9] used the maximum principle and Lyapunov functional theory to prove that in the weak competition case, if self-diffusion and/or cross-diffusion are relatively weaker than diffusion, then there is still no nonconstant steady-state solution. At the same time, they proved that in the weak competition case, with one of the cross-diffusion pressures arbitrarily given but fixed, it is expect to find non-constant steady-state solutions if the other cross-diffusion pressure is large enough [9]. Without considering the influence of self-diffusion, [10] obtained a sufficient condition such that the SKT model has no nonconstant steady-state solutions. When $a_{21} = a_{22} = 0$, Lou et al. [11] provided the parameter ranges such that the system has no nonconstant positive solutions for $a_{11} = 0$ and $a_{11} \neq 0$, respectively.

It is obvious to see that the above studies were conducted under Neumann boundary conditions, which is also the most extensively studied scenario. In addition, some scholars have also studied the SKT model under Dirichlet boundary conditions, which can be found in [3, 13, 17, 20] and references therein. For example, the sufficient conditions for the existence of positive steady-state solutions of the system are given in [13] using the fixed point theory in the case of fixed or sufficiently large cross-diffusion coefficients, respectively. The existence of steady-state solutions for a one-dimensional system was studied using the singular perturbation method [17].

Based on the previous work [19], where one species has cross-diffusion and another species has self-diffusion, now we consider the following steady-state model, which indicates that

there are self-diffusions in both competing species and there is no cross-diffusion in either,

$$\begin{cases} \Delta[(d_1 + a_{11}u)u] + u(1 - u - a_1v) = 0, & x \in \Omega, \\ \Delta[(d_2 + a_{22}v)v] + v(1 - a_2u - v) = 0, & x \in \Omega, \\ \alpha_1 u + \beta_1 \dfrac{\partial u}{\partial \nu} = \alpha_2 v + \beta_2 \dfrac{\partial v}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{1.2}$$

We aim to obtain sufficient conditions such that the system (1.2) has no coexisting solutions under three different boundary conditions, and establish the parameter ranges for the existence of constant coexisting solutions under Neumann boundary conditions. Considering that u and v represent species densities, we focus on the nonnegative classical solution (u, v) of (1.2), which means that $(u, v) \in (C^1(\overline{\Omega}) \cap C^2(\Omega))^2$, $u, v \geq 0$ in $\overline{\Omega}$, and satisfies (1.2) in the pointwise sense [19].

The remainder of this work is organized as follows. Section 2 gives some basic preliminaries which imply the strict positivity of the nontrivial solutions of system (1.2). In Section 3, based on the boundedness of solutions, we obtain two different parameter ranges for nonexistence of coexisting solutions under three boundary conditions. In Section 4, we establish the sufficient conditions for the existence of constant coexisting solutions under Neumann boundary conditions.

2 Preliminaries

First of all, we can obtain the positivity of the classical solutions of (1.2) in Ω, which is crucial in subsequent section.

Proposition 2.1. *Let (u, v) be a nonnegative classical solution of (1.2). Then if $u \not\equiv 0$, we have $u > 0$ in Ω, and if $v \not\equiv 0$, we have $v > 0$ in Ω.*

Proof. We only prove $u > 0$ in Ω whenever $u \not\equiv 0$, since the positivity of v in Ω can be proved in a similar way. Otherwise, there is $x_0 \in \Omega$ such that $u(x_0) = \min_{x\in\overline{\Omega}} u(x) = 0$.

It follows from the first equation of (1.2) that

$$(d_1 + 2a_{11}u)\Delta u + 2a_{11}|\nabla u|^2 + u(1 - u - a_1v) = 0.$$

Let

$$Lu = -(d_1 + 2a_{11}u)\Delta u - 2a_{11}|\nabla u|^2 + cu \quad \text{with } c = u + a_1v.$$

Then

$$c \geq 0 \quad \text{and} \quad Lu = u \geq 0 \quad \text{in } \Omega.$$

So, an application of the strong maximum principle shows that u is a constant in Ω, and thus $u = 0$, a contradiction to $u \not\equiv 0$. This completes the proof. □

Remark 2.2. In the case of Neumann or Robin boundary conditions, we can get further that $u, v > 0$ in $\overline{\Omega}$ by Hopf's boundary lemma. In fact, for example, considering the case of Robin boundary conditions, suppose that there is $x_0 \in \overline{\Omega}$ such that $u(x_0) = \min_{x\in\overline{\Omega}} u(x) = 0$. If $x_0 \in \Omega$, we can directly derive a contradiction by Proposition 2.1. If $x_0 \in \partial\Omega$, then $u(x_0) < u(x)$ for all $x \in \Omega$. Since $Lu \geq 0$ in Ω and Ω satisfies the interior ball condition at $x_0 \in \partial\Omega$, it follows from Hopf's boundary lemma that $\frac{\partial u}{\partial \nu}(x_0) < 0$. Hence

$$\alpha_1 u(x_0) + \beta_1 \frac{\partial u}{\partial \nu}(x_0) < 0,$$

a condiction. Therefore, $u > 0$ in $\overline{\Omega}$.

3 Nonexistence of coexisting steady-state solutions

In this section, we will discuss the nonexistence of coexisting solutions for system (1.2) under three different boundary conditions.

3.1 Neumann boundary condition

In this subsection, assume that $\alpha_1 = \alpha_2 = 0$, that is, we consider the following system,

$$\begin{cases} \Delta[(d_1 + a_{11}u)u] + u(1 - u - a_1 v) = 0, & x \in \Omega, \\ \Delta[(d_2 + a_{22}v)v] + v(1 - a_2 u - v) = 0, & x \in \Omega, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{3.1}$$

Firstly, we give the following lemma, which indicates that u and v are both bounded.

Lemma 3.1. *Suppose that (u, v) is a nonnegative classical solution of (3.1). If $u \not\equiv 0$, then $u \leq 1$ in $\overline{\Omega}$. Similarly, if $v \not\equiv 0$, then $v \leq 1$ in $\overline{\Omega}$.*

Proof. We only prove the boundedness of u, while the boundedness of v can be similarly obtained, leaving it for interested readers. Rewrite the first equation of the system (3.1) as follows

$$\begin{cases} (d_1 + 2a_{11}u)\Delta u + 2a_{11}|\nabla u|^2 + u(1 - u - a_1 v) = 0, & x \in \Omega, \\ \dfrac{\partial u}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{3.2}$$

Let $f(x) = u(x)(1 - u(x) - a_1 v(x))$, $x \in \Omega$. Proposition 2.2 in [9] implies that there exist $x_1, x_2 \in \overline{\Omega}$ such that

$$u(x_1) = \max_{x \in \overline{\Omega}} u(x) \triangleq M, \qquad u(x_2) = \min_{x \in \overline{\Omega}} u(x) \triangleq m,$$

and

$$f(x_1) \geq 0, \qquad f(x_2) \leq 0,$$

that is

$$M(1 - M - a_1 v(x_1)) \geq 0, \qquad m(1 - m - a_1 v(x_2)) \leq 0.$$

We thus have

$$1 - a_1 v(x_2) \leq m \leq u(x) \leq M \leq 1 - a_1 v(x_1) \quad \text{for all } x \in \overline{\Omega}.$$

Combining this with the nonnegativity of v, we obtain $u \leq 1$ in $\overline{\Omega}$. □

Next, we provide a sufficient condition for the nonexistence of coexisting solutions under Neumann boundary conditions.

Theorem 3.2. *Suppose that (u, v) is a nonnegative classical solution of (3.1). If*

(i) $$a_1 > 1 > a_2, \qquad d_1 > d_2 \quad \text{and} \quad d_1 \geq d_2 + 2a_{22}$$

or

(ii) $$a_1 < 1 < a_2, \qquad d_1 < d_2 \quad \text{and} \quad d_2 \geq d_1 + 2a_{11},$$

then system (3.1) *has no coexisting solutions, that is, at least one species is extinct.*

Proof. (i) We argue by contradiction. Suppose that $u \not\equiv 0$ and $v \not\equiv 0$. It follows from Proposition 2.1 that $u, v > 0$ in Ω, which allows us to rewrite system (3.1) as follows,

$$\begin{cases} \dfrac{\Delta[(d_1 + a_{11}u)u]}{u} = -1 + u + a_1 v, & x \in \Omega, \\ \dfrac{\Delta[(d_2 + a_{22}v)v]}{v} = -1 + a_2 u + v, & x \in \Omega, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{3.3}$$

Let

$$w_1 = d_1 + a_{11}u \quad \text{and} \quad w_2 = d_2 + a_{22}v. \tag{3.4}$$

Since $a_1 > 1 > a_2$, we can obtain that $\frac{\Delta(w_1 u)}{u} > \frac{\Delta(w_2 v)}{v}$, that is,

$$\frac{u\Delta w_1 + 2\nabla u \cdot \nabla w_1 + w_1 \Delta u}{u} > \frac{v\Delta w_2 + 2\nabla v \cdot \nabla w_2 + w_2 \Delta v}{v} \quad \text{in } \Omega. \tag{3.5}$$

We procedure the following calculation based on the inequality above,

$$\begin{aligned} &\operatorname{div}\Big[(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v)\frac{u}{v}\Big] \\ &\quad = \big(uv\Delta w_1 + v\nabla u\cdot\nabla w_1 + u\nabla v\cdot\nabla w_1 - uv\Delta w_2 - v\nabla u\cdot\nabla w_2 - u\nabla v\cdot\nabla w_2 \\ &\qquad + vw_1\Delta u + v\nabla u\cdot\nabla w_1 + w_1\nabla u\cdot\nabla v - uw_2\Delta v - u\nabla v\cdot\nabla w_2 - w_2\nabla u\cdot\nabla v\big)\frac{u}{v} \\ &\qquad + \big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\cdot\Big(\frac{1}{v}\nabla u - \frac{u}{v^2}\nabla v\Big) \\ &\quad > \big(u\nabla v\cdot\nabla w_1 - v\nabla u\cdot\nabla w_2 + w_1\nabla u\cdot\nabla v - w_2\nabla u\cdot\nabla v\big)\frac{u}{v} \\ &\qquad + \big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\cdot\Big(\frac{1}{v}\nabla u - \frac{u}{v^2}\nabla v\Big) \\ &\quad = |\nabla u|^2\big(a_{11}u + w_1\big) + |\nabla v|^2\big(a_{22}v + w_2\big)\frac{u^2}{v^2} \\ &\qquad + \nabla u\cdot\nabla v\Big[(a_{11}u + w_1)\frac{u}{v} + (-a_{22}v - w_2)\frac{u}{v} + (-a_{11}u - w_1 - a_{22}v - w_2)\frac{u}{v}\Big] \\ &\quad = |\nabla u|^2\big(d_1 + 2a_{11}u\big) + |\nabla v|^2\big(d_2 + 2a_{22}v\big)\frac{u^2}{v^2} - 2(d_2 + 2a_{22}v)\frac{u}{v}\nabla u\cdot\nabla v \\ &\quad = |\nabla u|^2\big(d_1 + 2a_{11}u - d_2 - 2a_{22}v\big) + \Big(\sqrt{d_2 + 2a_{22}v}\nabla u - \frac{u}{v}\sqrt{d_2 + 2a_{22}v}\nabla v\Big)^2. \end{aligned}$$

As $d_1 > d_2$, $d_1 \geq d_2 + 2a_{22}$ and $v \leq 1$, we have

$$d_1 + 2a_{11}u - d_2 - 2a_{22}v \geq d_1 + 2a_{11}u - d_2 - 2a_{22} \geq 0 \quad \text{in } \Omega.$$

Thus,

$$\operatorname{div}\Big[(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v)\frac{u}{v}\Big] > 0. \tag{3.6}$$

On the other hand, we can see from Neumann boundary conditions that

$$\begin{aligned}
&\int_\Omega \operatorname{div}\left[\left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\frac{u}{v}\right]\mathrm{d}x\\
&\quad= \int_{\partial\Omega}\left(uv\frac{\partial w_1}{\partial \nu} - uv\frac{\partial w_2}{\partial \nu} + vw_1\frac{\partial u}{\partial \nu} - uw_2\frac{\partial v}{\partial \nu}\right)\frac{u}{v}\mathrm{d}S\\
&\quad= \int_{\partial\Omega}\left(a_{11}uv\frac{\partial u}{\partial \nu} - a_{22}uv\frac{\partial v}{\partial \nu} + vw_1\frac{\partial u}{\partial \nu} - uw_2\frac{\partial v}{\partial \nu}\right)\frac{u}{v}\mathrm{d}S\\
&\quad= 0,
\end{aligned}$$

which is contradict to (3.6). Therefore, $u \equiv 0$ or $v \equiv 0$.

(ii) In this case, due to $a_1 < 1 < a_2$, we can see that $\frac{\Delta(w_1 u)}{u} < \frac{\Delta(w_2 v)}{v}$, which can be expanded into the following form

$$\frac{u\Delta w_1 + 2\nabla u\cdot\nabla w_1 + w_1\Delta u}{u} < \frac{v\Delta w_2 + 2\nabla v\cdot\nabla w_2 + w_2\Delta v}{v} \quad \text{in } \Omega, \tag{3.7}$$

where w_1, w_2 are defined in (3.4). Similar to the calculations of (i), we consider the process as follows

$$\begin{aligned}
&\operatorname{div}\left[\left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\frac{v}{u}\right]\\
&\quad< \left(u\nabla v\cdot\nabla w_1 - v\nabla u\cdot\nabla w_2 + w_1\nabla u\cdot\nabla v - w_2\nabla u\cdot\nabla v\right)\frac{v}{u}\\
&\qquad+ \left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\cdot\left(-\frac{v}{u^2}\nabla u + \frac{1}{u}\nabla v\right)\\
&\quad= |\nabla u|^2\left(-a_{11}u - w_1\right)\frac{v^2}{u^2} + |\nabla v|^2\left(-a_{22}v - w_2\right)\\
&\qquad+ \nabla u\cdot\nabla v\left[\left(a_{11}u + w_1\right)\frac{v}{u} + \left(-a_{22}v - w_2\right)\frac{v}{u} + \left(a_{11}u + w_1 + a_{22}v + w_2\right)\frac{v}{u}\right]\\
&\quad= -|\nabla u|^2\left(d_1 + 2a_{11}u\right)\frac{v^2}{u^2} - |\nabla v|^2\left(d_2 + 2a_{22}v\right) + 2\left(d_1 + 2a_{11}u\right)\frac{v}{u}\nabla u\cdot\nabla v\\
&\quad= |\nabla v|^2\left(-d_2 - 2a_{22}v + d_1 + 2a_{11}u\right) - \left(\frac{v}{u}\sqrt{d_1 + 2a_{11}u}\nabla u - \sqrt{d_1 + 2a_{11}u}\nabla v\right)^2.
\end{aligned}$$

Since $d_1 < d_2$, $d_2 \geq d_1 + 2a_{11}$ and $u \leq 1$, we see

$$-d_2 - 2a_{22}v + d_1 + 2a_{11}u \leq -d_2 - 2a_{22}v + d_1 + 2a_{11} \leq 0 \quad \text{in } \Omega.$$

It is shown that

$$\operatorname{div}\left[\left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\frac{v}{u}\right] < 0. \tag{3.8}$$

Now, based on the boundary conditions, we can still obtain the following result

$$\int_\Omega \operatorname{div}\left[\left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\frac{v}{u}\right]\mathrm{d}x = 0,$$

which leads to a contradiction. This completes the proof. □

Remark 3.3. Based on Proposition 2.1, we constructed two subtle auxiliary functions and proved the conclusion by contradiction. From the conclusion, it can be seen that the theorem provides a specific characterization that when the inter-specific competition rate and diffusion rate of some species are relatively high, it will lead to some species extinction.

Furthermore, under the conditions (i) and (ii) of Theorem 3.2, we selected two sets of values and conducted numerical simulations for the following system respectively,

$$\begin{cases} \dfrac{\partial u}{\partial t} = \Delta[(d_1 + a_{11}u)u] + u(1 - u - a_1 v), & x \in (0,1), t > 0, \\ \dfrac{\partial v}{\partial t} = \Delta[(d_2 + a_{22}v)v] + v(1 - a_2 u - v), & x \in (0,1), t > 0, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = 0, & x = 0, 1, t > 0, \\ u(x,0) = u_0(x) \geq 0,\ v(x,0) = v_0(x) \geq 0, & x \in (0,1), \end{cases} \tag{3.9}$$

as shown in Figure 3.1 and 3.2. The simulation results show that, species u becomes extinct under condition (i) while species v becomes extinct under condition (ii). Therefore, it is nature to ask whether species u necessarily extinct under condition (i) and species v necessarily extinct under condition (ii). Our results have not provided an answer, and this is our future work.

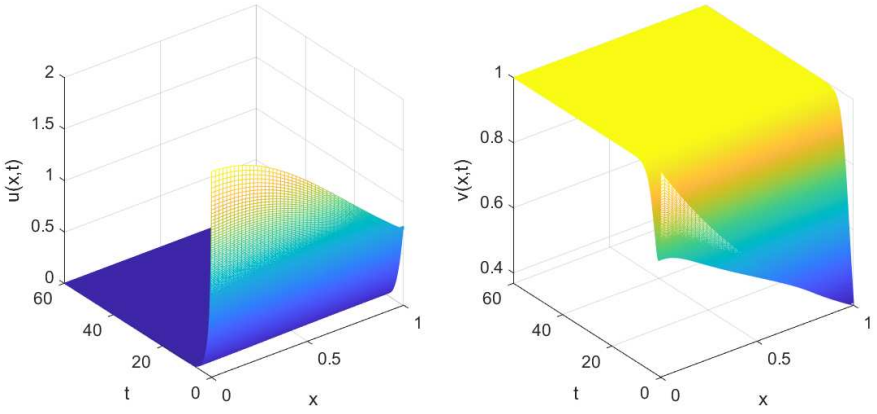

Figure 3.1: Numerical simulations for system (3.9) with $u_0(x) = 2e^{-x}$, $v_0(x) = e^{-x}$, $d_1 = 0.7, d_2 = 0.2, a_{11} = 0.1, a_{22} = 0.2$, $a_1 = 1.8$ and $a_2 = 0.5$.

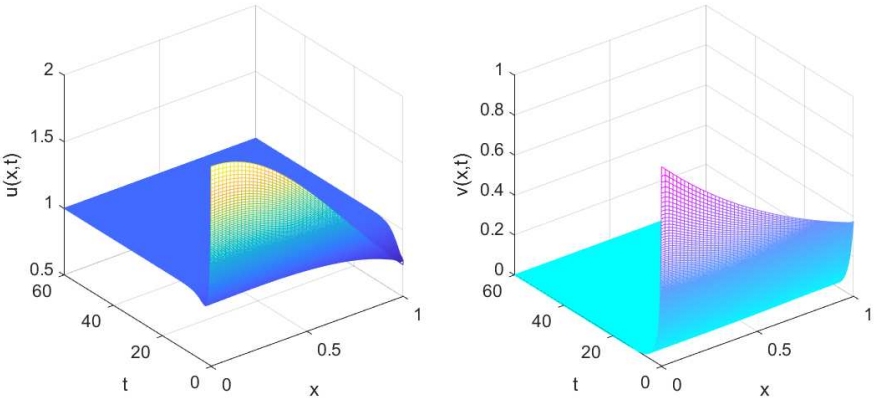

Figure 3.2: Numerical simulations for system (3.9) with $u_0(x) = 2e^{-x}$, $v_0(x) = e^{-x}$, $d_1 = 0.1, d_2 = 0.4, a_{11} = 0.1, a_{22} = 0.2$, $a_1 = 0.8$ and $a_2 = 1.5$.

3.2 Dirichlet boundary condition

In this subsection, we consider the case of $\beta_1 = \beta_2 = 0$, which leads to the following system,

$$\begin{cases} \Delta[(d_1 + a_{11}u)u] + u(1 - u - a_1 v) = 0, & x \in \Omega, \\ \Delta[(d_2 + a_{22}v)v] + v(1 - a_2 u - v) = 0, & x \in \Omega, \\ u = v = 0, & x \in \partial\Omega. \end{cases} \tag{3.10}$$

Now, we can also deduce that u and v are both bounded.

Lemma 3.4. *Suppose that (u, v) is a nonnegative classical solution of (3.10). If $u \not\equiv 0$, then $u \leq 1$ in $\overline{\Omega}$. Similarly, if $v \not\equiv 0$, then $v \leq 1$ in $\overline{\Omega}$.*

Proof. We only need to prove the boundedness of v. Proposition 2.1 implies that $v > 0$ in Ω if $v \not\equiv 0$. The second equation of system (3.10) can be transformed into the following form,

$$\begin{cases} (d_2 + 2a_{22}v)\Delta v + 2a_{22}|\nabla v|^2 + v(1 - a_2 u - v) = 0, & x \in \Omega, \\ v = 0, & x \in \partial\Omega. \end{cases} \tag{3.11}$$

Suppose on the contrary that there exists a point x_0 such that $v(x_0) = \max_{\overline{\Omega}} v(x) > 1$. Obviously, $x_0 \in \Omega$. So we have

$$\Delta v(x_0) \leq 0,\ \nabla v(x_0) = 0 \text{ and } v(x_0)(1 - a_2 u(x_0) - v(x_0)) \geq 0.$$

Since $v > 0$ in Ω, we obtain that $1 - a_2 u(x_0) - v(x_0) \geq 0$, that is, $1 \geq a_2 u(x_0) + v(x_0)$, a contradiction. □

If we restrict attention to the Dirichlet boundary conditions, we can establish the parameter ranges such that the system (3.10) has no coexisting solutions.

Theorem 3.5. *Suppose that (u, v) is a nonnegative classical solution of (3.10). If*

(i) $$a_1 > 1 > a_2, \qquad d_1 > d_2 \quad \text{and} \quad d_1 \geq d_2 + 2a_{22}$$

or

(ii) $$a_1 < 1 < a_2, \qquad d_1 < d_2 \quad \text{and} \quad d_2 \geq d_1 + 2a_{11},$$

then system (3.10) has no coexisting solutions.

Proof. (i) According to the proof of Theorem 3.2-(i), the following inequality still holds

$$\operatorname{div}\left[(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v)\frac{u}{v}\right] > 0,$$

where $w_1 = d_1 + a_{11}u$ and $w_2 = d_2 + a_{22}v$.

Now, we consider the following integral

$$\begin{aligned} &\int_\Omega \operatorname{div}\left[\left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\frac{u}{v}\right] \mathrm{d}x \\ &= \int_{\partial\Omega}\left(uv\frac{\partial w_1}{\partial \nu} - uv\frac{\partial w_2}{\partial \nu} + vw_1\frac{\partial u}{\partial \nu} - uw_2\frac{\partial v}{\partial \nu}\right)\frac{u}{v}\mathrm{d}S \\ &= \int_{\partial\Omega}\left(a_{11}u^2\frac{\partial u}{\partial \nu} - a_{22}u^2\frac{\partial v}{\partial \nu} + uw_1\frac{\partial u}{\partial \nu} - \left(d_2\frac{u^2}{v} + a_{22}u^2\right)\frac{\partial v}{\partial \nu}\right)\mathrm{d}S. \end{aligned}$$

It is easy to see that the function $\frac{u^2}{v}$ in the last term of the integrand does not make sense on $\partial\Omega$. So in such a case we cannot make calculations directly. Let

$$\Omega_\varepsilon = \{x \in \Omega \mid \operatorname{dist}(x, \partial\Omega) > \varepsilon\} \quad \text{for any small } \varepsilon > 0.$$

Since $(u, v) \in (C^1(\overline{\Omega}) \cap C^2(\Omega))^2$, we observe that

$$\big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\frac{u}{v} \in C^1(\overline{\Omega_\varepsilon}).$$

Then divergence theorem implies that

$$\begin{aligned}
&\int_\Omega \operatorname{div}\Big[\big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\frac{u}{v}\Big]\,\mathrm{d}x \\
&\quad= \lim_{\varepsilon\to 0}\int_{\Omega_\varepsilon} \operatorname{div}\Big[\big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\frac{u}{v}\Big]\,\mathrm{d}x \\
&\quad= \lim_{\varepsilon\to 0}\int_{\partial\Omega_\varepsilon}\left(a_{11}u^2\frac{\partial u}{\partial \nu} - a_{22}u^2\frac{\partial v}{\partial \nu} + uw_1\frac{\partial u}{\partial \nu} - \left(d_2\frac{u^2}{v} + a_{22}u^2\right)\frac{\partial v}{\partial \nu}\right)\mathrm{d}S.
\end{aligned}$$

Let

$$\begin{aligned}
I_1(\varepsilon) &= \int_{\partial\Omega_\varepsilon}\left(a_{11}u^2\frac{\partial u}{\partial \nu} - a_{22}u^2\frac{\partial v}{\partial \nu} + uw_1\frac{\partial u}{\partial \nu} - a_{22}u^2\frac{\partial v}{\partial \nu}\right)\mathrm{d}S, \\
I_2(\varepsilon) &= \int_{\partial\Omega_\varepsilon} d_2\frac{u^2}{v}\frac{\partial v}{\partial \nu}\mathrm{d}S.
\end{aligned}$$

Obviously, $I_1(\varepsilon)$ approaches zero as $\varepsilon \to 0$ in terms of Dirichlet boundary conditions. In order to deal with the term $I_2(\varepsilon)$, we write

$$V = \left\{\varphi(x) \in C^1(\overline{\Omega}) \mid \varphi(x) > 0, x \in \Omega;\ \varphi|_{\partial\Omega} = 0;\ \frac{\partial\varphi}{\partial\nu}\Big|_{\partial\Omega} < 0\right\}.$$

By Hopf's Lemma, we have $\frac{\partial u(x_0)}{\partial \nu} < 0$ and $\frac{\partial v(x_0)}{\partial \nu} < 0$ for any $x_0 \in \partial\Omega$, and thus $u \in V$ and $v \in V$. We now define

$$g(x) := \begin{cases} \dfrac{u(x)}{v(x)}, & x \in \Omega, \\ \dfrac{\partial u(x)}{\partial \nu}\Big/\dfrac{\partial v(x)}{\partial \nu}, & x \in \partial\Omega. \end{cases}$$

Then Lemma 2.4 in [18] shows that $g(x) \in C\big(\overline{\Omega}, (0, +\infty)\big)$. Therefore, we conclude that $I_2(\varepsilon)$ also approaches zero as $\varepsilon \to 0$. These considerations motivate that

$$\int_\Omega \operatorname{div}\Big[\big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\frac{u}{v}\Big]\,\mathrm{d}x = 0 \tag{3.12}$$

thanks to Lebesgue dominated convergence theorem and Dirichlet boundary conditions, a contradiction.

(ii) On one hand, it is obvious to see from Theorem 3.2-(ii) that

$$\operatorname{div}\Big[\big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\frac{v}{u}\Big] < 0, \tag{3.13}$$

due to $d_1 < d_2$, $d_2 \geq d_1 + 2a_{11}$ and Lemma 3.4.

On the other hand, we can deduce from the discussion on boundary integrals similar to (i) that

$$\int_\Omega \operatorname{div}\Big[\big(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\big)\frac{v}{u}\Big]\,\mathrm{d}x = 0. \tag{3.14}$$

Therefore, a contradiction can also be obtained, and the conclusion is valid. □

Remark 3.6. It is easy to see that the conditions of this theorem are the same as those of Theorem 3.2. In fact, since the equations in system (3.1) and (3.10) are the same, the conditions of Theorem 3.2 and 3.5 are given to ensure that the constructed auxiliary function is strictly positive or strictly negative within the region, which is independent of boundary conditions.

3.3 Robin boundary condition

In this subsection, we consider the following system

$$\begin{cases} \Delta[(d_1 + a_{11}u)u] + u(1 - u - a_1v) = 0, & x \in \Omega, \\ \Delta[(d_2 + a_{22}v)v] + v(1 - a_2u - v) = 0, & x \in \Omega, \\ \alpha_1 u + \beta_1 \dfrac{\partial u}{\partial \nu} = \alpha_2 v + \beta_2 \dfrac{\partial v}{\partial \nu} = 0, & x \in \partial\Omega, \end{cases} \tag{3.15}$$

where $\alpha_i > 0$, $\beta_i > 0$, $i = 1, 2$. Under this boundary conditions, the boundedness of u and v is also not difficult to obtain.

Lemma 3.7. *Suppose that (u, v) is a nonnegative classical solution of (3.15). If $u \not\equiv 0$, then $u \leq 1$ in $\overline{\Omega}$. Similarly, if $v \not\equiv 0$, then $v \leq 1$ in $\overline{\Omega}$.*

Proof. We only prove the previous statement. First, we can obtain that

$$\begin{cases} (d_1 + 2a_{11}u)\Delta u + 2a_{11}|\nabla u|^2 + u(1 - u - a_1v) = 0, & x \in \Omega, \\ \alpha_1 u + \beta_1 \dfrac{\partial u}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{3.16}$$

Suppose that there exists a point $x_0 \in \overline{\Omega}$, such that $u(x_0) = \max_{x\in\overline{\Omega}} u(x) > 1$.

(i) If $x_0 \in \Omega$, we have $\Delta u(x_0) \leq 0$, $\nabla v(x_0) = 0$ and $u(x_0)(1 - u(x_0) - a_1v(x_0)) \geq 0$. Since $u > 0$ in Ω, we obtain that $1 - u(x_0) - a_1v(x_0) \geq 0$, that is, $1 \geq u(x_0) + a_1v(x_0)$, a contradiction.

(ii) If $x_0 \in \partial\Omega$, then $u(x_0) > u(x)$ for all $x \in \Omega$. Thus we can see that $\frac{\partial u}{\partial \nu}(x_0) \geq 0$. Since $u > 0$ in $\overline{\Omega}$ by Remark 2.2, we have $\alpha_1 u(x_0) + \beta_1 \frac{\partial u}{\partial \nu}(x_0) > 0$, a contradiction. □

Theorem 3.8. *Suppose that (u, v) is a nonnegative classical solution of (3.15). If*

(i) $a_1 > 1 > a_2$, $d_1 > d_2$, $d_1 \geq d_2 + 2a_{22}$, $\alpha_1 \geq \beta_1$ *and* $\alpha_2 \leq \beta_2$

or

(ii) $a_1 < 1 < a_2$, $d_1 < d_2$, $d_2 \geq d_1 + 2a_{11}$, $\alpha_1 \leq \beta_1$ *and* $\alpha_2 \geq \beta_2$,

then system (3.15) has no coexisting solutions.

Proof. We only prove the first case. Now, we can still obtain

$$\operatorname{div}\left[(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v)\frac{u}{v}\right] > 0,$$

where $w_1 = d_1 + a_{11}u$ and $w_2 = d_2 + a_{22}v$.

Notice that $\frac{\partial u}{\partial \nu} = -\frac{\alpha_1}{\beta_1}u$, $\frac{\partial v}{\partial \nu} = -\frac{\alpha_2}{\beta_2}v$ in $\partial\Omega$. It consequently seems advisable to consider the following integral

$$\begin{aligned}
&\int_\Omega \operatorname{div}\left[\left(uv\nabla w_1 - uv\nabla w_2 + vw_1\nabla u - uw_2\nabla v\right)\frac{u}{v}\right]\mathrm{d}x \\
&= \int_{\partial\Omega}\left(a_{11}uv\frac{\partial u}{\partial \nu} - a_{22}uv\frac{\partial v}{\partial \nu} + vw_1\frac{\partial u}{\partial \nu} - uw_2\frac{\partial v}{\partial \nu}\right)\frac{u}{v}\mathrm{d}S \\
&= \int_{\partial\Omega}\left(-a_{11}\frac{\alpha_1}{\beta_1}u^3 + a_{22}\frac{\alpha_2}{\beta_2}u^2v - \frac{\alpha_1}{\beta_1}u^2w_1 + \frac{\alpha_2}{\beta_2}u^2w_2\right)\mathrm{d}S \\
&= \int_{\partial\Omega} u^2\left(-2a_{11}\frac{\alpha_1}{\beta_1}u + 2a_{22}\frac{\alpha_2}{\beta_2}v - d_1\frac{\alpha_1}{\beta_1} + d_2\frac{\alpha_2}{\beta_2}\right)\mathrm{d}S \\
&\le \int_{\partial\Omega} u^2\left(-2a_{11}\frac{\alpha_1}{\beta_1}u + 2a_{22}\frac{\alpha_2}{\beta_2} - d_1\frac{\alpha_1}{\beta_1} + d_2\frac{\alpha_2}{\beta_2}\right)\mathrm{d}S \\
&\le \int_{\partial\Omega} u^2\left(-2a_{11}\frac{\alpha_1}{\beta_1}u + 2a_{22} - d_1 + d_2\right)\mathrm{d}S \\
&\le 0,
\end{aligned}$$

due to Lemma 3.7, $\alpha_1 \ge \beta_1$, $\alpha_2 \le \beta_2$ and $d_1 \ge d_2 + 2a_{22}$, a contradiction. □

4 Existence of coexisting solutions

In this section, we will investigate the existence of coexisting solutions for system (3.1).

Theorem 4.1. *Let $a_1 < 1$ and $a_2 < 1$. Suppose that (u, v) is a nonnegative classical solution of (3.1). If $u \not\equiv 0$ and $v \not\equiv 0$, then*

$$u \equiv \frac{1-a_1}{1-a_1a_2} \quad \text{and} \quad v \equiv \frac{1-a_2}{1-a_1a_2}. \tag{4.1}$$

Proof. Recall from Lemma 3.1 that there exist $x_1, x_2 \in \overline{\Omega}$ such that

$$u(x_1) = \max_{x\in\overline{\Omega}} u(x) \triangleq M, \qquad u(x_2) = \min_{x\in\overline{\Omega}} u(x) \triangleq m,$$

and

$$1 - a_1v(x_2) \le m \le u(x) \le M \le 1 - a_1v(x_1) \quad \text{for all } x \in \overline{\Omega}. \tag{4.2}$$

Similarly, there exist $x_3, x_4 \in \overline{\Omega}$ such that

$$v(x_3) = \max_{x\in\overline{\Omega}} v(x) \triangleq M', \qquad v(x_4) = \min_{x\in\overline{\Omega}} v(x) \triangleq m',$$

and

$$1 - a_2u(x_4) \le m' \le v(x) \le M' \le 1 - a_2u(x_3) \quad \text{for all } x \in \overline{\Omega}. \tag{4.3}$$

We first prove $u \equiv \frac{1-a_1}{1-a_1a_2}$. Combining (4.2) with (4.3), we obtain

$$m \ge 1 - a_1v(x_2) \ge 1 - a_1(1 - a_2u(x_3)) \ge 1 - a_1 + a_1a_2m, \tag{4.4}$$

and

$$M \leq 1 - a_1 v(x_1) \leq 1 - a_1(1 - a_2 u(x_4)) \leq 1 - a_1 + a_1 a_2 M. \tag{4.5}$$

Notice that since $a_1 < 1$ and $a_2 < 1$, we have

$$\frac{1 - a_1}{1 - a_1 a_2} \leq m \leq u(x) \leq M \leq \frac{1 - a_1}{1 - a_1 a_2}. \tag{4.6}$$

Hence

$$u \equiv \frac{1 - a_1}{1 - a_1 a_2}.$$

Similarly, it can be proved that

$$\frac{1 - a_2}{1 - a_1 a_2} \leq m' \leq v(x) \leq M' \leq \frac{1 - a_2}{1 - a_1 a_2}. \tag{4.7}$$

Consequently,

$$v \equiv \frac{1 - a_2}{1 - a_1 a_2}.$$

This completes the proof. □

Remark 4.2. Here we only give sufficient conditions for the existence of nonzero constant solutions for the system under Neumann boundary conditions. In fact, for systems under the other two boundary conditions, it is easy to see that if there is a constant solution, it can only be the zero solution.

In addition, under the conditions of Theorem 4.1, we also selected a set of values and conducted numerical simulations for system (3.9), as shown in Figure 4.1. The simulation results show that species u and v tend to constant coexisting solutions $\left(\frac{1-a_1}{1-a_1a_2}, \frac{1-a_2}{1-a_1a_2}\right) \approx (0.33, 0.83)$.

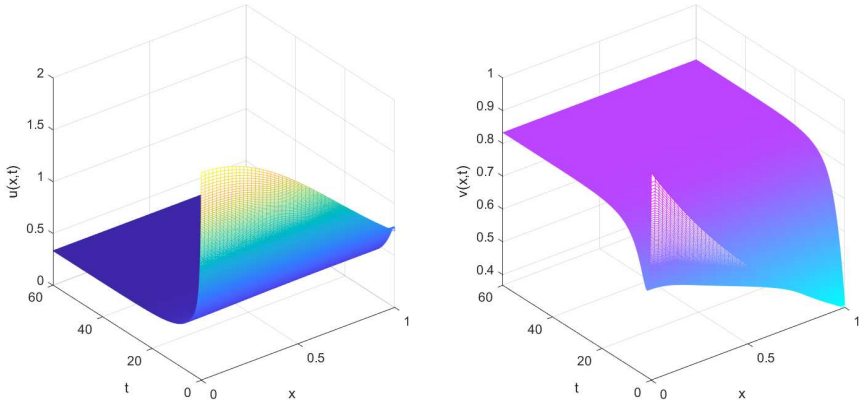

Figure 4.1: Numerical simulations for system (3.9) with $u_0(x) = 2e^{-x}$, $v_0(x) = e^{-x}$, $d_1 = 0.1, d_2 = 0.2, a_{11} = 0.1, a_{22} = 0.2$, $a_1 = 0.8$ and $a_2 = 0.5$.

Abstract. In this paper, we consider the following Kirchhoff Dirichlet problem with singular attractive term

$$\begin{cases} -\left(a+b\int_\Omega |\nabla u|^2 dx\right)\Delta u = u^{-\gamma}+\lambda f(u) & \text{in } \Omega, \\ u=0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is a smooth bounded domain in $\mathbb{R}^N$ $(N \geq 3)$, the parameters $a, b, \lambda, \gamma > 0$ and $f(u)$ is asymptotically linear reaction. In particular, we investigate both the strong singular case $(\gamma \geq 1)$ and the weak singular case $(0 < \gamma < 1)$ employing different techniques to reflect the distinct nature of each scenario. In the first case, ground state solutions are obtained via a direct minimizing methods, while in the latter case we combine variational theory with perturbation methods to prove the existence of ground state solutions for above Kirchhoff problem.

Keywords: positive solution, Kirchhoff Dirichlet problem, singularity, asymptotically linear reaction.

1 Introduction

Considering the following Kirchhoff Dirichlet problem

$$\begin{cases} -\left(a+b\int_\Omega |\nabla u|^2 dx\right)\Delta u = f(x,u) & \text{in } \Omega, \\ u=0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a smooth bounded domain in $\mathbb{R}^N$ $(N \geq 3)$, the parameters $a, b \geq 0$ and $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a continuous function. The equation (1.1) was first introduced by Kirchhoff [13] as

✉ Corresponding author. Email: math_chb@csu.edu.cn

an extension of the classical D'Alembert's wave equations for free vibration of elastic strings. It is worth mentioning that fundamental analysis approach was introduced by Lions in the pioneer work [21]. After then, the existence results for above equations have been widely investigated, we refer the reader to [5,6,9–12,14,18,19,23–26,30,31] and the references therein.

Very recently, there are some papers on the Kirchhoff Dirichlet problem involving singularity, see [15,16,20,22,27,28] and the references therein. For example, in [28], Wang and Yan consider a class of Kirchhoff Dirichlet problem with singularity and nonlinearity in a bounded domain:

$$\begin{cases} -\left(a+b\int_\Omega |\nabla u|^2 dx\right)\Delta u = \dfrac{f(x)}{u} - \mu u^p & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $1 < p < 2^* - 1$, $2^* = \frac{2N}{N-2}$, Ω is a smooth bounded domain in $\mathbb{R}^N (N \geq 3)$, the function $f(x) \in L^2(\Omega)$ is positive, and a, b, μ are real numbers. They using the approximation method, a unique positive solution is obtained.

In particular, in [20,22], the following Kirchhoff Dirichlet problem with singularity and Sobolev subcritical perturbation is considered:

$$\begin{cases} -\left(a+b\int_\Omega |\nabla u|^2 dx\right)\Delta u = u^p + \dfrac{\lambda}{u^\gamma} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $0 < p < 5$, $0 < \gamma < 1$, and existence of solutions was obtained via using variational methods. Later, Lei, Liao and Tang [16] extended main results in [20,22] from Sobolev subcritical case to Sobolev critical case $(p = 5)$:

$$\begin{cases} -\left(a+b\int_\Omega |\nabla u|^2 dx\right)\Delta u = u^5 + \dfrac{\lambda}{u^\gamma} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where Ω is a smooth bounded domain in $\mathbb{R}^3$, and λ is a real parameter, $\gamma \in (0,1)$ is a constant. Such problem may occur in various branches of mathematical physics. The authors obtain two positive solutions via the variational and perturbation methods. Moreover, in [15], Lei and Liao studied the multiplicity of solutions for above Kirchhoff Dirichlet problem with more general nonlinearity $f(x,u)$, instead of power term u^p. In addition, many scholars are also interested in the p-Laplacian type Kirchhoff equation with critical reactions [3,17].

To the best of our knowledge, for strong singular case $\gamma \geq 1$, the existence results of ground state solution has not been studied up to now. The study of ground state solutions was started in the seminal work of Berestycki and Lions [4] and Coleman, Glazer and Martin [8]. In the calculus of variations, the ground state solution is the function that minimizes a given energy functional. Thus in this paper we study the ground state solutions of Kirchhoff Dirichlet problem involving singular and asymptotically linear terms:

$$\begin{cases} -\left(a+b\int_\Omega |\nabla u|^2 dx\right)\Delta u = u^{-\gamma} + \lambda f(u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where Ω is a smooth bounded domain in $\mathbb{R}^N (N \geq 3)$, the parameters $a, b, \lambda, \gamma > 0$. The continuous function $f : \mathbb{R}^+ \mapsto \mathbb{R}^+, \mathbb{R}^+ = [0, +\infty)$ satisfies

(f_1) $\lim_{s\to\infty}\frac{f(s)}{s}=\theta$, for some $\theta\in(0,+\infty)$;

(f_2) the function $s\mapsto\frac{f(s)}{s}$ is non-increasing in $(0,+\infty)$.

The function $u(x)$ is called a weak solution of (1.2) if $0<u(x)\in H_0^1(\Omega)$ and for all $\varphi\in H_0^1(\Omega)$ it holds

$$(a+b\|u\|^2)\int_\Omega\nabla u\nabla\varphi dx-\lambda\int_\Omega f(u)\varphi dx-\int_\Omega u^{-\gamma}\varphi dx=0.$$

Define the function $G(t)$ as follows:

- for $0<\gamma<1$, $G(t)=\frac{(t^+)^{1-\gamma}}{1-\gamma}$, $t\in\mathbb{R}$;
- for $\gamma=1$, $G(t)=\begin{cases}\ln t, & t>0,\\ +\infty, & t=0;\end{cases}$ and for $\gamma>1$, $G(t)=\begin{cases}\frac{t^{1-\gamma}}{1-\gamma}, & t>0,\\ +\infty, & t=0.\end{cases}$

Let

$$f_0(t)=\begin{cases}f(t), & t\geq 0,\\ f(0), & t<0,\end{cases}\quad\text{and}\quad F(t)=\int_0^t f_0(s)ds.$$

Denote by δ_1 the first eigenvalue of $\left(-\Delta,H_0^1(\Omega)\right)$ [29] and set

$$\lambda_*=\frac{a\delta_1}{\theta}. \tag{1.3}$$

Now the main results can be described as follows.

Theorem 1.1. *Assume that $\gamma\geq 1$, the conditions (f_1)-(f_2) hold and*

$$D=\left\{u\in H_0^1(\Omega):\int_\Omega G(|u|)dx\in\mathbb{R}\right\}\neq\emptyset.$$

Then for every $\lambda\in(0,\lambda_*)$, there exists a positive ground state solution u_λ of (1.2). Moreover, u_λ is a global minimizer of the action functional I_λ, where

$$I_\lambda(u)=\frac{a}{2}\|u\|^2+\frac{b}{4}\|u\|^4-\lambda\int_\Omega F(u)dx-\int_\Omega G(|u|)dx.$$

Theorem 1.2. *Assume that $0<\gamma<1$ and the conditions (f_1)–(f_2) hold. Then for every $\lambda\in(0,\lambda_*)$, there exists a positive ground state solution $\tilde{u}_\lambda$ of (1.2). Moreover, $\tilde{u}_\lambda$ is a global minimizer of I_λ.*

Remark 1.3. (i) The set D in Theorem 1.1 is not closed as usual, see [1]. (ii) Theorems 1.1 extend main results in [15] from weak singular case $0<\gamma<1$ to strong singular case $\gamma\geq 1$. Moreover, following the ideas in [1,2], the methods in Theorem 1.2 to obtain global minimizer are more direct.

Notations: Throughout this paper, we make use of the following notations:

- The space $H_0^1(\Omega)$ is equipped with the norm $\|u\|^2=\int_\Omega|\nabla u|^2dx$, the norm in $L^p(\Omega)$ is denoted by $|\cdot|_p$;
- If A is a measurable set in $\mathbb{R}^{\mathbb{N}}$, we denote by $|A|$ the Lebesgue measure of A;
- $C,C_1,C_2,C_3,\ldots$, denote different positive constants ;

- Denote by d the distance function to the boundary;
- $u^+ = \max\{0, u\}$, $u_- = \max\{0, -u\}$.

The remainder of this paper is organized as follows. In Section 2, we consider the strong singular case and give the proof of Theorem 1.1. We consider the weak singular case and give the proof of Theorem 1.2 in Section 3.

2 The strong singular case: $\gamma \geq 1$

Since we are interested in positive solutions, we introduce the set

$$D^+ = \{u \in D : u \geq 0 \text{ a.e.} \quad \text{in } \Omega\}.$$

Now we show that $\inf_{u\in D} I_\lambda(u) = \inf_{u\in D^+} I_\lambda(u)$. In fact, it is easy to see that $\inf_{u\in D} I_\lambda(u) \leq \inf_{u\in D^+} I_\lambda(u)$. On the other hand, we have

$$\begin{aligned} I_\lambda(u) &= \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda\int_\Omega F(u)dx - \int_\Omega G(|u|)dx \\ &= \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda\int_{u<0} f(0)udx - \lambda\int_{u\geq 0} F(u)dx - \int_\Omega G(|u|)dx \\ &\geq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda\int_\Omega F(|u|)dx - \int_\Omega G(|u|)dx \\ &= I_\lambda(|u|) \geq \inf_{u\in D^+} I_\lambda(u), \quad \forall\, u \in D. \end{aligned}$$

Hence, $\inf_{u\in D} I_\lambda(u) = \inf_{u\in D^+} I_\lambda(u)$. This implies that a global minimum for $I_\lambda(u)$ exists if and only if there exists $v \in D^+$, such that $I_\lambda(v) = \inf_{u\in D^+} I_\lambda(u)$.

Now, we are in position to state the following lemma, which provides the existence of a global minimizer of $I_\lambda(u)$ for every $\lambda \in (0, \lambda_*)$.

Lemma 2.1. *Assume $\lambda \in (0, \lambda_*)$. Then, there exists $u_\lambda \in D^+$, such that*

$$I_\lambda(u_\lambda) = \inf_{u\in D^+} I_\lambda(u).$$

Proof. Take $\varepsilon > 0$, satisfies $\frac{\lambda(\theta+\varepsilon)}{a\delta_1} < 1$. From (f_1)–(f_2), for $\forall\, \varepsilon > 0$, there exist C_1, C_2, such that

$$\theta s \leq f(s) \leq (\theta+\varepsilon)s + C_1, \quad \forall\, s \geq 0, \tag{2.1}$$

$$\theta\frac{s^2}{2} \leq F(s) \leq \frac{\theta+\varepsilon}{2}s^2 + C_2 s, \quad \forall\, s \geq 0. \tag{2.2}$$

By (2.2), Sobolev embedding and Poincaré inequality, it follows that

$$\begin{aligned} I_\lambda(u) &\geq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda\int_\Omega \left(\frac{\theta+\varepsilon}{2}u^2 + C_2 u\right)dx - \int_\Omega G(|u|)dx \\ &\geq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \frac{\lambda(\theta+\varepsilon)}{2}\frac{\|u\|^2}{\delta_1} - C_3\|u\| - \int_\Omega G(|u|)dx \\ &= \frac{a}{2}\left(1 - \frac{\lambda(\theta+\varepsilon)}{a\delta_1}\right)\|u\|^2 + \frac{b}{4}\|u\|^4 - C_3\|u\| - \int_\Omega G(|u|)dx, \quad \forall\, u \in D^+. \end{aligned} \tag{2.3}$$

Now, we consider the following two cases:

Case i: $\gamma = 1$. By the inequality $\ln|u| \leq |u|$, (2.3) and Sobolev embedding, we deduce that

$$\begin{aligned} I_\lambda(u) &\geq \frac{a}{2}\left(1 - \frac{\lambda(\theta+\varepsilon)}{a\delta_1}\right)\|u\|^2 + \frac{b}{4}\|u\|^4 - C_3\|u\| - \int_\Omega \ln|u|dx \\ &\geq \frac{a}{2}\left(1 - \frac{\lambda(\theta+\varepsilon)}{a\delta_1}\right)\|u\|^2 + \frac{b}{4}\|u\|^4 - C_3\|u\| - \int_\Omega |u|dx \\ &\geq \frac{a}{2}\left(1 - \frac{\lambda(\theta+\varepsilon)}{a\delta_1}\right)\|u\|^2 + \frac{b}{4}\|u\|^4 - C_4\|u\|, \end{aligned}$$

which implies that $I_\lambda(u)$ is coercive in D^+. Let $\{u_n\} \subset D^+$ be a minimizing sequence, such that $I_\lambda(u_n) \to \inf_{u\in D^+} I_\lambda(u)$ as $n \to \infty$. Therefore, we may assume that $u_\lambda \in H_0^1(\Omega)$, such that

$$\begin{cases} u_n \rightharpoonup u_\lambda & \text{in } H_0^1(\Omega), \\ u_n \to u_\lambda & \text{in } L^p(\Omega), \quad p \in (0,6), \\ u_n \to u_\lambda & \text{a.e. in } \Omega. \end{cases} \tag{2.4}$$

Since $\{u_n\} \subset D^+$ one has $u_n \geq 0$ a.e. in Ω, thus $u_\lambda \geq 0$ a.e. in Ω. Moreover, since $u_n \to u_\lambda$ in $L^1(\Omega)$ there exists $h \in L^1(\Omega)$ such that $|u_n| \leq h$ a.e. in Ω. So, $\ln|u_n| \leq |u_n| \leq h$ a.e. in Ω, applying the Reverse Fatou's lemma, we have

$$-\infty < \limsup_{n\to\infty} \int_\Omega \ln|u_n|dx \leq \int_\Omega \limsup_{n\to\infty} \ln|u_n|dx = \int_\Omega \ln|u_\lambda|dx. \tag{2.5}$$

Note that if $u_\lambda = 0$ in a set of positive measure A, then $\int_\Omega \ln|u_\lambda|dx = \int_{\Omega\setminus A} \ln|u_\lambda|dx + \int_A \ln|u_\lambda|dx \to -\infty$, because $\ln|u_\lambda| = -\infty$ in A, it contradicts (2.5). Therefore, we obtain $u_\lambda > 0$ in Ω. Next, we show that the sequence $\{\int_\Omega G(|u_n|)dx\} = \{\int_\Omega \ln|u_n|dx\}$ is bounded, if not, we should have $-\int_\Omega \ln|u_n|dx \to +\infty$, then $\liminf_{n\to\infty} I_\lambda(u_n) = +\infty$, which is a contradiction with $\inf_{u\in D^+} I_\lambda(u) = \liminf_{n\to\infty} I_\lambda(u_n) \in \mathbb{R}$. This shows that $\{\int_\Omega G(|u_n|)dx\} = \{\int_\Omega \ln|u_n|dx\}$ is bounded. Then, we have $u_\lambda \in D^+$ and

$$\begin{aligned} \inf_{u\in D^+} I_\lambda(u) &= \liminf_{n\to\infty} I_\lambda(u_n) \\ &\geq \frac{a}{2}\|u_\lambda\|^2 + \frac{b}{4}\|u_\lambda\|^4 - \lambda\int_\Omega F(u_\lambda)dx - \limsup_{n\to\infty}\int \ln|u_n|dx \\ &\geq \frac{a}{2}\|u_\lambda\|^2 + \frac{b}{4}\|u_\lambda\|^4 - \lambda\int_\Omega F(u_\lambda)dx - \int_\Omega \ln|u_\lambda|dx = I_\lambda(u_\lambda) \geq \inf_{u\in D^+} I_\lambda(u). \end{aligned}$$

Thus, $I_\lambda(u_\lambda) = \inf_{u\in D^+} I_\lambda(u)$.

Case ii: $\gamma > 1$. From (2.3), we have

$$\begin{aligned} I_\lambda(u) &\geq \frac{a}{2}\left(1 - \frac{\lambda(\theta+\varepsilon)}{a\delta_1}\right)\|u\|^2 + \frac{b}{4}\|u\|^4 - C_3\|u\| - \frac{1}{1-\gamma}\int_\Omega |u|^{1-\gamma}dx \\ &> \frac{a}{2}\left(1 - \frac{\lambda(\theta+\varepsilon)}{a\delta_1}\right)\|u\|^2 + \frac{b}{4}\|u\|^4 - C_3\|u\|, \quad \forall u \in D^+, \end{aligned}$$

which implies that $I_\lambda(u)$ is coercive in D^+. Let $\{u_n\} \subset D^+$ be a minimizing sequence, such that $I_\lambda(u_n) \to \inf_{u\in D^+} I_\lambda(u)$ as $n \to \infty$. Therefore, we may assume that $0 \leq u_\lambda \in H_0^1(\Omega)$, such that (2.4) hold. Similar with Case i, we have $u_\lambda > 0$ and the sequence $\{\int_\Omega G(|u_n|)dx\} = \{\int_\Omega |u_n|^{1-\gamma}dx\}$ is bounded. By Fatou's lemma, one has

$$-\infty < \limsup_{n\to\infty} \int_\Omega \frac{1}{1-\gamma}|u_n|^{1-\gamma}dx \leq \int_\Omega \limsup_{n\to\infty} \frac{1}{1-\gamma}|u_n|^{1-\gamma}dx = \frac{1}{1-\gamma}\int_\Omega |u_\lambda|^{1-\gamma}dx,$$

which implies that $u_\lambda \in D^+$ and

$$\begin{aligned}\inf_{u\in D^+} I_\lambda(u) &= \liminf_{n\to\infty} I_\lambda(u_n)\\ &\geq \frac{a}{2}\|u_\lambda\|^2 + \frac{b}{4}\|u_\lambda\|^4 - \lambda\int_\Omega F(u_\lambda)dx - \limsup_{n\to\infty}\frac{1}{1-\gamma}\int_\Omega |u_n|^{1-\gamma}dx\\ &\geq \frac{a}{2}\|u_\lambda\|^2 + \frac{b}{4}\|u_\lambda\|^4 - \lambda\int_\Omega F(u_\lambda)dx - \int_\Omega \frac{1}{1-\gamma}|u_\lambda|^{1-\gamma}dx\\ &= I_\lambda(u_\lambda) \geq \inf_{u\in D^+} I_\lambda(u).\end{aligned}$$

Thus, $I_\lambda(u_\lambda) = \inf_{u\in D^+} I_\lambda(u)$. □

Proof of Theorem 1.1. Let u_λ be as in Lemma 2.1, we prove that u_λ is a solution of Eq. (1.2). For arbitrary $\varepsilon > 0$ and $\phi \in H_0^1(\Omega)$, $\phi \geq 0$ *in* Ω, to show that $u_\lambda + \varepsilon\phi \in D^+$, we divide the proof into two cases.

Case 1. $\gamma = 1$. Since $\ln(u) \leq u$ for all $u > 0$, and $u_\lambda \in D^+ \subset D$, then

$$-\infty < \int_\Omega \ln(u_\lambda) \leq \int_\Omega \ln(u_\lambda + \varepsilon\phi) \leq \int_\Omega (u_\lambda + \varepsilon\phi) < +\infty,$$

that is, $u_\lambda + \varepsilon\phi \in D^+$.

Case 2. $\gamma > 1$. Since $\gamma > 1, u_\lambda + \varepsilon\phi \geq u_\lambda > 0$, then

$$\int_\Omega |u_\lambda + \varepsilon\phi|^{1-\gamma}dx \leq \int_\Omega |u_\lambda|^{1-\gamma}dx < +\infty,$$

that is, $u_\lambda + \varepsilon\phi \in D^+$.

Thus, for $\gamma \geq 1$, we have

$$I_\lambda(u_\lambda + \varepsilon\phi) \geq I_\lambda(u_\lambda). \tag{2.6}$$

It follows from (2.6) that

$$\begin{aligned}&\frac{a}{2}(\|u_\lambda + \varepsilon\phi\|^2 - \|u_\lambda\|^2) - \lambda\int_\Omega (F(u_\lambda + \varepsilon\phi - F(u_\lambda))dx)\\ &+ \frac{b}{4}(\|u_\lambda + \varepsilon\phi\|^4 - \|u_\lambda\|^4) - \int_\Omega (G(u_\lambda + \varepsilon\phi) - G(u_\lambda))dx \geq 0.\end{aligned} \tag{2.7}$$

Dividing by $\varepsilon > 0$ and passing to the limit as $\varepsilon \to 0^+$ in (2.7), it gives

$$a\int_\Omega \nabla u_\lambda \nabla\phi dx + b\|u_\lambda\|^2\int_\Omega \nabla u_\lambda\nabla\phi dx - \lambda\int_\Omega f(u_\lambda)\phi dx - \int_\Omega u_\lambda^{-\gamma}\phi dx \geq 0. \tag{2.8}$$

Suppose for any $t > 0$, $tu_\lambda \in D^+$. Define $\psi \in C^1((0,+\infty),\mathbb{R})$ by $\psi(t) = I_\lambda(tu_\lambda)$. Obviously, ψ has a global minimum at $t = 1$, and so

$$0 = \psi'(1) = a\|u_\lambda\|^2 + b\|u_\lambda\|^4 - \lambda\int_\Omega f(u_\lambda)u_\lambda dx - \int_\Omega u_\lambda^{1-\gamma}dx. \tag{2.9}$$

Set $\Psi(x) = (u_\lambda(x) + \varepsilon\phi(x))^+$, $\forall\, \phi \in H_0^1(\Omega)$, $\varepsilon > 0$. From (2.8) and (2.9), it follows that

$$\begin{aligned}
0 &\le a\int_\Omega \nabla u_\lambda \nabla \Psi dx + b\|u_\lambda\|^2 \int_\Omega \nabla u_\lambda \nabla \Psi dx - \lambda \int_\Omega f(u_\lambda)\Psi dx - \int_\Omega u_\lambda^{-\gamma}\Psi dx \\
&= \int_{u_\lambda+\varepsilon\phi\ge 0} (a + b\|u_\lambda\|^2)\nabla u_\lambda \nabla (u_\lambda + \varepsilon\phi)dx \\
&\quad - \lambda \int_{u_\lambda+\varepsilon\phi\ge 0} f(u_\lambda)(u_\lambda+\varepsilon\phi)dx - \int_{u_\lambda+\varepsilon\phi\ge 0} u_\lambda^{-\gamma}(u_\lambda+\varepsilon\phi)dx \\
&= \int_\Omega [(a + b\|u_\lambda\|^2)\nabla u_\lambda \nabla (u_\lambda + \varepsilon\phi) - \lambda f(u_\lambda)(u_\lambda+\varepsilon\phi) - u_\lambda^{-\gamma}(u_\lambda+\varepsilon\phi)]dx \\
&\quad - \int_{u_\lambda+\varepsilon\phi<0} [(a + b\|u_\lambda\|^2)\nabla u_\lambda \nabla (u_\lambda + \varepsilon\phi) - \lambda f(u_\lambda)(u_\lambda+\varepsilon\phi) - u_\lambda^{-\gamma}(u_\lambda+\varepsilon\phi)]dx \qquad (2.10) \\
&\le \psi'(1) + \varepsilon \int_\Omega [(a + b\|u_\lambda\|^2)\nabla u_\lambda \nabla \phi - \lambda f(u_\lambda)\phi - u_\lambda^{-\gamma}\phi]dx \\
&\quad - \varepsilon \int_{u_\lambda+\varepsilon\phi<0} (a + b\|u_\lambda\|^2)\nabla u_\lambda \nabla \phi dx \\
&= \varepsilon \int_\Omega [(a + b\|u_\lambda\|^2)\nabla u_\lambda \nabla \phi - \lambda f(u_\lambda)\phi - \mu u_\lambda^{-\gamma}\phi]dx - \varepsilon(a + b\|u_\lambda\|^2)\int_{u_\lambda+\varepsilon\phi<0} \nabla u_\lambda \nabla \phi dx.
\end{aligned}$$

Since the measure of the domain of integration $|\{u_\lambda + \varepsilon\phi < 0\}| \to 0$ as $\varepsilon \to 0^+$, it follows that

$$\lim_{\varepsilon\to 0^+} \int_{u_\lambda+\varepsilon\phi<0} \nabla u_\lambda \nabla \phi dx = 0.$$

Therefore, dividing by $\varepsilon > 0$ and passing to the limit as $\varepsilon \to 0^+$ in (2.10), one sees that

$$0 \le (a + b\|u_\lambda\|^2)\int_\Omega \nabla u_\lambda \nabla \phi dx - \lambda \int_\Omega f(u_\lambda)\phi dx - \int_\Omega u_\lambda^{-\gamma}\phi dx.$$

By the arbitrariness of ϕ, this inequality also holds for $-\phi$, i.e.

$$(a + b\|u_\lambda\|^2)\int_\Omega \nabla u_\lambda \nabla \phi dx - \lambda \int_\Omega f(u_\lambda)\phi dx - \int_\Omega u_\lambda^{-\gamma}\phi dx = 0,$$

for every $\phi \in H_0^1(\Omega)$, which implies that u_λ is a solution of Eq. (1.2). □

3 The weak singular case: $0 < \gamma < 1$

Lemma 3.1. *If $u \in H_0^1(\Omega)$ is a global minimum of I_λ for some positive λ,then*

(a_1) *$u > 0$ a.e. in Ω;*

(a_2) *$u^{-\gamma}\varphi \in L^1$, $\forall\, \varphi \in H_0^1(\Omega)$.*

Proof. (a_1) Since u is a global minimum of I_λ, for $t \in [0,1]$, one has

$$\begin{aligned}
0 &\le \frac{I_\lambda(u + tu_-) - I_\lambda(u)}{t} \\
&= a\int_\Omega \nabla u \nabla u_- dx + b\|u\|^2 \int_\Omega \nabla u \nabla u_- dx + \frac{a}{2}t\|u_-\|^2 + bt\|u_-\|^4 \\
&\quad + \frac{b}{2}t\|u\|^2\|u_-\|^2 + bt^2\|u_-\|^2 \int_\Omega \nabla u \nabla u_- dx + \frac{b}{4}t^3\|u_-\|^3 \\
&\quad - \lambda \int_\Omega \frac{F(u + tu_-) - F(u)}{t}dx - \frac{1}{1-\gamma}\int_\Omega \frac{((u + tu_-)^+)^{1-\gamma} - (u^+)^{1-\gamma}}{t}dx.
\end{aligned} \qquad (3.1)$$

Notice that

$$\int_\Omega \frac{F(u+tu_-)-F(u)}{t}dx = \int_{u<0} \frac{F((1-t)u)-F(u)}{t}dx = -f(0)\int_{u<0} udx \geq 0, \tag{3.2}$$

$$\int_\Omega \frac{((u+tu_-)^+)^{1-\gamma}-(u^+)^{1-\gamma}}{t}dx = 0. \tag{3.3}$$

Combine (3.1), (3.2) and (3.3), we have

$$0 \leq -(a+b\|u\|^2)\|u_-\|^2 + \frac{a}{2}t\|u_-\|^2 + bt\|u_-\|^4 + \frac{b}{2}t\|u\|^2\|u_-\|^2 - bt^2\|u_-\|^4 + \frac{b}{4}t^3\|u_-\|^3.$$

As $t \to 0^+$, we obtain $\|u_-\|^2 \leq 0$, which implies that $u \geq 0$ a.e. in Ω.

Now we assume that there exists a set $A \subset \Omega$ of positive measure such that $u = 0$ for every $x \in A$. Thus we can choose a positive function $\varphi \in C_0^1(\bar{\Omega})$ such that for $t \in [0,1]$, we have $(u(x)+t\varphi(x))^{1-\gamma} \geq u(x)^{1-\gamma}$ a.e. in Ω. Notice that

$$\begin{aligned}\int_\Omega \frac{(u+t\varphi)^{1-\gamma}-u^{1-\gamma}}{t}dx &= \left(\int_{\Omega\setminus A}+\int_A\right)\frac{(u+t\varphi)^{1-\gamma}-u^{1-\gamma}}{t}dx \\ &\geq \int_A \frac{(u+t\varphi)^{1-\gamma}-u^{1-\gamma}}{t}dx = t^{-\gamma}\int_A \varphi^{1-\gamma}dx.\end{aligned}$$

From (3.1), one has

$$\begin{aligned}0 &\leq \frac{I_\lambda(u+t\varphi)-I_\lambda(u)}{t} \\ &\leq a\int_\Omega \nabla u\nabla\varphi dx + b\|u\|^2\int_\Omega \nabla u\nabla\varphi dx + \frac{a}{2}t\|\varphi\|^2 + bt\|\varphi\|^4 \\ &\quad + \frac{b}{2}t\|u\|^2\|\varphi\|^2 + bt^2\|\varphi\|^2\int_\Omega \nabla u\nabla\varphi dx + \frac{b}{4}t^3\|\varphi\|^3 \\ &\quad - \lambda\int_\Omega \frac{F(u+t\varphi)-F(u)}{t}dx - \frac{1}{1-\gamma}t^{-\gamma}\int_A \varphi^{1-\gamma}dx.\end{aligned} \tag{3.4}$$

As $t \to 0^+$, we obtain

$$\begin{aligned}&\frac{a}{2}t\|\varphi\|^2 + bt\|\varphi\|^4 + \frac{b}{2}t\|u\|^2\|\varphi\|^2 + bt^2\|\varphi\|^2\int_\Omega \nabla u\nabla\varphi dx \\ &\qquad + \frac{b}{4}t^3\|\varphi\|^3 - \lambda\int_\Omega \frac{F(u+t\varphi)-F(u)}{t}dx \to -\lambda\int_\Omega f(u)\varphi,\end{aligned}$$

and

$$-\frac{1}{1-\gamma}t^{-\gamma}\int_A \varphi^{1-\gamma}dx \to -\infty,$$

we know the right-hand of (3.4) goes to $-\infty$, which is a contradiction. Thus, $u > 0$ a.e. in Ω.
(a_2) If $\varphi \in H_0^1(\Omega)$ and t_n is a sequence in $[0,1]$, define

$$h_n(x) = \frac{[(u_n(x)+t_n\varphi(x))^+]^{1-\gamma}-u(x)^{1-\gamma}}{t_n}, \quad \text{a.e. } x \in \Omega,\ n \in \mathbb{N}.$$

In order to prove (a_2), it is enough to take $\varphi \in H_0^1(\Omega)$ with $\varphi \geq 0$. Fix a decreasing sequence $t_n \subseteq [0,1]$ with $\lim_{n\to+\infty} t_n = 0$, it follows that

$$h_n(x) = \frac{(u_n(x)+t_n\varphi(x))^{1-\gamma}-u(x)^{1-\gamma}}{t_n}, \tag{3.5}$$

are measurable non-negative functions and $t_n \subseteq [0,1]$ with $\lim_{n\to+\infty} h_n(x) = (1-\gamma)u(x)^{-\gamma}\varphi(x)$ for almost $x \in \Omega$. By Fatou's lemma, one has

$$(1-\gamma)\int_\Omega u^{-\gamma}\varphi dx \leq \liminf_{n\to+\infty}\int_\Omega h_n(x)dx. \tag{3.6}$$

From (3.5) and (3.6), we complete the proof of (a_2). □

As above, we are going to construct a minimum of I_λ under our assumptions. Set

$$C_+ = \{u \in C_0^1(\bar{\Omega}) : u(x) \geq 0 \quad \forall\, x \in \Omega\},$$

has a non-empty interior given by

$$\text{int}(C^+) = \left\{u \in C^+ : u(x) > 0, \forall\, x \in \Omega, \frac{\partial u}{\partial n}(x) < 0, \forall\, x \in \partial\Omega\right\}.$$

Lemma 3.2. *Assume that (f_1)–(f_2) hold and let λ_* be as in (1.3). Then, for any $\lambda \in (0,\lambda_*)$, there exists $\tilde{u}_\lambda \in H_0^1(\Omega)$ with the following properties*

(b_1) *$\tilde{u}_\lambda \geq c_\mu d(x)$ in Ω for some $c_\mu > 0$ (independent of λ);*

(b_2) *$I_\lambda(\tilde{u}_\lambda) = \inf_{u\in H_0^1(\Omega)} I_\lambda(u)$;*

(b_3) *$\tilde{u}_\lambda^{-\gamma}\varphi \in L^1, \forall\, \varphi \in H_0^1(\Omega)$.*

Proof. Choose a sequence $\{\varepsilon_n\} \subset [0,1]$ with $\lim_{n\to+\infty}\varepsilon_n = 0$. We consider the perturbed problem

$$\begin{cases} -\left(a + b\displaystyle\int_\Omega |\nabla u|^2 dx\right)\Delta u = \lambda f(u) + (u+\varepsilon_n)^{-\gamma} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.7}$$

which have variational structure. Indeed, if $G_n : \mathbb{R} \to \mathbb{R}$ is defined as

$$G_n(t) = \begin{cases} \frac{(t+\varepsilon_n)^{1-\gamma}}{1-\gamma}, & t \geq 0, \\ \varepsilon_n^{-\gamma}t + \frac{\varepsilon_n^{1-\gamma}}{1-\gamma}, & t < 0, \end{cases}$$

then $G_n'(t) = (t^+ + \varepsilon_n)^{-\gamma}$ for every $t \in \mathbb{R}$. The functional $I_n : H_0^1(\Omega) \to \mathbb{R}$

$$I_n(u) = \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda\int_\Omega F(u)dx - \int_\Omega G_n(u)dx$$

is well defined, sequentially weakly lower semi-continuous, coercive and Gâteaux differentiable in $H_0^1(\Omega)$. In particular,

$$I_n'(u)(\varphi) = (a + b\|u\|^2)\int_\Omega \nabla u\nabla\varphi dx - \lambda\int_\Omega f(u)\varphi dx - \int_\Omega (u^+ + \varepsilon_n)^{-\gamma}\varphi dx, \quad \forall\, u \in H_0^1(\Omega).$$

Therefore critical point of I_n turn out to be weak solution of (3.7). Let $u_n \in H_0^1(\Omega)$ such that $I_n(u_n) = \inf_{u\in H_0^1(\Omega)} I_n(u)$. From Lemma 3.1, $u_n > 0$ a.e. in Ω and is not zero, by the maximum principle, $u_n \in \text{int}(C_+)$. First, we prove that there exists a positive constant c_μ (independent n and λ), such that $u_n(x) \geq c_\mu d(x)$ for every $x \in \bar{\Omega}$. Consider the semilinear problem

$$\begin{cases} -\Delta u = 1 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

and denote by $\hat{u}$ its unique solution. By [7], we know that there exists a constant C such that $\hat{u}(x) \geq Cd(x)$, for every $x \in \bar{\Omega}$. Fix some positive number β, such that $\frac{\beta(a+b\beta^2\|\hat{u}\|^2)}{(\beta\|\hat{u}\|_\infty+\varepsilon_n)^{-\gamma}} < 1$. Then $\beta\hat{u}$ is a subsolution of (3.7). Indeed, if $\varphi \in H_0^1(\Omega)$, $\varphi \geq 0$, then

$$\begin{aligned}
&(a+b\|\beta\hat{u}\|^2)\int_\Omega \nabla(\beta\hat{u})\nabla\varphi dx - \lambda\int_\Omega f(\beta\hat{u})\varphi dx - \int_\Omega(\beta\hat{u}+\varepsilon_n)^{-\gamma}\varphi dx \\
&\leq (a+b\beta^2\|\hat{u}\|^2)\int_\Omega \beta\varphi dx - \int_\Omega(\beta\|\hat{u}\|_\infty+\varepsilon_n)^{-\gamma}\varphi dx \\
&= \int_\Omega[\beta(a+b\beta^2\|\hat{u}\|^2) - (\beta\|\hat{u}\|_\infty+\varepsilon_n)^{-\gamma}]\varphi dx \leq 0.
\end{aligned}$$

We have u_n is a supersolution of (3.7). Since the map $t \to \lambda\frac{f(t)}{t} + \frac{(t+\varepsilon_n)^{-\gamma}}{t}$ is decreasing in $(0,+\infty)$, then, $u_n \geq \beta\hat{u}$, hence, we obtain

$$u_n \geq c_\mu d(x). \tag{3.8}$$

Since u_n is a critical point of I_n, one has

$$(a+b\|u_n\|^2)\int_\Omega \nabla u_n\nabla\varphi dx = \lambda\int_\Omega f(u_n)\varphi dx + \int_\Omega(u_n+\varepsilon_n)^{-\gamma}\varphi dx, \tag{3.9}$$

for every $\varphi \in H_0^1(\Omega)$. Taking the test function $\varphi = u_n$, by (f_1), we obtain that

$$\begin{aligned}
(a+b\|u_n\|^2)\|u_n\|^2 &= \lambda\int_\Omega f(u_n)u_n dx + \int_\Omega(u_n+\varepsilon_n)^{-\gamma}u_n dx \\
&\leq \lambda\int_\Omega(\theta u_n^2 + C_5 u_n)dx + \int_\Omega u_n^{1-\gamma}dx \\
&\leq \frac{\lambda\theta}{\delta_1}\|u_n\|^2 + \lambda C_6\|u_n\| + C_7\|u_n\|^{1-\gamma}.
\end{aligned}$$

If $\|u_n\| \to +\infty$, as $n \to +\infty$, from above inequality, we have $0 < b \leq 0$, which is a contradiction. Thus, u_n is bounded in $H_0^1(\Omega)$. Therefore, there exist a subsequence (still denoted by u_n) and $u_0 \in H_0^1$ such that

$$\begin{cases}
u_n \rightharpoonup u_0 & \text{in } H_0^1(\Omega), \\
u_n \to u_0 & \text{in } L^p(\Omega), \quad p \in (0,6), \\
u_n \to u_0 & \text{a.e. in } \Omega.
\end{cases} \tag{3.10}$$

Now we prove the result with $\tilde{u}_\lambda = u_0$.

(b_1) It follows from (3.8). In particular, $u_0 > 0$ a.e. in Ω

(b_2) From (3.10), we have

$$\|u_0\|^2 \leq \liminf_{n\to\infty}\|u_n\|^2,$$

$$\int_\Omega F(u_n)dx \to \int_\Omega F(u_0)dx,$$

$$\int_\Omega G_n(u_n)dx \to \frac{1}{1-\gamma}\int_\Omega u_0^{1-\gamma}dx.$$

Thus we can deduce that $I_\lambda(u_0) \leq \liminf_{n\to\infty} I_n(u_n)$. Since u_n is a global minimum of I_n, we have

$$I_n(u_n) \leq I_n(|u|), \quad \forall\, u \in H_0^1(\Omega). \tag{3.11}$$

By passing to the limit as $n \to +\infty$, it gives

$$\begin{aligned} I_n(|u|) &= \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda \int_\Omega F(|u|)dx - \frac{1}{1-\gamma}\int_\Omega (|u|+\varepsilon_n)^{1-\gamma}dx \\ &\leq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda \int_\Omega F(|u|)dx - \frac{1}{1-\gamma}\int_\Omega |u|^{1-\gamma}dx = I_\lambda(|u|), \end{aligned} \tag{3.12}$$

and

$$\begin{aligned} I_\lambda(|u|) &= \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda \int_{\Omega_+} F(u)dx - \lambda \int_{\Omega_-} F(-u)dx \\ &\quad - \frac{1}{1-\gamma}\int_\Omega (u^+)^{1-\gamma}dx - \frac{1}{1-\gamma}\int_\Omega (u_-)^{1-\gamma}dx \\ &\leq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda \int_{\Omega_+} F(u)dx - \frac{1}{1-\gamma}\int_\Omega (u^+)^{1-\gamma}dx \\ &\leq \frac{a}{2}\|u\|^2 + \frac{b}{4}\|u\|^4 - \lambda \int_{\Omega_+} F(u)dx - \lambda f(0)\int_{\Omega_-} udx - \frac{\int_\Omega (u^+)^{1-\gamma}dx}{1-\gamma} = I_\lambda(u). \end{aligned} \tag{3.13}$$

By putting together (3.11), (3.12) and (3.13), we obtain that

$$I_\lambda(u_0) \leq \liminf_{n\to\infty} I_n(u_n) \leq \liminf_{n\to\infty} I_n(|u_n|) \leq I_\lambda(|u|) \leq I_\lambda(u).$$

(b_3) Since u_0 is a global minimum of I_λ, from Lemma 3.1-(a_2), we obtain that $\tilde{u}_0^{-\gamma}\varphi \in L^1, \forall\ \varphi \in H_0^1(\Omega)$. □

Proof of the Theorem 1.2. Choose $\varphi \in H_0^1(\Omega) \cap L^\infty(\Omega)$, from (3.11) we get

$$\int_\Omega \nabla u_n \nabla \varphi dx \to \int_\Omega \nabla u_0 \nabla \varphi dx,$$

$$\int_\Omega f(u_n)\varphi dx \to \int_\Omega f(u_0)\varphi dx,$$

$$(u_n+\varepsilon_n)^{-\gamma}\varphi \to u_0^{-\gamma}\varphi \quad \text{a.e. in } \Omega.$$

By (3.8), one has

$$|(u_n+\varepsilon_n)^{-\gamma}\varphi| \leq u_n^{-\gamma}|\varphi| \leq c_\mu^{-\gamma} d(x)^{-\gamma}\|\varphi\|_\infty \in L^1(\Omega).$$

By the Lebesgue dominated convergence theorem, we have

$$\int_\Omega (u_n+\varepsilon_n)^{-\gamma}\varphi dx \to \int_\Omega u_0^{-\gamma}\varphi dx.$$

Thus, according to (3.9), we deduce that

$$(a+b\|u_0\|^2)\int_\Omega \nabla u_0 \nabla \varphi dx = \lambda \int_\Omega f(u_0)\varphi dx + \int_\Omega u_0^{-\gamma}\varphi dx. \tag{3.14}$$

Let $0 \leq \varphi \in H_0^1(\Omega)$ and fix $\varepsilon > 0$, taking the test function $\varphi_\varepsilon = \frac{\varphi}{1+\varepsilon\varphi} \in H_0^1(\Omega) \cap L^\infty(\Omega)$, we have

$$(a+b\|u_0\|^2)\int_\Omega \nabla u_0 \frac{\nabla \varphi}{(1+\varepsilon\varphi)^2}dx = \lambda \int_\Omega f(u_0)\frac{\varphi}{1+\varepsilon\varphi}dx + \int_\Omega u_0^{-\gamma}\frac{\varphi}{1+\varepsilon\varphi}dx.$$

By the Lebesgue dominated convergence theorem and Lemma 3.2, as $\varepsilon \to 0^+$, we obtain

$$\int_\Omega \nabla u_0 \frac{\nabla \varphi}{(1+\varepsilon\varphi)^2} dx \to \int_\Omega \nabla u_0 \nabla \varphi dx,$$
$$\int_\Omega u_0^{-\gamma} \frac{\varphi}{1+\varepsilon\varphi} dx \to \int_\Omega u_0^{-\gamma} \varphi dx,$$
$$\int_\Omega f(u_0) \frac{\varphi}{1+\varepsilon\varphi} dx \to \int_\Omega f(u_0) \varphi dx,$$

which imply equality (3.14). Therefore, the result of theorem 1.2 follows at once, by recalling that for any $\varphi \in H_0^1(\Omega)$, $\varphi = \varphi^+ - \varphi_-$. □

Outstanding researcher, author, and educator of differential equations, Theodore A. Burton passed away on January 5, 2025, in his 90th year.

"Ted", as he was known to many, was a renowned personage of the community of differential equation people. He worked in the theory of ordinary, functional, partial differential equations, integral equations, and fractional differential equations. He enriched several branches of these fields, especially those of stability, periodicity, and oscillations, with fundamental achievements. He published more than 220 scientific papers in mathematical journals devoted to research in the theory of ordinary, integral, functional and fractional differential equations. He is the author of five monographs and also the editor of two books on mathematical biology. According to Mathematical Reviews, his works have been cited more than 2000 times by other leading authors and researchers, Google Scholar gives more than 9000 citations.

Born on September 7, 1935 in Longton, Kansas, USA, Theodore Allen Burton completed his elementary and high school in the Cascade Mountains of the state of Washington. In 1959, he graduated from Washington State College with a Bachelor of Science with Honors. On August 5, 1961, he married Fredda Jean Anderson.

At Washington State University, Ted earned both a Master's degree (1962) and his Ph.D. (1964), the latter under the direction of Professor Donald W. Bushaw. After completing his Ph.D., Ted accepted an academic position at the University of Alberta in Edmonton, Canada, where he worked for two years. In 1966, he joined the faculty of Southern Illinois University at Carbondale (SIUC) as an Associate Professor of Mathematics, and quickly contributed to the development of the doctoral program in Mathematics as led by J. M. H. Olmsted. Often referred to as the "Bear", perhaps because his wife, Fredda, called him "Mister Bear" and because of his features at the time (a bit rotund and a bushy beard). Ted attracted students to his research interests in differential equations early on. In fact, his first three Ph.D. students, all named John, were among the first to receive Ph.D.s in Mathematics from SIUC; there were only two earlier graduates of the program.

✉Corresponding author. Email: krisztin@math.u-szeged.hu

According to Ted's own assertion, one of his primary achievements in academia that gave him the most pleasure was his success at mentoring doctoral students. In all, he supervised thirteen young mathematicians who earned Ph.D.s in mathematics, each of whom enjoyed a successful career of their own as university professors. In addition to these thirteen students, the Mathematics Genealogy Project lists nine other Mathematical descendants of Ted. Speaking of descendants, Bushaw was a student of Solomon Lefschetz, not a bad lineage for Ted's students.

In 1998, Ted retired from teaching at SIUC and was immediately named Emeritus Professor. He relocated to the state of Washington and founded the Northwest Research Institute, where he continued doing research. He remained active as a plenary speaker at multiple international conferences.

Ted's activity in teaching and research was international in scope. Twice he was awarded a Fulbright senior scholarship to Eastern Europe, once at the University of Szeged and later at the Technical University of Budapest. He also held research appointments at the University of Florence and the University of Madrid. He lectured at more than eighty conferences around the world. He served on the editorial boards of multiple international mathematics journals.

He was one of the founding Editors-in-Chief (along with László Hatvani of the University of Szeged, Hungary) of the *Electronic Journal of Qualitative Theory of Differential Equations (EJQTDE)*, the first volume of which appeared in 1998. Ted was of the opinion that mathematical journals were too expensive, and as a consequence, some mathematical institutes were not able to ensure that new scientific information was readily available to their researchers. He wanted to start a new mathematical journal that would be free to anyone wishing to see its contents. Thus, the EJQTDE was born.

Ted loved the EJQTDE. He once said that, as one of the Editors-in-Chief, he read every paper before it appeared to ensure that there was nothing written that might make the Journal liable in any way. The editorial leadership of EJQTDE has since transitioned to Jeff Webb in 2012 and Tibor Krisztin in 2015. True to Ted's own standards with respect to scholarly publication, EJQTDE is a diamond open-access journal, meaning that no charges and fees to either the reader or the author. Today, according to several academic journal rankings, EJQTDE is a high quality journal in the field of differential equations.

Ted's own research embraced several different aspects of differential equations. During his doctoral years he studied the Liénard equation, a natural nonlinear generalization of the damped linear oscillator equation. Of primary interest, he showed that solutions of the nonlinear equation share properties similar to those of solutions to the linear oscillator equation.

Ted had a lifelong interest in stability theory and in Lyapunov's second (direct) method in particular. He felt that his most interesting contributions were in the construction of some explicit Lyapunov functions and functionals. It is clear that he contributed significantly to the theoretical foundations of Lyapunov theory and furthered the development of the direct method as well. Some of his early work was on the boundedness and stability of solutions of second-order nonlinear equations. This included his work on the Liénard equation and other results on the oscillation of nonlinear equations. He was an advocate of applying the Krasnosel'skii fixed point theorem for a mapping that is a sum of a compact map and a contraction map. In the last few years of his life, Ted became especially interested in various aspects of fractional differential equations.

The Bear loved mathematics and passed that love on to his students. His influence on them was profound; he was their mentor, their friend, and their colleague all at once.

Abstract. We establish the global existence of strong solutions to the nonhomogeneous incompressible magnetohydrodynamics (MHD) equations in a thin three-dimensional domain $\Omega = \mathbb{R}^2 \times (0,\epsilon)$, with $\epsilon \in (0,1]$, subject to Dirichlet boundary conditions on the top and bottom boundaries. Global well-posedness may hold for large initial data, provided the vertical thickness ϵ is sufficiently small. Moreover, when $\epsilon \to 0^+$, both the velocity and magnetic field tend to vanish away from the initial time. The analysis is based on *a priori* H^2 estimates of the solutions, with particular attention to the dependence on the vertical parameter ϵ.

Keywords: MHD system, thin domains, global existence.

2020 Mathematics Subject Classification: 35Q35, 76D03, 76W05.

1 Introduction

This work investigates nonhomogeneous incompressible magnetohydrodynamic (MHD) flows in thin 3D domains. The equations involve a coupling between the nonhomogeneous Navier–Stokes system and the Maxwell equations in $Q := \Omega \times (0,\infty)$, where $\Omega := \mathbb{R}^2 \times (0,\epsilon)$, with $0 < \epsilon \leq 1$, is a thin domain of $\mathbb{R}^3$. The governing equations, described extensively in textbooks such as [8,13,20], are as follows:

$$\begin{cases} \rho \boldsymbol{u}_t + \rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u} - \mu\Delta\boldsymbol{u} + \nabla\left(P + \frac{1}{2}|\boldsymbol{b}|^2\right) = (\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, \\ \boldsymbol{b}_t + (\boldsymbol{u}\cdot\nabla)\boldsymbol{b} - \eta\Delta\boldsymbol{b} = (\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, \\ \rho_t + \boldsymbol{u}\cdot\nabla\rho = 0, \\ \operatorname{div}\boldsymbol{u} = 0, \quad \operatorname{div}\boldsymbol{b} = 0. \end{cases} \tag{1.1}$$

✉Corresponding author. Email: felipe.wcruz@ufpe.br

Here, $\boldsymbol{u}(\boldsymbol{x},t) \in \mathbb{R}^3$ and $\boldsymbol{b}(\boldsymbol{x},t) \in \mathbb{R}^3$ denote the velocity and magnetic field of the fluid at each point $(\boldsymbol{x},t) \in Q$, respectively. The real-valued functions $\rho(\boldsymbol{x},t) \in \mathbb{R}^+$ and $P(\boldsymbol{x},t) \in \mathbb{R}$ represent the fluid density and hydrostatic pressure, respectively. The quantity $|\boldsymbol{b}|^2/2$ corresponds to the *magnetic pressure*. Accordingly, we define the total pressure of the fluid as $p := P + \frac{1}{2}|\boldsymbol{b}|^2$. The positive constants μ and η denote the viscosity and the resistivity coefficient, respectively. The latter is inversely proportional to the electrical conductivity and serves as the magnetic diffusivity of the magnetic field.

We complete the system (1.1) with the following initial and boundary conditions:

$$\begin{cases} (\rho, \boldsymbol{u}, \boldsymbol{b})\,\big|_{t=0} = (\rho_0, \boldsymbol{u}_0, \boldsymbol{b}_0) & \text{in } \Omega, \\ (\boldsymbol{u}(\boldsymbol{x},t), \boldsymbol{b}(\boldsymbol{x},t)) = (\boldsymbol{0}, \boldsymbol{0}) & \text{for all } (\boldsymbol{x},t) \in \Gamma \times (0,\infty), \end{cases} \tag{1.2}$$

where $\Gamma := \{(x_1, x_2, x_3) \,/\, (x_1, x_2) \in \mathbb{R}^2, x_3 = 0 \text{ or } x_3 = \epsilon\}$.

The magnetohydrodynamic (MHD) equations with variable density have been studied extensively in recent years; see [1,9,14,19,25] and the references therein (see also [3,4,6,10–12] for further results concerning the MHD equations). These results are closely related to those obtained for the variable-density Navier-Stokes equations. The study of the classical Navier–Stokes system in thin domains was initiated by Raugel and Sell in [22] and subsequently generalized in several directions; see, for example, [16] and the references therein. The first work addressing the variable-density Navier-Stokes equations in thin domains was carried out by Liao in [18].

In this work, we show that results analogous to those of Liao [18] are valid for the system (1.1)–(1.2). Specifically, we prove that global well-posedness may be achieved for large initial data when the vertical thickness ϵ is sufficiently small. For additional related work on fluid mechanics equations in thin domains, see, for instance, [5,7,17,23,24].

The paper is organized as follows. In Section 2, we introduce the basic notation and state the main result. In Section 3, we provide the proof of our main theorem (see Theorem 2.6 below).

2 Preliminaries and main result

In this section, we introduce the function spaces, definitions, and the main result that will be used throughout this work.

2.1 Functional framework

Throughout this paper, we employ the standard Lebesgue space $L^p(\Omega)$, for $1 \le p \le \infty$, and the Sobolev space

$$W^{m,p}(\Omega) := \left\{ f \in L^p(\Omega) \,:\, \|\partial^k f\|_p < \infty \text{ for all } |k| \le m \right\}, \quad m \in \mathbb{N} \cup \{0\},$$

with norms denoted by $\|\cdot\|_p$ and $\|\cdot\|_{W^{m,p}}$, respectively. In particular, we denote the L^2 norm and the L^2 inner product by $\|\cdot\|$ and $\langle\cdot,\cdot\rangle$, respectively.

Corresponding Sobolev spaces of vector-valued functions are denoted in boldface. For example, we write $\boldsymbol{L}^2(\Omega) := (L^2(\Omega))^n$ and $\boldsymbol{W}^{m,p}(\Omega) := (W^{m,p}(\Omega))^n$, where $n \in \mathbb{N}$.

Furthermore, we denote by $\boldsymbol{W}_0^{m,p}(\Omega)$ the closure of $\boldsymbol{C}_0^\infty(\Omega)$ in $\boldsymbol{W}^{m,p}(\Omega)$. When $p = 2$, we set

$$\boldsymbol{H}^m(\Omega) := \boldsymbol{W}^{m,2}(\Omega) \quad \text{and} \quad \boldsymbol{H}_0^m(\Omega) := \boldsymbol{W}_0^{m,2}(\Omega).$$

We define

$$\boldsymbol{\mathcal{V}}(\Omega) := \{\boldsymbol{v} \in \boldsymbol{C}_0^\infty(\Omega) \,:\, \operatorname{div} \boldsymbol{v} = 0 \text{ in } \Omega\},$$

and denote by $\boldsymbol{H}$ and $\boldsymbol{V}$ the closures of $\boldsymbol{\mathcal{V}}(\Omega)$ in $\boldsymbol{L}^2(\Omega)$ and $\boldsymbol{H}_0^1(\Omega)$, respectively.

Let X be a Banach space and $0 < T \leq \infty$. We denote by $L^p(0,T;X)$, or alternatively $L^p_T(X)$, the Banach space of X-valued (equivalence classes of) functions defined almost everywhere on $[0,T]$ that are L^p-integrable in the sense of Bochner. The associated norm is denoted by $\|\cdot\|_{L^p_T(X)}$.

We will frequently work with spaces of the form $L^p(0,T;X)$ where $X = \boldsymbol{W}^{m,q}(\Omega)$. In such cases, for any $\boldsymbol{v} \in L^p(0,T;\boldsymbol{W}^{m,q}(\Omega))$, the notation $\boldsymbol{v}(t)$ refers to the spatial function $\boldsymbol{v}(\cdot,t)$. We also use the notation $C^k([0,T);X)$ for the space of k times continuously differentiable functions on $[0,T)$ with values in X. Moreover, as usual, the letters $C, K, C_1, K_1, \ldots$ are positive constants, independents of $(\rho, \boldsymbol{u}, \boldsymbol{b})$, but their values may change from line to line.

Notation

As usual, we set

$$\|(\varphi,\psi)\|_X^2 := \|\varphi\|_X^2 + \|\psi\|_X^2.$$

In addition, we introduce the pair $\boldsymbol{z}(t) := (\boldsymbol{u}(t), \boldsymbol{b}(t))$ with initial data $\boldsymbol{z}_0 := \boldsymbol{z}(0) = (\boldsymbol{u}_0, \boldsymbol{b}_0)$, and the following norms:

$$\begin{aligned}
\|\boldsymbol{z}(t)\|^2 &:= \|\boldsymbol{u}(t)\|^2 + \|\boldsymbol{b}(t)\|^2, & \|\boldsymbol{z}_t(t)\|^2 &:= \|\boldsymbol{u}_t(t)\|^2 + \|\boldsymbol{b}_t(t)\|^2,\\
\|\nabla\boldsymbol{z}(t)\|^2 &:= \|\nabla\boldsymbol{u}(t)\|^2 + \|\nabla\boldsymbol{b}(t)\|^2, & \|\Delta\boldsymbol{z}(t)\|^2 &:= \|\Delta\boldsymbol{u}(t)\|^2 + \|\Delta\boldsymbol{b}(t)\|^2,\\
\|\nabla^2\boldsymbol{z}(t)\|^2 &:= \|\nabla^2\boldsymbol{u}(t)\|^2 + \|\nabla^2\boldsymbol{b}(t)\|^2, & \|\nabla\boldsymbol{z}_t(t)\|^2 &:= \|\nabla\boldsymbol{u}_t(t)\|^2 + \|\nabla\boldsymbol{b}_t(t)\|^2.
\end{aligned}$$

2.2 Auxiliary results

Following the approach in [18, Theorem 1.1], we obtain the following result concerning strong solutions to the system (1.1)–(1.2).

Theorem 2.1. *Assume that the initial data $(\rho_0, \boldsymbol{u}_0, \boldsymbol{b}_0)$ satisfy*

$$0 < \alpha \leq \rho_0(\boldsymbol{x}) \leq \beta < \infty \quad \text{in } \Omega, \text{ with } \alpha, \beta \in \mathbb{R}^+, \tag{2.1}$$

$$\boldsymbol{u}_0,\, \boldsymbol{b}_0 \in \boldsymbol{V}. \tag{2.2}$$

Then, there exists a time $T^* > 0$ and a unique strong solution $(\rho, \boldsymbol{u}, p, \boldsymbol{b})$ in $\Omega \times [0,T^*]$ for the problem (1.1)–(1.2) satisfying

$$\begin{gathered}
\alpha \leq \rho(x,t) \leq \beta,\\
\boldsymbol{u},\, \boldsymbol{b} \in L^\infty(0,T^*;\boldsymbol{V}) \cap L^2(0,T^*;\boldsymbol{V} \cap \boldsymbol{H}^2(\Omega)),\\
\nabla\boldsymbol{u},\, \nabla\boldsymbol{b} \in L^2(0,T^*;\boldsymbol{L}^\infty(\Omega) \cap \boldsymbol{W}^{1,6}(\Omega)),\\
\boldsymbol{u}_t,\, \boldsymbol{b}_t \in L^2(0,T^*;\boldsymbol{H}),\\
\nabla p \in L^\infty(0,T^*;\boldsymbol{L}^2(\Omega)) \cap L^2(0,T^*;\boldsymbol{L}^6(\Omega)).
\end{gathered}$$

Moreover, if $\boldsymbol{u}_0,\, \boldsymbol{b}_0 \in \boldsymbol{V} \cap \boldsymbol{H}^2(\Omega)$, then the unique solution satisfies

$$\boldsymbol{u},\, \boldsymbol{b} \in L^\infty(0,T^*;\boldsymbol{V} \cap \boldsymbol{H}^2(\Omega)) \quad \text{and} \quad \boldsymbol{u}_t,\, \boldsymbol{b}_t \in L^\infty(0,T^*;\boldsymbol{H}) \cap L^2(0,T^*;\boldsymbol{V}).$$

We will show that the unique solution to the problem (1.1)–(1.2) exists globally in time, provided that the initial data $\boldsymbol{u}_0$ and $\boldsymbol{b}_0$ satisfy the "smallness" condition

$$\epsilon^{\frac{1}{2}}\left(\|\nabla \boldsymbol{u}_0\|^2+\|\nabla \boldsymbol{b}_0\|^2\right)^{\frac{1}{2}} \leq c_0, \tag{2.3}$$

for some constant $c_0>0$ sufficiently small, depending only on α and β.

To this end, the following estimates will be instrumental.

Lemma 2.2 (See [18], Lemma 1.6, p. 174)**.** *If $\boldsymbol{v} \in \boldsymbol{H}_0^1(\Omega)$, then the following Poincaré and Sobolev's inequalities hold:*

$$\|\boldsymbol{v}\| \leq \epsilon\|\partial_3 \boldsymbol{v}\|, \qquad \|\boldsymbol{v}\|_6 \leq C\|\nabla \boldsymbol{v}\|.$$

Remark 2.3. Observe that if $\boldsymbol{u}_0, \boldsymbol{b}_0$ satisfy (2.2)–(2.3), then

$$\begin{aligned}
&\|\boldsymbol{u}_0\|\|\nabla \boldsymbol{u}_0\| \leq \epsilon\|\partial_3 \boldsymbol{u}_0\|\|\nabla \boldsymbol{u}_0\| \leq c_0^2, \qquad \|\boldsymbol{u}_0\|\|\nabla \boldsymbol{b}_0\| \leq \epsilon\|\partial_3 \boldsymbol{u}_0\|\|\nabla \boldsymbol{b}_0\| \leq c_0^2,\\
&\|\boldsymbol{b}_0\|\|\nabla \boldsymbol{u}_0\| \leq \epsilon\|\partial_3 \boldsymbol{b}_0\|\|\nabla \boldsymbol{u}_0\| \leq c_0^2, \qquad \|\boldsymbol{b}_0\|\|\nabla \boldsymbol{b}_0\| \leq \epsilon\|\partial_3 \boldsymbol{b}_0\|\|\nabla \boldsymbol{b}_0\| \leq c_0^2.
\end{aligned}$$

In particular, we have

$$\left(\|\boldsymbol{u}_0\|^2+\|\boldsymbol{b}_0\|^2\right)\left(\|\nabla \boldsymbol{u}_0\|^2+\|\nabla \boldsymbol{b}_0\|^2\right) \leq 4c_0^4.$$

Remark 2.4. From smallness condition (2.3), applying the Poincaré's inequality in the vertical direction on $\boldsymbol{u}_0$ and $\boldsymbol{b}_0$, we get the following smallness assumption:

$$\|\boldsymbol{u}_0\| \leq \epsilon\|\partial_3 \boldsymbol{u}_0\| \leq \epsilon\|\nabla \boldsymbol{u}_0\| \leq c_0\epsilon^{\frac{1}{2}} \quad \text{and} \quad \|\boldsymbol{b}_0\| \leq \epsilon\|\partial_3 \boldsymbol{b}_0\| \leq \epsilon\|\nabla \boldsymbol{b}_0\| \leq c_0\epsilon^{\frac{1}{2}}.$$

Remark 2.5. The "smallness" assumption (2.3) closely resembles the one proposed in [21]:

$$\|\boldsymbol{u}_0\|\|\nabla \boldsymbol{u}_0\| \leq \vartheta, \quad \text{with } \vartheta>0 \text{ sufficiently small.}$$

In fact, from Remark 2.2, we have

$$\|\boldsymbol{u}_0\|\|\nabla \boldsymbol{u}_0\| \leq c_0^2 \quad \text{and} \quad \|\boldsymbol{b}_0\|\|\nabla \boldsymbol{b}_0\| \leq c_0^2.$$

Therefore, under the smallness condition

$$\|\boldsymbol{u}_0\|\|\nabla \boldsymbol{u}_0\|+\|\boldsymbol{b}_0\|\|\nabla \boldsymbol{b}_0\| \leq 2c_0^2,$$

and following the approach in [21], we conclude that the strong solution given in Theorem 2.1 is global in time (i.e., $T^*=T$, and T could be $+\infty$).

2.3 Statement of the main result

Initially, we define

$$\begin{aligned}
\mathcal{U}(t) &:= \left\|(\boldsymbol{u},\boldsymbol{b})\right\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}+\left\|(\sqrt{\mu}\,\nabla \boldsymbol{u},\sqrt{\eta}\,\nabla \boldsymbol{b})\right\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))},\\
\mathcal{V}(t) &:= \left\|(\nabla \boldsymbol{u},\nabla \boldsymbol{b})\right\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}+\left\|(\boldsymbol{u}_t,\boldsymbol{b}_t,\Delta \boldsymbol{u},\Delta \boldsymbol{b})\right\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))},\\
\mathcal{W}(t) &:= \left\|(\boldsymbol{u}_t,\boldsymbol{b}_t,\nabla^2 \boldsymbol{u},\nabla^2 \boldsymbol{b},\nabla p)\right\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}+\left\|(\nabla \boldsymbol{u}_t,\nabla \boldsymbol{b}_t)\right\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))},
\end{aligned} \tag{2.4}$$

and

$$\mathcal{U}_0 := \|\boldsymbol{u}_0\|^2+\|\boldsymbol{b}_0\|^2, \quad \mathcal{V}_0 := \|\nabla \boldsymbol{u}_0\|^2+\|\nabla \boldsymbol{b}_0\|^2, \quad \mathcal{W}_0 := \|\nabla^2 \boldsymbol{u}_0\|^2+\|\nabla^2 \boldsymbol{b}_0\|^2. \tag{2.5}$$

The main result of this paper is the following.

Theorem 2.6. *Suppose that the initial data $(\rho_0, \boldsymbol{u}_0, \boldsymbol{b}_0)$ satisfy (2.1)–(2.3). Then the problem (1.1)–(1.2) has a unique global in time strong solution $(\rho, \boldsymbol{u}, p, \boldsymbol{b})$ such that, for all $T \in (0, \infty)$, the following inequalities hold*

$$\alpha \le \rho(\boldsymbol{x}, t) \le \beta, \qquad \mathcal{U}(T)C \le C\,\mathcal{U}_0, \qquad \mathcal{V}(T) \le \widetilde{C}\,\mathcal{V}_0,$$
$$\big\|(\boldsymbol{u}, \boldsymbol{b})\big\|^2_{L^\infty_T(\boldsymbol{L}^2(\Omega))} \le C\,\mathcal{U}_0\, e^{-\gamma\, T/\epsilon^2},$$
$$\big\|(\nabla \boldsymbol{u}, \nabla \boldsymbol{b})\big\|^2_{L^\infty_T(\boldsymbol{L}^2(\Omega))} \le \widetilde{C}\,\mathcal{V}_0\, e^{-\overline{\gamma}\, T/\epsilon^2},$$

where $C = C(\alpha, \beta) > 0$, $\widetilde{C} = \widetilde{C}(\alpha, \beta, \mu, \eta, c_0) > 0$, $\gamma := \min\big\{\frac{2\mu}{\beta}, 2\eta\big\}$ and $\overline{\gamma} := \min\big\{\frac{\widetilde{\gamma}}{\mu}, \frac{\widetilde{\gamma}}{\eta}\big\}$, with $\widetilde{\gamma} := \min\big\{\frac{\mu^2}{16\beta}, \frac{\eta^2}{16}\big\}$. Moreover, if $\boldsymbol{u}_0, \boldsymbol{b}_0 \in \boldsymbol{V} \cap \boldsymbol{H}^2(\Omega)$, then

$$\mathcal{W}(T) \le \widetilde{C}\,\mathcal{W}_0 \quad \text{and} \quad \big\|(\nabla^2 \boldsymbol{u}, \nabla^2 \boldsymbol{b})\big\|^2_{L^\infty_T(\boldsymbol{L}^2(\Omega))} \le \widetilde{C}\,\mathcal{W}_0\, e^{-\sigma\, T/\epsilon^2},$$

where $\sigma := \min\{\gamma, \overline{\gamma}\}$. In particular, for all $t_\star > 0$, we conclude that

$$\lim_{\epsilon \to 0^+} (\boldsymbol{u}, \boldsymbol{b}) = (\boldsymbol{0}, \boldsymbol{0}) \quad \text{uniformly in } C\big([t_\star, \infty); \boldsymbol{H}^2(\Omega)\big).$$

3 Proof of the main result

Theorem 2.6 follows as a consequence of Theorem 2.1 above, together with Propositions 3.1 and 3.3 established below.

A priori bounds

From now on, we denote by C, K, and $\widetilde{C}$ generic positive constants, which may vary from line to line. More specifically, C denotes a constant depending only on α and β; K depends solely on α, β, μ, and η; and $\widetilde{C}$ depends on α, β, μ, η, and c_0.

In the following, we derive *a priori* estimates for the strong solution $(\rho, \boldsymbol{u}, p, \boldsymbol{b})$ to the problem (1.1)–(1.2), defined on $\Omega \times [0, T]$, for $T \in (0, \infty)$.

Proposition 3.1 (Estimates in the $\boldsymbol{H}^1(\Omega)$ norm)**.** *Assume that the initial data $(\rho_0, \boldsymbol{u}_0, \boldsymbol{b}_0)$ satisfy (2.1)–(2.3). Let $(\rho, \boldsymbol{u}, p, \boldsymbol{b})$ be the strong solution furnished by Theorem 2.1 defined on $\Omega \times [0, T]$. There exist constants $C = C(\alpha, \beta) > 0$ and $\widetilde{C} = \widetilde{C}(\alpha, \beta, \mu, \eta, c_0) > 0$, such that*

$$\alpha \le \rho(\boldsymbol{x}, t) \le \beta, \qquad \forall\, (\boldsymbol{x}, t) \in \Omega \times [0, T], \quad (3.1)$$
$$\|\boldsymbol{u}(t)\|^2 + \|\boldsymbol{b}(t)\|^2 \le C\left(\|\boldsymbol{u}_0\|^2 + \|\boldsymbol{b}_0\|^2\right), \qquad \forall\, t \in [0, T], \quad (3.2)$$
$$\int_0^t \left(\mu\|\nabla \boldsymbol{u}(s)\|^2 + \eta\|\nabla \boldsymbol{b}(s)\|^2\right) ds \le C\left(\|\boldsymbol{u}_0\|^2 + \|\boldsymbol{b}_0\|^2\right), \qquad \forall\, t \in [0, T], \quad (3.3)$$
$$\|\boldsymbol{u}(t)\|^2 + \|\boldsymbol{b}(t)\|^2 \le C\left(\|\boldsymbol{u}_0\|^2 + \|\boldsymbol{b}_0\|^2\right) e^{-\gamma\, t/\epsilon^2}, \qquad \forall\, t \in [0, T], \quad (3.4)$$
$$\|\nabla \boldsymbol{u}(t)\|^2 + \|\nabla \boldsymbol{b}(t)\|^2 \le \widetilde{C}\left(\|\nabla \boldsymbol{u}_0\|^2 + \|\nabla \boldsymbol{b}_0\|^2\right), \qquad \forall\, t \in [0, T], \quad (3.5)$$
$$\int_0^t \left(\|\boldsymbol{u}_t(s)\|^2 + \|\boldsymbol{b}_t(s)\|^2\right) ds \le \widetilde{C}\left(\|\nabla \boldsymbol{u}_0\|^2 + \|\nabla \boldsymbol{b}_0\|^2\right), \qquad \forall\, t \in [0, T], \quad (3.6)$$
$$\int_0^t \left(\|\Delta \boldsymbol{u}(s)\|^2 + \|\Delta \boldsymbol{b}(s)\|^2\right) ds \le \widetilde{C}\left(\|\nabla \boldsymbol{u}_0\|^2 + \|\nabla \boldsymbol{b}_0\|^2\right), \qquad \forall\, t \in [0, T], \quad (3.7)$$
$$\|\nabla \boldsymbol{u}(t)\|^2 + \|\nabla \boldsymbol{b}(t)\|^2 \le \widetilde{C}\left(\|\nabla \boldsymbol{u}_0\|^2 + \|\nabla \boldsymbol{b}_0\|^2\right) e^{-\overline{\gamma}\, t/\epsilon^2}, \qquad \forall\, t \in [0, T], \quad (3.8)$$

with $\gamma := \min\big\{\frac{2\mu}{\beta}, 2\eta\big\}$ and $\overline{\gamma} := \min\big\{\frac{\widetilde{\gamma}}{\mu}, \frac{\widetilde{\gamma}}{\eta}\big\}$, where $\widetilde{\gamma} := \min\big\{\frac{\mu^2}{16\beta}, \frac{\eta^2}{16}\big\}$.

Proof. For a given $\boldsymbol{u} = \boldsymbol{u}(\boldsymbol{x}, t)$, one gets ρ, solution of $(1.1)_3$, through the classical method of characteristics. Indeed, if

$$\Pi(s) := \rho(\boldsymbol{x} + s\boldsymbol{u},\, t + s), \quad \forall\, s \in [-t, \infty) \qquad (\text{with } t \geq 0),$$

then

$$\frac{d}{ds}\Pi(s) = \nabla\rho(\boldsymbol{x} + s\boldsymbol{u},\, t + s) \cdot \boldsymbol{u}(\boldsymbol{x} + s\boldsymbol{u},\, t + s) + \rho_t(\boldsymbol{x} + s\boldsymbol{u},\, t + s) = 0, \quad \forall\, s \in (-t, \infty).$$

Thus, $\Pi(\cdot)$ is a constant function of s. Hence,

$$\rho(\boldsymbol{x}, t) = \Pi(0) = \Pi(-t) = \rho(\boldsymbol{x} - t\boldsymbol{u},\, 0) = \rho_0(\boldsymbol{x} - t\boldsymbol{u}).$$

Therefore, from the hypothesis (2.1), it follows that ρ satisfies bound (3.1). Testing equation $(1.1)_1$ by $\boldsymbol{u}$ and equation $(1.1)_2$ by $\boldsymbol{b}$, one obtains, respectively

$$\frac{1}{2}\frac{d}{dt}\left(\|\sqrt{\rho}\boldsymbol{u}\|^2\right) + \mu\|\nabla\boldsymbol{u}\|^2 = \langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, \boldsymbol{u}\rangle$$

and

$$\frac{1}{2}\frac{d}{dt}\left(\|\boldsymbol{b}\|^2\right) + \eta\|\nabla\boldsymbol{b}\|^2 = \langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, \boldsymbol{b}\rangle,$$

since $\rho_t = -\boldsymbol{u}\cdot\nabla\rho$ and $\operatorname{div}\boldsymbol{u} = 0$. Adding the above identities and noting that $\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, \boldsymbol{u}\rangle + \langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, \boldsymbol{b}\rangle = 0$, because $\operatorname{div}\boldsymbol{b} = 0$, we get the energy equation

$$\frac{d}{dt}\left(\|\sqrt{\rho}\boldsymbol{u}\|^2 + \|\boldsymbol{b}\|^2\right) + 2\left(\mu\|\nabla\boldsymbol{u}\|^2 + \eta\|\nabla\boldsymbol{b}\|^2\right) = 0. \tag{3.9}$$

Integrating (3.9) in time and using (3.1), we find

$$\alpha\|\boldsymbol{u}(t)\|^2 + \|\boldsymbol{b}(t)\|^2 + 2\int_0^t \left(\mu\|\nabla\boldsymbol{u}(s)\|^2 + \eta\|\nabla\boldsymbol{b}(s)\|^2\right) ds \leq \beta\|\boldsymbol{u}_0\|^2 + \|\boldsymbol{b}_0\|^2, \tag{3.10}$$

which proves the estimates (3.2) and (3.3).

Furthermore, applying Poincaré's inequality (see Lemma 2.2) to identity (3.9), we obtain

$$\frac{d}{dt}\left(\|\sqrt{\rho}\boldsymbol{u}\|^2 + \|\boldsymbol{b}\|^2\right) + \frac{\gamma}{\epsilon^2}\left(\|\sqrt{\rho}\boldsymbol{u}\|^2 + \|\boldsymbol{b}\|^2\right) \leq 0, \tag{3.11}$$

where $\gamma := \min\{2\mu/\beta, 2\eta\}$. Multiplying the above inequality by the integrating factor $e^{\gamma\epsilon^{-2}t}$, we get

$$\frac{d}{dt}\left(e^{\gamma\epsilon^{-2}t}\left[\|\sqrt{\rho}\boldsymbol{u}\|^2 + \|\boldsymbol{b}\|^2\right]\right) \leq 0.$$

Integrating from 0 to t, one obtains

$$\|\boldsymbol{u}(t)\|^2 + \|\boldsymbol{b}(t)\|^2 \leq C\left(\|\boldsymbol{u}_0\|^2 + \|\boldsymbol{b}_0\|^2\right)e^{-\gamma t/\epsilon^2}. \tag{3.12}$$

This proves bound (3.4).

On the other hand, taking the $\boldsymbol{L}^2$ scalar product of first and second equations in (1.1) by $\boldsymbol{u}_t$ and $\boldsymbol{b}_t$ respectively, and adding the resulting identities, one gets

$$\begin{aligned}\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2 + \frac{1}{2}\frac{d}{dt}\left(\mu\|\nabla\boldsymbol{u}\|^2 + \eta\|\nabla\boldsymbol{b}\|^2\right)&\\ = \langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, \boldsymbol{u}_t\rangle + \langle\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}, -\boldsymbol{u}_t\rangle + \langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, \boldsymbol{b}_t\rangle + \langle(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}, -\boldsymbol{b}_t\rangle.&\end{aligned} \tag{3.13}$$

Analogously, making the $\boldsymbol{L}^2$ inner product of first and second equations in (1.1) by $-\kappa\Delta\boldsymbol{u}$ and $-\widetilde{\kappa}\Delta\boldsymbol{b}$ respectively, with $\kappa, \widetilde{\kappa} > 0$ to be chosen later on, we obtain, after adding the resulting equations, that

$$\begin{aligned}\kappa\mu\|\Delta\boldsymbol{u}\|^2 + \widetilde{\kappa}\eta\|\Delta\boldsymbol{b}\|^2 = \kappa\langle\rho\boldsymbol{u}_t, \Delta\boldsymbol{u}\rangle + \kappa\langle\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}, \Delta\boldsymbol{u}\rangle + \kappa\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, -\Delta\boldsymbol{u}\rangle \\ + \widetilde{\kappa}\langle\boldsymbol{b}_t, \Delta\boldsymbol{b}\rangle + \widetilde{\kappa}\langle(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}, \Delta\boldsymbol{b}\rangle + \widetilde{\kappa}\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, -\Delta\boldsymbol{b}\rangle. \qquad (3.14)\end{aligned}$$

Then applying Cauchy–Schwarz and Young's inequalities, we bound each term on the right-hand side of equalities (3.13) and (3.14) as follows:

$$\begin{aligned}|\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, \boldsymbol{u}_t\rangle| &\le \frac{1}{6}\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \frac{3}{2\alpha}\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2,\\
|\langle\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}, -\boldsymbol{u}_t\rangle| &\le \frac{1}{6}\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \frac{3\beta}{2}\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2,\\
|\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, \boldsymbol{b}_t\rangle| &\le \frac{1}{6}\|\boldsymbol{b}_t\|^2 + \frac{3}{2}\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2,\\
|\langle(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}, -\boldsymbol{b}_t\rangle| &\le \frac{1}{6}\|\boldsymbol{b}_t\|^2 + \frac{3}{2}\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2,\\
\kappa|\langle\rho\boldsymbol{u}_t, \Delta\boldsymbol{u}\rangle| &\le \frac{1}{6}\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \frac{3}{2}\beta\kappa^2\|\Delta\boldsymbol{u}\|^2,\\
\kappa|\langle\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}, \Delta\boldsymbol{u}\rangle| &\le \frac{\beta}{4}\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2 + \frac{3}{2}\beta\kappa^2\|\Delta\boldsymbol{u}\|^2,\\
\kappa|\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}, -\Delta\boldsymbol{u}\rangle| &\le \frac{1}{4\alpha}\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2 + \beta\kappa^2\|\Delta\boldsymbol{u}\|^2,\\
\widetilde{\kappa}|\langle\boldsymbol{b}_t, \Delta\boldsymbol{b}\rangle| &\le \frac{1}{6}\|\boldsymbol{b}_t\|^2 + \frac{3}{2}\widetilde{\kappa}^2\|\Delta\boldsymbol{b}\|^2,\\
\widetilde{\kappa}|\langle(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}, \Delta\boldsymbol{b}\rangle| &\le \frac{1}{6}\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2 + \frac{3}{2}\widetilde{\kappa}^2\|\Delta\boldsymbol{b}\|^2,\\
\widetilde{\kappa}|\langle(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}, -\Delta\boldsymbol{b}\rangle| &\le \frac{1}{4}\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2 + \widetilde{\kappa}^2\|\Delta\boldsymbol{b}\|^2.\end{aligned}$$

Consequently, applying the estimates above to resulting equation of the sum of the identities (3.13) and (3.14) and choosing $\kappa = \mu/8\beta$ and $\widetilde{\kappa} = \eta/8$, one finds

$$\begin{aligned}\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2 + \frac{d}{dt}\left(\mu\|\nabla\boldsymbol{u}\|^2 + \eta\|\nabla\boldsymbol{b}\|^2\right) + \frac{1}{8}\left(\frac{\mu^2}{\beta}\|\Delta\boldsymbol{u}\|^2 + \eta^2\|\Delta\boldsymbol{b}\|^2\right) \\ \le C\left(\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2 + \|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2 + \|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2 + \|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2\right). \qquad (3.15)\end{aligned}$$

Now, using Hölder, standard interpolation, Sobolev and Young's inequalities (see [2]), we have

$$\begin{aligned}C\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2 \le C\|\boldsymbol{b}\|_6^2\|\nabla\boldsymbol{b}\|_3^2 \le C\|\boldsymbol{b}\|_6^2\|\nabla\boldsymbol{b}\|\,\|\Delta\boldsymbol{b}\| \le C\|\nabla\boldsymbol{b}\|^3\|\Delta\boldsymbol{b}\| \\ \le \frac{\eta^2}{32}\|\Delta\boldsymbol{b}\|^2 + K\|\nabla\boldsymbol{b}\|^6, \qquad (3.16)\\
C\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2 \le \frac{\mu^2}{32\beta}\|\Delta\boldsymbol{u}\|^2 + K\|\nabla\boldsymbol{u}\|^6, \qquad (3.17)\\
C\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2 \le \frac{\mu^2}{32\beta}\|\Delta\boldsymbol{u}\|^2 + K\|\nabla\boldsymbol{b}\|^4\|\nabla\boldsymbol{u}\|^2, \qquad (3.18)\\
C\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2 \le \frac{\eta^2}{32}\|\Delta\boldsymbol{b}\|^2 + K\|\nabla\boldsymbol{u}\|^4\|\nabla\boldsymbol{b}\|^2. \qquad (3.19)\end{aligned}$$

Thus, applying the estimates (3.16)–(3.19) to inequality (3.15), we find

$$\begin{aligned}\|\sqrt{\rho}\boldsymbol{u}_t\|^2+\|\boldsymbol{b}_t\|^2+\frac{d}{dt}\left(\mu\|\nabla\boldsymbol{u}\|^2+\eta\|\nabla\boldsymbol{b}\|^2\right)+\widetilde{\gamma}\left(\|\Delta\boldsymbol{u}\|^2+\|\Delta\boldsymbol{b}\|^2\right)\\ \leq K\left(\|\nabla\boldsymbol{u}\|^4+\|\nabla\boldsymbol{b}\|^4\right)\left(\|\nabla\boldsymbol{u}\|^2+\|\nabla\boldsymbol{b}\|^2\right),\end{aligned}\tag{3.20}$$

where $\widetilde{\gamma}:=\min\left\{\frac{\mu^2}{16\beta},\frac{\eta^2}{16}\right\}$. By integration of the above inequality over $[0,t]$, we obtain

$$\|\nabla\boldsymbol{z}(t)\|^2+\int_0^t\left(\|\boldsymbol{z}_t(s)\|^2+\|\Delta\boldsymbol{z}(s)\|^2\right)ds\leq K\|\nabla\boldsymbol{z}_0\|^2+K\int_0^t\|\nabla\boldsymbol{z}(s)\|^4\|\nabla\boldsymbol{z}(s)\|^2ds.$$

So we deduce from estimate (3.10) that

$$\begin{aligned}\|\nabla\boldsymbol{z}(t)\|^2+\int_0^t\left(\|\boldsymbol{z}_t(s)\|^2+\|\Delta\boldsymbol{z}(s)\|^2\right)ds&\leq K\left(\|\nabla\boldsymbol{z}_0\|^2+\|\nabla\boldsymbol{z}\|^4_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{z}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\right)\\&\leq K\left(\|\nabla\boldsymbol{z}_0\|^2+\|\boldsymbol{z}_0\|^2\|\nabla\boldsymbol{z}\|^4_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\right).\end{aligned}$$

Having in mind the identities (2.4) and (2.5), one concludes that

$$\mathcal{V}(t)\leq K\left(\mathcal{V}_0+\mathcal{U}_0\,\mathcal{V}(t)^2\right).$$

Hence, if c_0 is sufficiently small, we conclude that

$$\mathcal{V}(t)\leq\widetilde{C}\mathcal{V}_0,$$

for some positive constant $\widetilde{C}$ depending of α, β, μ, η and c_0. This proves inequalities (3.5)–(3.7).

Lastly, we will focus on the estimate (3.8). Notice that, by bound (3.20), one has

$$\frac{d}{dt}(\mu\|\nabla\boldsymbol{u}\|^2+\eta\|\nabla\boldsymbol{b}\|^2)+\widetilde{\gamma}(\|\Delta\boldsymbol{u}\|^2+\|\Delta\boldsymbol{b}\|^2)\leq K\Big(\|\nabla\boldsymbol{u}\|^4+\|\nabla\boldsymbol{b}\|^4\Big)(\|\nabla\boldsymbol{u}\|^2+\|\nabla\boldsymbol{b}\|^2).\tag{3.21}$$

Then similarly as we got estimate (3.11), we deduce, from bound (3.21) and Poincaré's inequality (see Lemma 2.2), that

$$\frac{d}{dt}(\mu\|\nabla\boldsymbol{u}\|^2+\eta\|\nabla\boldsymbol{b}\|^2)+\frac{\overline{\gamma}}{\epsilon^2}\Big(\mu\|\nabla\boldsymbol{u}\|^2+\eta\|\nabla\boldsymbol{b}\|^2\Big)\leq K\Big(\|\nabla\boldsymbol{u}\|^4+\|\nabla\boldsymbol{b}\|^4\Big)(\|\nabla\boldsymbol{u}\|^2+\|\nabla\boldsymbol{b}\|^2),$$

where $\overline{\gamma}:=\min\left\{\frac{\widetilde{\gamma}}{\mu},\frac{\widetilde{\gamma}}{\eta}\right\}$. Multiplying by the integrating factor $e^{\overline{\gamma}\epsilon^{-2}t}$ gives

$$\frac{d}{dt}\left\{e^{\overline{\gamma}\epsilon^{-2}t}\left(\mu\|\nabla\boldsymbol{u}\|^2+\eta\|\nabla\boldsymbol{b}\|^2\right)\right\}\leq K\,e^{\overline{\gamma}\epsilon^{-2}t}\left(\|\nabla\boldsymbol{u}\|^4+\|\nabla\boldsymbol{b}\|^4\right)\left(\|\nabla\boldsymbol{u}\|^2+\|\nabla\boldsymbol{b}\|^2\right).$$

Thus, integrating in time and using estimate (3.3), one finds

$$\begin{aligned}\|\nabla\boldsymbol{z}(t)\|^2&\leq K\|\nabla\boldsymbol{z}_0\|^2e^{-\overline{\gamma}\epsilon^{-2}t}+K\int_0^t e^{-\overline{\gamma}\epsilon^{-2}(t-s)}\|\nabla\boldsymbol{z}(s)\|^4\|\nabla\boldsymbol{z}(s)\|^2ds\\&\leq K\|\nabla\boldsymbol{z}_0\|^2e^{-\overline{\gamma}\epsilon^{-2}t}+K\|\nabla\boldsymbol{z}\|^4_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{z}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\\&\leq K\|\nabla\boldsymbol{z}_0\|^2e^{-\overline{\gamma}\epsilon^{-2}t}+K\|\boldsymbol{z}_0\|^2\|\nabla\boldsymbol{z}\|^4_{L^\infty_t(\boldsymbol{L}^2(\Omega))}.\end{aligned}$$

Consequently, if c_0 is small enough, then we deduce that

$$\|\nabla\boldsymbol{z}(t)\|^2\leq\widetilde{C}\|\nabla\boldsymbol{z}_0\|^2e^{-\overline{\gamma}t/\epsilon^2},$$

where $\widetilde{C}=\widetilde{C}(\alpha,\beta,\mu,\eta,c_0)>0$. The proposition follows. □

Remark 3.2 (Estimates for the "initial data" $\boldsymbol{u}_t(0)$ and $\boldsymbol{b}_t(0)$)**.** Multiplying the first equation in (1.1) by $\boldsymbol{u}_t$ in $\boldsymbol{L}^2(\Omega)$ and applying Cauchy–Schwarz and Young's inequalities, we get

$$\|\sqrt{\rho}\boldsymbol{u}_t\|^2 \leq 3\beta\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2 + \frac{3\mu^2}{\alpha}\|\Delta\boldsymbol{u}\|^2 + \frac{3}{\alpha}\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2,$$

since $\operatorname{div}\boldsymbol{u}_t = 0$. It follows from Gagliardo–Nirenberg inequalities that

$$\|\boldsymbol{u}_t\|^2 \leq K_1\left(\|\boldsymbol{u}\|\|\nabla\boldsymbol{u}\|\|\nabla^2\boldsymbol{u}\|^2 + \|\Delta\boldsymbol{u}\|^2 + \|\boldsymbol{b}\|\|\nabla\boldsymbol{b}\|\|\nabla^2\boldsymbol{b}\|^2\right),$$

where $K_1 > 0$ depends only on the constants α, β and μ. Due to Remark 2.3, we have

$$\begin{aligned}\|\boldsymbol{u}_t(0)\|^2 &\leq K_1\left(\|\boldsymbol{u}_0\|\|\nabla\boldsymbol{u}_0\|\|\nabla^2\boldsymbol{u}_0\|^2 + \|\Delta\boldsymbol{u}_0\|^2 + \|\boldsymbol{b}_0\|\|\nabla\boldsymbol{b}_0\|\|\nabla^2\boldsymbol{b}_0\|^2\right)\\ &\leq K_1\left(c_0^2\|\nabla^2\boldsymbol{u}_0\|^2 + \|\Delta\boldsymbol{u}_0\|^2 + c_0^2\|\nabla^2\boldsymbol{b}_0\|^2\right)\\ &\leq \widetilde{C}_1\|\nabla^2\boldsymbol{z}_0\|^2,\end{aligned} \tag{3.22}$$

where $\widetilde{C}_1 = \widetilde{C}_1(\alpha, \beta, \mu, c_0) > 0$. With similar arguments, we can find

$$\|\boldsymbol{b}_t(0)\|^2 \leq \widetilde{C}_2\|\nabla^2\boldsymbol{z}_0\|^2, \tag{3.23}$$

where $\widetilde{C}_2 = \widetilde{C}_2(\eta, c_0) > 0$. Hence, by bounds (3.22) and (3.23), one concludes that

$$\|\boldsymbol{u}_t(0)\|^2 + \|\boldsymbol{b}_t(0)\|^2 \leq \widetilde{C}\left(\|\nabla^2\boldsymbol{u}_0\|^2 + \|\nabla^2\boldsymbol{b}_0\|^2\right), \tag{3.24}$$

where $\widetilde{C} > 0$ is a constant depending only on α, β, μ, η and c_0.

Proposition 3.3 (Bounds in the $\boldsymbol{H}^2(\Omega)$ norm)**.** *Suppose that the initial data $(\rho_0, \boldsymbol{u}_0, \boldsymbol{b}_0)$ satisfy (2.1) and (2.3), with $\boldsymbol{u}_0, \boldsymbol{b}_0 \in \boldsymbol{V}\cap\boldsymbol{H}^2(\Omega)$. Let $(\rho, \boldsymbol{u}, p, \boldsymbol{b})$ be the strong solution furnished by Theorem 2.1 defined on $\Omega\times[0,T]$. There exists a constant $\widetilde{C} = \widetilde{C}(\alpha, \beta, \mu, \eta, c_0) > 0$ such that*

$$\|\boldsymbol{u}_t(t)\|^2 + \|\boldsymbol{b}_t(t)\|^2 \leq \widetilde{C}\left(\|\nabla^2\boldsymbol{u}_0\|^2 + \|\nabla^2\boldsymbol{b}_0\|^2\right), \tag{3.25}$$

$$\int_0^t \left(\|\nabla\boldsymbol{u}_t(s)\|^2 + \|\nabla\boldsymbol{b}_t(s)\|^2\right)ds \leq \widetilde{C}\left(\|\nabla^2\boldsymbol{u}_0\|^2 + \|\nabla^2\boldsymbol{b}_0\|^2\right), \tag{3.26}$$

$$\left\|(\nabla^2\boldsymbol{u}, \nabla^2\boldsymbol{b}, \nabla p)\right\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))} \leq \widetilde{C}\left(\|\nabla^2\boldsymbol{u}_0\|^2 + \|\nabla^2\boldsymbol{b}_0\|^2\right), \tag{3.27}$$

$$\|\boldsymbol{u}_t(t)\|^2 + \|\boldsymbol{b}_t(t)\|^2 \leq \widetilde{C}\left(\|\nabla^2\boldsymbol{u}_0\|^2 + \|\nabla^2\boldsymbol{b}_0\|^2\right)e^{-\sigma t/\epsilon^2}, \tag{3.28}$$

$$\left\|(\nabla^2\boldsymbol{u}, \nabla^2\boldsymbol{b}, \nabla p)\right\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))} \leq \widetilde{C}\left(\|\nabla^2\boldsymbol{u}_0\|^2 + \|\nabla^2\boldsymbol{b}_0\|^2\right)e^{-\sigma t/\epsilon^2}, \tag{3.29}$$

for all $t\in[0,T]$, with $\sigma := \min\{\widehat{\gamma}, \overline{\gamma}\}$, where $\widehat{\gamma} := \min\{\frac{\mu}{\beta}, \eta\}$, $\overline{\gamma} := \min\{\frac{\widetilde{\gamma}}{\mu}, \frac{\widetilde{\gamma}}{\eta}\}$ and $\widetilde{\gamma} := \min\{\frac{\mu^2}{16\beta}, \frac{\eta^2}{16}\}$.

Proof. Differentiating the equations $(1.1)_1$ and $(1.1)_2$ with respect to t, taking the dot product with $\boldsymbol{u}_t$ and $\boldsymbol{b}_t$, respectively, integrating the resulting identities on Ω and adding both results up, we get

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\left(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\right) + \mu\|\nabla\boldsymbol{u}_t\|^2 + \eta\|\nabla\boldsymbol{b}_t\|^2\\ &\quad= \langle(\boldsymbol{b}_t\cdot\nabla)\boldsymbol{b}, \boldsymbol{u}_t\rangle + 2\langle\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}_t, -\boldsymbol{u}_t\rangle + \langle\rho_t(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}, -\boldsymbol{u}_t\rangle\\ &\qquad+ \langle\rho(\boldsymbol{u}_t\cdot\nabla)\boldsymbol{u}, -\boldsymbol{u}_t\rangle + \langle(\boldsymbol{b}_t\cdot\nabla)\boldsymbol{u}, \boldsymbol{b}_t\rangle + \langle(\boldsymbol{u}_t\cdot\nabla)\boldsymbol{b}, -\boldsymbol{b}_t\rangle,\end{aligned} \tag{3.30}$$

since $\rho_t = -\boldsymbol{u}\cdot\nabla\rho$ and $\operatorname{div}\boldsymbol{u} = \operatorname{div}\boldsymbol{u}_t = \operatorname{div}\boldsymbol{b} = 0$.

Now, we estimate each term on the right-hand side of identity (3.30). Using Hölder, Sobolev, interpolation and Young's inequalities, we find

$$\begin{aligned}
|\langle(\boldsymbol{b}_t\cdot\nabla)\boldsymbol{b},\boldsymbol{u}_t\rangle| &\le \|\boldsymbol{b}_t\|_6\|\nabla\boldsymbol{b}\|\|\boldsymbol{b}_t\|_3\\
&\le \delta_1\|\nabla\boldsymbol{b}_t\|^2 + C_{\delta_1}\|\nabla\boldsymbol{b}\|^4\|\boldsymbol{b}_t\|^2,\\
2|\langle\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}_t,-\boldsymbol{u}_t\rangle| &\le 2\|\rho\|_\infty\|\boldsymbol{u}\|_6\|\nabla\boldsymbol{u}_t\|\|\boldsymbol{u}_t\|_3\\
&\le \delta_2\|\nabla\boldsymbol{u}_t\|^2 + C_{\delta_2}\|\nabla\boldsymbol{u}\|^4\|\boldsymbol{u}_t\|^2,\\
|\langle\rho_t(\boldsymbol{u}\cdot\nabla)\boldsymbol{u},-\boldsymbol{u}_t\rangle| &= |\langle\operatorname{div}(\rho\boldsymbol{u})(\boldsymbol{u}\cdot\nabla)\boldsymbol{u},\boldsymbol{u}_t\rangle|\\
&\le C\|\nabla\boldsymbol{u}\|^2\|\nabla^2\boldsymbol{u}\|\|\nabla\boldsymbol{u}_t\|\\
&\le \delta_2\|\nabla\boldsymbol{u}_t\|^2 + C_{\delta_2}\|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2,\\
|\langle\rho(\boldsymbol{u}_t\cdot\nabla)\boldsymbol{u},-\boldsymbol{u}_t\rangle| &\le \|\rho\|_\infty\|\boldsymbol{u}_t\|_6\|\nabla\boldsymbol{u}\|\|\boldsymbol{u}_t\|_3\\
&\le \delta_2\|\nabla\boldsymbol{u}_t\|^2 + C_{\delta_2}\|\nabla\boldsymbol{u}\|^4\|\boldsymbol{u}_t\|^2,\\
|\langle(\boldsymbol{b}_t\cdot\nabla)\boldsymbol{u},\boldsymbol{b}_t\rangle| &\le \|\boldsymbol{b}_t\|_6\|\nabla\boldsymbol{u}\|\|\boldsymbol{b}_t\|_3\\
&\le \delta_1\|\nabla\boldsymbol{b}_t\|^2 + C_{\delta_1}\|\nabla\boldsymbol{u}\|^4\|\boldsymbol{b}_t\|^2,\\
|\langle(\boldsymbol{u}_t\cdot\nabla)\boldsymbol{b},-\boldsymbol{b}_t\rangle| &\le \|\boldsymbol{u}_t\|_6\|\nabla\boldsymbol{b}\|\|\boldsymbol{b}_t\|_3\\
&\le C\|\nabla\boldsymbol{u}_t\|\|\nabla\boldsymbol{b}\|\|\boldsymbol{b}_t\|^{1/2}\|\nabla\boldsymbol{b}_t\|^{1/2}\\
&\le \delta_1\|\nabla\boldsymbol{b}_t\|^2 + \delta_2\|\nabla\boldsymbol{u}_t\|^2 + C_{\delta_1,\delta_2}\|\nabla\boldsymbol{b}\|^4\|\boldsymbol{b}_t\|^2.
\end{aligned}$$

So, applying the estimates above to equality (3.30) and taking $\delta_1 = \eta/6$ and $\delta_2 = \mu/8$, we obtain

$$\begin{aligned}
&\frac{d}{dt}\left(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\right) + \mu\|\nabla\boldsymbol{u}_t\|^2 + \eta\|\nabla\boldsymbol{b}_t\|^2\\
&\quad\le K\left(\|\nabla\boldsymbol{u}\|^4\|\boldsymbol{u}_t\|^2 + \|\nabla\boldsymbol{u}\|^4\|\boldsymbol{b}_t\|^2 + \|\nabla\boldsymbol{b}\|^4\|\boldsymbol{b}_t\|^2 + \|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2\right)\\
&\quad\le K\left[\left(\|\nabla\boldsymbol{u}\|^4 + \|\nabla\boldsymbol{b}\|^4\right)\left(\|\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\right) + \|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2\right].
\end{aligned}\tag{3.31}$$

Moreover, since $\alpha \le \rho(\boldsymbol{x},t) \le \beta$ for all $(\boldsymbol{x},t)\in\Omega\times[0,T]$, we deduce that

$$\begin{aligned}
&\frac{d}{dt}\left(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\right) + \mu\|\nabla\boldsymbol{u}_t\|^2 + \eta\|\nabla\boldsymbol{b}_t\|^2\\
&\quad\le K\left(\|\nabla\boldsymbol{u}\|^4 + \|\nabla\boldsymbol{b}\|^4\right)\left(\frac{1}{\alpha}\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\right) + K\|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2\\
&\quad\le C\left(\|\nabla\boldsymbol{u}\|^4 + \|\nabla\boldsymbol{b}\|^4\right)\left(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\right) + C\|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2.
\end{aligned}\tag{3.32}$$

Then, applying a generalized Gronwall inequality (see, for instance, [15, Lemma 4, p. 656]) and taking into account (3.24), we have

$$\begin{aligned}
\|\boldsymbol{z}_t(t)\|^2 &= \|\boldsymbol{u}_t(t)\|^2 + \|\boldsymbol{b}_t(t)\|^2\\
&\le \exp\left(C\int_0^t\left(\|\nabla\boldsymbol{u}(s)\|^4 + \|\nabla\boldsymbol{b}(s)\|^4\right)ds\right)\left(\widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2 + C\int_0^t\|\nabla\boldsymbol{u}(s)\|^4\|\nabla^2\boldsymbol{u}(s)\|^2\,ds\right)\\
&\le \exp\left(C\|\nabla\boldsymbol{u}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{u}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))} + C\|\nabla\boldsymbol{b}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{b}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\right)\\
&\quad\times\left(\widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2 + C\|\nabla\boldsymbol{u}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{u}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\nabla^2\boldsymbol{z}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\right).
\end{aligned}$$

This estimate, together with (3.3), (3.5), and Remark 2.3, implies that

$$\begin{aligned}\|z_t(t)\|^2 &\le \exp\Big(\widetilde{C}\|z_0\|^2\|\nabla z_0\|^2\Big)\Big(\widetilde{C}\|\nabla^2 z_0\|^2+\widetilde{C}\|z_0\|^2\|\nabla z_0\|^2\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\Big)\\ &\le \widetilde{C}\exp\Big(\widetilde{C}c_0^4\Big)\Big(\|\nabla^2 z_0\|^2+c_0^4\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\Big)\\ &\le \widetilde{C}\Big(\|\nabla^2 z_0\|^2+c_0^4\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\Big). \end{aligned} \tag{3.33}$$

Now, integrating (3.32) in time, and using again (3.3), (3.5), Remark 2.3, as well as (3.33), we obtain

$$\begin{aligned}&\|z_t(t)\|^2+\int_0^t\|\nabla z_t(s)\|^2\,ds\\ &\le \widetilde{C}\|\nabla^2 z_0\|^2+C\int_0^t\Big(\|\nabla \boldsymbol{u}(s)\|^4+\|\nabla \boldsymbol{b}(s)\|^4\Big)\|z_t(s)\|^2\,ds+C\int_0^t\|\nabla \boldsymbol{u}(s)\|^4\|\nabla^2\boldsymbol{u}(s)\|^2\,ds\\ &\le \widetilde{C}\|\nabla^2 z_0\|^2+C\|\nabla z\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|z_t\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &\quad+C\|\nabla z\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &\le \widetilde{C}\|\nabla^2 z_0\|^2+\widetilde{C}\|z_0\|^2\|\nabla z_0\|^2\|z_t\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}+\widetilde{C}\|z_0\|^2\|\nabla z_0\|^2\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &\le \widetilde{C}\|\nabla^2 z_0\|^2+\widetilde{C}c_0^4\|z_t\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}+\widetilde{C}c_0^4\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &\le \widetilde{C}\|\nabla^2 z_0\|^2+\widetilde{C}c_0^4\|\nabla^2 z_0\|^2+\widetilde{C}c_0^8\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}+\widetilde{C}c_0^4\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &\le \widetilde{C}\Big(\|\nabla^2 z_0\|^2+c_0^4\|\nabla^2 z\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\Big), \end{aligned} \tag{3.34}$$

since $c_0>0$ is sufficiently small.

On the other side, by identity (3.14), one concludes that

$$\|\nabla^2 z(t)\|^2\le K\big(\|z_t\|^2+\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2+\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2+\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2+\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2\big). \tag{3.35}$$

In addition, since $\operatorname{div}\boldsymbol{u}=0$, applying the divergence operator to the first in (1.1), we obtain

$$\Delta p=-\operatorname{div}\big(\rho\boldsymbol{u}_t+\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}-(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\big),$$

and therefore the total pressure p may be recovered by

$$\nabla p=-\nabla\Delta^{-1}\operatorname{div}\big(\rho\boldsymbol{u}_t+\rho(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}-(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\big). \tag{3.36}$$

Hence, we have

$$\|\nabla p(t)\|^2\le C_\beta\left(\|\boldsymbol{u}_t\|^2+\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2+\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2\right).$$

So, from bounds (3.35) and (3.36), we get

$$\|(\nabla^2\boldsymbol{u},\nabla^2\boldsymbol{b},\nabla p)\|^2\le K\left(\|\boldsymbol{u}_t\|^2+\|\boldsymbol{b}_t\|^2+F(t)\right), \tag{3.37}$$

where $F(t):=\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2+\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2+\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2+\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2$. To obtain the estimate of $\big\|(\nabla^2\boldsymbol{u},\nabla^2\boldsymbol{b},\nabla p)\big\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}$, it remains to control $F(t)$. Using Hölder, standard interpolation

and Sobolev's inequalities (see [2]), we find, from estimates (3.2) and (3.5), and Remark 2.3, that

$$\begin{aligned}\|(\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\|^2 &\le \|\boldsymbol{u}\|_3^2\,\|\nabla\boldsymbol{u}\|_6^2 \le C\|\boldsymbol{u}\|\|\nabla\boldsymbol{u}\|\|\nabla^2\boldsymbol{u}\|^2\\ &\le \widetilde{C}\|z_0\|\|\nabla z_0\|\|\nabla^2\boldsymbol{u}\|^2\\ &\le \widetilde{C}c_0^2\|\nabla^2\boldsymbol{u}\|^2, \qquad (3.38)\\ \|(\boldsymbol{u}\cdot\nabla)\boldsymbol{b}\|^2 &\le \|\boldsymbol{u}\|_3^2\,\|\nabla\boldsymbol{b}\|_6^2 \le C\|\boldsymbol{u}\|\|\nabla\boldsymbol{u}\|\|\nabla^2\boldsymbol{b}\|^2\\ &\le \widetilde{C}\|z_0\|\|\nabla z_0\|\|\nabla^2\boldsymbol{b}\|^2\\ &\le \widetilde{C}c_0^2\|\nabla^2\boldsymbol{b}\|^2. \qquad (3.39)\end{aligned}$$

Analogously, one has

$$\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{b}\|^2 \le \widetilde{C}c_0^2\|\nabla^2\boldsymbol{b}\|^2, \qquad (3.40)$$

$$\|(\boldsymbol{b}\cdot\nabla)\boldsymbol{u}\|^2 \le \widetilde{C}c_0^2\|\nabla^2\boldsymbol{u}\|^2. \qquad (3.41)$$

Consequently, by inequality (3.37), one obtains

$$\|(\nabla^2 z,\nabla p)\|^2 \le \widetilde{C}\big(\|z_t\|^2 + c_0^2\|\nabla^2 z\|^2\big). \qquad (3.42)$$

Since $c_0 > 0$ is sufficiently small, one gets

$$\|(\nabla^2 z,\nabla p)\|^2 \le \widetilde{C}\|z_t\|^2. \qquad (3.43)$$

Furthermore, having in mind the identities (2.4)–(2.5) and summing the bounds (3.34) and (3.43), one concludes that

$$\mathcal{W}(t) \le \widetilde{C}\Big(\mathcal{W}_0 + c_0^4\mathcal{W}(t)\Big).$$

Hence, the smallness of c_0 ensures that

$$\mathcal{W}(t) \le \widetilde{C}\mathcal{W}_0.$$

This proves estimates (3.25)–(3.27). Finally, using Poincaré's inequality (see Lemma 2.2), we get

$$\|\nabla\boldsymbol{u}_t\| \ge \epsilon^{-1}\|\boldsymbol{u}_t\| \quad \text{and} \quad \|\nabla\boldsymbol{b}_t\| \ge \epsilon^{-1}\|\boldsymbol{b}_t\|.$$

Thus, by estimate (3.31), we have

$$\begin{aligned}&\frac{d}{dt}\big(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\big) + \frac{\widehat{\gamma}}{\epsilon^2}\big(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\big)\\ &\quad\le K\Big[\Big(\|\nabla\boldsymbol{u}\|^4 + \|\nabla\boldsymbol{b}\|^4\Big)\big(\|\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\big) + \|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2\Big], \qquad (3.44)\end{aligned}$$

where $\widehat{\gamma} := \min\{\mu/\beta, \eta\}$. Multiplying inequality (3.44) by integrating factor $e^{\widehat{\gamma}\epsilon^{-2}t}$ yields

$$\begin{aligned}&\frac{d}{dt}\Big\{e^{\widehat{\gamma}\epsilon^{-2}t}\big(\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\big)\Big\}\\ &\quad\le K\,e^{\widehat{\gamma}\epsilon^{-2}t}\Big[\Big(\|\nabla\boldsymbol{u}\|^4 + \|\nabla\boldsymbol{b}\|^4\Big)\big(\|\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2\big) + \|\nabla\boldsymbol{u}\|^4\|\nabla^2\boldsymbol{u}\|^2\Big].\end{aligned}$$

Then, we deduce from estimate (3.24) that

$$\|\sqrt{\rho}\boldsymbol{u}_t\|^2 + \|\boldsymbol{b}_t\|^2 \leq \widetilde{C}\|\nabla^2 \boldsymbol{z}_0\|^2\, e^{-\widehat{\gamma}\epsilon^{-2}t} + K\int_0^t e^{-\widehat{\gamma}\epsilon^{-2}(t-s)}\left[\left(\|\nabla\boldsymbol{u}(s)\|^4 + \|\nabla\boldsymbol{b}(s)\|^4\right)\|\boldsymbol{z}_t(s)\|^2 + \|\nabla\boldsymbol{u}(s)\|^4\|\nabla^2\boldsymbol{u}(s)\|^2\right] ds.$$

Consequently, we have

$$\begin{aligned}\|\boldsymbol{z}_t(t)\|^2 \leq \widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\widehat{\gamma}\epsilon^{-2}t} &+ K\|\nabla\boldsymbol{u}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{u}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\boldsymbol{z}_t\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &+ K\|\nabla\boldsymbol{b}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{b}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\boldsymbol{z}_t\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\\ &+ K\|\nabla\boldsymbol{u}\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))}\|\nabla\boldsymbol{u}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}\|\nabla^2\boldsymbol{u}\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))}.\end{aligned}$$

Let us recall that estimates (3.3), (3.8), (3.25), and (3.27) yield the following bounds:

$$\|(\sqrt{\mu}\,\nabla\boldsymbol{u}, \sqrt{\eta}\,\nabla\boldsymbol{b})\|^2_{L^2_t(\boldsymbol{L}^2(\Omega))} \leq C\,\|\boldsymbol{z}_0\|^2,$$

$$\|(\nabla\boldsymbol{u}, \nabla\boldsymbol{b})\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))} \leq \widetilde{C}\,\|\nabla\boldsymbol{z}_0\|^2\, e^{-\overline{\gamma}\,t/\epsilon^2},$$

$$\|(\boldsymbol{u}_t, \boldsymbol{b}_t)\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))} \leq \widetilde{C}\,\|\nabla^2\boldsymbol{z}_0\|^2$$

and

$$\|(\nabla^2\boldsymbol{u}, \nabla^2\boldsymbol{b})\|^2_{L^\infty_t(\boldsymbol{L}^2(\Omega))} \leq \widetilde{C}\,\|\nabla^2\boldsymbol{z}_0\|^2,$$

respectively. These imply that

$$\|\boldsymbol{z}_t(t)\|^2 \leq \widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\widehat{\gamma}\epsilon^{-2}t} + \widetilde{C}\|\boldsymbol{z}_0\|^2\|\nabla\boldsymbol{z}_0\|^2\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\overline{\gamma}\epsilon^{-2}t},$$

where $\overline{\gamma} := \min\left\{\frac{\widetilde{\gamma}}{\mu}, \frac{\widetilde{\gamma}}{\eta}\right\}$ and $\widetilde{\gamma} := \min\left\{\frac{\mu^2}{16\beta}, \frac{\eta^2}{16}\right\}$. Moreover, by Remark 2.3, we have

$$\|\boldsymbol{z}_0\|^2\|\nabla\boldsymbol{z}_0\|^2 \leq 4c_0^4.$$

Hence,

$$\|\boldsymbol{z}_t(t)\|^2 \leq \widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\widehat{\gamma}\epsilon^{-2}t} + 4\widetilde{C}c_0^4\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\overline{\gamma}\epsilon^{-2}t}.$$

Therefore, choosing $\sigma := \min\{\widehat{\gamma}, \overline{\gamma}\}$, we infer

$$\|\boldsymbol{z}_t(t)\|^2 \leq \widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\sigma t/\epsilon^2},$$

which together with inequality (3.43) implies that

$$\|(\nabla^2\boldsymbol{z}, \nabla p)\|^2 \leq \widetilde{C}\|\nabla^2\boldsymbol{z}_0\|^2\, e^{-\sigma t/\epsilon^2}.$$

This proves estimates (3.28)–(3.29). The proof of Proposition 3.3 is finished. □

Abstract. In this paper, we study an overdetermined problem with Kirchhoff type nonlocal terms related to the celebrated work by Serrin. We obtain the precise number of solutions according to the value of the bifurcation parameter and study asymptotics of bifurcation curves of solutions when the bifurcation parameter is large in some cases.

Keywords: nonlocal elliptic equations, overdetermined problems.

2020 Mathematics Subject Classification: 34C23, 37G99.

1 Introduction

Let $\Omega \subset \mathbb{R}^N$ be a bounded domain with C^2 boundary. In this paper, we consider the following overdetermined elliptic problem with Kirchhoff type nonlocal terms:

$$\begin{cases} -A\left(\|u\|_{p_1}, \|\nabla u\|_{q_1}\right) \Delta u = \lambda B\left(\|u\|_{p_2}, \|\nabla u\|_{q_2}\right) & \text{in } \Omega, \\ u = 0 \quad \text{on } \partial\Omega, \\ \frac{\partial u}{\partial \nu} = c \quad \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $p_1, p_2, q_1, q_2 > 0$, $\lambda > 0$ are given constants, $\|\cdot\|_t$ stands for $\|\cdot\|_{L^t(\Omega)}$ for any $t > 0$, c is an unknown constant, ν is an outer unit normal to $\partial\Omega$, and $A(s,t)$, $B(s,t)$ are positive continuous functions in $(s,t) \in \mathbb{R}_+ \times \mathbb{R}_+$. The positive constant λ plays a role as a bifurcation parameter.

In a celebrated paper by Serrin [5], see also Weinberger [10], it is proven that if the overdetermined elliptic problem

$$\begin{cases} -\Delta u = 1 \quad \text{in } \Omega, \\ u = 0 \quad \text{on } \partial\Omega, \\ \frac{\partial u}{\partial \nu} = c \quad \text{on } \partial\Omega \end{cases} \tag{1.2}$$

✉ Corresponding author. Email: futoshi@omu.ac.jp

admits a solution $u \in C^2(\overline{\Omega})$, then Ω must be a ball and u is radially symmetric. Thus if $\Omega = B_R(x_0)$, a ball of radius R with center x_0, then the unique solution of (1.2) must be of the form

$$U_{R,x_0}(x) = \frac{R^2 - |x - x_0|^2}{2N}. \tag{1.3}$$

By a simple computation, we have

$$\|U_{R,x_0}\|^p_{L^p(B_R(x_0))} = \left(\frac{1}{2N}\right)^p \left(\frac{\omega_{N-1}}{2}\right) R^{2p+N} B\left(\frac{N}{2}, p+1\right),$$
$$\|\nabla U_{R,x_0}\|^q_{L^q(B_R(x_0))} = \left(\frac{1}{N}\right)^q \left(\frac{\omega_{N-1}}{N+q}\right) R^{N+q}$$

for any $p, q > 0$, where ω_{N-1} is the area of the unit sphere in $\mathbb{R}^N$ and $B(x,y) = \int_0^1 t^{x-1}(1-t)^{y-1}dt$ denotes the Beta function.

After [5, 10], many researches have been done around this topic and various generalizations (differential operators, spaces, and so on) have been obtained up to now. We refer to a survey paper [3] and the references there in. However, to the best of authors' knowledge, overdetermined problems with Kirchhoff type nonlocal terms have not been studied so far. Thus we initiate to study it in this paper.

In this paper, following an argument in [1], we prove

Theorem 1.1. *Let $A, B \in C(\mathbb{R}_+ \times \mathbb{R}_+; \mathbb{R}_+)$. Then if (1.1) admits a solution $u \in C^2(\overline{\Omega})$, then Ω must be a ball and u must be radially symmetric.*

On the other hand, consider the system of equations with respect to $(s_1, s_2, t_1, t_2) \in \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R}_+$:

$$\begin{cases} s_1 = \lambda \dfrac{B(s_2,t_2)}{A(s_1,t_1)} \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))} \\ s_2 = \lambda \dfrac{B(s_2,t_2)}{A(s_1,t_1)} \|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))} \\ t_1 = \lambda \dfrac{B(s_2,t_2)}{A(s_1,t_1)} \|\nabla U_{R,x_0}\|_{L^{q_1}(B_R(x_0))} \\ t_2 = \lambda \dfrac{B(s_2,t_2)}{A(s_1,t_1)} \|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))} \end{cases} \tag{1.4}$$

where U_{R,x_0} defined in (1.3) is the unique solution of (1.2) for $\Omega = B_R(x_0)$. Then for $\lambda > 0$, the problem (1.1) for $\Omega = B_R(x_0)$ has the same number of solutions of the system of equations (1.4). Also the number of solutions of (1.4) is the same as the number of solutions to the equation

$$g(s) = \lambda \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))} \tag{1.5}$$

with respect to $s > 0$, where

$$g(s) = \frac{sA\left(s, \dfrac{\|\nabla U_{R,x_0}\|_{L^{q_1}(B_R(x_0))}}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} s\right)}{B\left(\dfrac{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} s, \dfrac{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} s\right)} \tag{1.6}$$

Moreover, any solution u_λ of (1.1) is of the form

$$u_\lambda(x) = s_1 \frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} \tag{1.7}$$

where s_1 is a solution of (1.5).

As a result of Theorem 1.1, many bifurcation diagrams can be obtained for specific A and B in (1.1). Next are typical examples of the result.

Corollary 1.2. *Let $\Omega = B_R(x_0)$ and let $A(s,t) = (s-a)^2 + b$, $B(s,t) = s$ in* (1.1) *for $a, b > 0$. Then*

(i) if $0 < \lambda < \frac{b}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}}$, there is no solution to (1.1),

(ii) if $\lambda = \frac{b}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}}$, there is a unique solution to (1.1),

(iii) if $\frac{b}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}} < \lambda < \frac{(a^2+b)}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}}$, there are just two solutions to (1.1),

(iv) if $\lambda \geq \frac{(a^2+b)}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}}$, there is a unique solution to (1.1).

Also any solution u_λ is of the form

$$u_\lambda(x) = s_\lambda \frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}}, \quad x \in B_R(x_0)$$

where s_λ is a positive solution of the quadratic equation

$$(s-a)^2 + b = \lambda \|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}.$$

Corollary 1.3. *Let $\Omega = B_R(x_0)$ and let $A(s,t) = e^s$, $B(s,t) = t^r$ in* (1.1) *where $r > 1$. Then*

(i) if $0 < \lambda \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))} < \left(\frac{e}{r-1}\right)^{r-1} \left(\frac{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}}{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}}\right)^r$, there is no solution to (1.1),

(ii) if $\lambda \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))} = \left(\frac{e}{r-1}\right)^{r-1} \left(\frac{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}}{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}}\right)^r$, there is a unique solution to (1.1),

(iii) if $\lambda \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))} > \left(\frac{e}{r-1}\right)^{r-1} \left(\frac{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}}{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}}\right)^r$, there are just two solutions $u_{1,\lambda}$, $u_{2,\lambda}$ to (1.1).

Also we have

$$u_{1,\lambda}(x) = \frac{\lambda^{-\frac{1}{r-1}}}{\|\nabla U_{R,x_0}\|^{\frac{r}{r-1}}_{L^{q_2}(B_R(x_0))}} \left(1 + \frac{1}{r-1}(1+o(1))\lambda^{-\frac{1}{r-1}} \frac{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}}{\|\nabla U_{R,x_0}\|^{\frac{r}{r-1}}_{L^{q_2}(B_R(x_0))}}\right) U_{R,x_0}(x)$$

for $x \in B_R(x_0)$ as $\lambda \to \infty$, and

$$u_{2,\lambda}(x) = \{\log\lambda + (r-1)(\log\log\lambda)(1+o(1))\} \frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}}$$

for $x \in B_R(x_0)$ as $\lambda \to \infty$.

Here we mention some related works. Let $I = (-1,1) \subset \mathbb{R}$ be an interval. T. Shibata performed a bifurcation analysis on the one-dimensional Dirichlet problems with Kirchhoff type nonlocal terms of the form

$$\begin{cases} -A\left(\|u\|_{q_1}, \|u'\|_{r_1}\right) u''(x) = \lambda B\left(\|u\|_{q_2}, \|u'\|_{r_2}\right) u^p(x), & x \in I, \\ u(x) > 0, & x \in I, \\ u(\pm 1) = 0, \end{cases}$$

where $p > 1$ and $\lambda > 0$, and $\|\cdot\|_t$ stands for $\|\cdot\|_{L^t(I)}$ for any $t > 0$. We refer the readers to a series of works by T. Shibata [6–9]. Also, in the same spirit, we performed a bifurcation analysis on the nonlocal boundary blowup problem in one space dimension

$$\begin{cases} A\left(\|u\|_{q_1}, \|u'\|_{r_1}\right) u''(x) = \lambda B\left(\|u\|_{q_2}, \|u'\|_{r_2}\right) u^p(x), & x \in I, \\ u(x) > 0, & x \in I, \\ \lim_{x \to \pm 1} u(x) = +\infty, \end{cases}$$

where $p > 1$, $\lambda > 0$, $q_1, q_2 \in \left(0, \frac{p-1}{2}\right)$, and $r_1, r_2 \in \left(0, \frac{p-1}{p+1}\right)$, see [2,4]. We consider the problem (1.1) is a higher dimensional analogue of the problems above.

2 Proof of Theorem 1.1.

In this section, we prove Theorem 1.1.

Proof. First assume that there exists a solution $u \in C^2(\overline{\Omega})$ of (1.1) and put

$$v = \gamma u$$

where $\gamma > 0$ is chosen so that

$$\gamma^{-1} = \lambda \frac{B(\|u\|_{L^{p_2}(\Omega)}, \|\nabla u\|_{L^{q_2}(\Omega)})}{A(\|u\|_{L^{p_1}(\Omega)}, \|\nabla u\|_{L^{q_1}(\Omega)})}.$$

Then

$$-\Delta v(x) = \gamma(-\Delta u(x)) \overset{(1.2)}{=} \gamma\lambda \frac{B(\|u\|_{L^{p_2}(\Omega)}, \|\nabla u\|_{L^{q_2}(\Omega)})}{A(\|u\|_{L^{p_1}(\Omega)}, \|\nabla u\|_{L^{q_1}(\Omega)})} = 1$$

in Ω. Also we see $v = 0$ on $\partial\Omega$ and $\frac{\partial v}{\partial \nu} = \gamma c$ is a constant on $\partial\Omega$. Thus by the result of Serrin, we see that Ω must be a ball, say $\Omega = B_R(x_0)$ for some $R > 0$ and $x_0 \in \mathbb{R}^N$ and $v \equiv U_{R,x_0}(x)$. This implies that

$$u(x) = \gamma^{-1} U_{R,x_0}(x), \quad \nabla u(x) = \gamma^{-1} \nabla U_{R,x_0}(x). \tag{2.1}$$

Define

$$s_1 = \|u\|_{L^{p_1}(B_R(x_0))}, \quad s_2 = \|u\|_{L^{p_2}(B_R(x_0))}, \quad t_1 = \|\nabla u\|_{L^{q_1}(B_R(x_0))}, \quad t_2 = \|\nabla u\|_{L^{q_2}(B_R(x_0))}.$$

Then by (2.1), we have

$$\begin{cases} s_1 = \gamma^{-1} \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))} \\ s_2 = \gamma^{-1} \|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))} \\ t_1 = \gamma^{-1} \|\nabla U_{R,x_0}\|_{L^{q_1}(B_R(x_0))} \\ t_2 = \gamma^{-1} \|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))} \end{cases}$$

which is equivalent to (1.4). This shows that

$$(s_1, s_2, t_1, t_2) = (\|u\|_{L^{p_1}(B_R(x_0))}, \|u\|_{L^{p_2}(B_R(x_0))}, \|\nabla u\|_{L^{q_1}(B_R(x_0))}, \|\nabla u\|_{L^{q_2}(B_R(x_0))})$$

is a solution to (1.4) and thus

$$\sharp\{u : \text{solutions of (1.1)}\} \le \sharp\{(s_1, s_2, t_1, t_2) \in (\mathbb{R}_+)^4 : \text{solutions of (1.4)}\},$$

where $\sharp A$ denotes the cardinality of the set A.

On the other hand, let $\Omega = B_R(x_0)$ for some $R > 0$ and $x_0 \in \mathbb{R}^N$ and let $(s_1, s_2, t_1, t_2) \in (\mathbb{R}_+)^4$ be any solution to (1.4). Note that by (1.4), we see

$$\begin{aligned} \frac{s_1}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} &= \frac{s_2}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}} \\ &= \frac{t_1}{\|\nabla U_{R,x_0}\|_{L^{q_1}(B_R(x_0))}} = \frac{t_2}{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}} \\ &= \lambda \frac{B(s_2, t_2)}{A(s_1, t_1)}. \end{aligned} \tag{2.2}$$

Thus if we define

$$u(x) = s_1 \frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} \left(= s_2 \frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}} = t_1 \frac{U_{R,x_0}(x)}{\|\nabla U_{R,x_0}\|_{L^{q_1}(B_R(x_0))}} = t_2 \frac{U_{R,x_0}(x)}{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}} \right),$$

then we have $u(x) > 0$, $u = 0$, $\frac{\partial u}{\partial \nu} = const.$ on $\partial B_R(x_0)$ and

$$s_1 = \|u\|_{L^{p_1}(B_R(x_0))},\ s_2 = \|u\|_{L^{p_2}(B_R(x_0))},\ t_1 = \|\nabla u\|_{L^{q_1}(B_R(x_0))},\ t_2 = \|\nabla u\|_{L^{q_2}(B_R(x_0))}.$$

Moreover, by the definition of u, we have

$$\begin{aligned} -A\left(\|u\|_{L^{p_1}(B_R(x_0))}, \|\nabla u\|_{L^{q_1}(B_R(x_0))}\right) \Delta u(x) &= -A(s_1, t_1)\Delta u(x) \\ &= -A(s_1, t_1) \frac{s_1}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} \underbrace{\Delta U_{R,x_0}(x)}_{=-1} \\ &= A(s_1, t_1) \frac{s_1}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} \\ &\overset{(2.2)}{=} \lambda B(s_2, t_2). \end{aligned}$$

This shows that

$$\sharp\{u : \text{solutions of (1.1)}\} \ge \sharp\{(s_1, s_2, t_1, t_2) \in (\mathbb{R}_+)^4 : \text{solutions of (1.4)}\}.$$

Thus the number of solutions of (1.1) for $\Omega = B_R(x_0)$ and that of (1.4) are the same.

Also by (2.2), we can rewrite the system of equations (1.4) into a single equation for $s = s_1$

$$s_1 = \lambda \frac{B\left(\frac{\|U_{R,x_0}\|_{L^{p_2}(B_R(x_0))}}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} s_1, \frac{\|\nabla U_{R,x_0}\|_{L^{q_2}(B_R(x_0))}}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} s_1\right)}{A\left(s_1, \frac{\|\nabla U_{R,x_0}\|_{L^{q_1}(B_R(x_0))}}{\|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}} s_1\right)} \|U_{R,x_0}\|_{L^{p_1}(B_R(x_0))}$$

which is equivalent to (1.5) with $g(s)$ in (1.6). Thus the number of solutions of (1.4) for $\Omega = B_R(x_0)$ and that of (1.5) are also the same. □

Remark 2.1. Theorem 1.1 can be generalized to the overdetermined problem of the form

$$\begin{cases} -A\left(\|u\|_{\vec{p}}, \|\nabla u\|_{\vec{q}}\right)\Delta u = \lambda B\left(\|u\|_{\vec{r}}, \|\nabla u\|_{\vec{s}}\right), & \text{in } \Omega, \\ u = 0, & \text{on } \partial\Omega, \\ \frac{\partial u}{\partial \nu} = c, & \text{on } \partial\Omega \end{cases}$$

where

$$A\left(\|u\|_{\vec{p}}, \|\nabla u\|_{\vec{q}}\right) = A\left(\|u\|_{L^{p_1}(\Omega)}, \dots, \|u\|_{L^{p_I}(\Omega)}, \|\nabla u\|_{L^{q_1}(\Omega)}, \dots, \|\nabla u\|_{L^{q_J}(\Omega)}\right),$$
$$B\left(\|u\|_{\vec{r}}, \|\nabla u\|_{\vec{s}}\right) = B\left(\|u\|_{L^{r_1}(\Omega)}, \dots, \|u\|_{L^{r_K}(\Omega)}, \|\nabla u\|_{L^{s_1}(\Omega)}, \dots, \|\nabla u\|_{L^{s_L}(\Omega)}\right)$$

for $\{p_i\}_{i=1}^I, \{q_j\}_{j=1}^J, \{r_k\}_{k=1}^K, \{s_l\}_{l=1}^L \subset \mathbb{R}_+$. We treat A, B of the forms in Theorem 1.1 just for a simple presentation.

3 Proof of corollaries

In this section, we prove corollaries in §1. By Theorem 1.1, the number of solutions of (1.1) is the same as the number of solutions of (1.5) when $\Omega = B_R(x_0)$, and we have the expression of solution $u(x) = s\frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{L^{p_1}}}$ to (1.1) where $s > 0$ is any solution of (1.5). Here and in what follows, $\|\cdot\|_p$ stands for $\|\cdot\|_{L^p(B_R(x_0))}$ for any $p > 0$. Thus we just need to solve the equation (1.5) with $\lambda > 0$ for specific A and B.

Proof of Corollary 1.2. Since $A(s,t) = \{(s-a)^2 + b\}$ and $B(s,t) = s$, the function $g(s)$ defined in (1.6) becomes

$$g(s) = \frac{\|U_{R,x_0}\|_{p_1}}{\|U_{R,x_0}\|_{p_2}}\left\{(s-a)^2 + b\right\}.$$

Thus $g(s)$ is a quadratic function with respect to $s > 0$ and

$$\min_{s>0} g(s) = g(a) = b\frac{\|U_{R,x_0}\|_{p_1}}{\|U_{R,x_0}\|_{p_2}}, \qquad g(0) = (a^2+b)\frac{\|U_{R,x_0}\|_{p_1}}{\|U_{R,x_0}\|_{p_2}}.$$

Now, the equation (1.5) reads

$$\frac{\|U_{R,x_0}\|_{p_1}}{\|U_{R,x_0}\|_{p_2}}\left\{(s-a)^2 + b\right\} = \lambda\|U_{R,x_0}\|_{p_1}.$$

By a consideration of the graph of $g(s)$, we see that the number of positive solutions s of (1.5) according to the value of $\lambda > 0$ is:

(i) 0, if $0 < \lambda\|U_{R,x_0}\|_{p_1} < g(a) = \min_{s>0} g(s)$,

(ii) 1, if $\lambda\|U_{R,x_0}\|_{p_1} = g(a)$,

(iii) 2, if $g(a) < \lambda\|U_{R,x_0}\|_{p_1} < g(0)$,

(iv) 1, if $\lambda\|U_{R,x_0}\|_{p_1} \geq g(0)$.

This completes the proof of Corollary 1.2. □

Proof of Corollary 1.3. Let $A(s,t) = e^s$ and $B(s,t) = t^r$ for $r > 1$. Then the function $g(s)$ defined in (1.6) becomes

$$g(s) = \left(\frac{\|U_{R,x_0}\|_{p_1}}{\|\nabla U_{R,x_0}\|_{q_2}} \right)^r e^s s^{1-r}.$$

A computation yields that

$$\min_{s>0} g(s) = g(r-1) = \left(\frac{\|U_{R,x_0}\|_{p_1}}{\|\nabla U_{R,x_0}\|_{q_2}} \right)^r \left(\frac{e}{r-1} \right)^{r-1}$$

and $\lim_{s\to+0} g(s) = \lim_{s\to\infty} g(s) = +\infty$. Thus the number of solutions to (1.5) is

(i) 0, if $0 < \lambda\|U_{R,x_0}\|_{p_1} < \left(\frac{\|U_{R,x_0}\|_{p_1}}{\|\nabla U_{R,x_0}\|_{q_2}} \right)^r \left(\frac{e}{r-1} \right)^{r-1}$,

(ii) 1, if $\lambda\|U_{R,x_0}\|_{p_1} = \left(\frac{\|U_{R,x_0}\|_{p_1}}{\|\nabla U_{R,x_0}\|_{q_2}} \right)^r \left(\frac{e}{r-1} \right)^{r-1}$,

(iii) 2, if $\lambda\|U_{R,x_0}\|_{p_1} > \left(\frac{\|U_{R,x_0}\|_{p_1}}{\|\nabla U_{R,x_0}\|_{q_2}} \right)^r \left(\frac{e}{r-1} \right)^{r-1}$.

Let $0 < s_{1,\lambda} < s_{2,\lambda}$ be two solutions of $g(s) = \lambda\|U_{R,x_0}\|_{p_1}$ in the case (iii). Then we see $s_{1,\lambda} \to 0$ and $s_{2,\lambda} \to \infty$ as $\lambda \to \infty$. Since

$$e^{s_{i,\lambda}} = s_{i,\lambda}^{r-1} \lambda K$$

for $i = 1, 2$, where

$$K = \frac{\|\nabla U_{R,x_0}\|_{q_2}^r}{\|U_{R,x_0}\|_{p_1}^{r-1}},$$

by taking log of the above equation, we obtain

$$s_{i,\lambda} = (r-1)\log s_{i,\lambda} + \log(\lambda K). \tag{3.1}$$

Since $s_{1,\lambda} = o(1)$ as $\lambda \to \infty$, we have

$$o(1) = (r-1)\log s_{1,\lambda} + \log(\lambda K)$$

as $\lambda \to \infty$. By solving this with respect to $s_{1,\lambda}$, we see

$$s_{1,\lambda} = (\lambda K)^{-\frac{1}{r-1}} e^{o(1)} = (\lambda K)^{-\frac{1}{r-1}} (1+\delta) \tag{3.2}$$

where $\delta \to 0$ as $\lambda \to \infty$. Inserting (3.2) into the both sides of (3.1) and computing, we have

$$(\lambda K)^{-\frac{1}{r-1}} (1+\delta) = (r-1)\log(1+\delta) = (r-1)\delta(1+o(1)).$$

From this, we have

$$(\lambda K)^{-\frac{1}{r-1}} = (r-1)\frac{\delta}{1+\delta}(1+o(1)) = (r-1)\delta(1+o(1)).$$

Thus

$$\delta = \frac{1}{r-1}(1+o(1))(\lambda K)^{-\frac{1}{r-1}} \quad (\lambda \to \infty).$$

Inserting this into (3.2), we have

$$s_{1,\lambda} = (\lambda K)^{-\frac{1}{r-1}} \left(1 + \frac{1}{r-1}(1+o(1))(\lambda K)^{-\frac{1}{r-1}} \right)$$

and recalling $u_{1,\lambda} = s_{1,\lambda}\frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{p_1}}$, we obtain the formula for $u_{1,\lambda}$:

$$\begin{aligned} u_{1,\lambda}(x) &= (\lambda K)^{-\frac{1}{r-1}}\left(1+\frac{1}{r-1}(1+o(1))(\lambda K)^{-\frac{1}{r-1}}\right)\frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{p_1}} \\ &= \frac{\lambda^{-\frac{1}{r-1}}}{\|\nabla U_{R,x_0}\|_{q_2}^{\frac{r}{r-1}}}\left(1+\frac{1}{r-1}(1+o(1))\lambda^{-\frac{1}{r-1}}\frac{\|U_{R,x_0}\|_{p_1}}{\|\nabla U_{R,x_0}\|_{q_2}^{\frac{r}{r-1}}}\right)U_{R,x_0}(x) \end{aligned}$$

for $x \in B_R(x_0)$.

Similarly, from (3.1), we have

$$s_{2,\lambda} = (r-1)\log s_{2,\lambda} + \log(\lambda K).$$

Now, since $s_{2,\lambda} \to \infty$ as $\lambda \to \infty$, we have

$$s_{2,\lambda}\left(1-(r-1)\underbrace{\frac{\log s_{2,\lambda}}{s_{2,\lambda}}}_{=o(1)}\right) = \log(\lambda K) = (\log\lambda)\left(1+\underbrace{\frac{\log K}{\log\lambda}}_{=o(1)}\right)$$

as $\lambda \to \infty$. From this, we have

$$s_{2,\lambda} = \frac{1}{1-o(1)}(\log\lambda)(1+o(1)) = (1+\varepsilon)\log\lambda \tag{3.3}$$

as $\lambda \to \infty$, where $\varepsilon \to 0$ as $\lambda \to \infty$. Again, inserting this into (3.1), we have

$$(1+\varepsilon)\log\lambda = (r-1)\{\log(1+\varepsilon) + \log\log\lambda\} + \log\lambda + \log K,$$

which leads to

$$\begin{aligned} \varepsilon &= (r-1)\frac{\log\log\lambda}{\log\lambda}\left\{1+\underbrace{\frac{\log(1+\varepsilon)}{\log\log\lambda}+\frac{1}{r-1}\frac{\log K}{\log\log\lambda}}_{=o(1)}\right\} \\ &= (r-1)\frac{\log\log\lambda}{\log\lambda}(1+o(1)) \end{aligned}$$

as $\lambda \to \infty$. Then coming back to (3.3) and recalling that $u_{2,\lambda} = s_{2,\lambda}\frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{p_1}}$, we obtain the asymptotic formula for $u_{2,\lambda}$:

$$\begin{aligned} s_{2,\lambda} &= (1+\varepsilon)\log\lambda = \left(1+(r-1)\frac{\log\log\lambda}{\log\lambda}(1+o(1))\right)\log\lambda, \\ u_{2,\lambda}(x) &= \{\log\lambda + (r-1)(\log\log\lambda)(1+o(1))\}\frac{U_{R,x_0}(x)}{\|U_{R,x_0}\|_{p_1}} \end{aligned}$$

as $\lambda \to \infty$. □

Abstract. This paper analyzes the oscillation of the second-order neutral differential equation in noncanonical form

$$\left[r(t)\left((x(t)+p(t)x(\pi(t)))'\right)^{\alpha}\right]'+k(t)x^{\beta}(\eta(t))=0.$$

Using a combination of the linearization technique and the monotonicity properties of the neutral term, we derive new conditions for the studied equation to be oscillatory. Our findings provide new results applicable to linear, sublinear, superlinear, half-linear and other nonlinear forms of the studied equation, and moreover, for all these cases, the oscillation of the studied equation is attained via only one condition. Further, we illustrate the significance of our results with various examples, highlighting their superiority over known criteria in the existing literature.

Keywords: noncanonical, second-order, oscillation, neutral.

1 Introduction

The purpose of the present paper is to investigate the oscillatory behavior of solutions to the second-order noncanonical differential equation with bounded and unbounded neutral coefficients

$$\left[r(t)\left((x(t)+p(t)x(\pi(t)))'\right)^{\alpha}\right]'+k(t)x^{\beta}(\eta(t))=0,\quad t\in\mathcal{I}_0:=[t_0,\infty),\tag{1.1}$$

where $t_0\in\mathbb{R}_+:=(0,\infty)$, α and β are the ratios of odd positive integers with $\alpha\geq 1$. We also assume that:

✉ Email: ercantunc72@yahoo.com

(C_1) $r \in C(\mathcal{I}_0, \mathbb{R}_+)$ satisfies

$$\int_{t_0}^{\infty} \frac{1}{r^{1/\alpha}(t)} dt < \infty; \tag{1.2}$$

(C_2) $p, k \in C(\mathcal{I}_0, \mathbb{R}_0)$, $p(t) \geq \ell > 1$, and k does not vanish eventually;

(C_3) $\pi, \eta \in C(\mathcal{I}_0, \mathbb{R})$, $\pi(t) \leq t$, π is strictly increasing, η is nondecreasing, $\eta(t) \leq \pi(t)$, and $\lim_{t\to\infty} \pi(t) = \lim_{t\to\infty} \eta(t) = \infty$.

For simplicity, we put $z(t) := x(t) + p(t)x(\pi(t))$. Under a *solution* of (1.1), we mean a function $x \in C(\mathcal{I}_x, \mathbb{R})$, $\mathcal{I}_x := [t_x, \infty)$ for some $t_x \geq t_0$ such that $z \in C^1(\mathcal{I}_x, \mathbb{R})$, $r(z')^{\alpha} \in C^1(\mathcal{I}_x, \mathbb{R})$ and x satisfies (1.1) on $\mathcal{I}_x$. Since we are only interested in the oscillatory behavior of solutions, every solution $x(t)$ of (1.1) considered here is assumed to be continuable and nontrivial, i.e., $x(t)$ exists on some half-line $\mathcal{I}_x$ and $\sup_{t\geq T}\{|x(t)|\} > 0$ for any $T \geq t_x$. We say that a solution of (1.1) is *oscillatory* if it has an unbounded set of zeros on $\mathcal{I}_x$; it is called *nonoscillatory*, otherwise. The equation itself is called oscillatory if all its solutions oscillate.

Neutral differential equations are a type of functional differential equations in which the highest-order derivative of the unknown function appears both with and without deviating arguments. Equations of this type have attracted the interest of researchers not only from a theoretical point of view, but also because of their numerous applications in different fields. Those interested in the applications of such equations can refer to [17, 18] for some classical applications and to [7, 12] for more recent applications.

It is clearly observed from the literature review that the oscillation theory is one of the continuously developing important branches of the qualitative theory of differential equations. Its foundations are based on the pioneering work of Sturm [23] on well-known results concerning the zeros of solutions of second-order self-adjoint differential equations. Since then, oscillation criteria have been established for various classes of differential equations by researchers using different techniques and/or methods and the interesting results obtained have contributed significantly to the growth and development of this theory. There are different techniques and/or methods to establish oscillation criteria; among them, Riccati technique, integral averaging technique, comparison theorems and linearization techniques are some of the most influential; see, e.g., the books by Agarwal et al. [2,3], the papers [1,5,6,9–11,13,15,16,20–22,24] and the references quoted there.

We would like to point out that Eq. (1.1) is said to be in *noncanonical* form if (1.2) is satisfied, and Eq. (1.1) is said to be in *canonical* form if

$$\int_{t_0}^{\infty} \frac{1}{r^{1/\alpha}(t)} dt = \infty. \tag{1.3}$$

In particular, for the delay differential equation in canonical form

$$x''(t) + k(t)x(\eta(t)) = 0, \tag{1.4}$$

Koplatadze et al. [19] presented the following interesting oscillation criterion of lim sup-type

$$\limsup_{t\to\infty} \left\{ \eta(t) \int_t^{\infty} k(s)ds + \int_{\eta(t)}^{t} \eta(s)k(s)ds + \frac{1}{\eta(t)} \int_{t_0}^{\eta(t)} s\eta(s)k(s)ds \right\} > 1. \tag{1.5}$$

Later, Baculikova [4] extended the technique developed by Koplatadze et al.[19] to the second-order differential equation with deviating argument in noncanonical form

$$(r(t)x'(t))' + k(t)f(x(\eta(t))) = 0, \tag{1.6}$$

where f is nondecreasing and covers sublinear and linear cases ($f(u) = u^\beta$ with $\beta \in (0,1]$) and provided new oscillation criteria for equation (1.6).

Grace et al. [14] applied the same technique to the second-order neutral differential equation in noncanonical form

$$\left[r(t)\left(x(t)+p(t)x(\pi(t))\right)'\right]' + k(t)x^\beta(\eta(t)) = 0, \tag{1.7}$$

where $0 \le p(t) \le d < 1$ and $\beta \in (0,1]$, and derived new oscillation results for (1.7).

Tunç et al. [25] implemented the same technique to the equation with distributed deviating arguments in noncanonical form

$$\left[r(t)\left(x(t)+p(t)x(\pi(t))\right)'\right]' + \int_{c_1}^{c_2} k(t,\varrho)x^\beta(\phi(t,\varrho))d\varrho = 0, \tag{1.8}$$

where $0 < c_1 < c_2 < \infty$, $p(t) \ge \ell > 1$ and $\beta \in (0,1]$, and established novel criteria for the oscillation of (1.8).

From the above observations, it is clear that the results in [4, 14, 25] only cover the linear and sublinear cases, i.e., the results in [4, 14, 25] are only applicable to the cases ($\alpha = \beta = 1$) and ($\alpha = 1$ and $\beta < 1$); and so they provide no information for the superlinear case ($\alpha = 1$ and $\beta > 1$), half-linear case ($\beta = \alpha \ne 1$) and the other nonlinear cases such as ($1 \ne \alpha \ne \beta$) and ($\alpha > 1$ and $\beta = 1$).

Motivated by the above mentioned researches; using a combination of the linearization technique and the monotonicity properties of the neutral term, our goal here is to establish new oscillation criteria for Equation (1.1) that are applicable not only to the linear and sublinear cases, but also to the superlinear, half-linear and the other nonlinear cases the mentioned above. Furthermore, in contrast to the results reported in [14, 25], a key feature of our results is that the oscillation of the equation considered here is ensured through only one condition. It should also be noted that, as can be seen from the details in the proofs, the proofs for all these cases of α and β are not straightforward and require considerable effort. On the other hand, since we focus on the cases $1 < p(t) < \infty$ and $p(t) \to \infty$ as $t \to \infty$, our current results cannot be applied to the case $0 \le p(t) < 1$. However, with some standard calculations, the criteria here can be adjusted for the case $0 \le p(t) < 1$ as well. Additionally, a series of carefully selected examples are provided to illustrate the significance of our results and their superiority over known criteria in the existing literature.

We wish also point out that if x is a solution of (1.1), under our assumptions, $-x$ is also a solution of (1.1). Therefore, when considering nonoscillatory solutions, it is sufficient to consider only positive ones since the proofs for negative solutions are similar due to the form of (1.1).

2 Oscillation results for (1.1) in the case where $\beta \le \alpha$

In this section, we present the oscillation results for (1.1) in the case where $\beta \le \alpha$. For notational purposes, it would be convenient to set:

$$\kappa = (\ell-1)^\beta \ell^{-\beta},\ b(t) = \pi^{-1}(\eta(t)),\ A(t) = \int_{t_*}^{t} \frac{1}{r^{1/\alpha}(s)}ds,\ t_* \in \mathcal{I}_0,\ \lambda(t) = \int_t^\infty \frac{1}{r^{1/\alpha}(s)}ds.$$

Lemma 2.1. *Let x be an eventually positive solution of (1.1) on $\mathcal{I}_0$. If*

$$\int_{t_0}^\infty \lambda^\alpha(t)k(t)p^{-\beta}(b(t))dt = \infty, \tag{2.1}$$

then the corresponding function $z(t) = x(t) + p(t)x(\pi(t))$ *belongs to the class* $\mathcal{N}_0$ *eventually, where*

$$z(t) \in \mathcal{N}_0 \Leftrightarrow z(t) > 0, \quad r^{1/\alpha}(t)z'(t) < 0, \quad \left(r^{1/\alpha}z'\right)'(t) \leq 0.$$

Proof. Since x is an eventually positive solution of (1.1) on $\mathcal{I}_0$, there exists a $t_1 \in \mathcal{I}_0$ such that $x(t) > 0$ for $t \geq t_1$. In view of $\lim_{t\to\infty} \pi(t) = \lim_{t\to\infty} \eta(t) = \infty$, we can choose $t_2 \geq t_1$ such that $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_2$. Now, for $t \geq t_2$, $z(t) > 0$ and

$$\left(r(z')^{\alpha}\right)'(t) = -k(t)x^{\beta}(\eta(t)) \leq 0,$$

which implies that z' is of one sign eventually, i.e., either $z'(t) > 0$ or $z'(t) < 0$ eventually. We claim that $z'(t) < 0$ eventually. If this is not the case, then there exists a $t_3 \geq t_2$ such that $z'(t) > 0$ for $t \geq t_3$. Applying the chain-rule to $\left(r(z')^{\alpha}\right)'(t)$ yields

$$\left(r(z')^{\alpha}\right)'(t) = \alpha\left(r^{1/\alpha}(t)z'(t)\right)^{\alpha-1}\left(r^{1/\alpha}(t)z'(t)\right)'. \tag{2.2}$$

From (2.2) and the fact that α is the ratio of odd positive integers, we deduce that

$$\operatorname{sgn}\left(r^{1/\alpha}(t)z'(t)\right)' = \operatorname{sgn}\left(r(t)(z'(t))^{\alpha}\right)'.$$

Hence

$$z(t) > 0, \quad r^{1/\alpha}(t)z'(t) > 0, \quad \left(r^{1/\alpha}z'\right)'(t) \leq 0 \quad \text{for } t \geq t_3.$$

Now

$$z(t) \geq \int_{t_3}^{t} \frac{r^{1/\alpha}(s)z'(s)}{r^{1/\alpha}(s)}ds = A(t)r^{1/\alpha}(t)z'(t),$$

which implies that

$$\left(\frac{z(t)}{A(t)}\right)' \leq 0,$$

for $t \geq t_4$ for some $t_4 > t_3$, i.e., $z(t)/A(t)$ is nonincreasing for $t \geq t_4$. The definition of z leads to

$$\begin{aligned} x(t) &= \frac{1}{p(\pi^{-1}(t))}\left[z(\pi^{-1}(t)) - x(\pi^{-1}(t))\right] \\ &\geq \frac{z(\pi^{-1}(t))}{p(\pi^{-1}(t))} - \frac{z(\pi^{-1}(\pi^{-1}(t)))}{p(\pi^{-1}(t))p(\pi^{-1}(\pi^{-1}(t)))}. \end{aligned} \tag{2.3}$$

By (C_3), we see that π^{-1} is increasing, $t \leq \pi^{-1}(t)$, and

$$\pi^{-1}(t) \leq \pi^{-1}(\pi^{-1}(t)). \tag{2.4}$$

(2.4) together with the noincreasing nature of z/A yields

$$z\left(\pi^{-1}(\pi^{-1}(t))\right) \leq \frac{A\left(\pi^{-1}(\pi^{-1}(t))\right)z(\pi^{-1}(t))}{A\left(\pi^{-1}(t)\right)}. \tag{2.5}$$

Using (2.5) in (2.3) gives

$$x(t) \geq \frac{z(\pi^{-1}(t))}{p(\pi^{-1}(t))}\left[1 - \frac{A(\pi^{-1}(\pi^{-1}(t)))}{A(\pi^{-1}(t))}\frac{1}{p(\pi^{-1}(\pi^{-1}(t)))}\right] \quad \text{for } t \geq t_4. \tag{2.6}$$

By (C_2) and that

$$\lim_{t\to\infty}\frac{A(\pi^{-1}(t))}{A(t)}=1,$$

we see that there exists $t_5\geq t_4$ such that for any $\epsilon\in(0,\ell-1)$ and $t\geq t_5$,

$$\frac{A(\pi^{-1}(\pi^{-1}(t)))}{A(\pi^{-1}(t))}\frac{1}{p(\pi^{-1}(\pi^{-1}(t)))}\leq\frac{1+\epsilon}{\ell}.$$

Using this in (2.6) gives

$$x(t)\geq d\frac{z(\pi^{-1}(t))}{p(\pi^{-1}(t))}\quad\text{for } t\geq t_5, \tag{2.7}$$

where $d=1-(1+\epsilon)/\ell>0$. Substituting (2.7) into (1.1) yields

$$\left(r(z')^{\alpha}\right)'(t)+d^{\beta}k(t)p^{-\beta}(\pi^{-1}(\eta(t)))z^{\beta}\left(\pi^{-1}(\eta(t))\right)\leq 0, \tag{2.8}$$

for $t\geq t_6$. For $t\geq t_6$, we have $z(t)\geq z(t_6):=c>0$, and so inequality (2.8) leads to

$$\left(r(z')^{\alpha}\right)'(t)+c^{\beta}d^{\beta}k(t)p^{-\beta}(b(t))\leq 0\quad\text{for } t\geq t_7\geq t_6. \tag{2.9}$$

Since λ is positive, decreasing and $\lim_{t\to\infty}\lambda(t)=0$, we can choose a sufficiently large $t_*\in\mathcal{I}_0$ such that

$$0<\lambda(t)<1\quad\text{for } t\geq t_*. \tag{2.10}$$

Let $t_8=\max\{t_7,t_*\}$. Integrating (2.9) from t_7 to ∞ and taking (2.10) into account, we obtain

$$\begin{aligned}r(t_7)(z'(t_7))^{\alpha}\geq c^{\beta}d^{\beta}\int_{t_7}^{\infty}k(t)p^{-\beta}(b(t))dt&\geq c^{\beta}d^{\beta}\int_{t_8}^{\infty}k(t)p^{-\beta}(b(t))dt\\&\geq c^{\beta}d^{\beta}\int_{t_8}^{\infty}\lambda^{\alpha}(t)k(t)p^{-\beta}(b(t))dt,\end{aligned}$$

which is impossible in view of (2.1) and so $z'(t)<0$ eventually and thus the proof ends. □

Lemma 2.2. *Suppose that x is an eventually positive solution of (1.1) on $\mathcal{I}_0$. If (2.1) holds, then the following are satisfied eventually:*

(i) $$z(t)+\lambda(t)r^{1/\alpha}(t)z'(t)\geq 0;$$

(ii) $$\frac{z(t)}{\lambda(t)}\quad\textit{is nondecreasing;}$$

(iii) $$\left(\frac{z(b(t))}{r^{1/\alpha}(t)z'(t)}\right)^{\alpha-1}\geq\lambda^{\alpha-1}(t);$$

and

(iv) $$\lim_{t\to\infty}z(t)=0.$$

Proof. Pick a $t_1\in\mathcal{I}_0$ such that $x(t)>0$, $x(\pi(t))>0$ and $x(\eta(t))>0$ for $t\geq t_1$. Proceeding similarly as in the proof of Lemma 2.1, we again see that the corresponding function $z(t)$ belongs to the class $\mathcal{N}_0$ eventually, say for $t\geq t_2$, for some $t_2\geq t_1$. Since $r^{1/\alpha}z'$ is negative and decreasing,

$$z(t)\geq-\int_t^{\infty}\frac{r^{1/\alpha}(s)z'(s)}{r^{1/\alpha}(s)}ds\geq-\lambda(t)r^{1/\alpha}(t)z'(t), \tag{2.11}$$

which means that part (i) is fulfilled.

From (2.11),

$$\left(\frac{z(t)}{\lambda(t)}\right)' = \frac{\lambda(t)r^{1/\alpha}(t)z'(t) + z(t)}{\lambda^2(t)r^{1/\alpha}(t)} \geq 0,$$

i.e., part (ii) holds.

Since $b(t) \leq t$, we get

$$z(b(t)) \geq z(t). \tag{2.12}$$

By (2.11) and (2.12), we observe that

$$\left(\frac{z(b(t))}{r^{1/\alpha}(t)z'(t)}\right)^{\alpha-1} \geq \lambda^{\alpha-1}(t), \tag{2.13}$$

which proves part (iii).

Finally, we will show that part (iv) is true. From the monotonic properties of z on $[t_2, \infty)$, we can choose a constant $L_1 \geq 0$ such that

$$\lim_{t\to\infty} z(t) = L_1.$$

We will show that $L_1 = 0$. If $L_1 > 0$, then there exists a $T_1 \geq t_2$ such that for any $\epsilon > 0$,

$$L_1 < z(t) < L_1 + \epsilon \quad \text{for } t \geq T_1. \tag{2.14}$$

By (2.4) and $z'(t) < 0$,

$$z(\pi^{-1}(t)) \geq z(\pi^{-1}(\pi^{-1}(t))). \tag{2.15}$$

Using (2.15) in (2.3) leads to

$$x(t) \geq \frac{1}{p(\pi^{-1}(t))}\left[1 - \frac{1}{p(\pi^{-1}(\pi^{-1}(t)))}\right] z(\pi^{-1}(t)) \quad \text{for } t \geq t_2, \tag{2.16}$$

which together with (C_2) yields

$$x(t) \geq \kappa^{1/\beta}\frac{z(\pi^{-1}(t))}{p(\pi^{-1}(t))} \quad \text{for } t \geq t_2, \tag{2.17}$$

Substituting (2.17) into (1.1) gives

$$\left(r(z')^{\alpha}\right)'(t) + \kappa k(t)p^{-\beta}(b(t))z^{\beta}(b(t)) \leq 0, \tag{2.18}$$

for $t \geq t_3$, for some $t_3 \geq t_2$. In view of (2.2), we can rewrite (2.18) in the form

$$\left(r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\frac{z^{\alpha-1}(b(t))}{\left(r^{1/\alpha}(t)z'(t)\right)^{\alpha-1}}k(t)p^{-\beta}(b(t))z^{\beta-\alpha+1}(b(t)) \leq 0. \tag{2.19}$$

By virtue of (2.13) and (2.19), we obtain

$$\left(r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha-1}(t)k(t)p^{-\beta}(b(t))z^{\beta-\alpha+1}(b(t)) \leq 0 \quad \text{for } t \geq t_3. \tag{2.20}$$

Let $t_4 = \max\{t_3, T_1\}$. Then, from (2.14) and (2.20), we observe that

$$\left(r^{1/\alpha}z'\right)'(t) + d\lambda^{\alpha-1}(t)k(t)p^{-\beta}(b(t)) \leq 0 \quad \text{for } t \geq t_4, \tag{2.21}$$

where $d = \kappa L_1^{1+\beta}/\alpha(L_1+\epsilon)^{\alpha} > 0$. Integrating (2.21) two times gives

$$\begin{aligned} z(t_4) &\geq d\int_{t_4}^{\infty} \frac{1}{r^{1/\alpha}(u)} \int_{t_4}^{u} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))dsdu \\ &= d\int_{t_4}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds = \infty, \end{aligned}$$

which is a contradiction. The contradiction obtained proves that $L_1 = 0$. The proof is over. □

Lemma 2.3. *Let x be an eventually positive solution of (1.1) on $\mathcal{I}_0$. If (2.1) holds, then the corresponding function z satisfies the linear inequalities*

$$\left(r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha-1}(t)k(t)p^{-\beta}(b(t))z(b(t)) \leq 0 \tag{2.22}$$

and

$$\left(z + \lambda r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha}(t)k(t)p^{-\beta}(b(t))z(b(t)) \leq 0, \tag{2.23}$$

eventually.

Proof. Following again the same arguments in the proof of Lemma 2.2, we arrive at (2.20) for $t \geq t_3$. Since z is positive, decreasing and $\lim_{t\to\infty} z(t) = 0$, there exists a sufficiently large $t_4 \geq t_3$ such that

$$0 < z(t) < 1 \quad \text{for } t \geq t_4. \tag{2.24}$$

By (2.24) and $\beta \leq \alpha$, we have

$$z^{\beta/\alpha}(t) \geq z(t) \quad \text{for } t \geq t_4. \tag{2.25}$$

From (2.24) and the fact that $\beta - \alpha \leq 0$, we obtain

$$z^{\beta-\alpha}(t) \geq z^{(\beta-\alpha)/\alpha}(t) \quad \text{for } t \geq t_4. \tag{2.26}$$

Using (2.26) in (2.20) gives

$$\left(r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha-1}(t)k(t)p^{-\beta}(b(t))z^{\beta/\alpha}(b(t)) \leq 0 \tag{2.27}$$

for $t \geq t_5$, for some $t_5 \geq t_4$. Using (2.25) in (2.27) leads to

$$\left(r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha-1}(t)k(t)p^{-\beta}(b(t))z(b(t)) \leq 0 \quad \text{for } t \geq t_5, \tag{2.28}$$

which proves (2.22).

From (2.28) and the fact that

$$\left(z + \lambda r^{1/\alpha}z'\right)'(t) = \lambda(t)\left(r^{1/\alpha}(t)z'(t)\right)', \tag{2.29}$$

we observe that

$$\left(z + \lambda r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha}(t)k(t)p^{-\beta}(b(t))z(b(t)) \leq 0 \quad \text{for } t \geq t_5, \tag{2.30}$$

i.e., (2.23) holds. The proof is complete. □

We are now ready to give the oscillation results for (1.1) in the case where $\beta \leq \alpha$ based on Lemmas 2.1–2.3.

Theorem 2.4. *If*

$$\limsup_{t\to\infty} \mathrm{W}(t) > \frac{\alpha}{\kappa}, \tag{2.31}$$

where

$$\mathrm{W}(t) := \lambda(t)\int_{t_0}^{t} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds + \frac{1}{\lambda(b(t))}\int_{t}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))\lambda(b(s))ds,$$

then equation (1.1) *is oscillatory.*

Proof. Let $x(t)$ be a nonoscillatory solution of (1.1), say $x(t) > 0$, $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_1$, for some $t_1 \geq t_0$. It follows from (2.31) that there exists a positive constant k such that

$$\limsup_{t\to\infty} \mathrm{W}(t) \geq \mathrm{k}. \tag{2.32}$$

We now assert that (2.32) implies (2.1). Indeed, if not, then

$$\int^{\infty} \lambda^{\alpha}(t)k(t)p^{-\beta}(b(t))dt < \infty.$$

Thus, there exists a sufficiently large $t_2 \in [t_1, \infty)$ such that

$$\int_{t_2}^{\infty} \lambda^{\alpha}(t)k(t)p^{-\beta}(b(t))dt < \frac{\mathrm{k}}{4}. \tag{2.33}$$

Recalling again that λ is positive, decreasing and $\lim_{t\to\infty}\lambda(t) = 0$, we again see that there exists a sufficiently large $t_* \in [t_0, \infty)$ such that (2.10) holds. Let $t_3 = \max\{t_2, t_*\}$. Then, for $t \geq t_3$, it follows from (2.10) and (2.33) that

$$\begin{aligned}
\lambda(t)\int_{t_1}^{t} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds &= \lambda(t)\int_{t_1}^{t_3} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds \\
&\quad + \lambda(t)\int_{t_3}^{t} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds \\
&\leq \lambda(t)\int_{t_1}^{t_3} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds \\
&\quad + \int_{t_3}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds \\
&\leq \lambda(t)\int_{t_1}^{t_3} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds + \frac{\mathrm{k}}{4}.
\end{aligned} \tag{2.34}$$

Also, for $t \geq t_3$,

$$\begin{aligned}
\frac{1}{\lambda(b(t))}\int_{t}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))\lambda(b(s))ds &\leq \int_{t}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds \\
&\leq \int_{t_3}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds < \frac{\mathrm{k}}{4}.
\end{aligned} \tag{2.35}$$

From (2.34) and (2.35), we deduce that

$$\limsup_{t\to\infty} \mathrm{W}(t) \leq \frac{\mathrm{k}}{2},$$

which contradicts (2.32), and the contradiction obtained shows that (2.32) implies (2.1). Thereby, all results of Lemmas 2.1–2.3 are fulfilled. Proceeding similarly as in proof in Lemma 2.3, we again arrive at (2.28) and (2.30) for $t \geq t_5$. Integrating (2.30) from $t(\geq t_5)$ to ∞ leads to

$$(z + \lambda r^{1/\alpha} z')(t) \geq \frac{\kappa}{\alpha} \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) z(b(s)) ds. \tag{2.36}$$

An integration of (2.28) from t_5 to t gives

$$-(\lambda r^{1/\alpha} z')(t) \geq \frac{\kappa}{\alpha} \lambda(t) \int_{t_5}^t \lambda^{\alpha-1}(s) k(s) p^{-\beta}(b(s)) z(b(s)) ds. \tag{2.37}$$

From (2.36) and (2.37), we obtain

$$\begin{aligned} z(t) \geq \frac{\kappa}{\alpha} \lambda(t) \int_{t_5}^t \lambda^{\alpha-1}(s) k(s) p^{-\beta}(b(s)) z(b(s)) ds \\ + \frac{\kappa}{\alpha} \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) z(b(s)) ds. \end{aligned} \tag{2.38}$$

In view of the monotonicity properties of z, b and z/λ, we obtain

$$\int_{t_5}^t \lambda^{\alpha-1}(s) k(s) p^{-\beta}(b(s)) z(b(s)) ds \geq \left(\int_{t_5}^t \lambda^{\alpha-1}(s) k(s) p^{-\beta}(b(s)) ds \right) z(t), \tag{2.39}$$

and

$$\begin{aligned} \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) z(b(s)) ds &= \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) \lambda(b(s)) \frac{z(b(s))}{\lambda(b(s))} ds \\ &\geq \left(\frac{1}{\lambda(b(t))} \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) \lambda(b(s)) ds \right) z(t). \end{aligned} \tag{2.40}$$

Using (2.39) and (2.40) in (2.38), we arrive at

$$\frac{\alpha}{\kappa} \geq \lambda(t) \int_{t_5}^t \lambda^{\alpha-1}(s) k(s) p^{-\beta}(b(s)) ds + \frac{1}{\lambda(b(t))} \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) \lambda(b(s)) ds.$$

Taking lim sup as $t \to \infty$ in the latter inequality, we obtain a contradiction with (2.31). This completes the proof. □

Theorem 2.5. *If*

$$\limsup_{t \to \infty} \mathrm{H}(t) > \frac{\alpha}{\kappa}, \tag{2.41}$$

where

$$\begin{aligned} \mathrm{H}(t) := \lambda(b(t)) \int_{t_0}^{b(t)} \lambda^{\alpha-1}(s) k(s) p^{-\beta}(b(s)) ds + \int_{b(t)}^t \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) ds \\ + \frac{1}{\lambda(b(t))} \int_t^\infty \lambda^\alpha(s) k(s) p^{-\beta}(b(s)) \lambda(b(s)) ds, \end{aligned}$$

then (1.1) *oscillates.*

Proof. Suppose that $x(t)$ is a nonoscillatory solution of (1.1) such that $x(t) > 0$, $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_1$, for some $t_1 \geq t_0$. As in the proof of Theorem 2.4, it is not difficult to see that (2.1) holds. Thereby, all results of Lemmas 2.1–2.3 are fulfilled. Using exactly the same arguments as in the proof of Theorem 2.4, we see that (2.38) holds and leads to

$$z(b(t)) \geq \frac{\kappa}{\alpha}\lambda(b(t)) \int_{t_5}^{b(t)} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))z(b(s))ds + \frac{\kappa}{\alpha}\int_{b(t)}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))z(b(s))ds + \frac{\kappa}{\alpha}\int_{t}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))z(b(s))ds.$$

In view of the monotonicity properties of z and z/λ, we conclude from the latter inequality that

$$\frac{\alpha}{\kappa} \geq \lambda(b(t)) \int_{t_5}^{b(t)} \lambda^{\alpha-1}(s)k(s)p^{-\beta}(b(s))ds + \int_{b(t)}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds + \frac{1}{\lambda(b(t))}\int_{t}^{\infty} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))\lambda(b(s))ds.$$

The remainder of the proof follows from that of Theorem 2.4. □

Theorem 2.6. *If*

$$\limsup_{t\to\infty} \int_{b(t)}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds > \frac{\alpha}{\kappa}, \tag{2.42}$$

then equation (1.1) *is oscillatory.*

Proof. Suppose that $x(t)$ is a nonoscillatory solution of (1.1) such that $x(t) > 0$, $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_1$, for some $t_1 \geq t_0$. It is obvious that (2.42) implies (2.1). Thereby, all results of Lemmas 2.1–2.3 are fulfilled. By Lemma 2.3, we again have (2.30). Setting

$$y(t) := z(t) + \lambda(t)r^{1/\alpha}(t)z'(t),$$

and taking $0 \leq y(t) \leq z(t)$ into account, we observe from (2.30) that

$$y'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha}(t)k(t)p^{-\beta}(b(t))y(b(t)) \leq 0.$$

Integrating the latter inequality from $b(t)$ to t gives

$$y(b(t)) \geq \frac{\kappa}{\alpha}\int_{b(t)}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))y(b(s))ds \geq \left(\frac{\kappa}{\alpha}\int_{b(t)}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds\right) y(b(t)),$$

from which

$$\frac{\alpha}{\kappa} \geq \int_{b(t)}^{t} \lambda^{\alpha}(s)k(s)p^{-\beta}(b(s))ds.$$

Taking the lim sup as $t \to \infty$, we find a contradiction to (2.42). The proof is complete. □

3 Oscillation results for (1.1) in the case where $\beta > \alpha$

In this section, we will establish the oscillation criteria for the case when $\beta > \alpha$. While in the previous section we have established the oscillation criteria via $z(t) \to 0$ as $t \to \infty$; in this section we will establish the oscillation criteria via $z(t)/\lambda(t) \to \infty$ as $t \to \infty$.

Lemma 3.1. *Let x be an eventually positive solution of (1.1) on $\mathcal{I}_0$. If*

$$\int_{t_0}^{\infty} \lambda^{\beta}(t)k(t)p^{-\beta}(b(t))dt = \infty, \tag{3.1}$$

then $z(t) \in \mathcal{N}_0$ and

$$\lim_{t\to\infty} \frac{z(t)}{\lambda(t)} = \infty.$$

Proof. Recalling again the monotonic properties of λ, we again see that there exists a sufficiently large $t_* \in [t_0, \infty)$ such that (2.10) holds. By (2.10) and $\beta > \alpha$, we have

$$\lambda^{\beta}(t) \leq \lambda^{\alpha}(t) \quad \text{for } t \geq t_*, \tag{3.2}$$

from which,

$$\lambda^{\beta}(t)k(t)p^{-\beta}(b(t)) \leq \lambda^{\alpha}(t)k(t)p^{-\beta}(b(t)). \tag{3.3}$$

Now, in view of (3.3), it is clear that (3.1) implies (2.1). So, all results of Lemma 2.1 and lemma 2.2 are fulfilled. Following similar arguments as in the proof of Lemma 2.2, we see that (2.18) holds. Since $\lambda(t) \to 0$ as $t \to \infty$ and $z(t) \to 0$ as $t \to \infty$, by L'Hôpital's rule,

$$\lim_{t\to\infty} \frac{z(t)}{\lambda(t)} = \lim_{t\to\infty} -r^{1/\alpha}(t)z'(t).$$

We now will show that $\lim_{t\to\infty} -r^{1/\alpha}(t)z'(t) = \infty$. Suppose to the contrary that positive and increasing function $-r^{1/\alpha}(t)z'(t)$ has finite limit. This assumption implies that there is a constant $b_1 > 0$ such that

$$-r^{1/\alpha}(t)z'(t) \leq b_1 < \infty.$$

This together with an integration of (2.18) from t_3 to t yields

$$\begin{aligned} b_1^{\alpha} \geq -r(t)(z'(t))^{\alpha} &\geq \kappa \int_{t_3}^{t} k(s)p^{-\beta}(b(s))z^{\beta}(b(s))ds \\ &\geq \kappa \int_{t_3}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s)) \left(\frac{z(s)}{\lambda(s)}\right)^{\beta} ds \\ &\geq \kappa \left(\frac{z(t_3)}{\lambda(t_3)}\right)^{\beta} \int_{t_3}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))ds, \end{aligned}$$

which contradicts (3.1) and we deduce that

$$\lim_{t\to\infty} \frac{z(t)}{\lambda(t)} = \lim_{t\to\infty} -r^{1/\alpha}(t)z'(t) = \infty. \qquad \square$$

Lemma 3.2. *Let x be an eventually positive solution of (1.1) on $\mathcal{I}_0$. If (3.1) holds, then*

$$\left(r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\beta}(t)k(t)p^{-\beta}(b(t))\frac{z(b(t))}{\lambda(b(t))} \leq 0 \tag{3.4}$$

and

$$\left(z + \lambda r^{1/\alpha}z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\beta+1}(t)k(t)p^{-\beta}(b(t))\frac{z(b(t))}{\lambda(b(t))} \leq 0, \tag{3.5}$$

eventually.

Proof. Since (3.1) implies (2.1), we again see that all the results of Lemma 2.1, Lemma 2.2 and Lemma 3.1 are fulfilled. Following similar arguments as in the proof of Lemma 2.2, we see that (2.20) for $t \geq t_3$ is satisfied. Since $z(t)/\lambda(t) \to \infty$ as $t \to \infty$, there exists a sufficiently large $T_1 \in [t_0, \infty)$ such that

$$\frac{z(t)}{\lambda(t)} \geq 1 \quad \text{for } t \geq T_1. \tag{3.6}$$

By (3.6) and $\beta > \alpha$,

$$\left(\frac{z(t)}{\lambda(t)}\right)^{\beta/\alpha} \geq \frac{z(t)}{\lambda(t)} \quad \text{for } t \geq T_1, \tag{3.7}$$

and

$$\beta - \alpha \geq \frac{\beta - \alpha}{\alpha}. \tag{3.8}$$

Now (3.6) and (3.8) leads to

$$\left(\frac{z(t)}{\lambda(t)}\right)^{\beta-\alpha} \geq \left(\frac{z(t)}{\lambda(t)}\right)^{(\beta-\alpha)/\alpha} \quad \text{for } t \geq T_1. \tag{3.9}$$

Since $\lim_{t\to\infty} b(t) = \infty$, we can choose $T_2 \geq T_1$ such that $b(t) \geq T_1$ for $t \geq T_2$ and so from (3.9)

$$\left(\frac{z(b(t))}{\lambda(b(t))}\right)^{\beta-\alpha} \geq \left(\frac{z(b(t))}{\lambda(b(t))}\right)^{(\beta-\alpha)/\alpha} \quad \text{for } t \geq T_2. \tag{3.10}$$

Let $t_4 = \max\{t_3, T_2\}$. Using (3.10) in (2.20) gives

$$\left(r^{1/\alpha} z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\alpha-1}(t)k(t)p^{-\beta}(b(t))\lambda^{\beta-\alpha+1}(b(t))\left(\frac{z(b(t))}{\lambda(b(t))}\right)^{\beta/\alpha} \leq 0 \quad \text{for } t \geq t_4. \tag{3.11}$$

Using that λ is decreasing, $b(t) \leq t$ and $\beta > \alpha$, it follows from (3.11) that

$$\left(r^{1/\alpha} z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\beta}(t)k(t)p^{-\beta}(b(t))\left(\frac{z(b(t))}{\lambda(b(t))}\right)^{\beta/\alpha} \leq 0 \quad \text{for } t \geq t_4. \tag{3.12}$$

Using (3.7) in (3.12) yields

$$\left(r^{1/\alpha} z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\beta}(t)k(t)p^{-\beta}(b(t))\frac{z(b(t))}{\lambda(b(t))} \leq 0 \quad \text{for } t \geq t_4, \tag{3.13}$$

which proves (3.4). Recalling (2.29) again, we can rewrite (3.13) in the form

$$\left(z + \lambda r^{1/\alpha} z'\right)'(t) + \frac{\kappa}{\alpha}\lambda^{\beta+1}(t)k(t)p^{-\beta}(b(t))\frac{z(b(t))}{\lambda(b(t))} \leq 0 \quad \text{for } t \geq t_4, \tag{3.14}$$

which proves (3.5). The proof is complete. □

Theorem 3.3. *If*

$$\limsup_{t\to\infty} \mathrm{K}(t) > \frac{\alpha}{\kappa}, \tag{3.15}$$

where

$$\mathrm{K}(t) := \lambda(t)\int_{t_0}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \frac{1}{\lambda(b(t))}\int_{t}^{\infty} \lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds,$$

then (1.1) *oscillates.*

Proof. Pick $t_1 \in \mathcal{I}_0$ such that $x(t) > 0$, $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_1$. From (3.15), we can choose a $\delta > 0$ such that

$$\limsup_{t\to\infty} \mathrm{K}(t) \geq \delta. \tag{3.16}$$

We now claim that (3.16) implies (3.1). Indeed, if not, then

$$\int^{\infty} \lambda^{\beta}(t)k(t)p^{-\beta}(b(t))dt < \infty.$$

Thus, for a sufficiently large $t_2 \in [t_1, \infty)$,

$$\int_{t_2}^{\infty} \lambda^{\beta}(t)k(t)p^{-\beta}(b(t))dt < \frac{\delta}{4}. \tag{3.17}$$

Recalling again the monotonicity properties of λ, we see that there exists a sufficiently large $t_* \in [t_0, \infty)$ such that (2.10) holds. Let $t_3 = \max\{t_2, t_*\}$. Then, for $t \geq t_3$, (2.10) and (3.17) yields

$$\begin{aligned}
\lambda(t)\int_{t_1}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds &= \lambda(t)\int_{t_1}^{t_3} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds \\
&\quad + \lambda(t)\int_{t_3}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds \\
&\leq \lambda(t)\int_{t_1}^{t_3} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds \\
&\quad + \int_{t_3}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))ds \\
&\leq \lambda(t)\int_{t_1}^{t_3} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \frac{\delta}{4}.
\end{aligned} \tag{3.18}$$

Also, for $t \geq t_3$,

$$\begin{aligned}
\frac{1}{\lambda(b(t))}\int_{t}^{\infty} \lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds &\leq \int_{t}^{\infty} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))ds \\
&\leq \int_{t_3}^{\infty} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))ds < \frac{\delta}{4}.
\end{aligned} \tag{3.19}$$

From (3.18) and (3.19), we conclude that

$$\limsup_{t\to\infty} \mathrm{K}(t) \leq \frac{\delta}{2},$$

which contradicts (3.16). The contradiction obtained shows that (3.1) holds, and hence all results of Lemma 3.1 and Lemma 3.2 are fulfilled. Next, proceeding similarly as in proof in Lemma 3.2, we arrive at (3.13) and (3.14) for $t \geq t_4$. Integrating (3.14) from t to ∞ yields

$$\left(z + \lambda r^{1/\alpha} z'\right)(t) \geq \frac{\kappa}{\alpha}\int_{t}^{\infty} \lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds. \tag{3.20}$$

Integrating (3.13) from t_4 to t and then multiplying by $\lambda(t)$, we get

$$-\left(\lambda r^{1/\alpha} z'\right)(t) \geq \frac{\kappa}{\alpha}\lambda(t)\int_{t_4}^{t} \lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds. \tag{3.21}$$

It follows from (3.20) and (3.21) that

$$z(t) \geq \frac{\kappa}{\alpha}\lambda(t)\int_{t_4}^{t}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds + \frac{\kappa}{\alpha}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds. \tag{3.22}$$

In view of the monotonicity properties of z, b and z/λ, we obtain

$$\int_{t_4}^{t}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds \geq \left(\int_{t_4}^{t}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds\right)z(b(t)), \tag{3.23}$$

and

$$\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds \geq \left(\frac{1}{\lambda(b(t))}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds\right)z(b(t)). \tag{3.24}$$

Using (3.23) and (3.24) in (3.22) yields

$$\frac{\alpha}{\kappa}z(t) \geq \left(\lambda(t)\int_{t_4}^{t}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds\right)z(b(t)) + \left(\frac{1}{\lambda(b(t))}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds\right)z(b(t)). \tag{3.25}$$

Using that z is decreasing and $b(t) \leq t$, we deduce from (3.25) that

$$\frac{\alpha}{\kappa} \geq \lambda(t)\int_{t_4}^{t}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \frac{1}{\lambda(b(t))}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds.$$

Now take the lim sup as $t \to \infty$, we get a contradiction to (3.15) and complete the proof. □

Theorem 3.4. *If*

$$\limsup_{t\to\infty} \mathrm{V}(t) > \frac{\alpha}{\kappa}, \tag{3.26}$$

where

$$\mathrm{V}(t) := \lambda(b(t))\int_{t_0}^{b(t)}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \frac{1}{\lambda(b(t))}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds,$$

then equation (1.1) *is oscillatory.*

Proof. Pick $t_1 \in \mathcal{I}_0$ such that $x(t) > 0$, $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_1$. As in the proof of Theorem 3.3, it is not difficult to see that (3.1). Thus, as in the proof of Theorem 3.3, we see that (3.22) holds and leads to

$$z(b(t)) \geq \frac{\kappa}{\alpha}\lambda(b(t))\int_{t_4}^{b(t)}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds + \frac{\kappa}{\alpha}\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds + \frac{\kappa}{\alpha}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds. \tag{3.27}$$

Using the monotonic properties of z and z/λ, we deduce from (3.27) that

$$z(b(t)) \geq \left(\frac{\kappa}{\alpha}\lambda(b(t))\int_{t_4}^{b(t)}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds\right)z(b(t)) + \left(\frac{\kappa}{\alpha}\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds\right)z(b(t)) + \left(\frac{\kappa}{\alpha}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds\right)\frac{z(b(t))}{\lambda(b(t))},$$

from which

$$\frac{\alpha}{\kappa} \geq \lambda(b(t))\int_{t_4}^{b(t)}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds + \frac{1}{\lambda(b(t))}\int_{t}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))ds.$$

The rest of the proof is as that of Theorem 3.3. □

Theorem 3.5. *If*

$$\limsup_{t\to\infty}\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds > \frac{\alpha}{\kappa}, \tag{3.28}$$

then (1.1) *is oscillatory.*

Proof. Pick $t_1 \in \mathcal{I}_0$ such that $x(t) > 0$, $x(\pi(t)) > 0$ and $x(\eta(t)) > 0$ for $t \geq t_1$. It is clear that (3.28) implies that

$$\int_{t_0}^{\infty}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds = \infty. \tag{3.29}$$

Using the monotonicity properties of λ and b, we see that

$$\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds \leq \int_{b(t)}^{t}\lambda^{\beta}(s)k(s)p^{-\beta}(b(s))ds. \tag{3.30}$$

In view of (3.29) and (3.30), we observe that (3.28) implies (3.1). Thereby, all results of Lemmas 3.1–3.2 are fulfilled. Proceeding as in the proof of Lemma 3.2, we again arrive at (3.14). Integrating (3.14) from $b(t)$ to t yields

$$z(b(t)) + \lambda(b(t))r^{1/\alpha}(b(t))z'(b(t)) \geq \frac{\kappa}{\alpha}\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\frac{z(b(s))}{\lambda(b(s))}ds \geq \left(\frac{\kappa}{\alpha}\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds\right)z(b(t)),$$

which, together with $z'(t) < 0$, gives

$$z(b(t)) \geq \left(\frac{\kappa}{\alpha}\int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds\right)z(b(t)). \tag{3.31}$$

We now observe from (3.31) that

$$\frac{\alpha}{\kappa} \geq \int_{b(t)}^{t}\lambda^{\beta+1}(s)k(s)p^{-\beta}(b(s))\lambda^{-1}(b(s))ds.$$

Taking the lim sup as $t \to \infty$, we get a contradiction to (3.28) and ends the proof. □

4 Examples

Now the applicability of all theorems presented in this article will be demonstrated with examples for all cases of α and β, i.e., for $\alpha = \beta$, $\beta > \alpha$ and $\beta < \alpha$, respectively.

Example 4.1. Let us consider the half-linear equation

$$\left(t^{10}\left(\left(x(t)+2x\left(\frac{t}{2}\right)\right)'\right)^5\right)' + at^4x^5\left(\frac{t}{4}\right) = 0, \quad t \geq 1. \tag{4.1}$$

Here, $r(t) = t^{10}$, $p(t) = 2$, $\pi(t) = t/2$, $\eta(t) = t/4$, $\alpha = \beta = 5$, and $k(t) = at^4$ with $a > 0$. Then

$$\lambda(t) = 1/t, \quad \pi^{-1}(t) = 2t, \quad b(t) = t/2, \text{ and } \quad \lambda(b(t)) = 2/t.$$

Now, condition (2.31) becomes

$$\limsup_{t\to\infty} \mathrm{W}(t) = \frac{a}{16},$$

condition (2.41) becomes

$$\limsup_{t\to\infty} \mathrm{H}(t) = a2^{-5}\left(2+\ln 2\right),$$

condition (2.42) becomes

$$\limsup_{t\to\infty} \int_{t/2}^{t} \frac{a2^{-5}}{s} ds = a2^{-5}\ln 2.$$

Next, by applying Theorems 2.4–2.6 to equation (4.1), we deduce that (4.1) is oscillatory by Theorem 2.4 if $a > 2560$, Eq. (4.1) oscillates by Theorem 2.5 if $a > 1901.4$, and (4.1) is oscillatory by Theorem 2.6 if $a > 7386$.

Note that none of the results in [4,14,25] can be applied to equation (4.1) since the equation is half-linear and ($\alpha = \beta = 5$). Also, our findings required only one condition to obtain the result, but the approach in [14,25] requires two conditions.

Example 4.2. Consider the superlinear equation

$$\left(t^2\left(x(t)+4tx\left(\frac{t}{6}\right)\right)'\right)' + at^5x^3\left(\frac{t}{8}\right) = 0, \quad t \geq 1. \tag{4.2}$$

Here $r(t) = t^2$, $p(t) = 4t$, $\pi(t) = t/6$, $\eta(t) = t/8$, $\alpha = 1$, $\beta = 3$, and $k(t) = at^5$ with $a > 0$. Then

$$\lambda(t) = 1/t, \quad \pi^{-1}(t) = 6t, \quad b(t) = 3t/4, \quad \text{and} \quad \lambda(b(t)) = 4/3t.$$

Now, condition (3.15) becomes

$$\limsup_{t\to\infty} \mathrm{K}(t) = \frac{a}{18},$$

condition (3.26) becomes

$$\limsup_{t\to\infty} \mathrm{V}(t) = \frac{a}{36}(2+\ln\frac{4}{3}),$$

condition (3.28) becomes

$$\limsup_{t\to\infty} \int_{3t/4}^{t} \frac{a}{36s} ds = \frac{a}{36}\ln\frac{4}{3}.$$

Next, by applying Theorems 3.3–3.5 to equation (4.2), we deduce that (4.2) is oscillatory by Theorem 3.3 if $a > 128/3 = 42.667$, Eq. (4.2) oscillates by Theorem 3.4 if $a > 256/3(2 + \ln 4/3) = 37.301$, and (4.2) is oscillatory by Theorem 3.5 if $a > 296.62$.

Note that none of the results in [4,14,25] can be applied to equations (4.2) since the equation is superlinear ($\beta = 3 > \alpha = 1$).

Example 4.3. Consider the nonlinear equation

$$\left(t^{10}\left(\left(x(t)+10x\left(\frac{t}{2}\right)\right)'\right)^5\right)' + at^6x^7\left(\frac{t}{4}\right) = 0, \quad t \geq 1. \tag{4.3}$$

Here, $r(t) = t^{10}$, $p(t) = 10$, $\pi(t) = t/2$, $\eta(t) = t/4$, $\alpha = 5$, $\beta = 7$, and $k(t) = at^6$. Then

$$\lambda(t) = 1/t, \quad \pi^{-1}(t) = 2t, \quad b(t) = t/2, \quad \text{and} \quad \lambda(b(t)) = 2/t.$$

Now, condition (3.15) becomes

$$\limsup_{t\to\infty} \mathrm{K}(t) = a10^{-7},$$

condition (3.26) becomes

$$\limsup_{t\to\infty} \mathrm{V}(t) = a10^{-7}2^{-1}(2+\ln 2),$$

condition (3.28) becomes

$$\limsup_{t\to\infty} \int_{t/2}^{t} \frac{a10^{-7}}{2s} ds = a10^{-7}2^{-1}\ln 2.$$

Next, by applying Theorems 3.3–3.5 to equation (4.3), we deduce that (4.3) is oscillatory by Theorem 3.3 if $a > 10^{15}/2 \times 9^7$, Eq. (4.3) oscillates by Theorem 3.4 if $a > 10^{15}/9^7(2+\ln 2)$, and (4.3) is oscillatory by Theorem 3.5 if $a > 10^{15}/9^7 \ln 2$.

Example 4.4. Consider the nonlinear equation

$$\left(t^{6}\left(\left(x(t)+2tx\left(\frac{t}{3}\right)\right)'\right)^3\right)' + at^3x\left(\frac{t}{6}\right) = 0, \quad t \geq 1. \tag{4.4}$$

Then

$$\lambda(t) = 1/t, \quad \pi^{-1}(t) = 3t, \quad b(t) = t/2, \text{ and } \quad \lambda(b(t)) = 2/t.$$

Now, condition (2.31) becomes

$$\limsup_{t\to\infty} \mathrm{W}(t) = 2a,$$

condition (2.41) becomes

$$\limsup_{t\to\infty} \mathrm{H}(t) = a(2+\ln 2),$$

(2.42) becomes

$$\limsup_{t\to\infty} \int_{t/2}^{t} \frac{a}{s} ds = a\ln 2.$$

Next, by applying Theorems 2.4–2.6 to equation (4.4), we deduce that (4.4) is oscillatory by Theorem 2.4 if $a > 3$, Eq. (4.4) oscillates by Theorem 2.5 if $a > 2.2279$, and (4.4) is oscillatory by Theorem 2.6 if $a > 8.6562$.

Note that none of the results in [4, 14, 25] can be applied to equations (4.3) and (4.4) since ($\alpha = 5$ and $\beta = 7$) and ($\alpha = 3$ and $\beta = 1$), respectively.

Remark 4.5. It would be of interest to extend the results in [8] to equations of type (1.1) using the technique in [8].

5 Conclusion

This study analyzed the oscillation of solutions to a class of second-order differential equations with bounded and unbounded neutral coefficients in noncanonical form. The oscillation results were obtained by a combination of the linearization technique and the monotonicity properties of the neutral term. Our findings advance the current understanding in this area by providing new results that can be applied to linear ($\alpha = \beta = 1$), superlinear ($\alpha = 1$ and $\beta > 1$), sublinear ($\alpha = 1$ and $\beta < 1$), half-linear ($\alpha = \beta \neq 1$) and the other nonlinear [$(1 \neq \alpha \neq \beta)$ and $(\alpha > 1$ and $\beta = 1)$] forms of the equation under study. Moreover, the oscillation results for all these cases are established by means of only one condition. Hence, results designed specifically for different classes are important in their own right and have both weak and strong points. In some cases, they improve and extend some existing results in the literature; and in some cases, they are interesting in their own right, i.e., they neither include nor are included by the existing results, and these differences are explained to some extent by examples.

Communicated by Dimitri Mugnai

Abstract. This paper deals with the quasilinear predator–prey chemotaxis system with nonlinear indirect signal production under homogeneous Neumann boundary conditions. Based on the maximal Sobolev regularity and a priori estimates, the global boundedness of solution is investigated. Meanwhile, this work partially improves or extends the results of Wang and Ke [*Acta Appl. Math.* **190**(2024), Paper No. 9, 14 pp.].

Keywords: chemotaxis, predator–prey, nonlinear production, boundedness.

2020 Mathematics Subject Classification: 35B35, 35A01, 35K55, 92C17.

1 Introduction

The mathematical modeling of predator–prey has a long and distinguished history. The research on the predator–prey model was pioneered by Lotka and Volterra [26]. Predators naturally move towards areas with many prey, while prey move towards areas with fewer predators, effectively avoiding theirs pursuers. Thus, their movements are not accidental but are directional, forming what we call a chemotaxis phenomenon. Chemotaxis is the widespread phenomena in nature, for instance, the directional movement of biological cells, bacteria or organisms in response to some chemical substance, including the positive (chemo-attraction) chemotaxis and negative (chemo-repulsion) chemotaxis. The research on the famous classical Keller–Segel model described the chemotaxis was initiated by Keller and Segel [18]. Chemotaxis is the ability of certain living organisms to orient their movement along a chemical concentration gradient of chemical signal substance in their environment, plays an important role in a wide range of biological processes. From then on, the studies on modeling and analysis of predator–prey chemotaxis system have received more attention from theoretical and mathematical ecologists due to it has various interesting issues, such as, global solvability, finite time blow-up, time asymptotic behavior.

In this paper, we study the following quasilinear predator–prey chemotaxis with nonlinear indirect signal production

$$\begin{cases} u_t = \nabla\cdot(D_1(u)\nabla u) + \chi\nabla\cdot(u(u+1)^{\alpha-1}\nabla\omega) + \lambda_1 u(1-u^{r_1-1}-\mu_1 v), & x\in\Omega,\ t>0,\\ v_t = \nabla\cdot(D_2(v)\nabla v) - \xi\nabla\cdot(v(v+1)^{\beta-1}\nabla\omega) + \lambda_2 v(1-v^{r_2-1}+\mu_2 u), & x\in\Omega,\ t>0,\\ \omega_t = \Delta\omega - \omega + z^{\gamma}, & x\in\Omega,\ t>0,\\ 0 = \Delta z - z + f(u) + g(v), & x\in\Omega,\ t>0,\\ \frac{\partial u}{\partial\nu} = \frac{\partial v}{\partial\nu} = \frac{\partial\omega}{\partial\nu} = \frac{\partial z}{\partial\nu} = 0, & x\in\partial\Omega,\ t>0,\\ u(x,0)=u_0(x), v(x,0)=v_0(x), \omega(x,0)=\omega_0(x) & x\in\Omega, \end{cases} \tag{1.1}$$

where $\Omega\subset\mathbb{R}^n (n\geq 1)$ is a bounded domain with smooth boundary, ν is the unit outer normal vector on the boundary, the parameters $\chi,\xi,\lambda_1,\lambda_2,\mu_1,\mu_2,\gamma>0, r_1,r_2>1$ and $\alpha,\beta\in\mathbb{R}$. The initial date u_0, v_0 and ω_0 satisfy

$$u_0, v_0\in C^0(\overline{\Omega}) \quad\text{and}\quad \omega_0\in W^{1,\infty}(\Omega), \quad u_0, v_0, \omega_0\geq 0(\not\equiv 0) \text{ in } \overline{\Omega}. \tag{1.2}$$

Here $u(x,t)$ and $v(x,t)$ represent the population density of the prey and the predator, respectively. $\omega(x,t)$, $z(x,t)$ denote the concentration of chemical attractants, $z(x,t)$ is produced by $u(x,t)$ and $v(x,t)$, and $\omega(x,t)$ is secreted by $z(x,t)$. The nonlinear functions $D_1, D_2\in C^2([0,\infty))$ satisfy

$$D_1(u)\geq (u+1)^{m_1-1}, \qquad D_2(v)\geq (v+1)^{m_2-1} \tag{1.3}$$

with $m_1, m_2\in\mathbb{R}$. The functions $f(u), g(v)$ are smooth and satisfy

$$0<f(u)\leq (u+1)^{\gamma_1}, \qquad 0<g(v)\leq (v+1)^{\gamma_2} \tag{1.4}$$

with $\gamma_1,\gamma_2>0$.

Before entering our motivation and main results of this paper, we first retrace some important developments on the (1.1) and its variants. We begin with the following well-known chemotaxis system. The Keller–Segel system was first proposed in [17] to describe the chemotaxis of cellular slime system, which reads as

$$\begin{cases} u_t = \Delta u - \chi\nabla\cdot(u\nabla v), & x\in\Omega,\ t>0,\\ v_t = \Delta v - v + u, & x\in\Omega,\ t>0, \end{cases} \tag{1.5}$$

where $u(x,t)$ and $v(x,t)$ denote the cell density and chemical concentration, respectively. Osaki et al. [30] obtained that the system (1.5) possesses a unique global classical solution which is uniformly bounded if $n=1$. The solution of the system (1.5) may blow up in finite or infinite time for $n=2$ or $n\geq 3$ in [11,13,32,45,46].

The main focus of the above Keller–Segel system is chemoattraction, however, in practical application, chemorepulsion is also involved in many biological processes. In fact, there is a repulsive Keller–Segel system

$$\begin{cases} u_t = \Delta u + \xi\nabla\cdot(u\nabla v), & x\in\Omega,\ t>0,\\ v_t = \Delta v - v + u, & x\in\Omega,\ t>0. \end{cases} \tag{1.6}$$

Cieślak et al. [5] obtained the global existence of the smooth solutions to system (1.6) in the two dimensions and weak solutions in dimension $n=3,4$. for results on the repulsive Keller–Segel model were given in [35,57].

In order to better understand the system (1.1), we first mention the following chemotaxis system

$$\begin{cases} u_t = \nabla \cdot (D(u)\nabla u) - \nabla \cdot (S(u)\nabla v) + f(u), & x \in \Omega,\ t > 0, \\ v_t = \Delta v - v + g(u), & x \in \Omega,\ t > 0, \end{cases} \tag{1.7}$$

where $\Omega \subset \mathbb{R}^n (n \geq 1)$, $D(u)$ and $S(u)$ represent the self-diffusion of the cells and the density dependent cross-diffusion mechanism, respectively. Meanwhile, The function $f(u)$ and $g(u)$ denote the logistic source and the production of chemical substances, respectively.

• At first, we introduce the case where $f(u) \equiv 0, g(u) = u$. For the case $D(u)$ varies in algebraic form, the known results indicate that the asymptotic of $\frac{S(u)}{D(u)} \simeq u^{\frac{2}{n}} (u > 1)$ is the critical condition distinguishing between blow-up and global boundedness to (1.7). Winkler [43] proved that if $\frac{S(u)}{D(u)} \geq cu^{\frac{2}{n}+\varepsilon}$ for all $u > 1$, the model (1.7) with Ω being a ball admits smooth solutions that blow-up either in finite or infinite time, while Tao and Winkler [36] showed that if Ω is convex and $\frac{S(u)}{D(u)} \leq cu^{\frac{2}{n}-\varepsilon}$ for all $u > 1$, then the solutions are globally bounded. Later, if $D(u) = (u+1)^{\alpha-1}, S(u) = u(u+1)^{\beta-1}$, there existed a global bounded classical solution under $\alpha > \beta - \frac{2}{n} + 1$ [16]. and if $\alpha < \beta - \frac{2}{n} + 1$ and when $\Omega \subset \mathbb{R}^n$ is a ball, then for any $\alpha > 0$, the solutions for system (1.7) might blow up in finite or infinite time when $n \geq 2$ [6,48].

• Turn to the case that more general $g(u)$ satisfies $0 < g(u) \leq u^\gamma$. When $D(u) \equiv 1$ and $S(u) = u$, Liu [24] showed the solutions of (1.7) are bounded in time if $\gamma \in (0, \frac{2}{n})$ with $n \geq 2$; whereas when $\gamma > \frac{2}{n}$, Winkler obtained radial blow-up solutions to (1.7) with replacing the second equation by $0 = \Delta v + u^\gamma - \frac{1}{|\Omega|}\int_\Omega u^\gamma$ [47]. Moreover, Other more results on global boundedness or blow-up of solutions related to the system (1.7), we refer to [4,23,49] for more details.

• Now, we will introduce the situation with logistic source $f(u) = ru - \mu u^{1+\sigma}$. If $D(u) \equiv 1, S(u) = u, g(u) = u$, it has been proven that (1.7) admits a unique globally bounded solution with $\sigma = 1, n \geq 3$ and $\mu > \mu_0$, where $\mu_0 > 0$ [44]. Furthermore, Xiang [51] proved the boundedness and convergence of solutions to this model by giving the explicit formula of $\mu_0 > 0$. If there is no bigness restriction to $\mu > 0$, Lankeit [20] showed that the model has a global weak solution when $r > 0$ and $n \geq 3$, and then established the eventual smoothness of the weak solution under the condition that $n = 3$ and r is sufficiently small. If $D(u) \equiv 1, S(u) = u, 0 \leq g(u) \leq u(u+1)^{\gamma-1}$ with $\gamma > 0$, Zhuang et al. [59] established that (1.7) admits a globally bounded solution under $\beta + \gamma = \sigma + 1$ with sufficiently large μ, or under $\beta + \gamma < \sigma + 1$ for all $\mu > 0$; Next, we assume that $D(u) \simeq (u+1)^{-\alpha}$, $S(u) \simeq u(u+1)^{\beta-1}, g(u) = u$ with $\alpha, \beta \in \mathbb{R}, r, \mu, \sigma > 0$, it is shown that in [55] that the model admits globally bounded for $0 < \alpha + \beta < \max\{\sigma + \alpha, \frac{2}{n}\}$ or $\beta = \sigma$ with μ large enough. Whereas if $g(u) = u^\gamma$ with $\gamma > 0$, Ding et al. [9] proved that the model (1.7) possesses a globally bounded and classical solution if one of the following holds:

(i) $\alpha + \beta + \gamma < 1 + \dfrac{2}{n}$,

(ii) $\beta + \gamma < \sigma + 1$, or $\beta + \gamma = \sigma + 1$ with μ large enough.

One of the well-known variants form of (1.7) is the two-species and one-stimuli chemotaxis

system. To describe the movement of two species, the following chemotaxis model

$$\begin{cases} u_t = \nabla \cdot (D_1(u)\nabla u - S_1(u)\nabla \omega) + f(u,v), & x \in \Omega,\ t > 0, \\ v_t = \nabla \cdot (D_2(v)\nabla v - S_2(v)\nabla \omega) + g(u,v), & x \in \Omega,\ t > 0, \\ \tau \omega_t = \Delta \omega - \omega + h(u,v), & x \in \Omega,\ t > 0, \end{cases} \tag{1.8}$$

was firstly proposed by Tello and Winkler in [38], where $\tau \in \{0,1\}$. For system (1.8), $u(x,t)$ and $v(x,t)$ denote the density of different species respectively, and $\omega(x,t)$ represents the concentrations of chemical substances. The functions $f(u,v), g(u,v)$ are functional response functions which are used to describe the relationship between two species, for instance, the predator–prey effect or competition mechanisms, and $h(u,v)$ is the production of chemical substances.

Before stating our motivation and main results of this paper, we mention some previous contributions of model (1.8). On the one hand, if $D_1(u) \equiv 1, D_2(v) \equiv 1, S_1(u) = \chi u, S_2(v) = \xi v$ and $f(u,v) = \mu_1 u(1-u-a_1 v), g(u,v) = \mu_2 v(1-v-a_2 u), h(u,v) = u+v$, Tello and Winkler [38] showed that the system (1.8) with $\tau = 0$ admits a global existence and asymptotic behavior of solutions when $0 \le a_1, a_2 < 1$. For $a_1 > 1 > a_2 \ge 0$, Stinner et al. [34] proved that the global existence and convergence of classical solutions. Later on, for $\tau = 1$, Bai and Winkler [2] showed that the global boundedness and asymptotical behavior of solution with sufficiently large $\mu_1, \mu_2 > 0$ for the two cases $a_1 \ge 1, 0 < a_2 < 1$ and $0 < a_1, a_2 < 1$ when $n \le 2$. In corresponding of strong competition $a_1, a_2 \ge 1$, Pan et al. [31] have developed a method to solve the asymptotic behavior. In addition, When $K_{1i}(s+1)^{\alpha_i - 1} \le D_i(s) \le K_{2i}(s+1)^{\beta_i - 1}, \frac{S_i(s)}{D_i(s)} \le K_i(s+1)^{\gamma_i}, (i = 1,2)$, and $f(u,v), g(u,v) \equiv 0, h(u,v) = u+v$, it is proved that system (1.8) admits a global bounded solution for $0 < \gamma_i < \frac{2}{n}$ in [39].

On the other hand, if $f(u,v) = \mu_1 u(1-u-a_1 v)$ and $g(u,v) = \mu_2 v(1-v+a_2 u)$, the system (1.8) can be seen as a two-species predator–prey model with chemotaxis mechanism. When $D_1(u) \equiv 1, D_2(v) \equiv 1, S_1(u) = -\chi u, S_2(v) = \xi v$, in the case of $\tau = 1$, Fu and Miao [10] proved that the system (1.8) admits a globally bounded classical solution under the parameters μ_1, μ_2, a_1, a_2 satisfy some suitable conditions and $n \le 2$. Furthermore, the unique positive equilibrium point and the semi-trivial equilibrium point were established, respectively. For $n = 3$, Miao et al.[29] proved that the system (1.8) possesses a global and bounded classical solution. In the case $\tau = 0$, Ma et al. [28] derived that the system (1.8) admits a boundedness and convergence of solutions for $n = 2, 3$. Recently, Yang-Xu-Pan [54] extended the work in [28] to arbitrary dimensional $n \ge 1$. When $D_1(u) \equiv 1, D_2(v) \equiv 1, S_1(u) = -\chi u^m, S_2(v) = \xi v^m$ and $f(u,v) = \mu_1 u(1-u-a_1 v), g(u,v) = \mu_2 v(1-v+a_2 u), h(u,v) \le \alpha u^l + \beta v^l$, it is shown that system (1.8) with $\tau = 1$ possesses a global bounded solution if $\frac{\mu_2 a_2^{p+1}}{\mu_1} \le C$ with $p > \frac{n}{2}, n \ge 2$ and $l + m < 1 + \frac{2}{n}$ with $m \ge 1$ in [33]. Moreover, for more results on the predator–prey chemotaxis system with two chemicals, which can refer to the details in [22,25].

In the system mentioned above, the chemical stimulus are produced by population, directly. However, in some realistic biological processes, there are very few research results in multi-species and multi-stimuli chemotaxis systems, where the production mechanism of stimulus is indirect. This process can be described as

$$\begin{cases} u_t = d_1 \Delta u - \chi_1 \nabla \cdot (u \nabla \omega) + \mu_1 u(1-u-a_1 v), & x \in \Omega,\ t > 0, \\ v_t = d_2 \Delta v - \chi_2 \nabla \cdot (v \nabla \omega) + \mu_2 v(1-v-a_2 u), & x \in \Omega,\ t > 0, \\ \tau \omega_t = \Delta \omega - \omega + z, & x \in \Omega,\ t > 0, \\ \tau z_t = \Delta z - z + u + v, & x \in \Omega,\ t > 0, \end{cases} \tag{1.9}$$

where $\tau \in \{0,1\}$, $u(x,t)$ and $v(x,t)$ denote the density of two species, $\omega(x,t)$ and $z(x,t)$ represent the concentration of chemical substance, $\omega(x,t)$ is secreted by $z(x,t)$, $z(x,t)$ is secreted by $u(x,t), v(x,t)$. If $\tau = 1, n \leq 2$, Xiang et al. [53] proved that the system (1.9) has a unique global classical solution, which is bounded in $\Omega \times (0,\infty)$. And if $\tau = 0$, it is shown that regardless of the size of u_0, v_0, the system admits a global bounded classical solution under two-dimension. Furthermore, asymptotic stabilization of global bounded solution to system (1.9) is researched under some suitable conditions of a_i, μ_i. Based on system (1.9), Xiang et al. [52] also discussed a two-competing-species chemotaxis model with indirect signal consumption, which admits a globally bounded and classical solution and obtains asymptotic stabilization under certain conditions. Besides, there are also other results of relevant systems in [41, 58]. More results involving the indirect signal production mechanism can refer to [3, 21, 27, 42, 50, 56].

Based on the above analysis, it is an interesting topic to study the impact of nonlinear indirect signal mechanisms on the dynamic behavior of predator–prey systems. Therefore, we will consider the following quasilinear predator–prey system with nonlinear indirect signal production

$$\begin{cases} u_t = \nabla \cdot (D_1(u)\nabla u) + \chi \nabla \cdot (u(u+1)^{\alpha-1}\nabla \omega) + \lambda_1 u(1 - u^{r_1 - 1} - \mu_1 v), & x \in \Omega,\ t > 0, \\ v_t = \nabla \cdot (D_2(v)\nabla v) - \xi \nabla \cdot (v(v+1)^{\beta-1}\nabla \omega) + \lambda_2 v(1 - v^{r_2 - 1} + \mu_2 u), & x \in \Omega,\ t > 0, \\ \omega_t = \Delta \omega - \omega + z^{\gamma}, & x \in \Omega,\ t > 0, \\ 0 = \Delta z - z + f(u) + g(v), & x \in \Omega,\ t > 0, \end{cases} \tag{1.10}$$

where $\Omega \subset \mathbb{R}^n$ is a bounded domain with smooth boundary. When $D_1(u) = D_2(v) \equiv 1, \alpha = \beta = 1$ and $f(u) = u^{\gamma_1}, g(v) = v^{\gamma_2}$, Wang and Ke [40] proved that if $n \geq 1$ and $\gamma, \gamma_1, \gamma_2, n$ and r_1, r_2 satisfy suitable conditions, then the system (1.10) admitted a global bounded solution.

For the best of our knowledge, few rigorous result seem to be known about the quasilinear predator–prey system with nonlinear indirect signal production of (1.1). Thus, we will study the boundedness of the system (1.1), now we show the main result of the present paper.

Theorem 1.1. *Let $\Omega \subset \mathbb{R}^n (n \geq 1)$ be a bounded domain with smooth boundary and the parameters fulfill $\chi, \xi, \lambda_1, \lambda_2, \mu_1, \mu_2, \gamma, \gamma_1, \gamma_2 > 0$ and $m_1, m_2, \alpha, \beta \in \mathbb{R}$. If $r_1 > 1, r_2 > 2$, $m_1 + \frac{2}{n} > \max\{\alpha + \gamma(\gamma_1 + \gamma_2), \beta + \gamma(\gamma_1 + \gamma_2), 1\}$ and $m_2 + \frac{2}{n} > \max\{\alpha + \gamma(\gamma_1 + \gamma_2), \beta + \gamma(\gamma_1 + \gamma_2), 1\}$. Assume that the initial date $u_0, v_0 \in C^0(\overline{\Omega})$ and $\omega_0 \in W^{1,\infty}(\Omega)$ are nonnegative, then the system (1.1) admits a nonnegative global classical solution*

$$(u, v, \omega, z) \in (C^0(\overline{\Omega} \times [0,\infty)) \cap C^{2,1}(\overline{\Omega} \times (0,\infty)))^3 \times (C^{2,0}(\overline{\Omega} \times (0,\infty))).$$

Moreover, the solution is bounded in $\Omega \times (0,\infty)$, in other words, there exists $C > 0$ such that

$$\|u(\cdot,t)\|_{L^\infty(\Omega)} + \|v(\cdot,t)\|_{L^\infty(\Omega)} + \|\omega(\cdot,t)\|_{W^{1,\infty}(\Omega)} + \|z(\cdot,t)\|_{W^{1,\infty}(\Omega)} \leq C \tag{1.11}$$

for all $t > 0$.

2 Preliminaries

In this section, we first state the local existence of classical solutions to (1.1), which can be achieved by the fixed point theory and parabolic regularity. Refer to [8, 14, 19, 37] for more details.

Lemma 2.1. *Let $\Omega \subset \mathbb{R}^n (n \geq 1)$ be a bounded domain with smooth boundary and the initial date $u_0, v_0 \in C^0(\overline{\Omega})$ and $\omega_0 \in W^{1,\infty}(\Omega)$ are nonnegative. Then there exists $T_{\max} \in (0, \infty]$ and a uniquely determined trip*

$$(u, v, \omega, z) \in \left(C^0(\overline{\Omega} \times [0, T_{\max})) \cap C^{2,1}(\overline{\Omega} \times [0, T_{\max}))\right)^3 \times (C^{2,0}(\overline{\Omega} \times (0, T_{\max})))$$

solving (1.1) in the classical sense in $\Omega \times (0, T_{\max})$.

With

$$u, v, \omega, z \geq 0 \quad \text{in } \overline{\Omega} \times (0, T_{\max}).$$

Furthermore, if $T_{\max} < \infty$, then

$$\lim_{t \to T_{\max}} \|u(\cdot, t)\|_{L^\infty(\Omega)} + \|v(\cdot, t)\|_{L^\infty(\Omega)} + \|\omega(\cdot, t)\|_{W^{1,\infty}(\Omega)} + \|z(\cdot, t)\|_{W^{1,\infty}(\Omega)} = \infty.$$

Lemma 2.2. *Assume that (u, v, ω, z) be a solution to (1.1). Then for any $\tilde{\eta} > 0$ and $\theta > 1$, there exists $\eta = \eta(\theta, \tilde{\eta}, |\Omega|)$ such that*

$$\int_\Omega z^\theta \leq \eta \int_\Omega (f(u)^\theta + g(v)^\theta) \quad \text{for all } t \in (0, T_{\max}), \tag{2.1}$$

with $f(u), g(v)$ as given in system (1.1).

Proof. The proof can be obtained via the same method as in [12, Lemma 2.2], but we will provide a detailed proof process here. Integrating the fourth of (1.1) to obtain

$$\int_\Omega z \leq \int_\Omega \big(f(u) + g(v)\big). \tag{2.2}$$

Multiplying the fourth equation of (1.1) by $z^{\theta-1}$, and integrating on Ω, we get

$$\begin{aligned} \frac{4(\theta-1)}{\theta^2} \int_\Omega |\nabla z^{\frac{\theta}{2}}|^2 + \int_\Omega z^\theta &= \int_\Omega \big(f(u) + g(v)\big) z^{\theta-1} \\ &\leq \frac{\theta-1}{\theta} \int_\Omega z^\theta + \frac{1}{\theta} \int_\Omega \big(f(u) + f(v)\big)^\theta \end{aligned} \tag{2.3}$$

for all $t \in (0, T_{\max})$. By Young's inequality, and thus

$$\|z\|_{L^\theta(\Omega)} \leq \|f(u) + g(v)\|_{L^\theta(\Omega)}, \qquad t \in (0, T_{\max}), \tag{2.4}$$

$$\frac{4(\theta-1)}{\theta} \int_\Omega |\nabla z^{\frac{\theta}{2}}|^2 \leq \int_\Omega \big(f(u) + g(v)\big)^\theta, \qquad t \in (0, T_{\max}). \tag{2.5}$$

Using Ehrling's lemma, for any $\tilde{\eta} > 0$, $\theta > 1$, there exists $\tilde{C} = \tilde{C}(\tilde{\eta}, \theta) > 0$ such that

$$\|\phi\|^2_{L^2(\Omega)} \leq \tilde{\eta} \|\phi\|^2_{W^{1,2}(\Omega)} + \tilde{C} \|\phi\|^2_{L^{\frac{2}{\theta}}(\Omega)}, \ \phi \in W^{1,2}(\Omega). \tag{2.6}$$

Take $\phi = z^{\frac{\theta}{2}}$. we know from (2.2), (2.4) and (2.5) that

$$\int_\Omega z^\theta \leq \tilde{\eta} \int_\Omega \big(f(u) + g(v)\big)^\theta + c_0 \|f(u) + g(v)\|^\theta_{L^1} \tag{2.7}$$

with $c_0 = c_0(\tilde{\eta}, \theta) > 0$. We have by the Hölder inequality with (2.7) that

$$\begin{aligned} \int_\Omega z^\theta &\leq \tilde{\eta} \int_\Omega \big(f(u) + g(v)\big)^\theta + c_0 |\Omega|^{\theta-1} \int_\Omega \big(f(u) + g(v)\big)^\theta \\ &= (\tilde{\eta} + c_0 |\Omega|^{\theta-1}) \int_\Omega \big(f(u) + g(v)\big)^\theta \\ &\leq \eta \int_\Omega \big(f(u)^\theta + g(v)^\theta\big) \end{aligned} \tag{2.8}$$

with $\eta := 2^{\theta-1}(\tilde{\eta} + c_0 |\Omega|^{\theta-1})$. □

Lemma 2.3. *Let $\Omega \subset \mathbb{R}^n (n \geq 1)$ be a bounded domain with smooth boundary and the parameters satisfy $\chi, \xi, \lambda_1, \lambda_2, \mu_1, \mu_2, \gamma, \gamma_1, \gamma_2 > 0, r_1, r_2 > 1$ and $\alpha, \beta, m_1, m_2 \in \mathbb{R}$. Assume that (u, v, ω, z) be a solution to (1.1). Then there exists $C > 0$ such that*

$$\int_\Omega u + \int_\Omega v \leq C \tag{2.9}$$

for all $t \in (0, T_{\max})$.

Proof. Integrating the first two equation in (1.1) with respect to $x \in \Omega$, we get

$$\frac{d}{dt}\int_\Omega u + \int_\Omega u = \int_\Omega \lambda_1 u(1 - u^{r_1 - 1} - \mu_1 v) + \int_\Omega u \tag{2.10}$$

and

$$\frac{d}{dt}\int_\Omega v + \int_\Omega v = \int_\Omega \lambda_2 v(1 - v^{r_2 - 1} + \mu_2 u) + \int_\Omega v \tag{2.11}$$

for all $t \in (0, T_{\max})$. Multiplying the equation (2.10) and the equation (2.11) with $\lambda_2\mu_2$ and $\lambda_1\mu_1$, respectively, then we add them up and invoke Young's inequality to derive that there exists $c_1 > 0$ such that

$$\begin{aligned}
&\lambda_2\mu_2 \frac{d}{dt}\int_\Omega u + \lambda_2\mu_2 \int_\Omega u + \lambda_1\mu_1 \frac{d}{dt}\int_\Omega v + \lambda_1\mu_1 \int_\Omega v \\
&= \lambda_2\mu_2(\lambda_1 + 1)\int_\Omega u - \lambda_1\lambda_2\mu_2 \int_\Omega u^{r_1} + \lambda_1\mu_1(\lambda_2 + 1)\int_\Omega v - \lambda_1\lambda_2\mu_1 \int_\Omega v^{r_2} \\
&\leq -\frac{\lambda_1\lambda_2\mu_2}{2}\int_\Omega u^{r_1} - \frac{\lambda_1\lambda_2\mu_1}{2}\int_\Omega v^{r_2} + c_1 \\
&\leq c_1
\end{aligned} \tag{2.12}$$

for all $t \in (0, T_{\max})$. Thus, applying the ODE comparison principle to (2.12), there exists $c_2 > 0$ such that

$$\int_\Omega u + \int_\Omega v \leq c_2 \tag{2.13}$$

for all $t \in (0, T_{\max})$. □

Lemma 2.4 ([15, Lemma 3.6] and [7, Lemma 3.2])**.** *Let $q \in (1, \infty)$ and $T \in (0, \infty]$, Then, for $g \in L^q([0, T); L^q(\Omega))$ and $z_0 \in W^{2,q}(\Omega)$, with $\frac{\partial z_0}{\partial \nu} = 0$ on $\partial\Omega$, there exists $C_q = C_q(\Omega, q, \|z_0\|_{W^{2,q}(\Omega)}) > 0$ such that every solution $z \in W^{1,q}_{loc}([0, T); L^q(\Omega)) \cap L^q_{loc}([0, T); W^{2,q}(\Omega))$ of*

$$\begin{cases} z_t = \Delta z - z + g, & x \in \Omega,\ t > 0, \\ \frac{\partial z}{\partial \nu} = 0, & x \in \partial\Omega,\ t > 0, \\ z(x, 0) = z_0, & x \in \Omega, \end{cases} \tag{2.14}$$

satisfies

$$\int_0^t e^s \int_\Omega |\Delta z(\cdot, t)|^q ds \leq C_q \left(1 + \int_0^t e^s \int_\Omega |g(\cdot, t)|^q ds\right) \quad \text{for all } t \in (0, T). \tag{2.15}$$

3 Global existence and boundedness

In this section, in order to prove the global existence and uniform boundedness of solutions to the system (1.1), we first establish the L^p-estimate for u, v.

Lemma 3.1. *Let $\Omega \subset \mathbb{R}^n (n \geq 1)$ be a bounded domain with smooth boundary and the parameters satisfy $\chi, \xi, \lambda_1, \lambda_2, \mu_1, \mu_2, \gamma, \gamma_1, \gamma_2 > 0$ and $m_1, m_2, \alpha, \beta \in \mathbb{R}$. If $r_1 > 1, r_2 > 2$, $m_1 + \frac{2}{n} > \max\{\alpha + \gamma_(\gamma_1 + \gamma_2), \beta + \gamma(\gamma_1 + \gamma_2), 1\}$ and $m_2 + \frac{2}{n} > \max\{\alpha + \gamma(\gamma_1 + \gamma_2), \beta + \gamma(\gamma_1 + \gamma_2), 1\}$, then for any $p > \max\{1 - m_1, 1 - \alpha, 1 - \beta, 1 - m_2, 1 - \alpha + (1 - \gamma)(\gamma_1 + \gamma_2), 1 - \beta + (1 - \gamma)(\gamma_1 + \gamma_2), \frac{(2-r_1)(r_2-1)}{r_2-2}, 1\}$, there exists $C > 0$ such that*

$$\int_\Omega u^p + \int_\Omega v^p \leq C \quad \text{for all } t \in (0, T_{\max}). \tag{3.1}$$

Proof. For any $p > 1$, testing the first equation in system (1.1) by $(u+1)^{p-1}$, we have

$$\begin{aligned}
\frac{1}{p}\frac{d}{dt}\int_\Omega (u+1)^p =& -(p-1)\int_\Omega (u+1)^{p-2} D_1(u)|\nabla u|^2 - \chi(p-1)\int_\Omega u(u+1)^{p+\alpha-3}\nabla u \cdot \nabla \omega \\
&+ \lambda_1 \int_\Omega u(u+1)^{p-1} - \lambda_1 \int_\Omega u^{r_1}(u+1)^{p-1} - \lambda_1\mu_1 \int_\Omega u(u+1)^{p-1} v \\
\leq& -(p-1)\int_\Omega (u+1)^{p+m_1-3}|\nabla u|^2 - \chi(p-1)\int_\Omega u(u+1)^{p+\alpha-3}\nabla u \cdot \nabla \omega \\
&+ \lambda_1 \int_\Omega u(u+1)^{p-1} - \lambda_1 \int_\Omega u^{r_1}(u+1)^{p-1}
\end{aligned} \tag{3.2}$$

for all $t \in (0, T_{\max})$. Due to

$$(a+b)^s \leq 2^{s-1}(a^s + b^s)$$

for all $a, b > 0, s > 1$. We get

$$\frac{1}{2^{r_1-1}}\int_\Omega (u+1)^{p+r_1-1} \leq \int_\Omega (u+1)^{p-1}u^{r_1} + \int_\Omega (u+1)^{p-1} \tag{3.3}$$

with $t \in (0, T_{\max})$. Let $\varphi(t) := \frac{1}{p}\int_\Omega (u+1)^p$, $h_\alpha(u(\cdot,t)) := \int_0^u s(s+1)^{p+\alpha-3}ds$. Thus, by a simple calculation with (3.2) and (3.3), we obtain

$$\begin{aligned}
\varphi'(t) \leq& -\frac{4(p-1)}{(p+m_1-1)^2}\int_\Omega \left|\nabla (u+1)^{\frac{p+m_1-1}{2}}\right|^2 - \chi(p-1)\int_\Omega \nabla h_\alpha(u)\cdot\nabla\omega + \lambda_1\int_\Omega u(u+1)^{p-1} \\
&- \lambda_1 \int_\Omega u^{r_1}(u+1)^{p-1} \\
\leq& -\frac{4(p-1)}{(p+m_1-1)^2}\int_\Omega \left|\nabla (u+1)^{\frac{p+m_1-1}{2}}\right|^2 + \chi(p-1)\int_\Omega h_\alpha(u)\Delta\omega + \lambda_1\int_\Omega (u+1)^p \\
&+ \lambda_1 \int_\Omega (u+1)^{p-1} - \frac{\lambda_1}{2^{r_1-1}}\int_\Omega (u+1)^{p+r_1-1}
\end{aligned} \tag{3.4}$$

for all $t \in (0, T_{\max})$. For the term $h_\alpha(u(\cdot t))$, we achieve

$$\begin{aligned}
h_\alpha(u(\cdot,t)) &= \int_0^{u(\cdot,t)} s(s+1)^{p+\alpha-3}ds \\
&\leq \frac{1}{p+\alpha-1}(u(\cdot,t)+1)^{p+\alpha-1}
\end{aligned} \tag{3.5}$$

for all $t \in (0, T_{\max})$. Thus, by the simple calculation with (3.5) and Young's inequality, we get

$$\begin{aligned}
\chi(p-1)\int_\Omega h_\alpha(u)\Delta\omega &\leq \frac{\chi(p-1)}{p+\alpha-1}\int_\Omega (u+1)^{p+\alpha-1}|\Delta\omega| \\
&\leq \int_\Omega (u+1)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} + c_3\int_\Omega |\Delta\omega|^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma(\gamma_1+\gamma_2)}}
\end{aligned} \tag{3.6}$$

for all $t \in (0, T_{\max})$, where $c_3 = \left(\frac{\chi(p-1)}{p+\alpha-1}\right)^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma(\gamma_1+\gamma_2)}}$. Using Young's inequality once more, for $r_1 > 1$ we have

$$\begin{aligned}
&\lambda_1 \int_\Omega (u+1)^p + \lambda_1 \int_\Omega (u+1)^{p-1} - \frac{\lambda_1}{2^{r_1-1}} \int_\Omega (u+1)^{p+r_1-1} \\
&\quad \le \frac{\lambda_1}{2^{r_1}} \int_\Omega (u+1)^{p+r_1-1} - \frac{\lambda_1}{2^{r_1-1}} \int_\Omega (u+1)^{p+r_1-1} + c_4 \\
&\quad = -\frac{\lambda_1}{2^{r_1}} \int_\Omega (u+1)^{p+r_1-1} + c_4
\end{aligned} \tag{3.7}$$

for all $t \in (0, T_{\max})$. Substituting (3.6)–(3.7) into (3.4), we obtain

$$\begin{aligned}
\varphi'(t) \le & -\frac{4(p-1)}{(p+m_1-1)^2} \int_\Omega |\nabla (u+1)^{\frac{p+m_1-1}{2}}|^2 + \int_\Omega (u+1)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} \\
& + c_3 \int_\Omega |\Delta \omega|^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma(\gamma_1+\gamma_2)}} - \frac{\lambda_1}{2^{r_1}} \int_\Omega (u+1)^{p+r_1-1} + c_4
\end{aligned} \tag{3.8}$$

for all $t \in (0, T_{\max})$.

Now, we add to both sides of (3.8) the term $\frac{1}{p}\int_\Omega (u+1)^p$, and we multiply by e^t. Since $e^t\varphi'(t) + e^t\varphi(t) = \frac{d}{dt}\left(e^t\varphi(t)\right)$, an integration over $(0,t)$ provides for all $t \in (0, T_{\max})$

$$\begin{aligned}
e^t\varphi(t) \le \varphi(0) & - \frac{4(p-1)}{(p+m_1-1)^2} \int_0^t e^s \int_\Omega |\nabla (u+1)^{\frac{p+m_1-1}{2}}|^2 + \int_0^t e^s \int_\Omega (u+1)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} \\
& + c_3 \int_0^t e^s \int_\Omega |\Delta \omega|^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma(\gamma_1+\gamma_2)}} - \frac{\lambda_1}{2^{r_1}} \int_0^t e^s \int_\Omega (u+1)^{p+r_1-1} + \frac{1}{p} \int_0^t e^s \int_\Omega (u+1)^p \\
& + c_4 \int_0^t e^s ds.
\end{aligned} \tag{3.9}$$

Taking $q = \frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma(\gamma_1+\gamma_2)} > 1$ in the Lemma 2.4, according to (2.15) and the third equation in system (1.1), we know

$$\int_0^t e^s \int_\Omega |\Delta \omega|^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma(\gamma_1+\gamma_2)}} \le C_q \left(1 + \int_0^t e^s \int_\Omega z^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma_1+\gamma_2}} ds\right) \tag{3.10}$$

for all $t \in (0, T_{\max})$. Applying Lemma 2.2 with $\theta = \frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma_1+\gamma_2} > 1$, and by (1.4), this implies

$$\int_\Omega z^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma_1+\gamma_2}} \le \eta \int_\Omega \left((1+u)^{\frac{\gamma_1(p+\alpha-1+\gamma(\gamma_1+\gamma_2))}{\gamma_1+\gamma_2}} + (1+v)^{\frac{\gamma_2(p+\alpha-1+\gamma(\gamma_1+\gamma_2))}{\gamma_1+\gamma_2}}\right) \tag{3.11}$$

for all $t \in (0, T_{\max})$. By Young's inequality, we have

$$\int_\Omega z^{\frac{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}{\gamma_1+\gamma_2}} \le \int_\Omega \left((1+u)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} + (1+v)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)}\right) + c_5 \tag{3.12}$$

for all $t \in (0, T_{\max})$. Collecting (3.10)–(3.12), we know

$$\begin{aligned}
e^t\varphi(t) \le \varphi(0) & - \frac{4(p-1)}{(p+m_1-1)^2} \int_0^t e^s \int_\Omega |\nabla (u+1)^{\frac{p+m_1-1}{2}}|^2 + c_6 \int_0^t e^s \int_\Omega (u+1)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} \\
& + c_7 \int_0^t e^s \int_\Omega (v+1)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} + \frac{1}{p} \int_0^t e^s \int_\Omega (u+1)^p - \frac{\lambda_1}{2^{r_1}} \int_0^t e^s \int_\Omega (u+1)^{p+r_1-1} \\
& + c_8 \int_0^t e^s ds
\end{aligned} \tag{3.13}$$

for all $t \in (0, T_{\max})$. We get from (2.9) with the Gagliardo–Nirenberg inequality that

$$\begin{aligned}
&\hat{c}\int_\Omega (u+1)^{p+\alpha+\gamma(\gamma_1+\gamma_2)-1} \\
&\quad = \hat{c}\left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^{\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}(\Omega)} \\
&\quad \le c_9\left\|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\theta_1\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^2(\Omega)} \left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{(1-\theta_1)\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^{\frac{2}{p+m_1-1}}(\Omega)} \\
&\qquad + c_9\left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^{\frac{2}{p+m_1-1}}(\Omega)} \\
&\quad \le c_{10}\left(\int_\Omega \left|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right|^2\right)^{\theta_1\frac{p+\alpha+\gamma(\gamma_1+\gamma_2)-1}{p+m_1-1}} + c_{11}
\end{aligned} \tag{3.14}$$

for all $t \in (0, T_{\max})$ and $\theta_1 = \frac{\frac{p+m_1-1}{2} - \frac{p+m_1-1}{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}}{\frac{p+m_1-1}{2} - \frac{1}{2} + \frac{1}{n}} \in (0,1)$.

Since $m_1 + \frac{2}{n} > \alpha + \gamma(\gamma_1+\gamma_2)$ implies $\theta_1\frac{p+\alpha+\gamma(\gamma_1+\gamma_2)-1}{p+m_1-1} < 1$, we have by Young's inequality that

$$\hat{c}\int_\Omega (u+1)^{p+\alpha+\gamma(\gamma_1+\gamma_2)-1} \le \frac{(p-1)}{(p+m_1-1)^2}\int_\Omega \left|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right|^2 + c_{12} \tag{3.15}$$

for all $t \in (0, T_{\max})$. By (2.9) with the Gagliardo–Nirenberg inequality once more, we get

$$\begin{aligned}
\hat{c}\int_\Omega (u+1)^p &= \hat{c}\left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\frac{2p}{p+m_1-1}}_{L^{\frac{2p}{p+m_1-1}}(\Omega)} \\
&\le c_{13}\left\|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\theta_2\frac{2p}{p+m_1-1}}_{L^2(\Omega)} \left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{(1-\theta_2)\frac{2p}{p+m_1-1}}_{L^{\frac{2}{p+m_1-1}}(\Omega)} \\
&\quad + c_{13}\left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\frac{2p}{p+m_1-1}}_{L^{\frac{2}{p+m_1-1}}(\Omega)} \\
&\le c_{14}\left(\int_\Omega \left|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right|^2\right)^{\theta_2\frac{p}{p+m_1-1}} + c_{15}
\end{aligned} \tag{3.16}$$

for all $t \in (0, T_{\max})$ and $\theta_2 = \frac{\frac{p+m_1-1}{2} - \frac{p+m_1-1}{2p}}{\frac{p+m_1-1}{2} - \frac{1}{2} + \frac{1}{n}} \in (0,1)$. Due to $m_1 + \frac{2}{n} > 1$ implies $\theta_2\frac{p}{p+m_1-1} < 1$, we get by Young's inequality that

$$\hat{c}\int_\Omega (u+1)^p \le \frac{(p-1)}{(p+m_1-1)^2}\int_\Omega \left|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right|^2 + c_{15} \tag{3.17}$$

for all $t \in (0, T_{\max})$. Combining (3.15) and (3.17), we obtain

$$\begin{aligned}
e^t\varphi(t) \le \varphi(0) &- \frac{2(p-1)}{(p+m_1-1)^2}\int_0^t e^s\int_\Omega \left|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right|^2 + c_7\int_0^t e^s\int_\Omega (v+1)^{p+\alpha-1+\gamma(\gamma_1+\gamma_2)} \\
&- \frac{\lambda_1}{2^{r_1}}\int_0^t e^s\int_\Omega (u+1)^{p+r_1-1} + c_{16}\int_0^t e^s ds
\end{aligned} \tag{3.18}$$

for all $t \in (0, T_{\max})$. Multiplying the second equation in system (1.1) with $(1+v)^{p-1}$, for any

$p > 1$, we derive from integration by parts that

$$\begin{aligned}\tilde{\varphi}'(t) \leq & -\frac{4(p-1)}{(p+m_2-1)^2}\int_\Omega \left|\nabla(v+1)^{\frac{p+m_2-1}{2}}\right|^2 - \frac{\xi(p-1)}{p+\beta-1}\int_\Omega (v+1)^{p+\beta-1}|\Delta\omega| \\ & + \lambda_2\left(\int_\Omega (v+1)^p + \int_\Omega (v+1)^{p-1}\right) \\ & - \frac{\lambda_2}{2^{r_2-1}}\int_\Omega (v+1)^{p+r_2-1} + \lambda_2\mu_2\int_\Omega (v+1)^p u\end{aligned} \tag{3.19}$$

for all $t \in (0, T_{\max})$, where $\tilde{\varphi}(t) = \frac{1}{p}\int_\Omega (v+1)^p$. Due to $r_2 > 1$, applications of Young's inequality imply that

$$\lambda_2\int_\Omega (v+1)^p + \lambda_2\int_\Omega (v+1)^{p-1} \leq \frac{\lambda_2}{2^{r_2-2}}\int_\Omega (v+1)^{p+r_2-1} + c_{17} \tag{3.20}$$

and

$$\begin{aligned}\lambda_2\mu_2\int_\Omega (1+v)^p u &\leq \frac{\lambda_2}{2^{r_2-2}}\int_\Omega (v+1)^{p+r_2-1} + c_{18}\int_\Omega u^{\frac{p+r_2-1}{r_2-1}} \\ &\leq \frac{\lambda_2}{2^{r_2-2}}\int_\Omega (v+1)^{p+r_2-1} + c_{18}\int_\Omega (u+1)^{\frac{p+r_2-1}{r_2-1}}\end{aligned} \tag{3.21}$$

for all $t \in (0, T_{\max})$. Substituting (3.20)–(3.21) into (3.19), we conclude that

$$\begin{aligned}\tilde{\varphi}'(t) \leq & -\frac{4(p-1)}{(p+m_2-1)^2}\int_\Omega \left|\nabla(v+1)^{\frac{p+m_2-1}{2}}\right|^2 - \frac{\xi(p-1)}{p+\beta-1}\int_\Omega (v+1)^{p+\beta-1}|\Delta\omega| \\ & + c_{18}\int_\Omega (u+1)^{\frac{p+r_2-1}{r_2-1}} + c_{19}\end{aligned} \tag{3.22}$$

for all $t \in (0, T_{\max})$. Invoking the same procedure as dealing with u, we have

$$\begin{aligned}e^t\tilde{\varphi}(t) \leq \tilde{\varphi}(0) & - \frac{2(p-1)}{(p+m_2-1)^2}\int_0^t e^s\int_\Omega \left|\nabla(v+1)^{\frac{p+m_2-1}{2}}\right|^2 + c_{20}\int_0^t e^s\int_\Omega (u+1)^{p+\beta-1+\gamma(\gamma_1+\gamma_2)} \\ & + c_{18}\int_0^t e^s\int_\Omega (u+1)^{\frac{p+r_2-1}{r_2-1}} + c_{21}\int_0^t e^s ds\end{aligned} \tag{3.23}$$

for all $t \in (0, T_{\max})$. By (2.9) with the Gagliardo–Nirenberg inequality once more, we obtain

$$\begin{aligned}&\hat{c}\int_\Omega (u+1)^{p+\beta+\gamma(\gamma_1+\gamma_2)-1} \\ &\quad = \hat{c}\left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\frac{2(p+\beta+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^{\frac{2(p+\beta+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}(\Omega)} \\ &\quad \leq c_{22}\left\|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\theta_3\frac{2(p+\beta+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^2(\Omega)} \left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{(1-\theta_1)\frac{2(p+\beta+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^{\frac{2}{p+m_1-1}}(\Omega)} \\ &\qquad + c_{22}\left\|(u+1)^{\frac{p+m_1-1}{2}}\right\|^{\frac{2(p+\beta+\gamma(\gamma_1+\gamma_2)-1)}{p+m_1-1}}_{L^{\frac{2}{p+m_1-1}}(\Omega)} \\ &\quad \leq c_{23}\left(\int_\Omega \left|\nabla(u+1)^{\frac{p+m_1-1}{2}}\right|^2\right)^{\theta_3\frac{p+\beta+\gamma(\gamma_1+\gamma_2)-1}{p+m_1-1}} + c_{24}\end{aligned} \tag{3.24}$$

for all $t \in (0, T_{\max})$ and $\theta_3 = \frac{\frac{p+m_1-1}{2} - \frac{p+m_1-1}{2(p+\beta+\gamma(\gamma_1+\gamma_2)-1)}}{\frac{p+m_1-1}{2} - \frac{1}{2} + \frac{1}{n}} \in (0,1)$.

Since $m_1 + \frac{2}{n} > \beta + \gamma(\gamma_1+\gamma_2)$ implies $\theta_3\frac{p+\beta+\gamma(\gamma_1+\gamma_2)-1}{p+m_1-1} < 1$, which in conjunction with

Young's inequality deduces that

$$\hat{c}\int_\Omega (u+1)^{p+\beta+\gamma(\gamma_1+\gamma_2)-1} \le \frac{2(p-1)}{(p+m_1-1)^2}\int_\Omega |\nabla (u+1)^{\frac{p+m_1-1}{2}}|^2 + c_{25} \tag{3.25}$$

for all $t \in (0, T_{\max})$. In view of the Gagliardo–Nirenberg inequality, there exists $c_{26} > 0$ such that

$$\begin{aligned}
&\hat{c}\int_\Omega (v+1)^{p+\alpha+\gamma(\gamma_1+\gamma_2)-1} \\
&\quad = \hat{c}\left\|(v+1)^{\frac{p+m_2-1}{2}}\right\|^{\frac{2(p+\alpha+\gamma(\gamma_2+\gamma_3)-1)}{p+m-1}}_{L^{\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_2-1}}(\Omega)} \\
&\quad \le c_{26}\left\|\nabla(v+1)^{\frac{p+m_2-1}{2}}\right\|^{\theta_4\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_2-1}}_{L^2(\Omega)} \left\|(u+1)^{\frac{p+m_2-1}{2}}\right\|^{(1-\theta_4)\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_2-1}}_{L^{\frac{2}{p+m_2-1}}(\Omega)} \\
&\qquad + c_{26}\left\|(v+1)^{\frac{p+m_2-1}{2}}\right\|^{\frac{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}{p+m_2-1}}_{L^{\frac{2}{p+m_2-1}}(\Omega)} \\
&\quad \le c_{27}\left(\int_\Omega \left|\nabla(v+1)^{\frac{p+m_2-1}{2}}\right|^2\right)^{\theta_4\frac{p+\alpha+\gamma(\gamma_1+\gamma_2)-1}{p+m_2-1}} + c_{28}
\end{aligned} \tag{3.26}$$

for all $t \in (0, T_{\max})$ and $\theta_4 = \frac{\frac{p+m_2-1}{2} - \frac{p+m_2-1}{2(p+\alpha+\gamma(\gamma_1+\gamma_2)-1)}}{\frac{p+m_2-1}{2}-\frac{1}{2}+\frac{1}{n}} \in (0,1)$.

Due to $m_2 + \frac{2}{n} > \alpha + \gamma(\gamma_1+\gamma_2)$ implies $\theta_4\frac{p+\alpha+\gamma(\gamma_1+\gamma_2)-1}{p+m_2-1} < 1$, we get by Young's inequality that

$$\hat{c}\int_\Omega (v+1)^{p+\alpha+\gamma(\gamma_1+\gamma_2)-1} \le \frac{2(p-1)}{(p+m_2-1)^2}\int_\Omega \left|\nabla(v+1)^{\frac{p+m_2-1}{2}}\right|^2 + c_{30} \tag{3.27}$$

for all $t \in (0, T_{\max})$. Combing (3.18), (3.23), (3.25), and (3.27), we obtain

$$\begin{aligned}
\frac{1}{p}e^t\int_\Omega u^p + \frac{1}{p}e^t\int_\Omega v^p &\le \frac{1}{p}e^t\int_\Omega (u+1)^p + \frac{1}{p}e^t\int_\Omega (v+1)^p \\
&= e^t\varphi(t) + e^t\tilde{\varphi}(t) \\
&\le \varphi(0) + \tilde{\varphi}(0) - \frac{\lambda_1}{2^{r_1}}\int_0^t e^s\int_\Omega (u+1)^{p+r_1-1} \\
&\quad + c_{18}\int_0^t e^s\int_\Omega (u+1)^{\frac{p+r_2-1}{r_2-1}} + c_{31}\int_0^t e^s ds
\end{aligned} \tag{3.28}$$

for all $t \in (0, T_{\max})$. Since $r_2 > 2$, $p > \frac{(2-r_1)(r_2-1)}{r_2-2}$, it is not difficult to compute that

$$\begin{aligned}
p + r_1 - 1 - \frac{p+r_2-1}{r_2-1} &= \frac{(p+r_1-1)(r_2-1) - (p+r_2-1)}{r_2-1} \\
&= \frac{p(r_2-2) + (r_1-1)(r_2-1) - (r_2-1)}{r_2-1} \\
&= \frac{p(r_2-2)}{r_2-1} + r_1 - 2 > 0.
\end{aligned} \tag{3.29}$$

Thus, we can conclude from Young's inequality that

$$c_{18}\int_0^t e^s\int_\Omega (u+1)^{\frac{p+r_2-1}{r_2-1}} \le \frac{\lambda_1}{2^{r_1}}\int_0^t e^s\int_\Omega (u+1)^{p+r_1-1} + c_{32} \tag{3.30}$$

for all $t \in (0, T_{\max})$. Combining (3.28) and (3.30), we have

$$e^t \left(\int_\Omega u^p + \int_\Omega v^p \right) \leq c_{33} + c_{34}(e^t - 1) \tag{3.31}$$

for all $t \in (0, T_{\max})$. Thus, we conclude that

$$\int_\Omega u^p + \int_\Omega v^p \leq c_{35} \tag{3.32}$$

for all $t \in (0, T_{\max})$. Therefore, the proof of Lemma 3.1 is complete. □

Now, we are in a position to complete the Theorem 1.1.

Proof of Theorem 1.1. For any $p > \max\{1 - m_1, 1 - m_2, 1 - \alpha, 1 - \beta, 1 - \alpha + (1 - \gamma)(\gamma_1 + \gamma_2), 1 - \beta + (1 - \gamma)(\gamma_1 + \gamma_2), \frac{(2-r_1)(r_2-1)}{r_2-2}, n\gamma_1, n\gamma_2, 1\}$ with $\gamma, \gamma_1, \gamma_2 > 0, m_1, m_2, \alpha, \beta \in \mathbb{R}$ and $n \geq 1$, by the elliptic L^p-estimate to the fourth equation in system (1.1) ensures the existence of $c_{36} > 0$ fulfilling

$$\|z(\cdot, t)\|_{W^{2, \frac{p}{\max\{\gamma_1, \gamma_2\}}}(\Omega)} \leq c_{36}, \qquad t \in (0, T_{\max}).$$

Thus

$$\|z(\cdot, t)\|_{W^{1,\infty}(\Omega)} \leq c_{37}, \quad t \in (0, T_{\max}), \quad \text{with } c_{37} > 0,$$

by the Sobolev imbedding theorem. Applying the parabolic regularity to the third equation in system (1.1), we have $\|\omega(\cdot, t)\|_{W^{1,\infty}(\Omega)} \leq c_{38}$ for all $t \in (0, T_{\max})$, with $c_{38} > 0$. From Lemma 3.1, we apply Moser iteration technique [1, 36] ensures

$$\|u(\cdot, t)\|_{L^\infty(\Omega)} \leq c_{39},$$

$$\|v(\cdot, t)\|_{L^\infty(\Omega)} \leq c_{40}$$

for all $t \in (0, T_{\max})$, with $c_{39}, c_{40} > 0$. Recalling Lemma 2.1, we infer that $T_{\max} = \infty$. Thus, we complete the proof of Theorem 1.1. □

Abstract. In this paper, we investigate the oscillatory behavior of second-order neutral delay differential equations with a canonical operator of the form

$$\left(a(x)\left(v'(x)\right)^m\right)' + C(x, u(\varphi(x))) = 0.$$

We introduce new monotonicity properties of the non-oscillatory solutions of these equations, which are then used to linearize the equations and derive new oscillatory criteria. The presented results significantly improve upon existing criteria.

Keywords: second order neutral delay differential equations, asymptotic properties, linearization, oscillation theory.

2020 Mathematics Subject Classification: 34K40, 34K25, 34K06, 34K11.

1 Introduction

The aim of our paper is to investigate the asymptotic and oscillatory behavior of solutions for second-order neutral delay differential equations

$$\left(a(x)\left(v'(x)\right)^m\right)' + C(x, u(\varphi(x))) = 0, \tag{1.1}$$

where $v(x) = u(x) + b(x)u(\psi(x))$.

We make the following assumptions throughout the paper:

(H1) $a(x) \in C([x_0, \infty), (0, \infty))$ and m is a ratio of two positive odd integers,

(H2) $c(x), b(x) \in C([x_0, \infty), (0, \infty))$ and $\frac{C(x,u(x))}{u^m(x)} \geq c(x)$, $b(x) \leq 1$,

(H3) $\psi(x) \in C([x_0, \infty))$ and $\psi(x) \leq x$, $\lim_{x \to \infty} \psi(x) = \infty$,

(H4) $\varphi(x) \in C([x_0, \infty))$ and $\varphi(x) \leq x$, $\lim_{x \to \infty} \varphi(x) = \infty$.

✉Corresponding author. Email: temtek@erciyes.edu.tr

Additionally, we require the canonical condition

$$A(x) = \int_{x_0}^{x} \frac{dy}{a^{1/m}(y)} \to \infty \quad \text{as } x \to \infty \tag{1.2}$$

which ensures proper asymptotic behavior of solutions.

A solution of (1.1) is defined to be a function $u(x) \in C^1([T_0, \infty))$ with $T_0 \geq x_0$, satisfying $a(x)(v'(x))^m \in C^1([T_0, \infty))$ and equation (1.1) on $[T_0, \infty)$. We only consider solutions $u(x)$ of (1.1) that satisfy $\sup\{|u(x)| : x \geq T\} > 0$ for all $T \geq T_0$, and assume that such solutions exist. A solution of (1.1) is classified as oscillatory if it has arbitrarily large zeros on $[T_0, \infty)$, and non-oscillatory otherwise. The equation is said to be oscillatory if all of its solutions are oscillatory.

Second-order delay differential equations have been the focus of significant research for several decades. Numerous papers have been dedicated to the problem of establishing oscillatory criteria for various types of differential equations. Notable monographs in this area include those by Blanka Baculíková and Josef Džurina [4], Agarwal et al. [1], Došly and Řehák [5], Erbe et al. [8], Kiguradze and Chanturia [10], Ladde et al. [13], and Győri and Ladas [9], as well as numerous works [2,3,6,7,11,14,15].

Such a criterion for the second-order delay differential equations, as presented by Koplatadze et al. [11], is based on the monotonic properties $u(x) \uparrow$ and $\frac{u(x)}{x} \downarrow$ of positive solutions of $u''(x) + c(x)u(\varphi(x)) = 0$. These properties have been widely used in the literature to establish oscillatory behavior in various types of differential equations.

In this paper, we aim to establish new comparison theorems and oscillatory criteria for the investigation of second-order neutral delay differential equations by utilizing the monotonic properties of non-oscillatory solutions. Building upon the previous work of Blanka Baculíková and Josef Džurina [4], we present novel monotonic properties that can be utilized to linearize the equation, which in turn allows us to deduce the oscillation of the original equation from its linear forms. Our first objective is to establish new comparison theorems for equation (1.1). The second objective is to provide oscillatory criteria that consider the linear forms of (1.1). Finally, we seek to test the strength of the general criteria with an example. The presented results in this paper significantly enhance the existing oscillatory criteria.

Our work builds upon previous research in the field and provides a novel and useful contribution to the theory of second-order neutral delay differential equations.

2 Preliminary results

We start with some useful lemmas concerning monotonic properties of nonoscillatory solutions for studied equation.

Lemma 2.1. *Let $u(x)$ be a positive solution of (1.1). Then*

(i) $a(x)(v'(x))^m > 0$,

(ii) $\frac{v(x)}{A(x)}$ *is decreasing*

for $x \geq x_1 \geq x_0$. Moreover if

$$\int_{x_0}^{\infty} A^m(\varphi(y))(1 - b(\varphi(y)))^m c(y)dy = \infty \tag{2.1}$$

holds, then

(iii) $\lim_{x\to\infty} \frac{v(x)}{A(x)} = 0$.

Proof. Suppose that $u(x)$ is a positive solution of (1.1). Then

$$\Big(a(x)\big(v'(x)\big)^m\Big)' < 0,$$

and there exists $x_1 \geq x_0$ such that $a(x)(v'(x))^m$ has a constant sign for $x \geq x_1$. Now assume the opposite, i.e., $a(x)(v'(x))^m < 0$. This implies the existence of a constant $k > 0$ such that $a(x)(v'(x))^m \leq -k < 0$. Integrating the previous inequality from x_1 to x and using (1.2), we obtain

$$v(x) \leq v(x_1) - k^{1/m}A(x) \to -\infty \quad \text{as } x \to \infty.$$

Hence, we have shown that assuming $a(x)(v'(x))^m < 0$ leads to a contradiction, and therefore we can conclude that $a(x)(v'(x))^m > 0$.

Using the monotonicity of $a^{1/m}(x)v'(x)$, we get

$$v(x) \geq \int_{x_1}^{x} \frac{a^{1/m}(y)v'(y)}{a^{1/m}(y)}dy \geq a^{1/m}(x)v'(x)A(x), \tag{2.2}$$

which implies $\big(\frac{v(x)}{A(x)}\big)' < 0$.

On the other hand, as $\frac{v(x)}{A(x)}$ is a positive and decreasing function, there exists a positive constant δ such that

$$\lim_{x\to\infty} \frac{v(x)}{A(x)} = \delta \geq 0.$$

Assume on the contrary that $\delta > 0$. Then $\frac{v(x)}{A(x)} \geq \delta$ for $x \geq x_1$. From the definition of $v(x)$ we have

$$\begin{aligned} u(x) &= v(x) - b(x)u(\psi(x)) \\ &\geq v(x) - b(x)v(\psi(x)) \\ &\geq v(x)(1 - b(x)). \end{aligned} \tag{2.3}$$

Integrating (1.1) from x_1 to x, we obtain

$$a(x_1)\big(v'(x_1)\big)^m \geq \delta^m \int_{x_1}^{x} c(y)A^m(\varphi(y))(1 - b(\varphi(y)))^m dy$$

which for $x \to \infty$ contradicts with (2.1). So that $\lim_{x\to\infty} \frac{v(x)}{A(x)} = 0$. The proof is completed. □

Since $A(x)$ is increasing, there exists $\lambda \geq 1$ such that

$$\frac{A(x)}{A(\varphi(x))} \geq \lambda. \tag{2.4}$$

Theorem 2.2. *Let* (2.1) *hold and there exist a positive constant* n *such that*

$$\frac{1}{m}A^m(\varphi(x))a^{1/m}(x)A(x)c(x)(1 - b(\varphi(x)))^m \geq n \quad \text{for } x \geq x_0. \tag{2.5}$$

If $u(x)$ *is a positive solution of* (1.1)*, then*

(i) $\frac{v(x)}{A^{1-n}(x)}$ *is decreasing for* $x \geq x_1$,

(ii) $\frac{v(x)}{A^{n_0}(x)}$ *is increasing for* $x \geq x_1$, *where* $n_0 = n^{1/m}\lambda^n$.

Proof. Assume that $u(x)$ is a positive solution of (1.1). It is important to note that condition (iii) of Lemma 2.1 implies

$$\lim_{x\to\infty} a^{1/m}(x)v'(x) = 0. \tag{2.6}$$

Therefore, an integration of (1.1) yields

$$a^{1/m}(x)v'(x) = \left(\int_x^\infty C(y, u(\varphi(y)))dy\right)^{1/m}. \tag{2.7}$$

It is easy to see that

$$\left[\left(a^{1/m}(x)v'(x)\right)^m\right]' = m\left(a^{1/m}(x)v'(x)\right)^{m-1}\left(a^{1/m}(x)v'(x)\right)'. \tag{2.8}$$

Setting into (1.1), we have

$$\left(a^{1/m}(x)v'(x)\right)' + \frac{1}{m}\left(a^{1/m}(x)v'(x)\right)^{1-m} C(x, u(\varphi(x))) = 0. \tag{2.9}$$

Then $w(x) = a^{1/m}(x)v'(x)$ is positive decreasing and satisfies

$$w'(x) + \frac{1}{m}w^{1-m}(x)C(x, u(\varphi(x))) = 0,$$

and from (H2) we get

$$w'(x) + \frac{1}{m}w^{1-m}(x)c(x)u^m(\varphi(x)) \le 0. \tag{2.10}$$

On the other hand, (2.2) and (2.3) implies

$$\begin{aligned} v(x) &\ge a^{1/m}(x)v'(x)A(x) \\ v(x) &\ge w(x)A(x) \\ \frac{u(x)}{(1-b(x))} &\ge w(x)A(x) \end{aligned}$$

and so

$$u(\varphi(x)) \ge w(x)A(\varphi(x))(1 - b(\varphi(x))). \tag{2.11}$$

Substituting the last inequality into (2.10), we get

$$w'(x) + \frac{1}{m}c(x)A^m(\varphi(x))(1 - b(\varphi(x)))^m w(x) \le 0$$

and

$$w'(x) + \frac{n}{A(x)a^{1/m}(x)}w(x) \le 0$$

which implies

$$-w'(x)A(x) \ge \frac{n}{a^{1/m}(x)}w(x) = nv'(x).$$

We can skip the proof of the theorem as it is similar to [4, Theorem 2.3]. □

The previous results did not distinguish between the cases $m < 1$ and $m \ge 1$. However, in order to provide oscillatory criteria for (1.1), we need to consider these cases separately.

3 Oscillatory results for $m \geq 1$

To simplify our notation let us denote

$$\kappa = \frac{(1-n)^{1-m}\lambda^{n(m-1)}}{m}.$$

Now we will provide new comparison principles that significantly simplify the examination of neutral delay differential equations.

Theorem 3.1. *Let $m \geq 1$, and (2.1), (2.5) hold. Then (1.1) is oscillatory provided that*

$$\Big(a^{1/m}(x)v'(x)\Big)' + \kappa A^{m-1}(\varphi(x))c(x)(1-b(\varphi(x)))^m v(\varphi(x)) = 0 \tag{3.1}$$

is oscillatory.

Proof. Suppose the opposite of the desired result, namely that $u(x)$ is a positive solution of (1.1). Since $\frac{v(x)}{A^{1-n}(x)}$ is decreasing, we have the inequality

$$v(x) \geq \frac{a^{1/m}(x)v'(x)}{(1-n)}A(x), \tag{3.2}$$

which for $m \geq 1$ yields

$$v^{1-m}(x) \leq \frac{\big(a^{1/m}(x)v'(x)\big)^{1-m}}{(1-n)^{1-m}}A^{1-m}(x).$$

Hence

$$\Big(a^{1/m}(x)v'(x)\Big)^{1-m} \geq (1-n)^{1-m}\frac{v^{1-m}(x)}{A^{1-m}(x)}. \tag{3.3}$$

Using again the monotonic property of $\frac{v(x)}{A^{1-n}(x)}$, we get

$$v^{1-m}(x) \geq \frac{v^{1-m}(\varphi(x))}{A^{(1-m)(1-n)}(\varphi(x))}A^{(1-m)(1-n)}(x). \tag{3.4}$$

Substituting (3.4) from (3.3), we have in view of (2.4) that

$$\begin{aligned}\Big(a^{1/m}(x)v'(x)\Big)^{1-m} &\geq (1-n)^{1-m}\frac{A^{(1-m)(1-n)}(x)}{A^{(1-m)(1-n)}(\varphi(x))}\frac{v^{1-m}(\varphi(x))}{A^{1-m}(x)} \\ &\geq (1-n)^{1-m}\lambda^{n(m-1)}\frac{v^{1-m}(\varphi(x))}{A^{1-m}(\varphi(x))}.\end{aligned} \tag{3.5}$$

By combining (2.10) and (3.5), we can derive that $v(x)$ satisfies the linear differential inequality

$$\Big(a^{1/m}(x)v'(x)\Big)' + \kappa c(x)A^{m-1}(\varphi(x))(1-b(\varphi(x)))^m v(\varphi(x)) \leq 0. \tag{3.6}$$

Conversely, by [12, Corollary 1], it is ensured that the corresponding differential equation (3.1) possesses a positive solution, which contradicts the assumption made earlier, thus completing the proof. □

We will utilize the outcomes of the previous theorem to establish novel oscillatory criteria.

Theorem 3.2. *Let $m \geq 1$, and (2.1), (2.5) hold. If*

$$\limsup_{x\to\infty}\Bigg\{A^{n-1}(\varphi(x))\int_{x_1}^{\varphi(x)} c(y)A(y)A^{m-n}(\varphi(y))(1-b(\varphi(y)))^m dy + A^{n}(\varphi(x))\int_{\varphi(x)}^{x} c(y)A^{m-n}(\varphi(y))(1-b(\varphi(y)))^m dy + A^{1-n_0}(\varphi(x))\int_{x}^{\infty} c(y)A^{m+n_0-1}(\varphi(y))(1-b(\varphi(y)))^m dy\Bigg\} > \frac{1}{\kappa}$$

then (1.1) is oscillatory.

Proof. The proof of the theorem closely follows the approach taken in [4, Theorem 4.1], making it unnecessary to provide a full proof here. □

For practical applications, we often need criteria that are easier to verify. The next theorem provides such conditions:

Theorem 3.3. *Let $m \geq 1$, and (2.1), (2.5) hold. If*

$$\liminf_{x\to\infty}\int_{\varphi(x)}^{x} c(y)A^m(\varphi(y))(1-b(\varphi(y)))^m dy > \frac{1}{\kappa e}$$

then (1.1) is oscillatory.

Proof. Suppose, for the sake of contradiction, that (1.1) has a positive solution $u(x)$. By Theorem 3.2, equation (3.1) is nonoscillatory, and we can assume that it has an eventually positive solution $v(x)$. Then, we can define $w(x) = a^{1/m}(x)v'(x)$, which is positive and decreasing. Therefore, we have

$$\begin{aligned} v(x) &= v(x_1) + \int_{x_1}^{x} v'(y)dy \geq \int_{x_1}^{x} \frac{a^{1/m}(y)v'(y)}{a^{1/m}(y)}dy \\ &\geq a^{1/m}(x)v'(x)\int_{x_1}^{x}\frac{dy}{a^{1/m}(y)} = w(x)A(x). \end{aligned}$$

By substituting the expression for $v(x)$ into (3.1), we obtain a first-order differential inequality of the form

$$w'(x) + \kappa A^m(\varphi(x))c(x)(1-b(\varphi(x)))^m w(\varphi(x)) \leq 0 \tag{3.7}$$

with positive solution $w(x)$. According to [13, Theorem 2.1.1], (3.7) has no positive solution if

$$\liminf_{x\to\infty}\int_{\varphi(x)}^{x} \kappa c(y)A^m(\varphi(y))(1-b(\varphi(y)))^m dy > \frac{1}{e}.$$

This contradicts our assumption that (1.1) has a positive solution. Hence, the proof is complete. □

4 Oscillatory results for $m \in (0,1)$

We now turn our attention to the case where $0 < m < 1$. This case requires different techniques due to the different nature of the nonlinearity. The following results parallel those of the previous section, but with important modifications to account for the changed parameter range.

To simplify the notation, we define

$$\omega = \frac{n^{\frac{1-m}{m}}\lambda^{1-m}}{m(1-n_0)^{\frac{1-m}{m}}}.$$

Theorem 4.1. *Let $0 < m < 1$, and (2.1), (2.5) hold. Then (1.1) is oscillatory provided that*

$$\left(a^{1/m}(x)v'(x)\right)' + \omega A^{m-1}(x)c(x)(1-b(\varphi(x)))^m v(\varphi(x)) = 0 \tag{4.1}$$

is oscillatory.

Proof. Assume the contrary that $u(x)$ is a positive solution of (1.1). Differentiating (2.7) with respect to x leads to the equation

$$\left(a^{1/m}(x)v'(x)\right)' + \frac{1}{m}\left(\int_x^\infty C(y,u(\varphi(y)))dy\right)^{\frac{1-m}{m}} C(x,u(\varphi(x))) = 0.$$

Employing the fact that $\frac{v(x)}{A^{n_0}(x)}$ is an increasing function, we can rewrite the previous inequality as follows:

$$\left(a^{1/m}(x)v'(x)\right)' + \frac{1}{m}\frac{v^{1-m}(\varphi(x))}{A^{(1-m)n_0}(\varphi(x))}\left(\int_x^\infty \frac{c(y)b_0^m(x)dy}{A^{-mn_0}(\varphi(y))}\right)^{\frac{1-m}{m}} \frac{c(x)v^m(\varphi(x))}{b_0^{-m}(x)} \le 0,$$

where $b_0(x) = 1 - b(\varphi(x))$. Consequently, we can conclude that $u(x)$ must satisfy the linear differential inequality

$$\left(a^{1/m}(x)v'(x)\right)' + \frac{1}{m}\left(\int_x^\infty \frac{c(y)b_0^m(y)dy}{A^{-mn_0}(\varphi(y))}\right)^{\frac{1-m}{m}} \frac{b_0^m(x)c(x)v(\varphi(x))}{A^{(1-m)n_0}(\varphi(x))} \le 0. \tag{4.2}$$

Additionally, by utilizing (2.4) and (2.5), we can derive

$$\begin{aligned}\int_x^\infty \frac{c(y)(1-b(\varphi(y)))^m}{A^{-mn_0}(\varphi(y))}dy &\ge \int_x^\infty mn\frac{A^{mn_0}(\varphi(y))}{A^m(\varphi(y))a^{1/m}(y)A(y)}dy \\ &\ge mn\lambda^{m(n_0-1)}\int_x^\infty \frac{A^{m(n_0-1)-1}(y)}{a^{1/m}(y)}dy \\ &\ge \frac{n\lambda^{m(n_0-1)}}{1-n_0}A^{m(n_0-1)}(x).\end{aligned}$$

Substituting (4.2), we get

$$\left(a^{1/m}(x)v'(x)\right)' + \frac{n^{\frac{1-m}{m}}\lambda^{1-m}}{m(1-n_0)^{\frac{1-m}{m}}}\frac{A^{(1-m)(n_0-1)}(x)}{A^{(1-m)n_0}(\varphi(x))}(1-b(\varphi(x)))^m c(x)v(\varphi(x)) \le 0.$$

By applying [12, Corollary 1], we can conclude that the corresponding differential equation (4.1) also has a positive solution. This contradicts the assumption that (4.1) has no positive solutions, and therefore the proof is complete. □

Theorem 4.2. *Let* $0 < m < 1$, *and* (2.1), (2.5) *hold. If*

$$\limsup_{x\to\infty}\Bigg\{A^{n-1}(\varphi(x))\int_{x_1}^{\varphi(x)}A^{1-n}(\varphi(y))A^m(y)c(y)(1-b(\varphi(y)))^m dy + A^n(\varphi(y))\int_{\varphi(x)}^{x}A^{1-n}(\varphi(y))A^{m-1}(y)c(y)(1-b(\varphi(y)))^m dy + A^{1-n_0}(\varphi(y))\int_{x}^{\infty}A^{n_0}(\varphi(y))A^{m-1}(y)c(y)(1-b(\varphi(y)))^m dy\Bigg\} > \frac{1}{\omega},$$

then (1.1) *is oscillatory.*

Proof. The proof of the theorem closely follows the approach used in [4, Theorem 4.2]. □

Theorem 4.3. *Let* $0 < m < 1$, *and* (2.1), (2.5) *hold. If*

$$\liminf_{x\to\infty}\int_{\varphi(x)}^{x}A(\varphi(y))A^{m-1}(y)c(y)(1-b(\varphi(y)))^m dy > \frac{1}{\omega e}$$

then (1.1) *is oscillatory.*

Proof. Since the proof of the theorem closely resembles that of [4, Theorem 4.3], it may be omitted. □

5 Example

Example 5.1. Consider a second-order neutral delay differential equation in the form of a general Euler differential equation

$$\left(x^k\left(v'(x)\right)^m\right)' + \frac{c_0}{x^{(m-k+1)}}u^m(\varphi_0 x) = 0, \tag{5.1}$$

where $v(x) = u(x) + b_0u(\psi(x))$ with $c_0 > 0$, $\varphi_0 \in (0,1)$ and $0 \le b_0 < 1$.

Then

$$A(x) = \frac{mx^{\left(1-\frac{k}{m}\right)}}{m-k},\quad A(\varphi_0 x) = \frac{m(\varphi_0 x)^{\left(1-\frac{k}{m}\right)}}{m-k},\quad \lambda = \frac{A(x)}{A(\varphi_0 x)} = \varphi_0^{\left(\frac{k}{m}-1\right)},$$

$$n = \frac{c_0\varphi_0^{(m-k)}}{m}\left(\frac{m}{m-k}\right)^{(m+1)}(1-b_0)^m,\quad n_0 = \frac{c_0^{\left(\frac{1}{m}\right)}m\varphi_0^{\left(1-\frac{k}{m}\right)(1-n)}}{(m-k)^{\left(1+\frac{1}{m}\right)}}(1-b_0)$$

$$\kappa = \frac{(1-n)^{(1-m)}\varphi_0^{n(1-m)\left(1-\frac{k}{m}\right)}}{m}$$

and

$$\omega = \frac{n^{\frac{1}{m}-1}\varphi_0^{(1-m)\left(\frac{k}{m}-1\right)}}{m(1-n_0)^{\frac{1}{m}-1}}.$$

Equation (5.1) with $m \geq 1$ is oscillatory provided that,

$$mn\left\{\frac{\varphi_0^{n\left(\frac{k}{m}-1\right)}}{1-n}+\frac{\varphi_0^{n\left(\frac{k}{m}-1\right)}-1}{n}+\frac{1}{1-n_0}\right\}>\frac{1}{\kappa}$$

by Theorem 3.2, or

$$n(m-k)\ln\frac{1}{\varphi_0}>\frac{1}{e\kappa}$$

by Theorem 3.3.

Equation (5.1) with $0 < m < 1$ is oscillatory provided that,

$$mn\varphi_0^{(1-m)\left(1-\frac{k}{m}\right)}\left\{\frac{\varphi_0^{n\left(\frac{k}{m}-1\right)}}{1-n}+\frac{\varphi_0^{n\left(\frac{k}{m}-1\right)}-1}{n}+\frac{1}{1-n_0}\right\}>\frac{1}{\omega}$$

by Theorem 4.2 or

$$n(m-k)\varphi_0^{(1-m)\left(1-\frac{k}{m}\right)}\ln\frac{1}{\varphi_0}>\frac{1}{e\omega}$$

by Theorem 4.3.

6 Conclusion

In this paper, we have established new oscillation criteria for second-order neutral delay differential equations by utilizing the monotonic properties of non-oscillatory solutions. Our approach generalizes previous results by considering a neutral term and a more general nonlinearity. The presented theorems provide effective tools for determining the oscillatory behavior of these equations.

It is worth noting that when we set $b(x) = 0$ (eliminating the neutral term) and $C(x, u(x)) = c(x)u^m(x)$, our results reduce to those obtained by Baculíková and Džurina [4]. This confirms the consistency of our approach while demonstrating its broader applicability to more complex equations.

Abstract. The existence and asymptotic behavior of positive decreasing solutions to the cyclic second-order nonlinear difference system

$$\Delta(p_i(n)|\Delta x_i(n)|^{\alpha_i-1}\Delta x_i(n)) = q_i(n)|x_{i+1}(n+1)|^{\beta_i-1}x_{i+1}(n+1), \quad i=\overline{1,N},$$

are studied, where $x_{N+1}=x_1$, $p_i=\{p_i(n)\}$ and $q_i=\{q_i(n)\}$ are positive real sequences, and the constants α_i and β_i, $i=\overline{1,N}$ are positive and satisfy the sublinear condition $\alpha_1\alpha_2\cdot\ldots\cdot\alpha_N>\beta_1\beta_2\cdot\ldots\cdot\beta_N$. Two distinct types of positive decreasing solutions are considered, depending on whether the series $\sum_{n=1}^{\infty}p_i(n)^{-1/\alpha_i}$ is divergent or convergent. In the first case, necessary and sufficient conditions for the existence of solutions tending to a positive constant as well as solutions tending to zero, while their associated quasi-differences approach a nonzero limit, are rigorously derived using fixed point techniques. In the second case, the analysis is focused on solutions whose components and quasi-differences both tend to zero. Under the additional assumption that the coefficient sequences are regularly varying, necessary and sufficient conditions for the existence of such solutions are obtained, and their precise asymptotic behavior is determined using the theory of discrete regular variation.

Keywords: cyclic system of difference equations, Emden–Fowler type difference equation, nonlinear difference equations, decreasing solutions, asymptotic behavior, regularly varying sequence.

2020 Mathematics Subject Classification: 39A22, 39A12, 26A12.

1 Introduction

The cyclic second-order nonlinear system of difference equations examined in this paper is of the following form:

$$\Delta(p_i(n)|\Delta x_i(n)|^{\alpha_i-1}\Delta x_i(n)) = q_i(n)|x_{i+1}(n+1)|^{\beta_i-1}x_{i+1}(n+1), \tag{SE}$$

where $i=\overline{1,N}$, $x_{N+1}=x_1$, $n\in\mathbb{N}$, and following conditions hold:

✉ Corresponding author. Email: akapesic@pmf.ni.ac.rs

(a) α_i and β_i, $i = \overline{1,N}$ are positive constants such that

$$\alpha_1\alpha_2 \cdot \ldots \cdot \alpha_N > \beta_1\beta_2 \cdot \ldots \cdot \beta_N;$$

(b) $p_i = \{p_i(n)\}$ and $q_i = \{q_i(n)\}$ are positive real sequences;

(c) All p_i, $i = \overline{1,N}$ simultaneously satisfy either

(I)
$$S_i = \sum_{n=1}^{\infty} \frac{1}{p_i(n)^{1/\alpha_i}} = \infty,$$

or

(II)
$$S_i = \sum_{n=1}^{\infty} \frac{1}{p_i(n)^{1/\alpha_i}} < \infty.$$

If (I) holds, the following notation will be used

$$P_i(n) = \sum_{k=1}^{n-1} \frac{1}{p_i(k)^{1/\alpha_i}}, \quad i = \overline{1,N} \tag{1.1}$$

while if (II) holds, the following notation will be used

$$\pi_i(n) = \sum_{k=n}^{\infty} \frac{1}{p_i(k)^{1/\alpha_i}}, \quad i = \overline{1,N} \tag{1.2}$$

System (SE) is referred to as sublinear if the condition (a) holds. When the opposite inequality is satisfied, the system is termed superlinear. If $\alpha_1\alpha_2 \cdot \ldots \cdot \alpha_N = \beta_1\beta_2 \cdot \ldots \cdot \beta_N$, then system is called half-linear.

Over the past fifty years, the application of difference equations in solving problems throughout statistics, engineering, and various scientific disciplines has significantly expanded. The development of high-speed digital computer technology has motivated the application of difference equations to ordinary and partial differential equations. Apart from this, difference equations are very useful for analyzing electrical, mechanical, thermal and other systems, the behavior of electric-wave filters and other filters, insulator strings, crankshafts of multi-cylinder engines among others.

As the generalization of the most studied second-order nonlinear differential equation, known as Emden–Fowler type equation, many authors have studied the differential equation

$$\big(p(t)|x'(t)|^{\alpha-1}x'(t)\big)' \pm q(t)|x(t)|^{\beta-1}x(t) = 0,$$

whose properties such as existence, uniqueness and continuity of the solution, oscillatory and nonoscillatory behavior of solutions have been examined in monographs [15, 27] as well as in papers [9, 10, 22, 35, 49]. The discrete counterpart of this equation

$$\Delta(p(n)|\Delta x(n)|^{\alpha-1}\Delta x(n)) \pm q(n)|x(n+1)|^{\beta-1}x(n+1) = 0, \tag{1.3}$$

has also attracted many researchers, see e.g. [11–14] and monographs [1, 3].

The qualitative analysis of second-order nonlinear difference equations was further extended to the study of two-dimensional first-order and second-order nonlinear difference systems [4, 21, 28, 30, 31], as well as to symmetric and close-to-symmetric systems of difference equations [6, 41, 42, 44–46].

As a further development of the research on second-order difference equations of Emden–Fowler type, the consideration of cyclic second-order systems of difference equations was naturally imposed. The study of such systems was first suggested in [17], and further attention has been given to them and to the close-to-cyclic difference equations in [29,38–40,43,47], in addition to the already quoted papers. A system of the form (SE) could be observed in the analysis of numerical methods for heat and fluid transfer in layered materials (e.g., cylindrical thermal insulation or heat transfer through geological layers).

In the continuous case, this type of system has been studied by Jaroš and Kusano in [18–20]. However, in the existing literature, there are no results concerning asymptotic analysis of solutions of a cyclic system of second-order difference equations, except in the work of Kapešić [23]. In this regard, the first task will be to classify positive decreasing solutions based on their behavior at infinity. Finding the necessary and sufficient conditions for the existence of all possible types of positive decreasing solutions is the second task. The last and most challenging task is obtaining the precise asymptotic formulas of these solutions.

It should be mentioned that the obtained results can be applied to cyclic systems of N first-order difference equations, in the case N is even.

2 Classification of positive decreasing solutions

By a solution of (SE) we mean a vector sequence

$$\mathbf{x} = (x_1, x_2, \dots, x_N) \in {}^{\mathbb{N}}\mathbb{R} \times \dots \times {}^{\mathbb{N}}\mathbb{R}, \qquad x_i = \{x_i(n)\}_{n\in\mathbb{N}}$$

where ${}^{\mathbb{N}}\mathbb{R} = \{f \mid f : \mathbb{N} \to \mathbb{R}\}$, whose components $x_i = \{x_i(n)\}_{n\in\mathbb{N}}$, $i = \overline{1,N}$ satisfy (SE). In what following, we will observe sequences x_i for sufficiently large n, i.e. $n \geq n_0$, for some $n_0 \in \mathbb{N}$. Therefore, we introduced notation ${}^{\mathbb{N}_{n_0}}\mathbb{R} = \{f \mid f : \mathbb{N}_{n_0} \to \mathbb{R}\}$, where $\mathbb{N}_{n_0} = \{n \in \mathbb{N} \mid n \geq n_0\}$.

A solution $\mathbf{x}$ is called nonoscillatory if all its components are eventually of one sign. Because of sign condition on the coefficients, if one component is nonoscillatory, then all components are nonoscillatory and eventually monotone, and therefore they have limit. A nonoscillatory solution is called positive if all its components are eventually positive. Our aim is to study the existence and asymptotic behavior of positive decreasing solutions of (SE), that is, solutions whose components are both eventually positive and decreasing, i.e. satisfying

$$x_i(n) > 0, \quad \Delta x_i(n) < 0, \quad \text{for } n \geq n_0, \quad i = \overline{1,N}. \tag{2.1}$$

We denote by $\mathcal{DS}$ the set of all the solutions of (SE) whose components are all eventually positive decreasing. From (2.1), for x_i, $i = \overline{1,N}$, one of the following two cases holds:

$$(i) \quad \lim_{n\to\infty} x_i(n) = k_i,\ k_i > 0 \quad \text{or} \quad (ii) \quad \lim_{n\to\infty} x_i(n) = 0.$$

For every component of any solution $\mathbf{x}$ of (SE), let we denote by $x_i^{[1]} = \{x_i^{[1]}(n)\}$ its quasi-difference $x_i^{[1]}(n) = p_i(n)|\Delta x_i(n)|^{\alpha_i - 1}\Delta x_i(n)$, $i = \overline{1,N}$. Then, for $x_i^{[1]}$, $i = \overline{1,N}$, one of the following two cases holds:

$$(iii) \quad \lim_{n\to\infty} x_i^{[1]}(n) = -\omega_i,\ \omega_i > 0 \quad \text{or} \quad (iv) \quad \lim_{n\to\infty} x_i^{[1]}(n) = 0.$$

However, if (I) holds, then only (iv) may hold. Indeed, if (iii) holds, then $-p_i(n)(-\Delta x_i(n))^{\alpha_i} \leq -\omega_i$, $n \geq n_0$ i.e. $x_i(n) \leq x_i(n_0) - \omega_i^{1/\alpha_i} \sum_{k=n_0}^{n-1} p_i(k)^{-1/\alpha_i}$. As the right-hand side tends to $-\infty$ contradicts positivity of x_i, we have the desired conclusion.

These leads to the following classification of positive decreasing solution: if (I) holds, each component x_i of positive decreasing solution $\mathbf{x}$ satisfies:

$$(SD1)\ \lim_{n\to\infty} x_i(n) = \lim_{n\to\infty} x_i^{[1]}(n) = 0,$$

$$(AC)\ \lim_{n\to\infty} x_i(n) = k_i > 0 \quad \Leftrightarrow \quad x_i(n) \sim k_i,\ n \to \infty,$$

while if (II) holds each component x_i of positive decreasing solution $\mathbf{x}$ satisfies

$$(SD2)\ \lim_{n\to\infty} x_i(n) = \lim_{n\to\infty} x_i^{[1]}(n) = 0,$$

$$(P1)\ \lim_{n\to\infty} x_i(n) = 0,\ \lim_{n\to\infty} x_i^{[1]}(n) = -\omega_i < 0,$$
$$\Leftrightarrow \quad x_i(n) \sim W_i\, \pi_i(n),\ n \to \infty, \quad W_i = \omega_i^{1/\alpha_i}$$

$$(AC)\ \lim_{n\to\infty} x_i(n) = k_i > 0 \quad \Leftrightarrow \quad x_i(n) \sim k_i,\ n \to \infty,$$

where the following asymptotic relation has been used

$$f(n) \sim g(n),\ n \to \infty \ \Leftrightarrow\ \lim_{n\to\infty} \frac{f(n)}{g(n)} = 1.$$

Using the Stolz–Cesàro Theorem (see Theorem 4.5), solutions satisfying $(SD1)$ and $(SD2)$ can be characterized as

$$(SD1) \quad x_i(n) \prec P_i(n),\ n \to \infty, \qquad (SD2) \quad x_i(n) \prec \pi_i(n),\ n \to \infty,$$

where the following asymptotic relation has been used

$$f(n) \prec g(n),\ n \to \infty \ \Leftrightarrow\ \lim_{n\to\infty} \frac{f(n)}{g(n)} = 0.$$

Solutions of type $(P1)$ and (AC) are called *primitive solutions*, while solutions $(SD1)$, $(SD2)$ are called *strongly decreasing*. Necessary and sufficient conditions for the existence of primitive solutions will be established in the Section 5. On the other hand, the existence and precise asymptotic formulas of strongly decreasing solutions are not easy to determine in the general case. Therefore, in Section 6, we will assume that the coefficients of the system are regularly varying sequences and thus, restricting consideration to the class of regularly varying solutions, we provide necessary and sufficient conditions for the existence of such solutions.

3 Regularly varying sequences

The theory of regularly varying sequences, often called Karamata sequences (see [26]), was developed during the seventies by Galambos, Seneta and Bojanić in [8, 16]. However, until the appearance of the paper of Matucci and Řehák [32], the connection between regularly varying sequences and difference equations was not considered. In this paper, as well as in the following ones [33, 34, 36, 37], the theory of regularly varying sequences is further developed and applied in the asymptotic analysis of linear and half-linear difference equations of the second-order, giving necessary and sufficient conditions for the existence of regularly varying solutions of these equations. After this, further development of the discrete theory of regular variation, as well as its application to nonlinear difference equations of type Emden–Fowler type, can be found in [5], as well as in [24].

In this section, we present basic definitions and properties of regularly varying sequences that will be used in the main results. For a thorough discussion of regular variation, the reader is referred to Bingham et al. [7].

There are two main approaches in the basic theory of regularly varying sequences: the approach due to Karamata [26], based on a definition that can be understood as a direct discrete counterpart of simple and elegant continuous definition (Definition 3.1), and the approach due to Galambos and Seneta [16], based on purely sequential definition (Definition 3.2). Bojanić and Seneta have shown in [8] the equivalence of these two definitions.

Definition 3.1 (Karamata [26])**.** A positive sequence $y = \{y(k)\}$, $k \in \mathbb{N}$ is said to be *regularly varying of index* $\rho \in \mathbb{R}$ if

$$\lim_{k\to\infty} \frac{y([\lambda k])}{y(k)} = \lambda^\rho \quad \text{for } \forall \lambda > 0,$$

where $[n]$ denotes the integer part of n.

Definition 3.2 (Galambos and Seneta [16])**.** A positive sequence $y = \{y(k)\}, n \in \mathbb{N}$ is said to be *regularly varying of index* $\rho \in \mathbb{R}$ if there exists a positive sequence $\{\alpha(k)\}$ satisfying

$$\lim_{k\to\infty} \frac{y(k)}{\alpha(k)} = C, \quad 0 < C < \infty, \qquad \lim_{k\to\infty} k\,\frac{\Delta\alpha(k-1)}{\alpha(k)} = \rho\,.$$

If $\rho = 0$, then y is said to be *slowly varying*. The sets of regularly varying sequences with index ρ and slowly varying sequences are denoted $\mathcal{RV}(\rho)$ and $\mathcal{SV}$, respectively.

The concept of normalized regularly varying sequences was introduced by Matucci and Rehak in [33], where they also offered a modification of Definition 3.2, i.e. they proved that the second limit in Definition 3.2 can be replaced with

$$\lim_{k\to\infty} k\,\frac{\Delta\alpha(k)}{\alpha(k)} = \rho\,.$$

Definition 3.3. A positive sequence $y = \{y(k)\}, k \in \mathbb{N}$ is said to be *normalized regularly varying of index* $\rho \in \mathbb{R}$ if it satisfies

$$\lim_{k\to\infty} \frac{k\Delta y(k)}{y(k)} = \rho.$$

If $\rho = 0$, then y is called a *normalized slowly varying sequence.*

The notations $\mathcal{NRV}(\rho)$ and $\mathcal{NSV}$ are most commonly used to denote the set of all normalized regularly varying sequences of index ρ and the set of all normalized slowly varying sequences, respectively.

Typical examples are:

$$\{\log k\} \in \mathcal{NSV}, \quad \{k^\rho \log k\} \in \mathcal{NRV}(\rho), \quad \{1 + (-1)^k/k\} \in \mathcal{SV} \setminus \mathcal{NSV}\,.$$

In order to present results for a system of difference equations, we need to define a regularly varying vector $\mathbf{x} \in {}^{\mathbb{N}}\mathbb{R} \times \ldots \times {}^{\mathbb{N}}\mathbb{R}$, where ${}^{\mathbb{N}}\mathbb{R} = \{f \mid f : \mathbb{N} \to \mathbb{R}\}$.

Definition 3.4. A vector $\mathbf{x} \in {}^{\mathbb{N}}\mathbb{R} \times \ldots \times {}^{\mathbb{N}}\mathbb{R}$, $\mathbf{x} = (\{x_1(n)\}, \ldots, \{x_N(n)\})$ is said to be regularly varying of index $(\rho_1, \rho_2, \ldots, \rho_N)$ if $x_i = \{x_i(n)\} \in \mathcal{RV}(\rho_i)$ for $i = \overline{1, N}$. If all ρ_i are positive (or negative), then $\mathbf{x}$ is called regularly varying vector sequence of positive (or negative) index $(\rho_1, \rho_2, \ldots, \rho_N)$. The set of all regularly varying vectors of index $(\rho_1, \rho_2, \ldots, \rho_N)$ is denoted by $\mathcal{RV}(\rho_1, \rho_2, \ldots, \rho_N)$.

Various necessary and sufficient conditions for a sequence of positive numbers to be regularly varying have been established (see [8,16,32,33]) and consequently, any of these can be used to define regularly varying sequence. The one that is the most important is the following Representation theorem (see [8, Theorem 3]), while some other representation formula for regularly varying sequences was established in [33, Lemma 1].

Theorem 3.5 (Representation theorem). *A positive sequence $\{y(k)\}, k \in \mathbb{N}$ is said to be regularly varying of index $\rho \in \mathbb{R}$ if and only if there exists sequences $\{c(k)\}$ and $\{\delta(k)\}$ such that*

$$\lim_{k\to\infty} c(k) = c_0 \in (0,\infty) \quad \textit{and} \quad \lim_{k\to\infty} \delta(k) = 0,$$

and

$$y(k) = c(k)\, k^{\rho} \exp\left(\sum_{i=1}^{k} \frac{\delta(i)}{i}\right).$$

In [8], a very useful embedding theorem was proved, which gives the possibility of using the continuous theory in developing a theory of regularly varying sequences. However, as noted in [8], such development is not generally straightforward and sometimes far from a simple imitation of arguments for regularly varying functions.

Theorem 3.6 (Embedding Theorem). *If $y = \{y(n)\}$ is regularly varying sequence of index $\rho \in \mathbb{R}$, then function $Y(t)$ defined on $[0,\infty)$ by $Y(t) = y([t])$ is a regularly varying function of index ρ. Conversely, if $Y(t)$ is a regularly varying function on $[0,\infty)$ of index ρ, then a sequence $\{y(k)\}$, $y(k) = Y(k)$, $k \in \mathbb{N}$ is regularly varying of index ρ.*

Next, we state some important properties of $\mathcal{RV}$ sequences useful for the development of the asymptotic behavior of solutions of (SE) in the subsequent sections (for more properties and proofs see [8,32]).

Theorem 3.7. *The following properties hold:*

(i) $y \in \mathcal{RV}(\rho)$ *if and only if* $y(k) = k^{\rho}\, l(k)$, *where* $l = \{l(k)\} \in \mathcal{SV}$.

(ii) Let $x \in \mathcal{RV}(\rho_1)$ *and* $y \in \mathcal{RV}(\rho_2)$. *Then,* $xy \in \mathcal{RV}(\rho_1+\rho_2)$, $x+y \in \mathcal{RV}(\rho)$, $\rho = \max\{\rho_1,\rho_2\}$ *and* $1/x \in \mathcal{RV}(-\rho_1)$.

(iii) If $y \in \mathcal{RV}(\rho)$, *then* $\lim_{k\to\infty} \frac{y(k+1)}{y(k)} = 1$.

(iv) If $l \in \mathcal{SV}$ *and* $l(k) \sim L(k)$, $k \to \infty$, *then,* $L \in \mathcal{SV}$.

(v) If $l \in \mathcal{SV}$, *then for any* $\varepsilon > 0$,

$$\lim_{k\to\infty} k^{\varepsilon} l(k) = \infty, \qquad \lim_{k\to\infty} k^{-\varepsilon} l(k) = 0,$$

(vi) If $y \in \mathcal{NRV}(\rho)$, *then* $\{k^{-\sigma}y(k)\}$ *is eventually increasing for each* $\sigma < \rho$ *and* $\{k^{-\mu}y(k)\}$ *is eventually decreasing for each* $\mu > \rho$.

The following theorem can be seen as *the discrete analog of the Karamata's integration theorem* and plays a central role in proving this paper main results. Proof of this theorem can be found in [24]. Also, some parts of this theorem's proof can be found in [8] and [36].

Theorem 3.8. *Let $l = \{l(n)\} \in \mathcal{SV}$.*

(i) If $\alpha > -1$, then $\lim_{n\to\infty} \frac{1}{n^{\alpha+1}l(n)} \sum_{k=1}^{n} k^{\alpha} l(k) = \frac{1}{1+\alpha}$;

(ii) If $\alpha < -1$, then $\lim_{n\to\infty} \frac{1}{n^{\alpha+1}l(n)} \sum_{k=n}^{\infty} k^{\alpha} l(k) = -\frac{1}{1+\alpha}$;

(iii) If $\sum_{k=1}^{\infty} \frac{l(k)}{k} < \infty$, then $S_{\star}(n) = \sum_{k=n}^{\infty} \frac{l(k)}{k}$, $S_{\star} \in \mathcal{SV}$ and $\lim_{n\to\infty} \frac{S_{\star}(n)}{l(n)} = \infty$;

(iv) If $\sum_{k=1}^{\infty} \frac{l(k)}{k} = \infty$, then $S^{\star}(n) = \sum_{k=1}^{n} \frac{l(k)}{k}$, $S^{\star} \in \mathcal{SV}$ and $\lim_{n\to\infty} \frac{S^{\star}(n)}{l(n)} = \infty$.

Remark 3.9. It is easy to see, in view of Theorem 3.7-(iii) and Theorem 3.8-(i), that for $l \in \mathcal{SV}$, if $\alpha > -1$, we have

$$\sum_{k=1}^{n-1} k^{\alpha} l(k) \sim \frac{(n-1)^{\alpha+1} l(n-1)}{\alpha+1} \sim \frac{n^{\alpha+1} l(n)}{\alpha+1} \sim \sum_{k=1}^{n} k^{\alpha} l(k), \qquad n \to \infty,$$

and since $\lim_{n\to\infty} \sum_{k=1}^{n-1} k^{\alpha} l(k) = \infty$, we also get

$$\sum_{k=n_0}^{n} k^{\alpha} l(k) \sim \sum_{k=1}^{n} k^{\alpha} l(k), \qquad n \to \infty.$$

If $\lim_{n\to\infty} \sum_{k=1}^{n} k^{-1} l(k) = \infty$, we have

$$\sum_{k=n_0}^{n} k^{-1} l(k) \sim \sum_{k=1}^{n} k^{-1} l(k), \qquad n \to \infty.$$

4 Basic concepts

In this section, we will state the basic notation and assertions necessary for the proofs of the main results in the following sections.

The existence of solutions will be demonstrated using fixed point techniques. Actually, the following two fixed point theorems will be applied throughout the paper.

Theorem 4.1 (Knaster–Tarski fixed point theorem [2])**.** *Let X be a partially ordered Banach space with ordering $\leq$. Let M be a subset of X with the following properties: The infimum of M belongs to M and every nonempty subset of M has a supremum which belongs to M. Let $\mathcal{F} : M \to M$ be an increasing mapping, i.e. $x \geq y$ implies $\mathcal{F}x \geq \mathcal{F}y$. Then $\mathcal{F}$ has a fixed point in M.*

Theorem 4.2 (Schauder–Tychonoff fixed point theorem [2])**.** *Let S be closed, convex, nonempty subset of a locally convex topological vector space X. Let T be a continuous mapping from S to itself, such that TS is relatively compact. Then T has a fixed point.*

To prove that appropriately constructed operator T is continuous, we will apply the following theorem.

Theorem 4.3 (Discrete Lebesgue's dominated convergence theorem [1])**.** *Let $\{a^{(m)}(k)\}$ be a double real sequence, $a^{(m)}(k) \geq 0$ for $m, k \in \mathbb{N}$ such that $\lim_{m\to\infty} a^{(m)}(k) = A(k)$, for every $k \in \mathbb{N}$. Assume that the series $\sum_{k=1}^{\infty} a^{(m)}(k)$ is totally convergent, that is, there exists a sequence $\{\alpha(k)\}$ such that $a^{(m)}(k) \leq \alpha(k)$ for all $m, k \in \mathbb{N}$, with $\sum_{k=1}^{\infty} \alpha(k) < \infty$. Then, the series $\sum_{k=1}^{\infty} A(k)$ converges and*

$$\lim_{m\to\infty} \sum_{k=1}^{\infty} a^{(m)}(k) = \sum_{k=1}^{\infty} A(k).$$

To apply the Schauder–Tychonoff fixed point theorem, relatively compactness of the set TS must be verified and for that purpose the following statement will be used. This theorem represent a discrete version of the Arzelà–Ascoli theorem and it is known as Cheng–Patula theorem (see [14]).

Theorem 4.4. *A bounded, uniformly Cauchy subset Ω of l^∞ is relatively compact.*

For the proof of regularity of solutions, Stolz–Cesàro Theorem will be used. Therefore, we recall two variants of the Stolz–Cesàro theorem (see [48]).

Theorem 4.5. *If $f = \{f(n)\}$ is a strictly increasing sequence of positive real numbers, such that $\lim_{n\to\infty} f(n) = \infty$, then for any sequence $g = \{g(n)\}$ of positive real numbers one has the inequalities:*

$$\liminf_{n\to\infty} \frac{\Delta f(n)}{\Delta g(n)} \leq \liminf_{n\to\infty} \frac{f(n)}{g(n)} \leq \limsup_{n\to\infty} \frac{f(n)}{g(n)} \leq \limsup_{n\to\infty} \frac{\Delta f(n)}{\Delta g(n)}.$$

In particular, if the sequence $\{\Delta f(n)/\Delta g(n)\}$ has a limit, then

$$\lim_{n\to\infty} \frac{f(n)}{g(n)} = \lim_{n\to\infty} \frac{\Delta f(n)}{\Delta g(n)}. \tag{4.1}$$

Theorem 4.6. *Let $f = \{f(n)\}$, $g = \{g(n)\}$ be sequences of positive real numbers, such that*

(i) $\lim_{n\to\infty} f(n) = \lim_{n\to\infty} g(n) = 0$;

(ii) the sequence g is strictly monotone;

(iii) the sequence $\{\Delta f(n)/\Delta g(n)\}$ has a limit.

Then, a sequence $\{f(n)/g(n)\}$ is convergent and (4.1) holds.

In Section 6 analyzing the regularly varying solutions of the system with regularly varying coefficients, we assume $p_i \in \mathcal{RV}(\lambda_i)$, $q_i \in \mathcal{RV}(\mu_i)$, $i = \overline{1,N}$ and express them as follows:

$$p_i(n) = n^{\lambda_i} l_i(n), \quad q_i(n) = n^{\mu_i} m_i(n), \quad l_i, m_i \in \mathcal{SV}, \quad i = \overline{1,N}, \tag{4.2}$$

while components of the regularly varying solutions $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \ldots, \rho_N)$ of the observed system are expressed in the form

$$x_i(n) = n^{\rho_i} \xi_i(n), \quad \xi_i \in \mathcal{SV}, \quad i = \overline{1,N}. \tag{4.3}$$

We also assume that all sequences p_i, $i = \overline{1,N}$ satisfy either (I) or (II). Condition (I) is satisfied if and only if index of regularity λ_i satisfies either

$$\lambda_i < \alpha_i, \tag{4.4}$$

or

$$\lambda_i = \alpha_i \quad \text{and} \quad S_i = \sum_{n=1}^{\infty} n^{-1} l_i(n)^{-\frac{1}{\alpha_i}} = \infty. \tag{4.5}$$

Using Theorem 3.8, if (4.4) holds, the following asymptotic relation is obtained for the sequence $P_i = \{P_i(n)\}$ defined by (1.1):

$$P_i(n) \sim \frac{\alpha_i}{\alpha_i - \lambda_i} n^{\frac{\alpha_i - \lambda_i}{\alpha_i}} l_i(n)^{-\frac{1}{\alpha_i}}, \quad n \to \infty, \tag{4.6}$$

implying that $P_i \in \mathcal{RV}\left(\frac{\alpha_i-\lambda_i}{\alpha_i}\right)$. Clearly, if (4.5) holds, $P_i \in \mathcal{SV}$. Condition (II) is satisfied if and only if either

$$\lambda_i > \alpha_i, \tag{4.7}$$

or

$$\lambda_i = \alpha_i \quad \text{and} \quad S_i = \sum_{n=1}^{\infty} n^{-1} l_i(n)^{-\frac{1}{\alpha_i}} < \infty. \tag{4.8}$$

If (4.7) holds, using Theorem 3.8, the following asymptotic relation is obtained for the sequence $\pi_i = \{\pi_i(n)\}$ defined by (1.2):

$$\pi_i(n) \sim \frac{\alpha_i}{\lambda_i - \alpha_i} n^{\frac{\alpha_i-\lambda_i}{\alpha_i}} l_i(n)^{-\frac{1}{\alpha_i}}, \quad n \to \infty, \tag{4.9}$$

implying that $\pi_i \in \mathcal{RV}\left(\frac{\alpha_i-\lambda_i}{\alpha_i}\right)$. If (4.8) holds, $\pi_i \in \mathcal{SV}$.

Also, to simplify notation we denote $A_N = \alpha_1\alpha_2 \cdot \ldots \cdot \alpha_N$, $B_N = \beta_1\beta_2 \cdot \ldots \cdot \beta_N$ and use matrix

$$M = \begin{pmatrix} 1 & \frac{\beta_1}{\alpha_1} & \frac{\beta_1\beta_2}{\alpha_1\alpha_2} & \ldots & \frac{\beta_1\beta_2\cdot\ldots\cdot\beta_{N-2}}{\alpha_1\alpha_2\cdot\ldots\cdot\alpha_{N-2}} & \frac{\beta_1\beta_2\cdot\ldots\cdot\beta_{N-1}}{\alpha_1\alpha_2\cdot\ldots\cdot\alpha_{N-1}} \\ \frac{\beta_2\beta_3\cdot\ldots\cdot\beta_N}{\alpha_2\alpha_3\cdot\ldots\cdot\alpha_N} & 1 & \frac{\beta_2}{\alpha_2} & \ldots & \frac{\beta_2\beta_3\cdot\ldots\cdot\beta_{N-2}}{\alpha_2\alpha_3\cdot\ldots\cdot\alpha_{N-2}} & \frac{\beta_2\beta_3\cdot\ldots\cdot\beta_{N-1}}{\alpha_2\alpha_3\cdot\ldots\cdot\alpha_{N-1}} \\ \frac{\beta_3\beta_4\cdot\ldots\cdot\beta_N}{\alpha_3\alpha_4\cdot\ldots\cdot\alpha_N} & \frac{\beta_3\cdot\ldots\cdot\beta_N\beta_1}{\alpha_3\cdot\ldots\cdot\alpha_N\alpha_1} & 1 & \ldots & \frac{\beta_3\beta_4\cdot\ldots\cdot\beta_{N-2}}{\alpha_3\alpha_4\cdot\ldots\cdot\alpha_{N-2}} & \frac{\beta_3\beta_4\cdot\ldots\cdot\beta_{N-1}}{\alpha_3\alpha_4\cdot\ldots\cdot\alpha_{N-1}} \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \frac{\beta_{N-1}\beta_N}{\alpha_{N-1}\alpha_N} & \frac{\beta_{N-1}\beta_N\beta_1}{\alpha_{N-1}\alpha_N\alpha_1} & \frac{\beta_{N-1}\beta_N\beta_1\beta_2}{\alpha_{N-1}\alpha_N\alpha_1\alpha_2} & \ldots & 1 & \frac{\beta_{N-1}}{\alpha_{N-1}} \\ \frac{\beta_N}{\alpha_N} & \frac{\beta_N\beta_1}{\alpha_N\alpha_1} & \frac{\beta_N\beta_1\beta_2}{\alpha_N\alpha_1\alpha_2} & \ldots & \frac{\beta_N\beta_1\cdot\ldots\cdot\beta_{N-2}}{\alpha_N\alpha_1\cdot\ldots\cdot\alpha_{N-2}} & 1 \end{pmatrix}, \tag{4.10}$$

whose elements will be denoted by $M = (M_{ij})$. The i-th row of (M_{ij}) is obtained by shifting the vector

$$\left(1, \frac{\beta_i}{\alpha_i}, \frac{\beta_i\beta_{i+1}}{\alpha_i\alpha_{i+1}}, \ldots, \frac{\beta_i\beta_{i+1}\cdot\ldots\beta_{i+(N-2)}}{\alpha_i\alpha_{i+1}\cdot\ldots\alpha_{i+(N-2)}}\right), \quad \alpha_{N+j} = \alpha_j,\ \beta_{N+j} = \beta_j,\ j = \overline{1, N-2}$$

$(i-1)$-times to the right cyclically, so that elements $M_{ij}, M_{ji}, i > j$, satisfy the relation

$$M_{ij}M_{ji} = \frac{\beta_1\beta_2 \cdot \ldots \cdot \beta_N}{\alpha_1\alpha_2 \cdot \ldots \cdot \alpha_N}, \quad i > j, \quad i = \overline{2, N}.$$

It is easy to see that elements of matrix M satisfy for $i = \overline{1, N}$, $j = \overline{1, N}$

$$M_{i+1,i}\frac{\beta_i}{\alpha_i} = \frac{B_N}{A_N}, \quad M_{i+1,j}\frac{\beta_i}{\alpha_i} = M_{ij} \quad \text{for } j \neq i,\ M_{N+1,j} = M_{1,j}. \tag{4.11}$$

The next matrix also plays important note in the proof of main results:

$$A = \begin{pmatrix} 1 & -\frac{\beta_1}{\alpha_1} & 0 & \ldots & 0 & 0 \\ 0 & 1 & -\frac{\beta_2}{\alpha_2} & \ldots & 0 & 0 \\ \vdots & \vdots & \ddots & & \vdots & \vdots \\ \vdots & \vdots & & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \ldots & 1 & -\frac{\beta_{N-1}}{\alpha_{N-1}} \\ -\frac{\beta_N}{\alpha_N} & 0 & 0 & \ldots & 0 & 1 \end{pmatrix}. \tag{4.12}$$

Since,

$$\det(A) = 1 - \frac{\beta_1\beta_2 \cdot \ldots \cdot \beta_N}{\alpha_1\alpha_2 \cdot \ldots \cdot \alpha_N} > 0\,,$$

the matrix A is invertible and its inverse matrix is given by

$$A^{-1} = \frac{A_N}{A_N - B_N} M. \tag{4.13}$$

Throughout the text, $n \geq n_0$ means that n is sufficiently large so that n_0 need not to be the same at each occurrence.

5 Existence of primitive decreasing solutions

The asymptotic behavior of primitive solutions is evident from the classification itself. The following theorems provide necessary and sufficient conditions for the existence of these solutions, using Fixed point theory and without the assumption that coefficients are regularly varying sequences.

Theorem 5.1. *The system (SE) has a solution $\mathbf{x} \in \mathcal{DS}$ with each component satisfying (AC) if and only if*

$$\sum_{n=1}^{\infty} \left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) \right)^{\frac{1}{\alpha_i}} < \infty, \quad i = \overline{1, N}. \tag{5.1}$$

Proof. The "only if" part: Let $\mathbf{x} = (x_1, x_2, \ldots, x_N) \in \mathcal{DS}$ be a solution of (SE) with each component satisfying $\lim_{n\to\infty} x_i(n) = c_i$. Then, there exist $n_0 \in \mathbb{N}$ such that $x_i(n) \geq c_i$, $n \geq n_0$, $i = \overline{1, N}$.

If (I) holds, as previously shown $\lim_{n\to\infty} x_i^{[1]}(n) = 0$, $i = \overline{1, N}$. By summing equations of (SE) twice, first from n to ∞, and then from n_0 to ∞, we derive that

$$x_i(n_0) = c_i + \sum_{n=n_0}^{\infty} \left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i} \right)^{\frac{1}{\alpha_i}} \geq c_{i+1}^{\frac{\beta_i}{\alpha_i}} \sum_{n=n_0}^{\infty} \left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) \right)^{\frac{1}{\alpha_i}},$$

for $i = \overline{1, N}$. From the previous equation, we see that condition (5.1) is satisfied.

If (II) holds, then, since $x_i^{[1]}$, $i = \overline{1, N}$ are eventually negative and increasing, we may assume that $x_i^{[1]}(n) \leq -\omega_i \leq 0$ for $n \geq n_0$, $i = \overline{1, N}$. By summing equations of (SE) from n_0 to n, we obtain for $i = \overline{1, N}$

$$-\omega_i - x_i^{[1]}(n_0) \geq x_i^{[1]}(n) - x_i^{[1]}(n_0) = \sum_{k=n_0}^{n} q_i(k) x_{i+1}(k+1)^{\beta_i} \geq c_{i+1}^{\beta_i} \sum_{k=n_0}^{n} q_i(k), \quad n \geq n_0.$$

Letting $n \to \infty$, we find

$$\sum_{n=n_0}^{\infty} q_i(n) < \infty, \quad i = \overline{1, N},$$

which together with (II) yields that the condition (5.1) is satisfied.

The "if" part: Suppose that (5.1) holds. Then, there exists $n_0 \in \mathbb{N}$ such that

$$\sum_{n=n_0}^{\infty} \left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) \right)^{\frac{1}{\alpha_i}} < 2^{1-\frac{\beta_i}{\alpha_i}}, \quad i = \overline{1, N}. \tag{5.2}$$

Denote by $\mathcal{L}_{n_0}$ the space of all vectors $\mathbf{x} = (x_1, x_2, \ldots, x_N)$, such that $x_i = \{x_i(n)\} \in {}^{\mathbb{N}_{n_0}}\mathbb{R}$, $i = \overline{1, N}$ are bounded. Then, $\mathcal{L}_{n_0}$ is a Banach space endowed with the norm

$$\|\mathbf{x}\| = \max_{1\le i\le N}\Big\{\sup_{n\ge n_0}|x_i(n)|\Big\}. \tag{5.3}$$

Set

$$\Lambda_1 = \Big\{\mathbf{x}\in\mathcal{L}_{n_0}\;\Big|\; c_i\le x_i(n)\le 2c_i,\quad n\ge n_0,\quad i=\overline{1,N}\Big\}, \tag{5.4}$$

where c_i, $i=\overline{1,N}$ are positive constants such that

$$c_i \ge 2c_{i+1}^{\frac{\beta_i}{\alpha_i}},\quad i=\overline{1,N},\quad c_{N+1}=c_1. \tag{5.5}$$

Define operators $\mathcal{F}_i : {}^{\mathbb{N}_{n_0}}\mathbb{R}\to{}^{\mathbb{N}_{n_0}}\mathbb{R}$ by

$$\mathcal{F}_i x(n) = c_i + \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)x(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}},\quad n\ge n_0,\quad i=\overline{1,N}, \tag{5.6}$$

and the mapping $\Theta:\Lambda_1\to\mathcal{L}_{n_0}$ by

$$\Theta(x_1,x_2,\dots,x_N) = \big(\mathcal{F}_1x_2,\mathcal{F}_2x_3,\dots,\mathcal{F}_Nx_{N+1}\big),\quad x_{N+1}=x_1. \tag{5.7}$$

We will show that Θ has a fixed point by using Schauder–Tychonoff fixed point theorem. Namely, the operator Θ has the following properties:

(i) Θ *maps* Λ_1 *into itself*: Let $\mathbf{x}\in\Lambda_1$. Then, using (5.2), (5.4), (5.5) and (5.6), we see that

$$c_i \le \mathcal{F}_i x_{i+1}(n) \le c_i + (2c_{i+1})^{\frac{\beta_i}{\alpha_i}}\sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)\right)^{\frac{1}{\alpha_i}} \le c_i + 2^{\frac{\beta_i}{\alpha_i}}\cdot\frac{c_i}{2}\cdot 2^{1-\frac{\beta_i}{\alpha_i}} = 2c_i,$$

for $i=\overline{1,N}$ and $n\ge n_0$.

(ii) Θ *is continuous*: Let $\varepsilon_i>0, i=\overline{1,N}$ and $\{\mathbf{x}^{(m)}\}_{m\in\mathbb{N}} = \big\{(x_1^{(m)},x_2^{(m)},\dots,x_N^{(m)})\big\}_{m\in\mathbb{N}}$, be a sequence in Λ_1 which converges to $\mathbf{x}=(x_1,x_2,\dots,x_N)$ as $m\to\infty$. Since, Λ_1 is closed, $\mathbf{x}\in\Lambda_1$. The rest of the proof does not depend on i, so let $i\in\{1,2,\dots,N\}$ be arbitrary fixed. For every $n\ge n_0$, we have

$$\begin{aligned}&\Big|\mathcal{F}_i x_{i+1}^{(m)}(n) - \mathcal{F}_i x_{i+1}(n)\Big|\\ &\qquad\le \sum_{k=n}^{\infty}\frac{1}{p_i(k)^{\frac{1}{\alpha_i}}}\left|\left(\sum_{s=k}^{\infty}q_i(s)x_{i+1}^{(m)}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}} - \left(\sum_{s=k}^{\infty}q_i(s)x_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}\right|.\end{aligned}$$

Since (5.1) implies that $\sum_{n=n_0}^{\infty}q_i(n)$ is convergent, we conclude that $\sum_{n=n_0}^{\infty}q_i(n)\,x_{i+1}^{(m)}(n+1)^{\beta_i}$ is totally convergent, because $q_i(n)\,x_{i+1}^{(m)}(n+1)^{\beta_i}\le(2c_{i+1})^{\beta_i}q_i(n)$, for every $n\ge n_0, m\in\mathbb{N}$. Then, by a discrete analogue of Lebesgue dominated convergence theorem (Theorem 4.3), it holds for every $k\ge n_0$

$$\lim_{m\to\infty}\left|\left(\sum_{s=k}^{\infty}q_i(s)x_{i+1}^{(m)}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}} - \left(\sum_{s=k}^{\infty}q_i(s)x_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}\right| = 0,$$

which shows that

$$\lim_{m\to\infty}\sup_{n\ge n_0}\Big|\mathcal{F}_i x_{i+1}^{(m)}(n) - \mathcal{F}_i x_{i+1}(n)\Big| = 0.$$

Therefore, $\|\Theta\mathbf{x}^{(m)} - \Theta\mathbf{x}\| \to 0$ as $m \to \infty$, i.e. Θ is continuous.

(iii) $\Theta(\Lambda_1)$ *is relatively compact*: To show this, by Theorem 4.4, it is sufficient to show that $\Theta(\Lambda_1)$ is uniformly Cauchy in the topology of $\mathcal{L}_{n_0}$. For $\mathbf{x} \in \Lambda_1$ and $m > n \geq n_0$ we have

$$\begin{aligned}|\mathcal{F}_i x_{i+1}(m) - \mathcal{F}_i x_{i+1}(n)| &= \left|\sum_{k=n}^{m-1}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty} q_i(s)x_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}\right| \\ &\leq \sum_{k=n}^{m-1}\frac{1}{p_i(k)^{\frac{1}{\alpha_i}}}\left|\sum_{s=k}^{\infty} q_i(s)x_{i+1}(s+1)^{\beta_i}\right|^{\frac{1}{\alpha_i}} \\ &\leq (2c_{i+1})^{\frac{\beta_i}{\alpha_i}}\sum_{k=n}^{m-1}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty} q_i(s)\right)^{\frac{1}{\alpha_i}}.\end{aligned}$$

According to (5.1) it follows that $\Theta(\Lambda_1)$ is uniformly Cauchy.

Therefore, all the hypotheses of Schauder–Tychonoff fixed point theorem are fulfilled implying the existence of a fixed point $\mathbf{x} \in \Lambda_1$ of the mapping Θ, which satisfies

$$x_i(n) = c_i + \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty} q_i(s)x_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}, \quad n \geq n_0, \quad i = \overline{1,N}.$$

It is clear that $\mathbf{x}$ is a positive decreasing solution of (SE) whose all components tend to constants. □

Theorem 5.2. *Let (II) hold. The system (SE) has a solution $\mathbf{x} \in \mathcal{DS}$ with each component satisfying $(P1)$ if and only if*

$$\sum_{n=1}^{\infty} q_i(n)\pi_{i+1}(n+1)^{\beta_i} < \infty, \quad i = \overline{1,N}. \tag{5.8}$$

Proof. The "only if" part: Let $\mathbf{x} = (x_1, x_2, \ldots, x_N) \in \mathcal{DS}$ be a solution with each component satisfying $(P1)$. Since $x_i^{[1]}$, $i = \overline{1,N}$ are eventually negative and increasing, we may assume that $x_i^{[1]}(n) \leq -\omega_i < 0$ for $n \geq n_0$, $i = \overline{1,N}$. Then, for $n \geq n_0$, we have

$$x_i(n) = \sum_{k=n}^{\infty}\frac{\left(-x_i^{[1]}(k)\right)^{1/\alpha_i}}{p_i(k)^{1/\alpha_i}} \geq \omega_i^{\frac{1}{\alpha_i}}\pi_i(n), \quad i = \overline{1,N}.$$

Summing equations of the system (SE) from n_0 to n we get for $n \geq n_0$,

$$-\omega_i - x_i^{[1]}(n_0) \geq x_i^{[1]}(n+1) - x_i^{[1]}(n_0) = \sum_{k=n_0}^{n} q_i(k)x_{i+1}(k+1)^{\beta_i} \geq \omega_{i+1}^{\frac{\beta_i}{\alpha_{i+1}}}\sum_{k=n_0}^{n} q_i(k)\pi_{i+1}(k+1)^{\beta_i} \tag{5.9}$$

Letting that $n \to \infty$ in (5.9), we conclude that (5.8) holds.

The "if" part: Suppose that (5.8) holds. Then, there exists $n_0 \in \mathbb{N}$ such that

$$\sum_{n=n_0}^{\infty} q_i(n)\pi_{i+1}(n+1)^{\beta_i} < 2^{\alpha_i-\beta_i}\left(2^{\alpha_i}-1\right), \quad i = \overline{1,N}. \tag{5.10}$$

Denote by $\mathcal{X}_{n_0}$ the space of all vectors $\mathbf{x} = (x_1, x_2, \ldots, x_N)$, $x_i \in {}^{\mathbb{N}_{n_0}}\mathbb{R}$, $i = \overline{1,N}$, such that $\{x_i(n)/\pi_i(n)\}$, $i = \overline{1,N}$ are bounded. Then, $\mathcal{X}_{n_0}$ is a Banach space endowed with the norm

$$\|\mathbf{x}\| = \max_{1\le i\le N}\left\{\sup_{n\ge n_0}\left|\frac{x_i(n)}{\pi_i(n)}\right|\right\}. \tag{5.11}$$

Further, $\mathcal{X}_{n_0}$ is partially ordered, with usual pointwise ordering $\le$: for $\mathbf{x}, \mathbf{y} \in \mathcal{X}_{n_0}$, $\mathbf{x} \le \mathbf{y}$ means $x_i(n) \le y_i(n)$ for all $n \ge n_0$ and $i = \overline{1,N}$. Set

$$\Lambda_2 = \left\{\mathbf{x} \in \mathcal{X}_{n_0} \;\middle|\; c_i\pi_i(n) \le x_i(n) \le 2c_i\pi_i(n), \quad n \ge n_0, \quad i = \overline{1,N}\right\}, \tag{5.12}$$

where c_i, $i = \overline{1,N}$ are positive constants which satisfy (5.5). For any subset B of Λ_2, it is obvious that $\sup B \in \Lambda_2$ and $\inf B \in \Lambda_2$.

Let $\Theta : \Lambda_2 \to \mathcal{X}_{n_0}$ be the mapping given by (5.7), where $\mathcal{F}_i : {}^{\mathbb{N}_{n_0}}\mathbb{R} \to {}^{\mathbb{N}_{n_0}}\mathbb{R}$ is operator defined by

$$\mathcal{F}_i x(n) = \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\left(c_i^{\alpha_i} + \sum_{s=k}^{\infty} q_i(s)x(s+1)^{\beta_i}\right)\right)^{\frac{1}{\alpha_i}}, \quad n \ge n_0, \quad i = \overline{1,N}, \tag{5.13}$$

We will show that Θ has a fixed point by using Theorem 4.1. Namely, the operator Θ has the following properties:

(i) Θ *maps* Λ_2 *into itself*: Let $\mathbf{x} \in \Lambda_2$. Then, using (5.5), (5.10), (5.12) and (5.13), we see that for $n \ge n_0$

$$\begin{aligned} c_i\pi_i(n) \le \mathcal{F}_i x_{i+1}(n) &\le \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\left(c_i^{\alpha_i} + (2c_{i+1})^{\beta_i}\sum_{s=k}^{\infty} q_i(s)\pi_{i+1}(s+1)^{\beta_i}\right)\right)^{\frac{1}{\alpha_i}} \\ &\le \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\left(c_i^{\alpha_i} + 2^{\alpha_i}\left(2^{\alpha_i}-1\right)c_{i+1}^{\beta_i}\right)\right)^{\frac{1}{\alpha_i}} \\ &\le \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\left(c_i^{\alpha_i} + \left(2^{\alpha_i}-1\right)c_i^{\alpha_i}\right)\right)^{\frac{1}{\alpha_i}} = 2c_i\pi_i(n), \end{aligned}$$

(ii) Θ *is increasing*, i.e. for any $\mathbf{x}, \mathbf{y} \in \Lambda_2$, $\mathbf{x} \le \mathbf{y}$ implies $\Theta\mathbf{x} \le \Theta\mathbf{y}$.

Thus, all the hypotheses of Theorem 4.1 are fulfilled, implying the existence of a fixed point $\mathbf{x} \in \Lambda_2$ of the mapping Θ. It is easy to see that $\mathbf{x}$ is a positive decreasing solution of the system (SE) and that its components satisfy $(P1)$. □

6 Existence and asymptotic behavior of strongly decreasing $\mathcal{RV}$-solutions

This section is devoted to the problem of existence and asymptotic behavior of strongly decreasing solutions for system (SE). Every strongly decreasing solution of (SE) is a solution of the system

$$x_i(n) = \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{j=k}^{\infty} q_i(j)x_{i+1}(j+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}, \quad i = \overline{1,N}, \quad n \ge n_0, \tag{6.1}$$

for some $n_0 \in \mathbb{N}$. We consider existence and asymptotic behavior of strongly decreasing $\mathcal{RV}$-solutions with a negative index of regularity. However, due to computing difficulties, the existence problem and asymptotic behavior of strongly decreasing slowly varying solutions will be excluded for the time being.

Assuming that condition (I) is satisfied and that coefficients are regularly varying, the following theorem gives the necessary and sufficient conditions for a system (SE) to posses a regularly varying solution $\mathbf{x}$ of a negative index $(\rho_1, \rho_2, \dots, \rho_N)$ of regularity and moreover determine their asymptotic behavior at infinity precisely.

Theorem 6.1. *Let $p_i \in \mathcal{RV}(\lambda_i)$, $q_i \in \mathcal{RV}(\mu_i)$, $i = \overline{1,N}$. Suppose that (I) holds. The system (SE) has a regularly varying solution $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \dots, \rho_N)$ with $\rho_i < 0$, $i = \overline{1,N}$ if and only if*

$$\sum_{j=1}^{N} M_{ij} \frac{\alpha_j - \lambda_j + \mu_j + 1}{\alpha_j} < 0, \quad i = \overline{1,N} \tag{6.2}$$

holds, in which case ρ_i are uniquely determined by

$$\rho_i = \frac{A_N}{A_N - B_N} \sum_{j=1}^{N} M_{ij} \frac{\alpha_j - \lambda_j + \mu_j + 1}{\alpha_j}, \quad i = \overline{1,N} \tag{6.3}$$

and the asymptotic behavior of each component of any such solution is governed by the unique formula

$$x_i(n) \sim \left[\prod_{j=1}^{N} \left(\frac{n^{\frac{\alpha_j+1}{\alpha_j}} p_j(n)^{-\frac{1}{\alpha_j}} q_j(n)^{\frac{1}{\alpha_j}}}{D_j} \right)^{M_{ij}} \right]^{\frac{A_N}{A_N - B_N}}, \quad n \to \infty, \quad i = \overline{1,N}, \tag{6.4}$$

where

$$D_j = \left(\alpha_j - \lambda_j - \alpha_j \rho_j\right)^{\frac{1}{\alpha_j}} (-\rho_j), \quad j = \overline{1,N}. \tag{6.5}$$

Proof. The "only if" part: Let $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \dots, \rho_N)$ with all $\rho_i < 0$ be a solution of (SE). Then, by Theorem 3.7-(vi) and Theorem 3.7-(v) each x_i satisfies (2.1) and $x_i(n) \to 0, n \to \infty$. Also, since (I) holds, as shown in Section 2 we have that $x_i^{[1]}(n) \to 0$, as $n \to \infty$.

Using (4.2) and (4.3), and applying Theorem 3.7-(iii), we obtain

$$\begin{aligned} -x_i^{[1]}(n) &= \sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i} \sim \sum_{k=n}^{\infty} q_i(k) x_{i+1}(k)^{\beta_i} \\ &= \sum_{k=n}^{\infty} k^{\mu_i + \beta_i \rho_{i+1}} m_i(k) \xi_{i+1}(k)^{\beta_i}, \quad n \to \infty, \ i = \overline{1,N}. \end{aligned} \tag{6.6}$$

and

$$-\Delta x_i(n) = \left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i} \right)^{\frac{1}{\alpha_i}} \sim n^{-\frac{\lambda_i}{\alpha_i}} l_i(n)^{-\frac{1}{\alpha_i}} H_i(n)^{\frac{1}{\alpha_i}}, \quad n \to \infty, \tag{6.7}$$

where $H_i(n) = \sum_{k=n}^{\infty} k^{\mu_i + \beta_i \rho_{i+1}} m_i(k) \xi_{i+1}(k)^{\beta_i}$. As the left-hand side of (6.6) tends to zero as $n \to \infty$, it must be $\mu_i + \beta_i \rho_{i+1} \leq -1$, $i = \overline{1,N}$. If $\mu_i + \beta_i \rho_{i+1} = -1$, for some i, then $H_i \in \mathcal{SV}$, so that summing (6.7) from n to ∞, we obtain

$$x_i(n) \sim \sum_{k=n}^{\infty} k^{-\frac{\lambda_i}{\alpha_i}} l_i(k)^{-\frac{1}{\alpha_i}} H_i(k)^{\frac{1}{\alpha_i}}, \quad n \to \infty. \tag{6.8}$$

Since $x_i(n) \to 0, n \to \infty$, using that either (4.4) or (4.5) is satisfied, it is only possible that $\lambda_i = \alpha_i$, in which case $x_i \in \mathcal{SV}$, contradicting the assumption that $\rho_i < 0$. Therefore, it follows that $\mu_i + \beta_i \rho_{i+1} < -1$ for all $i = \overline{1,N}$. Application of Theorem 3.8 to (6.7) gives for $i = \overline{1,N}$

$$-\Delta x_i(n) \sim \frac{n^{\frac{-\lambda_i+\mu_i+\beta_i\rho_{i+1}+1}{\alpha_i}} l_i(n)^{-\frac{1}{\alpha_i}} m_i(n)^{\frac{1}{\alpha_i}} \xi_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}}{(-(\mu_i + \beta_i\rho_{i+1} + 1))^{\frac{1}{\alpha_i}}}, \tag{6.9}$$

as $n \to \infty$. Summing (6.9) from n to ∞, we obtain

$$x_i(n) \sim \sum_{k=n}^{\infty} \frac{k^{\frac{-\lambda_i+\mu_i+\beta_i\rho_{i+1}+1}{\alpha_i}} l_i(k)^{-\frac{1}{\alpha_i}} m_i(k)^{\frac{1}{\alpha_i}} \xi_{i+1}(k)^{\frac{\beta_i}{\alpha_i}}}{(-(\mu_i + \beta_i\rho_{i+1} + 1))^{\frac{1}{\alpha_i}}}, \quad n \to \infty. \tag{6.10}$$

Using that $x_i(n) \to 0, n \to \infty$, we conclude that $(-\lambda_i + \mu_i + \beta_i\rho_{i+1} + 1)/\alpha_i \le -1$, $i = \overline{1,N}$. All inequalities should be strict, because if the equality holds for some i, then (6.10) leads to the contradiction that $\rho_i = 0$. Therefore, $(-\lambda_i + \mu_i + \beta_i\rho_{i+1} + 1)/\alpha_i < -1$, $i = \overline{1,N}$. Applying Theorem 3.8 at (6.10), we conclude that

$$x_i(n) \sim \frac{n^{\frac{-\lambda_i+\mu_i+\beta_i\rho_{i+1}+1}{\alpha_i}+1} l_i(n)^{-\frac{1}{\alpha_i}} m_i(n)^{\frac{1}{\alpha_i}} \xi_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}}{-\left(\frac{-\lambda_i+\mu_i+\beta_i\rho_{i+1}+1}{\alpha_i} + 1\right)(-(\mu_i + \beta_i\rho_{i+1} + 1))^{\frac{1}{\alpha_i}}}, \quad n \to \infty, \quad i = \overline{1,N}. \tag{6.11}$$

From the previous relation, we see that

$$\rho_i = \frac{-\lambda_i + \mu_i + \beta_i\rho_{i+1} + 1}{\alpha_i} + 1, \quad i = \overline{1,N}, \quad \rho_{N+1} = \rho_1 \tag{6.12}$$

which is equivalent to a linear cyclic system of equations

$$\rho_i - \frac{\beta_i}{\alpha_i}\rho_{i+1} = \frac{\alpha_i - \lambda_i + \mu_i + 1}{\alpha_i}, \quad i = \overline{1,N}, \quad \rho_{N+1} = \rho_1. \tag{6.13}$$

The matrix of the system (6.13) is given by (4.12). As shown in Section 4 the matrix A is invertible, implying that the system (6.13) has the unique solution $(\rho_1, \dots, \rho_N)$. Using (4.13), we derive that these ρ_i are given explicitly by (6.3). It is obvious that $\rho_i < 0$, $i = \overline{1,N}$ if and only if (6.2) holds.

Using (4.2) and (4.3), we can transform (6.11) into the following system of asymptotic relations

$$x_i(n) \sim \frac{n^{\frac{\alpha_i+1}{\alpha_i}} p_i(n)^{-\frac{1}{\alpha_i}} q_i(n)^{\frac{1}{\alpha_i}} x_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}}{D_i}, \quad n \to \infty, \quad i = \overline{1,N}, \tag{6.14}$$

where D_i are given by (6.5). Without difficulty, we can obtain that each component x_i of regularly varying solution $\mathbf{x}$ satisfies the explicit asymptotic formula

$$\begin{aligned} x_i(n) &\sim \left[\prod_{j=1}^{N} \left(\frac{n^{\frac{\alpha_j+1}{\alpha_j}} p_j(n)^{-\frac{1}{\alpha_j}} q_j(n)^{\frac{1}{\alpha_j}}}{D_j}\right)^{M_{ij}}\right]^{\frac{A_N}{A_N - B_N}} \\ &= n^{\rho_i}\left[\prod_{j=1}^{N} \left(\frac{l_j(n)^{-\frac{1}{\alpha_j}} m_j(n)^{\frac{1}{\alpha_j}}}{D_j}\right)^{M_{ij}}\right]^{\frac{A_N}{A_N - B_N}}, \quad n \to \infty, \quad i = \overline{1,N}. \end{aligned} \tag{6.15}$$

It is clear from (6.15) that the regularity index of each x_i is exactly ρ_i.

The "if" part: Suppose now that (6.2) holds. Define ρ_i with (6.3) and sequences X_i, $i=\overline{1,N}$, by

$$X_i(n)=\left[\prod_{j=1}^{N}\left(\frac{n^{\frac{\alpha_j+1}{\alpha_j}}p_j(n)^{-\frac{1}{\alpha_j}}q_j(n)^{\frac{1}{\alpha_j}}}{D_j}\right)^{M_{ij}}\right]^{\frac{A_N}{A_N-B_N}}=n^{\rho_i}\chi_i(n),\quad i=\overline{1,N},\tag{6.16}$$

where D_j, $j=\overline{1,N}$ are given by (6.5) and

$$\chi_i(n)=\left[\prod_{j=1}^{N}\left(\frac{l_j(n)^{-\frac{1}{\alpha_j}}m_j(n)^{\frac{1}{\alpha_j}}}{D_j}\right)^{M_{ij}}\right]^{\frac{A_N}{A_N-B_N}},\quad \chi_i\in\mathcal{SV}.$$

From, (6.2) we have that $\rho_i<0$, $i=\overline{1,N}$. First, we show that sequences $X_i\in\mathcal{RV}(\rho_i)$ satisfy the system of asymptotic relations

$$\sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)X_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}\sim X_i(n),\quad n\to\infty,\quad i=\overline{1,N},\tag{6.17}$$

where $X_{N+1}=X_1$. To that end, let us note that from "the only if" part we conclude that $(\rho_1,\dots,\rho_N)$, with ρ_i given by (6.3) is in fact the unique solution of the linear cyclic system of equations (6.13). In order to apply Theorem 3.8, it must hold that $\mu_i+\rho_{i+1}\beta_i<-1$, $i=\overline{1,N}$. From the fact $\rho_i<0$ and (6.12) we have

$$\mu_i+\rho_{i+1}\beta_i=(\rho_i-1)\alpha_i+\lambda_i-1<-\alpha_i+\lambda_i-1\le-1.$$

Therefore, using (6.12) and applying Theorem 3.8, we obtain

$$\left(\frac{1}{p_i(n)}\sum_{k=n}^{\infty}q_i(k)X_{i+1}(k+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}\sim\frac{n^{\rho_i-1}l_i(n)^{-\frac{1}{\alpha_i}}m_i(n)^{\frac{1}{\alpha_i}}\chi_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}}{(\alpha_i-\lambda_i-\alpha_i\rho_i)^{\frac{1}{\alpha_i}}},\quad n\to\infty,$$

and

$$\sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)X_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}\sim\frac{n^{\rho_i}l_i(n)^{-\frac{1}{\alpha_i}}m_i(n)^{\frac{1}{\alpha_i}}\chi_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}}{D_i},\quad n\to\infty.\tag{6.18}$$

Using relation (4.11) for matrix elements M_{ij}, the right-hand side of the relation (6.18) can be transformed as follows

$$\begin{aligned}\frac{l_i(n)^{-\frac{1}{\alpha_i}}m_i(n)^{\frac{1}{\alpha_i}}}{D_i}\chi_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}&=\frac{l_i(n)^{-\frac{1}{\alpha_i}}m_i(n)^{\frac{1}{\alpha_i}}}{D_i}\left[\prod_{j=1}^{N}\left(\frac{l_j(n)^{-\frac{1}{\alpha_j}}m_j(n)^{\frac{1}{\alpha_j}}}{D_j}\right)^{M_{i+1,j}\frac{\beta_i}{\alpha_i}}\right]^{\frac{A_N}{A_N-B_N}}\\&=\left[\prod_{j=1}^{N}\left(\frac{l_j(n)^{-\frac{1}{\alpha_j}}m_j(n)^{\frac{1}{\alpha_j}}}{D_j}\right)^{M_{ij}}\right]^{\frac{A_N}{A_N-B_N}}=\chi_i(n),\quad i=\overline{1,N},\quad \chi_{N+1}=\chi_N,\end{aligned}$$

so from (6.18), we obtain that X_i, $i = \overline{1,N}$ satisfy (6.17).

It follows from (6.17) that there exists $n_0 > 1$ such that for $n > n_0$ holds

$$\frac{1}{2}X_i(n) \le \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)X_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}} \le 2X_i(n), \quad i = \overline{1,N}. \tag{6.19}$$

Let we choose positive constants ω_i and W_i so that

$$\omega_i \le \frac{1}{2}\omega_{i+1}^{\frac{\beta_i}{\alpha_i}}, \quad W_i \ge 2W_{i+1}^{\frac{\beta_i}{\alpha_i}}, \quad i = \overline{1,N}, \quad \omega_{N+1} = \omega_1, \quad W_{N+1} = W_1. \tag{6.20}$$

Consider the space Y_{n_0} of all vectors $\mathbf{x} = (x_1, x_2, \dots, x_N)$, $x_i \in {}^{\mathbb{N}_{n_0}}\mathbb{R}$, $i = \overline{1,N}$, such that $\{x_i(n)/X_i(n)\}$, $i = \overline{1,N}$ are bounded. Then, Y_{n_0} is a Banach space endowed with the norm

$$\|\mathbf{x}\| = \max_{1\le i\le N}\left\{\sup_{n\ge n_0}\left|\frac{x_i(n)}{X_i(n)}\right|\right\}$$

Further, Y_{n_0} is partially ordered, with the usual pointwise ordering $\le$: For $\mathbf{x}, \mathbf{y} \in \mathrm{Y}_{n_0}$, $\mathbf{x} \le \mathbf{y}$ means $x_i(n) \le y_i(n)$ for all $n \ge n_0$ and $i = \overline{1,N}$. Define the subset $\mathcal{X} \subset \mathrm{Y}_{n_0}$ with

$$\mathcal{X} = \left\{\mathbf{x} \in \mathrm{Y}_{n_0} \;\middle|\; \omega_i X_i(n) \le x_i(n) \le W_i X_i(n), \quad n \ge n_0, \quad i = \overline{1,N}\right\}. \tag{6.21}$$

It is easy to see that for any $\mathbf{x} \in \mathcal{X}$, the norm of $\mathbf{x}$ is finite. Also, for any subset $B \subset \mathcal{X}$, it is obvious that $\inf B \in \mathcal{X}$ and $\sup B \in \mathcal{X}$. We will define the operators $\mathcal{F}_i : {}^{\mathbb{N}_{n_0}}\mathbb{R} \to {}^{\mathbb{N}_{n_0}}\mathbb{R}$ by

$$\mathcal{F}_i x(n) = \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)x(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}, \quad n \ge n_0, \quad i = \overline{1,N}, \tag{6.22}$$

and define the mapping $\Phi : \mathcal{X} \to \mathrm{Y}_{n_0}$ by

$$\Phi(x_1, x_2, \dots, x_N) = \left(\mathcal{F}_1 x_2, \mathcal{F}_2 x_3, \dots, \mathcal{F}_N x_{N+1}\right), \quad x_{N+1} = x_1. \tag{6.23}$$

We will show that Φ has a fixed point by using Theorem 4.1. Namely, the operator Φ has the following properties:

(i) Φ *maps* $\mathcal{X}$ *into itself*: Let $\mathbf{x} \in \mathcal{X}$. Then, using (6.19)–(6.22), we see that for $n \ge n_0$,

$$\mathcal{F}_i x_{i+1}(n) \le W_{i+1}^{\frac{\beta_i}{\alpha_i}}\sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)X_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}} \le 2W_{i+1}^{\frac{\beta_i}{\alpha_i}}X_i(n) \le W_i X_i(n),$$

and

$$\mathcal{F}_i x_{i+1}(n) \ge \omega_{i+1}^{\frac{\beta_i}{\alpha_i}}\sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)X_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}} \ge \frac{1}{2}\omega_{i+1}^{\frac{\beta_i}{\alpha_i}}X_i(n) \ge \omega_i X_i(n).$$

This shows that $\Phi\mathbf{x} \in \mathcal{X}$, that is, Φ is a self-map on $\mathcal{X}$.

(ii) Φ *is increasing*, i.e. for any $\mathbf{x}, \mathbf{y} \in \mathcal{X}$, $\mathbf{x} \le \mathbf{y}$ implies $\Phi\mathbf{x} \le \Phi\mathbf{y}$.

Thus all the hypotheses of Theorem 4.1 are fulfilled implying the existence of a fixed point $\mathbf{x} \in \mathcal{X}$ of Φ, which satisfies

$$x_i(n) = \mathcal{F}_i x_{i+1}(n) = \sum_{k=n}^{\infty}\left(\frac{1}{p_i(k)}\sum_{s=k}^{\infty}q_i(s)x_{i+1}(s+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}, \quad n \ge n_0, \quad i = \overline{1,N}.$$

It is easy to see that this solution is positive and decreasing. Since $\mathbf{x} \in \mathcal{X}$, it is clear that $x_i(n) \to 0$, $n \to \infty$. Furthermore, using (6.12), (6.16) and applying Theorem 3.8 we have

$$\begin{aligned} p_i(n)(-\Delta x_i(n))^{\alpha_i} &= \sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i} \le W_{i+1}^{\beta_i} \sum_{k=n}^{\infty} q_i(k) X_{i+1}(k+1)^{\beta_i} \\ &\sim W_{i+1}^{\beta_i} \frac{n^{(\rho_i-1)\alpha_i+\lambda_i} m_i(n) \chi_{i+1}(n)^{\beta_i}}{(1-\rho_i)\alpha_i - \lambda_i}, \quad n \to \infty, \quad i = \overline{1,N}. \end{aligned}$$

Since $(\rho_i - 1)\alpha_i + \lambda_i < \lambda_i - \alpha_i \le 0$, we conclude that $x_i^{[1]}(n) \to 0$, $n \to \infty$. This shows that $\mathbf{x} \in \mathcal{X}$ is a strongly decreasing solution of the system (SE).

It remains to verify that $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \dots, \rho_N)$. We define

$$u_i(n) = \sum_{k=n}^{\infty} \left(\frac{1}{p_i(k)} \sum_{s=k}^{\infty} q_i(s) X_{i+1}(s+1)^{\beta_i} \right)^{\frac{1}{\alpha_i}}, \quad i = \overline{1,N},$$

and put

$$r_i = \liminf_{n\to\infty} \frac{x_i(n)}{u_i(n)}, \quad R_i = \limsup_{n\to\infty} \frac{x_i(n)}{u_i(n)}.$$

Since $\omega_i X_i(n) \le x_i(n) \le W_i X_i(n)$, $n \ge n_0$, $i = \overline{1,N}$ and

$$u_i(n) \sim X_i(n), \quad n \to \infty, \quad i = \overline{1,N}, \tag{6.24}$$

it follows that $0 < r_i \le R_i < \infty$, $i = \overline{1,N}$. Using Lemma 4.5 we obtain

$$\begin{aligned} r_i &\ge \liminf_{n\to\infty} \frac{\Delta x_i(n)}{\Delta u_i(n)} = \liminf_{n\to\infty} \frac{-\left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}}{-\left(\frac{1}{p_i(n)} \sum_{k=n}^{\infty} q_i(k) X_{i+1}(k+1)^{\beta_i}\right)^{\frac{1}{\alpha_i}}} \\ &= \liminf_{n\to\infty} \left(\frac{\sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i}}{\sum_{k=n}^{\infty} q_i(k) X_{i+1}(k+1)^{\beta_i}} \right)^{\frac{1}{\alpha_i}} = \left(\liminf_{n\to\infty} \frac{\sum_{k=n}^{\infty} q_i(k) x_{i+1}(k+1)^{\beta_i}}{\sum_{k=n}^{\infty} q_i(k) X_{i+1}(k+1)^{\beta_i}} \right)^{\frac{1}{\alpha_i}} \\ &\ge \left(\liminf_{n\to\infty} \frac{-q_i(n) x_{i+1}(n+1)^{\beta_i}}{-q_i(n) X_{i+1}(n+1)^{\beta_i}} \right)^{\frac{1}{\alpha_i}} = \liminf_{n\to\infty} \left(\frac{x_{i+1}(n+1)}{X_{i+1}(n+1)} \right)^{\frac{\beta_i}{\alpha_i}} = r_{i+1}^{\frac{\beta_i}{\alpha_i}} \end{aligned}$$

where (6.24) has been used in the last step. Thus, r_i satisfy the cyclic system of inequalities

$$r_i \ge r_{i+1}^{\frac{\beta_i}{\alpha_i}}, \quad i = \overline{1,N}, \quad r_{N+1} = r_1. \tag{6.25}$$

Similarly, by taking the upper limits instead of the lower limits, we get that R_i satisfy the cyclic system of inequalities

$$R_i \le R_{i+1}^{\frac{\beta_i}{\alpha_i}}, \quad i = \overline{1,N}, \quad R_{N+1} = R_1. \tag{6.26}$$

From (6.25) and (6.26) we easily see that

$$r_i \ge r_i^{\frac{\beta_1\beta_2\dots\beta_N}{\alpha_1\alpha_2\dots\alpha_N}}, \quad R_i \le R_i^{\frac{\beta_1\beta_2\dots\beta_N}{\alpha_1\alpha_2\dots\alpha_N}},$$

whence, because of the hypothesis $\beta_1\beta_2\dots\beta_N/\alpha_1\alpha_2\dots\alpha_N < 1$, we find that $r_i \ge 1$ and $R_i \le 1$, $i = \overline{1,N}$. It follows therefore that $r_i = R_i = 1$ i.e. $\lim_{n\to\infty} x_i(n)/u_i(n) = 1$ for $i = \overline{1,N}$. Combined this with (6.24) implies that $x_i(n) \sim u_i(n) \sim X_i(n)$ as $n \to \infty$, which shows that each x_i is a regularly varying sequence of index ρ_i. Thus, the proof of the "if" part of Theorem 6.1. is completed. □

Assuming that condition (II) is satisfied, taking into account that (II) is satisfied if and only if (4.7) or (4.8) holds, the next two theorems provide the necessary and sufficient conditions for a system (SE) to posses a regularly varying solution $\mathbf{x}$ with the index of regularity $(\rho_1, \rho_2, \dots, \rho_N)$ such that $\rho_i < \frac{\alpha_i - \lambda_i}{\alpha_i}$, $i = \overline{1,N}$ if (4.7) holds and such that $\rho_i < 0$, $i = \overline{1,N}$ if (4.8) holds, and moreover determine their asymptotic behavior at infinity precisely.

Theorem 6.2. *Let $p_i \in \mathcal{RV}(\lambda_i)$, $q_i \in \mathcal{RV}(\mu_i)$. Suppose that (4.7) holds. The system (SE) has a regularly varying solution $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \dots, \rho_N)$ with $\rho_i < \frac{\alpha_i - \lambda_i}{\alpha_i}$, $i = \overline{1,N}$ if and only if*

$$\sum_{j=1}^{N} M_{ij} \left(\frac{\mu_j + 1}{\alpha_j} + \frac{\beta_j(\alpha_{j+1} - \lambda_{j+1})}{\alpha_j \alpha_{j+1}} \right) < 0, \quad i = \overline{1,N}, \ \ \alpha_{N+1} = \alpha_1, \lambda_{N+1} = \lambda_1, \tag{6.27}$$

holds, in which case ρ_i are uniquely determined by (6.3) and the asymptotic behavior of each component of any such solution is governed by the unique formula (6.4) with D_j, $j = \overline{1,N}$ given by (6.5).

Proof. The "only if" part: Let $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \dots, \rho_N)$ with all $\rho_i < (\alpha_i - \lambda_i)/\alpha_i$ be a solution of (SE). Since from (4.7), ρ_i, $i = \overline{1,N}$ are negative, from Theorem 3.7-(v) we have that $x_i(n) \to 0$, $n \to \infty$. Also, we have that $\pi_i \in \mathcal{RV}\left(\frac{\alpha_i - \lambda_i}{\alpha_i}\right)$, from the asymptotic relation (4.9) for π_i holding if (4.7) is satisfied. Therefore, we conclude that index of regularity of each x_i/π_i, $i = \overline{1,N}$ is less then zero, implying by Theorem 3.7-(v) that $\lim_{n\to\infty} x_i(n)/\pi_i(n) = 0$. Therefore, $\lim_{n\to\infty} x_i^{[1]}(n) = 0$. Using (4.2) and (4.3), and applying Theorem 3.7-(iii), we obtain (6.6). Then, $\lim_{n\to\infty} x_i^{[1]}(n) = 0$ implies that $\mu_i + \beta_i \rho_{i+1} \le -1$, $i = \overline{1,N}$. If $\mu_i + \beta_i \rho_{i+1} = -1$ for some i, then as in the proof of Theorem 6.1 we obtain that (6.8) holds. Since (4.7) holds, application of Theorem 3.8 gives

$$x_i(n) \sim \sum_{k=n}^{\infty} k^{-\frac{\lambda_i}{\alpha_i}} l_i(k)^{-\frac{1}{\alpha_i}} H_i(k)^{\frac{1}{\alpha_i}} \sim \frac{\alpha_i}{\lambda_i - \alpha_i} n^{\frac{\alpha_i - \lambda_i}{\alpha_i}} l_i(n)^{-\frac{1}{\alpha_i}} H_i(n)^{\frac{1}{\alpha_i}}, \quad n \to \infty,$$

where $H_i(n) = \sum_{k=n}^{\infty} k^{-1} m_i(k) \xi_{i+1}(k)^{\beta_i}$, $H_i \in \mathcal{SV}$. Thus, $x_i \in \mathcal{RV}\left(\frac{\alpha_i - \lambda_i}{\alpha_i}\right)$, contradicting the hypothesis $\rho_i < \frac{\alpha_i - \lambda_i}{\alpha_i}$. Therefore, $\mu_i + \beta_i \rho_{i+1} < -1$ for all $i = \overline{1,N}$. Proceeding exactly as in the proof of Theorem 6.1, we get that (6.9) holds and conclude that $(-\lambda_i + \mu_i + \beta_i \rho_{i+1} + 1)/\alpha_i \le -1$ for all i. All inequalities should be strict, because if the equality holds for some i, then $\lambda_i - \alpha_i = \mu_i + \beta_i \rho_{i+1} + 1 < 0$, contradicting the assumption (4.7). Thus, (6.11) holds, which yields that $(\rho_1, \dots, \rho_N)$ is the unique solution of the linear cyclic system of equations (6.13), so that ρ_i, $i = \overline{1,N}$ are uniquely determined by (6.3). That the asymptotic behavior of each component of solution $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \dots, \rho_N)$ with all $\rho_i < (\alpha_i - \lambda_i)/\alpha_i$ is governed by the unique formula (6.4) with D_j, $j = \overline{1,N}$ given by (6.5) is obtain as in the proof of Theorem 6.1.

To verify the condition (6.27), let we denote $d_i = \rho_i + \lambda_i/\alpha_i - 1$, $i = \overline{1,N}$. Then, the linear system of equations (6.13) is transformed into the system

$$d_i - \frac{\beta_i}{\alpha_i} d_{i+1} = \frac{\mu_i + 1}{\alpha_i} + \frac{\beta_i(\alpha_{i+1} - \lambda_{i+1})}{\alpha_i \alpha_{i+1}}, \quad i = \overline{1,N}, \quad d_{N+1} = d_1. \tag{6.28}$$

Matrix of the system (6.28) is given by (4.12). Since A is nonsingular, the system (6.28) has the unique solution $d_i, i = \overline{1,N}$, where

$$d_i = \sum_{j=1}^{N} M_{ij} \left(\frac{\mu_j + 1}{\alpha_j} + \frac{\beta_j(\alpha_{j+1} - \lambda_{j+1})}{\alpha_j \alpha_{j+1}} \right), \quad i = \overline{1,N}. \tag{6.29}$$

Since $\rho_i < \frac{\alpha_i - \lambda_i}{\alpha_i}$ if and only if $d_i < 0$, we conclude that the condition (6.27) holds.

The "if" part: Suppose that (6.27) holds. Define ρ_i with (6.3) and sequences $X_i \in \mathcal{RV}(\rho_i)$, $i = \overline{1,N}$, by (6.16). The indices of regularity of X_i, are the unique solution of the linear cyclic system (6.13). According to the assumption (6.27), we conclude that $\rho_i < (\alpha_i - \lambda_i)/\alpha_i < 0$, $i = \overline{1,N}$. Then, in a manner similar to that of the previous theorem proof, it can be demonstrated that X_i, $i = \overline{1,N}$, satisfy the asymptotic relation (6.17). Therefore, the "if" part of the theorem as well as asymptotic formulas for each component x_i of $\mathcal{RV}$-solution $\mathbf{x}$ can be obtained as in the "if" part proof of the previous theorem. □

Theorem 6.3. *Let $p_i \in \mathcal{RV}(\lambda_i)$, $q_i \in \mathcal{RV}(\mu_i)$. Suppose that (4.8) holds. The system (SE) has a regularly varying solution $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \ldots, \rho_N)$ with $\rho_i < 0$, $i = \overline{1,N}$ if and only if*

$$\sum_{j=1}^{N} M_{ij} \frac{\mu_j + 1}{\alpha_j} < 0, \quad i = \overline{1,N} \tag{6.30}$$

in which case ρ_i are uniquely determined by

$$\rho_i = \frac{A_N}{A_N - B_N} \sum_{j=1}^{N} M_{ij} \frac{\mu_j + 1}{\alpha_j}, \quad i = \overline{1,N} \tag{6.31}$$

and the asymptotic behavior of any such solution is governed by the unique formulas (6.4) with $D_j = \left(\alpha_j(-\rho_j)^{\alpha_j+1}\right)^{1/\alpha_j}$, $j = \overline{1,N}$.

Proof. The "only if" part: Suppose that the system (SE) has a solution $\mathbf{x} \in \mathcal{RV}(\rho_1, \rho_2, \ldots, \rho_N)$, $\rho_i < 0$, $i = \overline{1,N}$. The assumption (4.8) implies that

$$\pi_i(n) = \sum_{k=n}^{\infty} k^{-1} l_i(k)^{-\frac{1}{\alpha_i}},$$

so that $\pi_i \in \mathcal{SV}$, implying that index of regularity of each x_i/π_i is $\rho_i < 0$ for $i = \overline{1,N}$. Therefore, by Theorem 3.7-(v), we have that $\lim_{n\to\infty} x_i(n) = 0$ and $\lim_{n\to\infty} x_i(n)/\pi_i(n) = 0$, implying that $\lim_{n\to\infty} x_i^{[1]}(n) = 0$. From (6.6), since the left-hand side tends to zero, we conclude that it must be $\mu_i + \beta_i\rho_{i+1} \leq -1$. If $\mu_i + \beta_i\rho_{i+1} = -1$ holds for some i, then as in the proof of Theorem 6.1 we obtain from (6.8) with $H_i \in \mathcal{SV}$, which due to the assumption (4.8) has the form

$$x_i(n) \sim \sum_{k=n}^{\infty} k^{-1} l_i(k)^{-\frac{1}{\alpha_i}} H_i(k)^{\frac{1}{\alpha_i}}, \quad n \to \infty, \quad i = \overline{1,N},$$

implying the contradiction $x_i \in \mathcal{SV}$. Therefore, $\mu_i + \beta_i\rho_{i+1} < -1$ for all $i = \overline{1,N}$. Then as in the proof of Theorem 6.1 we obtain (6.10) and since $x_i(n) \to 0$, $n \to \infty$ it must be

$$\frac{-\lambda_i + \mu_i + \beta_i\rho_{i+1} + 1}{\alpha_i} = -1 + \frac{\mu_i + \beta_i\rho_{i+1} + 1}{\alpha_i} \leq -1, \quad i = \overline{1,N}.$$

If equality holds for some i, then (6.10) yields the contradiction $x_i \in \mathcal{SV}$. Thus, $\mu_i + \beta_i\rho_{i+1} < -1$, $i = \overline{1,N}$, and applying Theorem 3.8 at (6.10), we conclude that

$$x_i(n) \sim \frac{n^{\frac{\mu_i+\beta_i\rho_{i+1}+1}{\alpha_i}} l_i(n)^{-\frac{1}{\alpha_i}} m_i(n)^{\frac{1}{\alpha_i}} \xi_{i+1}(n)^{\frac{\beta_i}{\alpha_i}}}{-\frac{\mu_i+\beta_i\rho_{i+1}+1}{\alpha_i} \left(-(\mu_i + \beta_i\rho_{i+1} + 1)\right)^{\frac{1}{\alpha_i}}}, \quad n \to \infty, \quad i = \overline{1,N}. \tag{6.32}$$

Therefore, (6.32) implies that $(\rho_1, \dots, \rho_N)$ is the unique solution of the linear cyclic system of equations

$$\rho_i - \frac{\beta_i}{\alpha_i}\rho_{i+1} = \frac{\mu_i + 1}{\alpha_i}, \quad i = \overline{1, N}, \quad \rho_{N+1} = \rho_1, \tag{6.33}$$

since the matrix of the system (6.33), given by (4.12), is invertible. Using (4.13), we obtain that $\rho_i, i = \overline{1, N}$ is given by (6.31). Proceeding exactly as in the proof of Theorem 6.1, we obtain that the unique asymptotic formula for each x_i is given by (6.4), where constants D_j are reduced to $D_j = \left(\alpha_j/(-\rho_i)^{\alpha_j+1}\right)^{1/\alpha_j}, j = \overline{1, N}$. Since all ρ_i are negative if and only if (6.30) holds, the "only if" part of the theorem is proved.

The "if" part of the theorem is proved and the explicit asymptotic formula for each component x_i of $\mathcal{RV}$-solution $\mathbf{x}$ can be obtained as in the proof of Theorem 6.1. □

Application. The one-dimensional system with positive coefficients $\{p(n)\}, \{q(n)\}$ is in fact the second-order difference equation of Emden–Fowler type (see (1.3)):

$$\Delta(p(n)|\Delta x(n)|^{\alpha-1}\Delta x(n)) = q(n)|x(n+1)|^{\beta-1}x(n+1), \tag{6.34}$$

This equation has been studied in [24, 25]. In this case, Theorems 6.1 and 6.2 reduce to Theorem 3.8 from [25]. However, since the case where the regularity index of the coefficient p is equal to α, was not considered neither in [25] nor in the existing literature so far, the new result is obtained as the corollary of Theorem 6.1 and Theorem 6.3. This result provides necessary and sufficient condition for the existence of $\mathcal{RV}$ strongly decreasing solutions of type $(SD1)$ if $S = \infty$ as well as of $\mathcal{RV}$ strongly decreasing solutions of type $(SD2)$ if $S < \infty$, where $S = \sum_{n=1}^{\infty} \frac{1}{p(n)^{\alpha}}$.

Corollary 6.4. *Let $\{p(n)\} \in \mathcal{RV}(\alpha)$ and $\{q(n)\} \in \mathcal{RV}(\mu)$. The equation (6.34) possesses a regularly varying solution of index $\rho < 0$ if and only if $\mu < -1$, in which case ρ is given by*

$$\rho = \frac{\mu + 1}{\alpha - \beta}$$

and the asymptotic behavior of any such solution x is governed by the unique formula

$$x(n) \sim \left[\frac{n^{\alpha+1}p(n)^{-1}q(n)}{\alpha(-\rho)^{\alpha+1}}\right]^{\frac{1}{\alpha-\beta}}, \quad n \to \infty.$$

Following example illustrate results obtained in the last corollary.

Example 6.5. Consider the difference equation

$$\Delta\left(-n^2\sqrt{\log n}(\Delta x(n))^2\right) = \frac{\gamma(n)}{n^6 \log^{17/6} n}\sqrt[3]{x(n+1)}, \quad n \geq 2, \tag{6.35}$$

where $\gamma(n)$ is positive real-valued sequence such that $\lim_{n\to\infty}\gamma(n) = \delta$. In this equation, $\alpha = 3$, $\beta = \frac{1}{3}$, $\{p(n)\} \in \mathcal{RV}(2)$, and $\{q(n)\} \in \mathcal{RV}(-6)$.

Since $\mu = -6 < -1$, by Corollary 6.4 we conclude that equation (6.35) has a strongly decreasing $\mathcal{RV}-$solution of index $\rho = -3$. The asymptotic behavior of such a solution is

$$x(n) \sim \left(\frac{\delta}{54}\right)^{\frac{3}{5}} n^{-3}(\log n)^{-2}, \quad n \to \infty.$$

If

$$\gamma(n) = n^2(n+1)(\log n)^{\frac{9}{2}}(\log(n+1))^{\frac{2}{3}}\left(\psi(n) - \left(\frac{n}{n+1}\right)^4 \frac{\sqrt{\log(n+1)}}{\log n}\psi(n+1)\right),$$

where

$$\psi(n) = \left(\left(\frac{n}{n+1}\right)^3 \frac{1}{(\log(n+1))^2} - \frac{1}{(\log n)^2}\right)^2,$$

then $\delta = 54$ and equation (6.35) has the exact solution $x(n) = n^{-3}(\log n)^{-2}$.

Abstract. In this paper, existence results are obtained for a system of second order boundary value problems

$$\begin{cases} u''_{\overline{g}}(t) = f(t, u(t), u'_{\overline{g}}(t)), \ \mu_{\overline{g}}\text{-a.e. } t \in [0,1) \\ u(0) = \overline{\alpha} \\ u(1) + ku(\theta) = \overline{\beta}, \end{cases}$$

with Stieltjes derivatives with respect to different derivators on different coordinates.

Using an appropriate Green function and Schauder's fixed point theorem, a very general existence result is obtained, thus overcoming several outcomes in literature.

Keywords: Stieltjes derivative, three-point boundary value problem, second order equation.

2020 Mathematics Subject Classification: 34A06, 34B10, 26A24, 26A42.

1 Introduction

The interest for second order differential equations with multi-point boundary conditions has robust roots in engineering (e.g. [17]) and it was, therefore, intensively studied. We refer the reader to [17, 31, 33] and the references therein and to [7] or [1, 24] for the framework of impulsive problems, respectively of dynamic equations on time scales.

At the same time, problems involving the Stieltjes derivative with respect to nondecreasing functions have recently found significant applications in studying real processes where stationary intervals and abrupt changes are equally present (see [11–13, 18] or [19]); this kind of behaviour was investigated through the theory of measure differential equations (e.g. [6]) and inclusions (for instance, [4] or [5]). Starting with the paper [16] (following an idea in [32]), a more convenient, equivalent writing using the Stieltjes derivative became increasingly popular (see [8, 9, 11, 12, 20, 23, 27, 28] for the single-valued case or [26, 29] for the set-valued setting).

✉ Email: bisatco@usm.ro

Second order equations with Stieltjes derivative were considered, to the best of the author's knowledge, only in the linear case with initial value boundary conditions in [8,9] and in the nonlinear case with periodic conditions in [22].

When speaking about systems of differential problems, as described in [12,14,19] or [21], it is important to allow the variation speed of different unknown variables to depend on different nondecreasing functions and thus, to have different impulsive moments or stationary intervals of time; this means to consider a vector-valued derivator.

With all these in mind, we hereby develop a study of systems of nonlinear second order Stieltjes differential equations with three-point boundary conditions and several derivators:

$$\begin{cases} u''_{\overline{g}}(t) = f(t, u(t), u'_{\overline{g}}(t)), \ \mu_{\overline{g}}\text{-a.e. } t \in [0,1) \\ u(0) = \overline{\alpha} \\ u(1) + ku(\theta) = \overline{\beta}. \end{cases}$$

Inspired by [33], a Green's function is adapted to the present framework, allowing one to get existence and uniqueness for single-valued linear second order equations on the real line. A fixed point theorem is then applied to get an existence result in the nonlinear case for systems of second order Stieltjes differential problems with three-point boundary conditions and several derivators.

It is well-known that the theory of Stieltjes differential equations is strongly related to other types of problems: generalized differential equations ([30]), impulsive differential equations ([16]) or dynamic problems on time scales ([6]); consequently, the outcomes presented here can be used to get existence and uniqueness results for systems of second-order equations with three-point boundary conditions in the mentioned settings.

2 Notations and auxiliary results.

Let $g : [0,1] \to \mathbb{R}$ be a nondecreasing left-continuous function. Without any loss of generality, one may suppose that $g(0) = 0$. The g-measurability means the measurability with respect to (shortly, w.r.t.) the σ-algebra defined by g, μ_g is the Stieltjes measure generated by g (see [10]) and the Lebesgue–Stieltjes (shortly, LS-) integrability w.r.t. g is the abstract Lebesgue integrability w.r.t. the measure μ_g. Let $L^1_g([0,1])$ be the space of real LS-integrable functions w.r.t. g with its natural topological structure given by the norm

$$\|f\|_1 = \int_{[0,1)} |f(t)| dg(t).$$

Consider the following sets:

$$D_g = \{t \in [0,1] : g(t+) - g(t) > 0\}$$

and

$$C_g = \{t \in [0,1] : g \text{ is constant on } (t-\varepsilon, t+\varepsilon) \text{ for some } \varepsilon > 0\}$$

along with

$$N_g = \{u_n, v_n : n \in \mathbb{N}\} \setminus D_g,$$

where $C_g = \bigcup_{n\in\mathbb{N}}(u_n, v_n)$ with $(u_n, v_n)_n$ pairwise disjoint. Let $N_g^- = \{u_n : n \in \mathbb{N}\} \setminus D_g$ and $N_g^+ = \{v_n : n \in \mathbb{N}\} \setminus D_g$. As $\mu_g(C_g) = \mu_g(N_g) = 0$ (proved in [16]), these two sets are irrelevant in the study of differential equations. Note also that $D_g \cap C_g = \emptyset$.

Let us now recall the notion of differentiability related to Stieltjes integrals introduced in [8] (which extends that in [16] in such a way that the points in C_g are also covered).

Definition 2.1. Let $g : [0,1] \to \mathbb{R}$ be a nondecreasing left-continuous function such that $0 \notin N_g^-$ and $1 \notin C_g \cup N_g^+$. The derivative with respect to g (or the g-derivative) of $f : [0,1] \to \mathbb{R}$ at $\bar{t} \in [0,1]$ is defined by

$$f'_g(\bar{t}) = \lim_{t \to \bar{t}} \frac{f(t) - f(\bar{t})}{g(t) - g(\bar{t})} \quad \text{if } t \notin D_g \cup C_g,$$

$$f'_g(\bar{t}) = \lim_{t \to \bar{t}+} \frac{f(t) - f(\bar{t})}{g(t) - g(\bar{t})} \quad \text{if } t \in D_g,$$

$$f'_g(\bar{t}) = \lim_{t \to v_n+} \frac{f(t) - f(v_n)}{g(t) - g(v_n)} \quad \text{if } t \in (u_n, v_n) \subseteq C_g,$$

if the limits exist. In this case f is said to be g-differentiable at t.

The points of N_g must be approached in the following manner:

$$f'_g(\bar{t}) = \lim_{t \to \bar{t}+} \frac{f(t) - f(\bar{t})}{g(t) - g(\bar{t})} \quad \text{if } t \in N_g^+,$$

$$f'_g(\bar{t}) = \lim_{t \to \bar{t}-} \frac{f(t) - f(\bar{t})}{g(t) - g(\bar{t})} \quad \text{if } t \in N_g^-.$$

Note that if $t \in D_g$, the g-derivative $f'_g(t)$ exists if and only if the right limit $f(t+)$ exists, and in this case

$$f'_g(t) = \frac{f(t+) - f(t)}{g(t+) - g(t)},$$

while if $t \in (u_n, v_n) \subseteq C_g$ the g-derivative $f'_g(t)$ exists if and only if there exists the right g-derivative at v_n.

The g-derivative is very useful when trying to solve many interesting problems where abrupt modifications (corresponding to discontinuity points of g) and stationary times (corresponding to intervals where g is constant) are both part of the state behaviour, such as in [11, 12] or [13].

Connecting Stieltjes integrals and the Stieltjes derivative is one of the main technical issues of the theory; such connections are provided by Fundamental Theorems of Calculus ([16, Theorems 5.4, 6.2, 6.5]).

In order to state them, let us remind the reader (e.g. [16]) that f is called g-absolutely continuous ($f \in \mathcal{AC}_g([0,1])$) if for every $\varepsilon > 0$ there exists $\delta_\varepsilon > 0$ such that

$$\sum_{j=1}^{m} |f(b_j) - f(a_j)| < \varepsilon$$

for any set $\{(a_j, b_j); j = 1, \dots, m\}$ of disjoint subintervals of $[0,1]$ satisfying

$$\sum_{j=1}^{m} (g(b_j) - g(a_j)) < \delta_\varepsilon.$$

Theorem 2.2.

a) ([16, Theorem 2.4]) Let $f : [0,1] \to \mathbb{R}$ be LS-integrable with respect to g. Then

$$F(t) = \int_{[0,t)} f(s)\, dg(s), \quad t \in [0,1]$$

defines a map g-absolutely continuous and μ_g-a.e. g-differentiable on $[0,1)$ with the property that $F_g'(t) = f(t)$, μ_g-a.e.

b) ([16, Theorem 5.4], see also [11, Theorem 5.1]) If $F : [0,1] \to \mathbb{R}$ is g-absolutely continuous, then F_g' exists μ_g-a.e. and

$$F(t) = F(0) + \int_{[0,t)} F_g'(s)\, dg(s) \quad \text{for every } t \in [0,1].$$

Remark 2.3. It easily follows that if $f \in L_g^1([0,1])$,

$$\tilde{F}(t) = \int_{[t,1)} f(s)\, dg(s), \quad t \in [0,1)$$

defines a map μ_g-a.e. g-differentiable with the property that $\tilde{F}_g'(t) = -f(t)$, μ_g-a.e.

Let us also recall ([11]) that a map $f : [0,1] \to \mathbb{R}$ is g-continuous at a point $t \in [0,1]$ if for every $\varepsilon > 0$ one can find $\delta_{t,\varepsilon} > 0$ such that

$$s \in [0,1],\ |g(t) - g(s)| < \delta_{t,\varepsilon} \ \Rightarrow\ |f(t) - f(s)| < \varepsilon$$

and that g-continuity on $[0,1]$ means g-continuity at every $t \in [0,1]$.

Any g-absolutely continuous function is g-continuous and it was proved in [16, Proposition 5.3] that g-absolutely continuous functions are left-continuous and constant on the intervals where g is constant.

Note that g-continuous functions are not necessarily bounded, this is the reason to consider the space $\mathcal{BC}_g([0,1])$ of functions which are bounded and g-continuous ([11]). It is a Banach space when endowed with the norm

$$\|u\|_C = \sup_{t \in [0,1]} |u(t)|$$

and $\mathcal{AC}_g([0,1]) \subset \mathcal{BC}_g([0,1])$.

We add to Theorem 2.2 the result below.

Lemma 2.4. *Let $F : [0,1] \to \mathbb{R}$ be g-absolutely continuous such that there exists $f \in \mathcal{BC}_g([0,1])$ satisfying*

$$F_g'(t) = f(t), \quad \mu_g\text{-a.e.}$$

Then F is g-differentiable everywhere and $F_g't) = f(t)$ for every $t \in [0,1]$.

Proof. By Theorem 2.2.b), for every $t \in [0,1]$,

$$F(t) = F(0) + \int_{[0,t)} F_g'(t) dg(t)$$

whence, by hypothesis,

$$F(t) = F(0) + \int_{[0,t)} f(t) dg(t), \quad \text{for every } t \in [0,1].$$

Applying [8, Lemma 3.14] we obtain that F is g-differentiable everywhere and $F_g't) = f(t)$ for every $t \in [0,1]$. □

The following consequence of [8, Proposition 3.9] (see [9, Remark 2.11]) provides a useful rule for the g-derivative of a product.

Lemma 2.5. *Let $f_1, f_2 : [0,1] \to \mathbb{R}$ be g-continuous and g-differentiable at the point $t \in [0,1]$. Then*

$$(f_1 f_2)'_g(t) = (f_1)'_g(t) f_2(t) + f_1(t)(f_2)'_g(t) + (f_1)'_g(t)(f_2)'_g(t)\Delta g(t^*),$$

where $\Delta g(t^*) = g(t^*+) - g(t^*)$ is the jump of g at the point

$$t^* = \begin{cases} t, & \text{if } t \notin C_g \\ v_n, & \text{if } t \in (u_n, v_n) \subset C_g. \end{cases}$$

The recent works [8, 9] opened the way to study higher order differential equations with Stieltjes derivative. The space $\mathcal{BC}^1_g([0,1])$ was defined as the space of functions $f : [0,1] \to \mathbb{R}$ such that f is g-differentiable everywhere on $[0,1]$ and its g-derivative f'_g is bounded and g-continuous. Endowed with the norm

$$\|f\|_{\mathcal{BC}^1_g([0,1])} = \|f\|_C + \|f'_g\|_C$$

it is, by [8, Theorem 3.15], a Banach space.

The matter of compactness in $\mathcal{BC}_g([0,1])$ was addressed in [11].

Theorem 2.6 ([11, Proposition 5.6])**.** *Let $\mathcal{S} \subset \mathcal{AC}_g([0,1])$ be such that $\{u(0) : u \in \mathcal{S}\}$ is bounded and there exists $\phi \in L^1_g([0,1])$satisfying*

$$|u'_g(t)| \le \phi(t), \quad \mu_g\text{-a.e. in } (0,1] \text{ and for all } u \in \mathcal{S}.$$

Then $\mathcal{S}$ is relatively compact in $\mathcal{BC}_g([0,1])$.

Besides,

Lemma 2.7 ([15, Lemma 3.8])**.** *Let $(u_k)_k \subset \mathcal{AC}_g([0,1])$ be pointwise convergent to $u : [0,1] \to \mathbb{R}$. If there exists $\phi \in L^1_g([0,1])$ such that for all $k \in \mathbb{N}$,*

$$|(u_k)'_g(t)| \le \phi(t), \quad \mu_g\text{-a.e. in } (0,1],$$

then u is also g-absolutely continuous.

3 Main results

3.1 Second order linear Stieltjes differential equations with a single derivator

The aim of this subsection is to study the linear single-valued setting, namely the problem

$$\begin{cases} u''_g(t) = f(t), \ \mu_g\text{-a.e. } t \in [0,1) \\ u(0) = \alpha \\ u(1) + ku(\theta) = \beta \end{cases} \tag{3.1}$$

where $g : [0,1] \to \mathbb{R}$ is a nondecreasing left-continuous function, $k \in \mathbb{R}$ and $\theta \in (0,1)$ satisfy $g(1) + kg(\theta) \neq 0$ and $\alpha, \beta \in \mathbb{R}$.

Definition 3.1. A function $u \in \mathcal{BC}_g^1([0,1))$ is a solution of (3.1) if it verifies the boundary conditions $u(0) = \alpha$ and $u(1) + ku(\theta) = \beta$, its first g-derivative u_g' is g-absolutely continuous on $[0,1)$ and its second g-derivative (which is well defined μ_g-a.e. by Theorem 2.2) satisfies

$$u_g''(t) = f(t), \quad \mu_g\text{-a.e. in } [0,1).$$

The existence result given below involves a Green-type function appropriate for the present framework, inspired by [33].

Theorem 3.2. *Let $f : [0,1] \to \mathbb{R}$ be LS-integrable with respect to the nondecreasing left-continuous function $g : [0,1] \to \mathbb{R}$. Then $u_f : [0,1] \to \mathbb{R}$,*

$$\begin{aligned} u_f(t) = &\int_{[0,1)} G(t,s) f(s) dg(s) - \chi_{(\theta,1]}(t) \cdot A(g(t) - g(\theta)) \\ &+ \frac{g(1) - g(t) + k(g(\theta) - g(t))}{g(1) + kg(\theta)} \alpha + \frac{g(t)}{g(1) + kg(\theta)} \tilde{\beta} \end{aligned}$$

is a solution of (3.1).

Here $G : [0,1] \times [0,1] \to \mathbb{R}$ is defined as follows: if $t \leq \theta$,

$$G(t,s) = \begin{cases} \frac{-g(s)[g(1)-g(t)+k(g(\theta)-g(t))]}{g(1)+kg(\theta)} - \Delta g(s^*), & \text{if } 0 \leq s < t \\ \frac{-g(t)[g(1)-g(s)+k(g(\theta)-g(s))]}{g(1)+kg(\theta)}, & \text{if } t \leq s < \theta \\ \frac{-g(t)(g(1)-g(s))}{g(1)+kg(\theta)}, & \text{if } \theta \leq s \leq 1, \end{cases}$$

while if $t > \theta$,

$$G(t,s) = \begin{cases} \frac{-g(s)[g(1)-g(t)+k(g(\theta)-g(t))]}{g(1)+kg(\theta)} - \Delta g(s^*), & \text{if } 0 \leq s < \theta \\ \frac{-g(s)(g(1)-g(t))+kg(\theta)(g(t)-g(s))}{g(1)+kg(\theta)} - \Delta g(s^*) & \text{if } \theta \leq s < t \\ \frac{-g(t)(g(1)-g(s))}{g(1)+kg(\theta)}, & \text{if } t \leq s \leq 1. \end{cases}$$

Besides,

$$\chi_{(\theta,1]}(t) = \begin{cases} 0, & \text{if } 0 \leq t \leq \theta \\ 1, & \text{if } \theta < t \leq 1, \end{cases}$$

$$A = \frac{-k}{g(1) + kg(\theta)} \int_{[0,\theta)} f(s)(g(s) + 1) dg(s)$$

and

$$\tilde{\beta} = \beta + \left(\int_{[0,1)} \Delta g(s^*) f(s) dg(s) + k \int_{[0,\theta)} \Delta g(s^*) f(s) dg(s) + A(g(1) - g(\theta)) \right).$$

Proof. Let us first note that if $t \leq \theta$,

$$\begin{aligned} u_f(t) = &\int_{[0,t)} -g(s) f(s) dg(s) + \frac{g(t)}{g(1) + kg(\theta)} \int_{[0,t)} g(s)(1+k) f(s) dg(s) - \int_{[0,t)} \Delta g(s^*) f(s) dg(s) \\ &- \frac{g(t)}{g(1) + kg(\theta)} \int_{[t,\theta)} [g(1) - g(s) + k(g(\theta) - g(s))] f(s) dg(s) \\ &- \frac{g(t)}{g(1) + kg(\theta)} \int_{[\theta,1)} (g(1) - g(s)) f(s) dg(s) \\ &+ \frac{g(1) - g(t) + k(g(\theta) - g(t))}{g(1) + kg(\theta)} \alpha + \frac{g(t)}{g(1) + kg(\theta)} \tilde{\beta}. \end{aligned}$$

Then, using Theorem 2.2.a) and Lemma 2.5, u_f is g-absolutely continuous on $[0,\theta]$ and μ_g-a.e. on $[0,\theta)$,

$$\begin{aligned}(u_f)'_g(t) = & -g(t)f(t) + \frac{1+k}{g(1)+kg(\theta)}\int_{[0,t)} g(s)f(s)dg(s) + \frac{g^2(t)}{g(1)+kg(\theta)}(1+k)f(t)\\ & + \frac{1}{g(1)+kg(\theta)}g(t)(1+k)f(t)\Delta g(t^*) - \Delta g(t^*)f(t)\\ & - \frac{1}{g(1)+kg(\theta)}\int_{[t,\theta)}[g(1)-g(s)+k(g(\theta)-g(s))]f(s)dg(s)\\ & + \frac{g(t)}{g(1)+kg(\theta)}[g(1)-g(t)+k(g(\theta)-g(t))]f(t)\\ & + \frac{g(1)-g(t)+k(g(\theta)-g(t))}{g(1)+kg(\theta)}f(t)\Delta g(t^*)\\ & - \frac{1}{g(1)+kg(\theta)}\int_{[\theta,1)}(g(1)-g(s))f(s)dg(s) - \frac{(1+k)\alpha-\tilde{\beta}}{g(1)+kg(\theta)}.\end{aligned}$$

Using Lemma 2.4 we get that for every $t\in[0,\theta)$,

$$\begin{aligned}(u_f)'_g(t) = & \frac{1+k}{g(1)+kg(\theta)}\int_{[0,t)} g(s)f(s)dg(s)\\ & - \frac{1}{g(1)+kg(\theta)}\int_{[t,\theta)}[g(1)-g(s)+k(g(\theta)-g(s)]f(s)dg(s)\\ & - \frac{1}{g(1)+kg(\theta)}\int_{[\theta,1)}(g(1)-g(s))f(s)dg(s)\\ & - \frac{(1+k)\alpha-\tilde{\beta}}{g(1)+kg(\theta)}.\end{aligned} \tag{3.2}$$

It is g-absolutely continuous on $[0,\theta]$ and for μ_g-almost every $t\in[0,\theta)$,

$$(u_f)''_g(t) = \frac{1+k}{g(1)+kg(\theta)}g(t)f(t) + \frac{g(1)-g(t)+kg(\theta)-kg(t)}{g(1)+kg(\theta)}f(t) = f(t).$$

Also, for $t>\theta$,

$$\begin{aligned}u_f(t) = & \int_{[0,\theta)} -g(s)f(s)dg(s) + \frac{g(t)}{g(1)+kg(\theta)}\int_{[0,\theta)}(g(s)-k)f(s)dg(s)\\ & - \int_{[0,\theta)}\Delta g(s^*)f(s)dg(s) + \int_{[\theta,t)} -g(s)f(s)dg(s)\\ & + \frac{g(t)}{g(1)+kg(\theta)}\int_{[\theta,t)}(g(s)+kg(\theta))f(s)dg(s) - \int_{[\theta,t)}\Delta g(s^*)f(s)dg(s)\\ & - \frac{g(t)}{g(1)+kg(\theta)}\int_{[t,1)}(g(1)-g(s))f(s)dg(s)\\ & - A(g(t)-g(\theta)) + \frac{g(1)-g(t)+k(g(\theta)-g(t))}{g(1)+kg(\theta)}\alpha + \frac{g(t)}{g(1)+kg(\theta)}\tilde{\beta}.\end{aligned}$$

Then u_f is g-absolutely continuous on $(\theta,1)$ and μ_g-a.e. on $(\theta,1)$,

$$\begin{aligned}(u_f)'_g(t) = &\frac{1}{g(1)+kg(\theta)}\int_{[0,\theta)}(g(s)-k)f(s)dg(s) - g(t)f(t)\\ &+\frac{1}{g(1)+kg(\theta)}\int_{[\theta,t)}(g(s)+kg(\theta))f(s)dg(s)\\ &+\frac{g(t)}{g(1)+kg(\theta)}(g(t)+kg(\theta))f(t)+\frac{(g(t)+kg(\theta))f(t)}{g(1)+kg(\theta)}\Delta g(t^*)-\Delta g(t^*)f(t)\\ &-\frac{1}{g(1)+kg(\theta)}\int_{[t,1)}(g(1)-g(s))f(s)dg(s)+\frac{g(t)}{g(1)+kg(\theta)}(g(1)-g(t))f(t)\\ &+\frac{(g(1)-g(t))f(t)}{g(1)+kg(\theta)}\Delta g(t^*)-A-\frac{(1+k)\alpha-\tilde{\beta}}{g(1)+kg(\theta)}.\end{aligned}$$

Again by Lemma 2.4 we infer that u_f is g-differentiable on $(\theta,1)$ and that

$$\begin{aligned}(u_f)'_g(t) = &\frac{1}{g(1)+kg(\theta)}\int_{[0,\theta)}(g(s)-k)f(s)dg(s)\\ &+\frac{1}{g(1)+kg(\theta)}\int_{[\theta,t)}(g(s)+kg(\theta))f(s)dg(s)\\ &-\frac{1}{g(1)+kg(\theta)}\int_{[t,1)}(g(1)-g(s))f(s)dg(s)-A-\frac{(1+k)\alpha-\tilde{\beta}}{g(1)+kg(\theta)}.\end{aligned}\tag{3.3}$$

Consequently, $(u_f)'_g$ is g-absolutely continuous on $(\theta,1)$ and for μ_g-a.e. $t\in(\theta,1)$,

$$(u_f)''_g(t)=\frac{1}{g(1)+kg(\theta)}(g(t)+kg(\theta))f(t)+\frac{1}{g(1)+kg(\theta)}(g(1)-g(t))f(t)=f(t).$$

On the other hand, if $t=\theta\in D_g$, then using (3.2), (3.3) we can see that

$$\begin{aligned}(u_f)''_g(\theta) &= \frac{(u_f)'_g(\theta+)-(u_f)'_g(\theta-)}{\Delta g(\theta)}\\ &= \frac{1}{\Delta g(\theta)}\left(f(\theta)\Delta g(\theta)-\frac{k}{g(1)+kg(\theta)}\cdot\int_{[0,\theta)}f(s)(1+g(s))dg(s)-A\right)\\ &= f(\theta).\end{aligned}$$

Since in the case where $\theta\notin D_g$, $\mu_g(\{\theta\})=0$, we can conclude that $(u_f)''_g(t)=f(t)$ for μ_g-a.e. $t\in[0,1)$.

Besides, as u_f and $(u_f)'_g$ are both continuous at θ if $\theta\notin D_g$, it follows that $u\in\mathcal{BC}^1_g([0,1])$ and $(u_f)'_g$ is g-absolutely continuous on $[0,1]$.

As for the boundary conditions, it can be easily checked that

$$u_f(0)=\int_{[0,1)}G(0,s)f(s)dg(s)+\alpha=\alpha$$

and

$$\begin{aligned}
u_f(1)+ku_f(\theta) = &\int_{[0,1)} G(1,s)f(s)dg(s) - A(g(1)-g(\theta)) + \frac{k(g(\theta)-g(1))}{g(1)+kg(\theta)}\alpha + \frac{g(1)\tilde{\beta}}{g(1)+kg(\theta)}\\
&+k\int_{[0,1)} G(\theta,s)f(s)dg(s) + k\frac{g(1)-g(\theta)}{g(1)+kg(\theta)}\alpha + k\frac{g(\theta)\tilde{\beta}}{g(1)+kg(\theta)}\\
=\tilde{\beta} &+ \int_{[0,\theta)} \frac{-kg(s)(g(\theta)-g(1)))}{g(1)+kg(\theta)}f(s)dg(s) - \int_{[0,\theta)} \Delta g(s^*)f(s)dg(s)\\
&+\int_{[\theta,1)} \frac{kg(\theta)(g(1)-g(s))}{g(1)+kg(\theta)}f(s)dg(s)\\
&-\int_{[\theta,1)} \Delta g(s^*)f(s)dg(s) - A(g(1)-g(\theta))\\
&+k\int_{[0,\theta)} \frac{-g(s)(g(1)-g(\theta))}{g(1)+kg(\theta)}f(s)dg(s)\\
&-k\int_{[0,\theta)} \Delta g(s^*)f(s)dg(s) + k\int_{[\theta,1)} \frac{-g(\theta)(g(1)-g(s))}{g(1)+kg(\theta)}f(s)dg(s) = \beta. \qquad \square
\end{aligned}$$

Corollary 3.3. *A map $u:[0,1]\to\mathbb{R}$ is a solution of (3.1) if and only if*

$$\begin{aligned}
u(t) = &\int_{[0,1)} G(t,s)f(s)dg(s) - \chi_{(\theta,1]}(t)\cdot A(g(t)-g(\theta))\\
&+\frac{g(1)-g(t)+k(g(\theta)-g(t))}{g(1)+kg(\theta)}\alpha + \frac{g(t)}{g(1)+kg(\theta)}\tilde{\beta}
\end{aligned}$$

Proof. One implication is proved in Theorem 3.2; as for the other one, suppose u_1, u_2 are two solutions of the considered problem. Then

$$\begin{cases}
(u_1-u_2)''_g(t) = 0,\ \mu_g\text{-a.e. } t\in[0,1)\\
(u_1-u_2)(0) = 0\\
(u_1-u_2)(1)+k(u_1-u_2)(\theta) = 0.
\end{cases} \tag{3.4}$$

Using the g-absolute continuity of $(u_1-u_2)'_g$ one infers that for every $t\in[0,1]$,

$$(u_1-u_2)'_g(t) = (u_1-u_2)'_g(0) + \int_{[0,t)} (u_1-u_2)''_g(s)dg(s) = (u_1-u_2)'_g(0)$$

and so, by the g-absolute continuity of u_1-u_2,

$$(u_1-u_2)(t) = (u_1-u_2)(0) + \int_{[0,t)} (u_1-u_2)'_g(s)dg(s) = (u_1-u_2)(0) + (u_1-u_2)'_g(0)\cdot g(t).$$

Now the boundary conditions lead us to

$$(u_1-u_2)(0) = 0$$

respectively

$$(u_1-u_2)'_g(0)\cdot(g(1)+kg(\theta)) = 0.$$

It follows that $(u_1-u_2)'_g(0) = 0$ and, consequently, $u_1(t) = u_2(t)$ for every $t\in[0,1]$. $\square$

Remark 3.4. Taking into account that, by Lemma 2.5, $s = s^*$ μ_g-almost everywhere, in Theorem 3.2 the following expression could have been used instead for $G(t,s)$:
if $t \leq \theta$,

$$G(t,s) = \begin{cases} \frac{-g(s)[g(1)-g(t)+k(g(\theta)-g(t))]}{g(1)+kg(\theta)} - \Delta g(s), & \text{if } 0 \leq s < t \\ \frac{-g(t)[g(1)-g(s)+k(g(\theta)-g(s))]}{g(1)+kg(\theta)}, & \text{if } t \leq s < \theta \\ \frac{-g(t)(g(1)-g(s))}{g(1)+kg(\theta)}, & \text{if } \theta \leq s \leq 1, \end{cases}$$

while if $t > \theta$,

$$G(t,s) = \begin{cases} \frac{-g(s)[g(1)-g(t)+k(g(\theta)-g(t))]}{g(1)+kg(\theta)} - \Delta g(s), & \text{if } 0 \leq s < \theta \\ \frac{-g(s)(g(1)-g(t))+kg(\theta)(g(t)-g(s))}{g(1)+kg(\theta)} - \Delta g(s), & \text{if } \theta \leq s < t \\ \frac{-g(t)(g(1)-g(s))}{g(1)+kg(\theta)}, & \text{if } t \leq s \leq 1. \end{cases}$$

3.2 Second order linear Stieltjes differential systems with several derivators

As described in [12, 19] or [21], differential systems with several derivators naturally occur when investigating physical processes; more precisely, it leads to studying the existence (and uniqueness) of $u : [0,1] \to \mathbb{R}^d$ such that

$$\begin{cases} u''_{\overline{g}}(t) = \overline{f}(t), \ \mu_{\overline{g}}\text{-a.e. } t \in [0,1) \\ u(0) = \overline{\alpha} \\ u(1) + ku(\theta) = \overline{\beta} \end{cases} \tag{3.5}$$

where $\overline{g} = (g_1, \ldots, g_d) : [0,1] \to \mathbb{R}^d$ with g_i left-continuous and nondecreasing for each $i \in \{1, \ldots, d\}$, $\overline{f} : [0,1] \to \mathbb{R}^d$, $\overline{\alpha} = (\alpha_1, \ldots, \alpha_d), \overline{\beta} = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d$ and $\theta \in (0,1)$ satisfy the assumption: $g_i(1) + kg_i(\theta) \neq 0$ for each $i \in \{1, \ldots, d\}$.

The $\overline{g}$-derivative is to be understood as the vector $((u_1)'_{g_1}, \ldots, (u_d)'_{g_d})$, thus the system (3.5) must be understood as:

$$\begin{cases} (u_i)''_{g_i}(t) = f_i(t), \ \mu_{g_i}\text{-a.e. } t \in [0,1) \\ u_i(0) = \alpha_i \\ u_i(1) + ku_i(\theta) = \beta_i \end{cases} \tag{3.6}$$

for every $i = 1, \ldots, d$.

Denote (as in [19, page 6]) by

$$\mathcal{BC}_{\overline{g}}([0,1], \mathbb{R}^d) = \prod_{i=1}^{d} \mathcal{BC}_{g_i}([0,1]),$$

by

$$\mathcal{BC}^1_{\overline{g}}([0,1], \mathbb{R}^d) = \prod_{i=1}^{d} \mathcal{BC}^1_{g_i}([0,1]),$$

respectively by

$$\mathcal{AC}_{\overline{g}}([0,1], \mathbb{R}^d) = \prod_{i=1}^{d} \mathcal{AC}_{g_i}([0,1]).$$

Definition 3.5. A function $u \in \mathcal{BC}^1_{\overline{g}}([0,1],\mathbb{R}^d)$ is a solution of (3.5) if for each i it verifies the boundary conditions $u_i(0) = \alpha_i$ and $u_i(1) + ku_i(\theta) = \beta_i$, the first g_i-derivative $(u_i)'_{g_i}$ is g_i-absolutely continuous and its g_i-derivative (which is well defined μ_{g_i}-a.e.) satisfies

$$(u_i)''_{g_i}(t) = f_i(t), \quad \mu_{g_i}\text{-a.e. in } [0,1).$$

Reasoning componentwise, Theorem 3.2 and Corollary 3.3 involve the following result.

Theorem 3.6. *Let $\overline{g} = (g_1,\dots,g_d) : [0,1] \to \mathbb{R}^d$ where g_i is left-continuous and nondecreasing for each $i \in \{1,\dots,d\}$ and let $\overline{f} \in L^1_{\overline{g}}([0,1],\mathbb{R}^d) = \prod_{i=1}^d L^1_{g_i}([0,1])$. Then $u : [0,1] \to \mathbb{R}^d$ is a solution of (3.5) if and only if for every $i \in \{1,\dots,d\}$:*

$$\begin{aligned} u_i(t) = &\int_{[0,1)} G_i(t,s) f_i(s) dg(s) - \chi_{(\theta,1]}(t) \cdot A_i(g_i(t) - g_i(\theta)) \\ &+ \frac{g_i(1) - g_i(t) + k(g_i(\theta) - g_i(t))}{g_i(1) + kg_i(\theta)} \alpha_i + \frac{g_i(t)}{g_i(1) + kg_i(\theta)} \tilde{\beta}_i, \quad \forall\, t \in [0,1], \end{aligned}$$

where $G_i : [0,1] \times [0,1] \to \mathbb{R}$ is defined as follows: if $t \le \theta$,

$$G_i(t,s) = \begin{cases} \frac{-g_i(s)[g_i(1)-g_i(t)+k(g_i(\theta)-g_i(t))]}{g_i(1)+kg_i(\theta)} - \Delta g_i(s_i^*), & \text{if } 0 \le s < t \\ \frac{-g_i(t)[g_i(1)-g_i(s)+k(g_i(\theta)-g_i(s))]}{g_i(1)+kg_i(\theta)}, & \text{if } t \le s < \theta \\ \frac{-g_i(t)(g_i(1)-g_i(s))}{g_i(1)+kg_i(\theta)}, & \text{if } \theta \le s \le 1, \end{cases}$$

while if $t > \theta$,

$$G_i(t,s) = \begin{cases} \frac{-g_i(s)[g_i(1)-g_i(t)+k(g_i(\theta)-g_i(t))]}{g_i(1)+kg_i(\theta)} - \Delta g_i(s_i^*), & \text{if } 0 \le s < \theta \\ \frac{-g_i(s)(g_i(1)-g_i(t))+kg_i(\theta)(g_i(t)-g_i(s))}{g_i(1)+kg_i(\theta)} - \Delta g_i(s_i^*), & \text{if } \theta \le s < t \\ \frac{-g_i(t)(g_i(1)-g_i(s))}{g_i(1)+kg_i(\theta)}, & \text{if } t \le s \le 1, \end{cases}$$

$$A_i = \frac{-k}{g_i(1) + kg_i(\theta)} \int_{[0,\theta)} f_i(s)(g_i(s) + 1) dg_i(s)$$

and

$$\tilde{\beta}_i = \beta_i + \left(\int_{[0,1)} \Delta g_i(s_i^*) f_i(s) dg_i(s) + k \int_{[0,\theta)} \Delta g_i(s_i^*) f_i(s) dg_i(s) + A_i(g_i(1) - g_i(\theta)) \right).$$

3.3 Existence result for systems of nonlinear second order boundary value equations

In this subsection, we focus on nonlinear differential problems of second order with boundary value conditions

$$\begin{cases} u''_{\overline{g}}(t) = f(t, u(t), u'_{\overline{g}}(t)), \ \mu_{\overline{g}}\text{-a.e. } t \in [0,1) \\ u(0) = \overline{\alpha} \\ u(1) + ku(\theta) = \overline{\beta}, \end{cases} \tag{3.7}$$

with $\overline{g} = (g_1,\dots,g_d) : [0,1] \to \mathbb{R}^d$ such that g_i is left-continuous and nondecreasing for each $i \in \{1,\dots,d\}$, $\overline{\alpha} = (\alpha_1,\dots,\alpha_d), \overline{\beta} = (\beta_1,\dots,\beta_d) \in \mathbb{R}^d$ and $k \in \mathbb{R}$, $\theta \in (0,1)$ satisfy the assumption: $g_i(1) + kg_i(\theta) \neq 0$ for each $i \in \{1,\dots,d\}$.

Definition 3.7. A function $u \in \mathcal{BC}^1_{\overline{g}}([0,1],\mathbb{R}^d)$ is a solution of (3.7) if $u(0)=\overline{\alpha}$, $u(1)+ku(\theta)=\overline{\beta}$, its first $\overline{g}$-derivative $u'_{\overline{g}} \in \mathcal{AC}_{\overline{g}}([0,1],\mathbb{R}^d)$ and its second $\overline{g}$-derivative satisfies

$$u''_{\overline{g}}(t)=f(t,u(t),u'_{\overline{g}}(t)), \quad \mu_{\overline{g}}\text{-a.e. in } [0,1),$$

i.e. for every $i \in \{1,\dots,d\}$:

$$(u_i)''_{g_i}(t)=f_i(t,u(t),u'_{\overline{g}}(t)), \quad \mu_{g_i}\text{-a.e. in } [0,1).$$

Theorem 3.8. *Let $f:[0,1]\times\mathbb{R}^d\times\mathbb{R}^d\to\mathbb{R}^d$ satisfy, for each $i\in\{1,\dots,d\}$, the following conditions:*

(1) *there exists $M_i \in L^1_{g_i}([0,1])$ such that*

$$|f_i(t,x,y)|\le M_i(t), \quad \mu_{g_i}\text{-a.e. } t\in[0,1],\ \forall\, x,y\in\mathbb{R}^d;$$

(2) *$f_i(\cdot,x,y)$ is g_i-measurable, for every $x,y\in\mathbb{R}^d$;*

(3) *$f_i(t,\cdot,\cdot)$ is continuous on $\mathbb{R}^d\times\mathbb{R}^d$, for μ_{g_i}-almost every $t\in[0,1]$.*

Then the problem (3.7) has solutions.

Proof. Let us prove that the set

$$\mathcal{K}=\left\{u\in\mathcal{BC}^1_{\overline{g}}([0,1],\mathbb{R}^d);|(u_i)''_{g_i}(t)|\le M_i(t),\mu_{g_i}\text{-a.e., }\forall\, i \text{ and } u(0)=\overline{\alpha},\ u(1)+ku(\theta)=\overline{\beta}\right\}$$

is nonempty, convex and compact in $\mathcal{BC}^1_{\overline{g}}([0,1],\mathbb{R}^d)$.

First, note that any map $f\in L^1_{\overline{g}}([0,1],\mathbb{R}^d)$ such that $|f_i(t)|\le M_i(t)$ for all $i\in\{1,\dots,d\}$ provides, thanks to Theorem 3.2, an element of $\mathcal{K}$ (which is, therefore, nonempty) and that the convexity can be easily checked.

Then, let us see that $\mathcal{K}$ is compact in $\mathcal{BC}^1_{\overline{g}}([0,1],\mathbb{R}^d)$.

To this aim, consider a sequence $(u_n)_n\subset\mathcal{K}$. It can be seen from the proof of Theorem 3.2 that for each $i\in\{1,\dots,n\}$, if $t<\theta$,

$$\begin{aligned}((u_n)_i)'_{g_i}(t)=&\frac{1+k}{g_i(1)+kg_i(\theta)}\int_{[0,t)}g_i(s)((u_n)_i)''_{g_i}(s)dg_i(s)\\&-\frac{1}{g_i(1)+kg_i(\theta)}\int_{[t,\theta)}[g_i(1)-g_i(s)+k(g_i(\theta)-g_i(s)]((u_n)_i)''_{g_i}(s)dg_i(s)\\&-\frac{1}{g_i(1)+kg_i(\theta)}\int_{[\theta,1)}(g_i(1)-g_i(s))((u_n)_i)''_{g_i}(s)dg_i(s)-\frac{(1+k)\alpha_i-\tilde{\beta}_i}{g_i(1)+kg_i(\theta)},\end{aligned}$$

while if $t>\theta$,

$$\begin{aligned}((u_n)_i)'_{g_i}(t)=&\frac{1}{g_i(1)+kg_i(\theta)}\int_{[0,\theta)}(g_i(s)-k)((u_n)_i)''_{g_i}(s)dg(s)-g_i(t)((u_n)_i)''_{g_i}(t)\\&+\frac{1}{g_i(1)+kg_i(\theta)}\int_{[\theta,t)}(g_i(s)+kg_i(\theta))((u_n)_i)''_{g_i}(s)dg_i(s)\\&+\frac{g_i(t)}{g_i(1)+kg_i(\theta)}(g_i(t)+kg_i(\theta))((u_n)_i)''_{g_i}(t)\\&-\frac{1}{g_i(1)+kg_i(\theta)}\int_{[t,1)}(g_i(1)-g_i(s))((u_n)_i)''_{g_i}(s)dg_i(s)\\&+\frac{g_i(t)}{g_i(1)+kg_i(\theta)}(g_i(1)-g_i(t))((u_n)_i)''_{g_i}(t)-A_i-\frac{(1+k)\alpha_i-\tilde{\beta}_i}{g_i(1)+kg_i(\theta)}.\end{aligned}$$

Using Theorem 2.6 on each coordinate, $((u_n)'_{\overline{g}})_n$ is relatively compact in the space $\mathcal{BC}_{\overline{g}}([0,1],\mathbb{R}^d)$. One can choose a subsequence, denoted again by $(u_n)_n$ such that $\left((u_n)'_{\overline{g}}\right)_n$ is uniformly convergent to a function $v \in \mathcal{AC}_{\overline{g}}([0,1],\mathbb{R}^d)$.

In both cases, as $u_n(0) = \overline{\alpha}, \forall\, n$, $(u_n)_n$ satisfies as well the hypotheses of Theorem 2.6, therefore one can choose a further subsequence (not re-labelled) such that $(u_n)_n$ uniformly converges to a function $u \in \mathcal{AC}_{\overline{g}}([0,1],\mathbb{R}^d)$.

Since for every $i \in \{1,\dots,d\}$, the sequence $\left(((u_n)_i)'_{g_i}\right)_n$ uniformly converges to v, we infer that for each $t \in [0,1]$:

$$\int_{[0,t)} ((u_n)_i)'_{g_i}(s)dg_i(s) \to \int_{[0,t)} v(s)dg_i(s)$$

and remark that, by Theorem 2.2,

$$\int_{[0,t)} ((u_n)_i)'_{g_i}(s)dg_i(s) = (u_n)_i(t) - \alpha_i \to u_i(t) - \alpha_i;$$

it follows that

$$v(t) = u'_{\overline{g}}(t).$$

Moreover, note that $((u_n)''_{\overline{g}})_n$ is, by hypothesis, relatively weakly compact in $L^1_{\overline{g}}([0,1],\mathbb{R}^d)$, so on convex combinations we may suppose that $((u_n)''_{\overline{g}})_n$ converges pointwise to a function $w \in L^1_{\overline{g}}([0,1],\mathbb{R}^d)$. Applying a dominated convergence theorem one gets for each $i \in \{1,\dots,d\}$, if $t < \theta$,

$$\begin{aligned}((u_n)_i)'_{g_i}(t) \to\ & \frac{1+k}{g_i(1)+kg_i(\theta)} \int_{[0,t)} g_i(s)w_i(s)dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,\theta)} [g_i(1) - g_i(s) + k(g_i(\theta) - g_i(s)]w_i(s)dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,1)} (g_i(1) - g_i(s))w_i(s)dg_i(s) - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}.\end{aligned}$$

while if $t > \theta$,

$$\begin{aligned}((u_n)_i)'_{g_i}(t) \to\ & \frac{1}{g_i(1)+kg_i(\theta)} \int_{[0,\theta)} (g_i(s) - k)w_i(s)dg(s) - g_i(t)w_i(t) \\ & + \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,t)} (g_i(s) + kg_i(\theta))w_i(s)dg_i(s) \\ & + \frac{g_i(t)}{g_i(1)+kg_i(\theta)} (g_i(t) + kg_i(\theta))w_i(t) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,1)} (g_i(1) - g_i(s))w_i(s)dg_i(s) \\ & + \frac{g_i(t)}{g_i(1)+kg_i(\theta)} (g_i(1) - g_i(t))w_i(t) - A_i - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}.\end{aligned}$$

On the other hand, it was seen that for each $i \in \{1,\dots,d\}$, $\left(((u_n)_i)'_{g_i}\right)_n$ uniformly converges to $(u_i)'_{g_i}$ which is equal to

$$\begin{aligned}& \frac{1+k}{g_i(1)+kg_i(\theta)} \int_{[0,t)} g_i(s)(u_i)''_{g_i}(s)dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,\theta)} [g_i(1) - g_i(s) + k(g_i(\theta) - g_i(s)](u_i)''_{g_i}(s)dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,1)} (g_i(1) - g_i(s))(u_i)''_{g_i}(s)dg_i(s) - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}.\end{aligned}$$

if $t < \theta$, respectively to

$$\begin{aligned}
&\frac{1}{g_i(1)+kg_i(\theta)}\int_{[0,\theta)}(g_i(s)-k)(u_i)''_{g_i}(s)dg(s) - g_i(t)(u_i)''_{g_i}(t)\\
&\quad+\frac{1}{g_i(1)+kg_i(\theta)}\int_{[\theta,t)}(g_i(s)+kg_i(\theta))(u_i)''_{g_i}(s)dg_i(s)\\
&\quad+\frac{g_i(t)}{g_i(1)+kg_i(\theta)}(g_i(t)+kg_i(\theta))(u_i)''_{g_i}(t)\\
&\quad-\frac{1}{g_i(1)+kg_i(\theta)}\int_{[t,1)}(g_i(1)-g_i(s))(u_i)''_{g_i}(s)dg_i(s)\\
&\quad+\frac{g_i(t)}{g_i(1)+kg_i(\theta)}(g_i(1)-g_i(t))(u_i)''_{g_i}(t) - A_i - \frac{(1+k)\alpha_i-\tilde{\beta}_i}{g_i(1)+kg_i(\theta)}
\end{aligned}$$

if $t > \theta$.

Consequently,

$$w(t) = u''_{\overline{g}}(t), \quad \mu_{\overline{g}}\text{-almost everywhere on } [0,1).$$

Therefore, $|(u_i)''_{g_i}(t)| \leq M_i(t), \mu_{g_i}$-a.e., $\forall\, i$ and so, $u \in \mathcal{K}$. The compactness of $\mathcal{K}$ is thus proved.

Let us now check that the operator $\Xi : \mathcal{K} \to \mathcal{K}$,

$$\Xi(u) = v \in \mathcal{K} \quad \text{such that } v''_{\overline{g}}(t) = f(t, u(t), u'_{\overline{g}}(t)),\ \mu_{\overline{g}}\text{-a.e.}$$

satisfies the conditions of Schauder's fixed point theorem.

At the beginning, note that Ξ is well-defined by Theorem 3.2 and Corollary 3.3, since as in [11, Lemma 7.2] it can be proved that for any $u \in \mathcal{K}$, $f(\cdot, u(\cdot), u'_{\overline{g}}(\cdot)) \in L^1_{\overline{g}}([0,1], \mathbb{R}^d)$.

All we have to check now is that Ξ is continuous.

Let $(u_n)_n \subset \mathcal{K}$ converge to $u \in \mathcal{K}$ and we aim to prove that $(\Xi(u_n))_n = (v_n)_n$ converges to $\Xi(u) = v$.

As $(u_n)_n$ uniformly converges to u and $\left((u_n)'_{\overline{g}}\right)_n$ uniformly converges to $u'_{\overline{g}}$, hypothesis (3) involves that for each $i \in \{1, \dots, d\}$,

$$\left(f_i(\cdot, u_n(\cdot), (u_n)'_{\overline{g}}(\cdot))\right)_n \quad \text{converges to } f_i(\cdot, u(\cdot), u'_{\overline{g}}(\cdot)),\ \mu_{g_i}\text{-a.e.}$$

By Theorem 3.2, for every $n \in \mathbb{N}$ and $i \in \{1, \dots, d\}$:

$$\begin{aligned}
(v_n)_i(t) = &\int_{[0,1)} G_i(t,s) f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg_i(s) - \chi_{(\theta,1]}(t)\cdot A_i(g_i(t)-g_i(\theta))\\
&+\frac{g_i(1)-g_i(t)+k(g_i(\theta)-g_i(t))}{g_i(1)+kg_i(\theta)}\alpha_i + \frac{g_i(t)}{g_i(1)+kg_i(\theta)}\tilde{\beta}_i
\end{aligned}$$

and

$$\begin{aligned}
v_i(t) = &\int_{[0,1)} G_i(t,s) f_i(s, u(s), u'_{\overline{g}}(s)) dg_i(s) - \chi_{(\theta,1]}(t)\cdot A_i(g_i(t)-g_i(\theta))\\
&+\frac{g_i(1)-g_i(t)+k(g_i(\theta)-g_i(t))}{g_i(1)+kg_i(\theta)}\alpha_i + \frac{g_i(t)}{g_i(1)+kg_i(\theta)}\tilde{\beta}_i
\end{aligned}$$

for all $t \in [0,1]$.

The hypothesis (1) ensures that the dominated convergence theorem can be applied on each coordinate and so,

$$(v_n)_n \to v \quad \text{uniformly on } [0,1].$$

Likewise, from the proof of Theorem 3.2 it can be seen that for each $i \in \{1, \dots, n\}$, if $t < \theta$,

$$\begin{aligned}((v_n)_i)'_{g_i}(t) = {} & \frac{1+k}{g_i(1)+kg_i(\theta)} \int_{[0,t)} g_i(s) f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,\theta)} [g_i(1) - g_i(s) + k(g_i(\theta) - g_i(s)] f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,1)} (g_i(1) - g_i(s)) f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg_i(s) - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}\end{aligned}$$

while if $t > \theta$,

$$\begin{aligned}& ((v_n)_i)'_{g_i}(t) \\ & = \frac{1}{g_i(1)+kg_i(\theta)} \int_{[0,\theta)} (g_i(s) - k) f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg(s) - g_i(t) f_i(t, u_n(t), (u_n)'_{\overline{g}}(t)) \\ & \quad + \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,t)} (g_i(s) + kg_i(\theta)) f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg_i(s) \\ & \quad + \frac{g_i(t)}{g_i(1)+kg_i(\theta)} (g_i(t) + kg_i(\theta)) f_i(t, u_n(t), (u_n)'_{\overline{g}}(t)) \\ & \quad - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,1)} (g_i(1) - g_i(s)) f_i(s, u_n(s), (u_n)'_{\overline{g}}(s)) dg_i(s) \\ & \quad + \frac{g_i(t)}{g_i(1)+kg_i(\theta)} (g_i(1) - g_i(t)) f_i(t, u_n(t), (u_n)'_{\overline{g}}(t)) - A_i - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}.\end{aligned}$$

Also, if $t < \theta$,

$$\begin{aligned}(v_i)'_{g_i}(t) = {} & \frac{1+k}{g_i(1)+kg_i(\theta)} \int_{[0,t)} g_i(s) f_i(s, u(s), u'_{\overline{g}}(s)) dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,\theta)} [g_i(1) - g_i(s) + k(g_i(\theta) - g_i(s)] f_i(s, u(s), u'_{\overline{g}}(s)) dg_i(s) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,1)} (g_i(1) - g_i(s)) f_i(s, u(s), u'_{\overline{g}}(s)) dg_i(s) - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}\end{aligned}$$

while if $t > \theta$,

$$\begin{aligned}(v_i)'_{g_i}(t) = {} & \frac{1}{g_i(1)+kg_i(\theta)} \int_{[0,\theta)} (g_i(s) - k) f_i(s, u(s), u'_{\overline{g}}(s)) dg(s) - g_i(t) f_i(t, u(t), u'_{\overline{g}}(t)) \\ & + \frac{1}{g_i(1)+kg_i(\theta)} \int_{[\theta,t)} (g_i(s) + kg_i(\theta)) f_i(s, u(s), u'_{\overline{g}}(s)) dg_i(s) \\ & + \frac{g_i(t)}{g_i(1)+kg_i(\theta)} (g_i(t) + kg_i(\theta)) f_i(t, u(t), u'_{\overline{g}}(t)) \\ & - \frac{1}{g_i(1)+kg_i(\theta)} \int_{[t,1)} (g_i(1) - g_i(s)) f_i(s, u(s), u'_{\overline{g}}(s)) dg_i(s) \\ & + \frac{g_i(t)}{g_i(1)+kg_i(\theta)} (g_i(1) - g_i(t)) f_i(t, u(t), u'_{\overline{g}}(t)) - A_i - \frac{(1+k)\alpha_i - \tilde{\beta}_i}{g_i(1)+kg_i(\theta)}.\end{aligned}$$

In both cases, again by dominated convergence theorem it follows that $((v_n)'_{\overline{g}})_n$ uniformly converges to $v'_{\overline{g}}$.

So, $\Xi(u_n) = v_n \to \Xi(u) = v$ in $\mathcal{BC}^1_{\overline{g}}([0,1], \mathbb{R}^d)$ and the continuity of Ξ is proved.

In conclusion, Ξ has fixed points which are solutions of the considered problem. □

Remark 3.9. To the best of the author's knowledge, this is the first study of systems of second order equations involving Stieltjes derivatives (besides, with several derivators) and three-point conditions on the boundary.

When $g(t) = t$ on $[0,1]$ we cover or complement already known results with various boundary value conditions (e.g. [17,31,33] and their references, see also [2,3,25]). Note finally that the strong connection between the theory of Stieltjes differential equations and other types of differential problems implies that the outcomes presented in this work lead to new results for systems of second-order generalized differential equations, impulsive differential equations (e.g. [7]) and also dynamic problems on time scales (see [1, 24]) with three-point boundary conditions.

Abstract. We establish the Dancer-type unilateral global bifurcation theorem for nonlinear operator equation of $u + f(\lambda, u) = F(\lambda, u) = 0$, where X is a real Banach space and $f : \mathbb{R} \times X \to X$ is completely continuous with $f(\lambda, 0) = 0$ and C^1 with respect to u at $u = 0$. We shall show that, if $\dim \mathrm{Ker}(D_u F(\mu, 0)) = 1$ for some $\mu \in \mathbb{R}$ and $D_u F(\lambda, 0)$ has an odd crossing number at $\lambda = \mu$, there exist two branches $\mathscr{C}_\mu^\nu$ ($\nu \in \{+, -\}$) emanating from $(\mu, 0)$, such that either $\mathscr{C}_\mu^+$ and $\mathscr{C}_\mu^-$ are both unbounded or $\mathscr{C}_\mu^+ \cap \mathscr{C}_\mu^- \neq \{(\mu, 0)\}$. As one of applications, we obtain the unilateral global bifurcation result for an overdetermined problem in $\mathbb{S}^N \times \mathbb{R}$ and $\mathbb{H}^N \times \mathbb{R}$.

Keywords: unilateral global bifurcation, odd crossing number, completely continuous, overdetermined problem.

1 Introduction

Let X be real Banach space. We investigate the structure of the set of nontrivial solutions for the following nonlinear parameter-dependent problem

$$u + f(\lambda, u) = F(\lambda, u) = 0, \ (\lambda, u) \in \mathbb{R} \times X, \tag{1.1}$$

where $f : \mathbb{R} \times X \to X$ is completely continuous with $f(\lambda, 0) = 0$ for $\lambda \in \mathbb{R}$ and C^1 with respect to u at $u = 0$.

For $f(\lambda, u) = -\lambda L u - H(\lambda, u)$ where $L : X \to X$ is a linear compact operator and $H : \mathbb{R} \times X \to X$ is completely continuous with $H = o(\|u\|)$ near $u = 0$ uniformly on bounded λ sets, Krasnosel'skii [12] has shown that all characteristic values of L which are of odd multiplicity are bifurcation points. Rabinowitz [20] has extended this result by showing that bifurcation has global consequences.

Rabinowitz [20] also established two unilateral global bifurcation theorems from simple eigenvalues, i.e., Theorem 1.27 and Theorem 1.40 of [20]. As pointed out by Dancer [6], the

✉Corresponding author. Email: xujia@nwnu.edu.cn

proofs of these two theorems both contain gaps. Dancer [6,7] constructed a counterexample to Theorem 1.40 of [20]. López-Gómez [15] also pointed out that the proof of Theorem 1.27 is insufficient. Moreover, Dancer [6] established the so-called Dancer-type unilateral global bifurcation theorem from simple eigenvalues. Concretely, if μ^{-1} is an eigenvalue of L of algebraic multiplicity 1, then there exist two sub-continua, $\mathscr{C}_\mu^+$ and $\mathscr{C}_\mu^-$, of $\mathscr{C}_\mu$ bifurcating from $(\mu,0)$, such that either $\mathscr{C}_\mu^+$ and $\mathscr{C}_\mu^-$ are both unbounded or $\mathscr{C}_\mu^+ \cap \mathscr{C}_\mu^- \neq \{(\mu,0)\}$. Further, Dancer [7] also proved that the above beautiful unilateral global bifurcation result is also valid for the case of μ^{-1} being an eigenvalue of L with geometric multiplicity 1 and odd algebraic multiplicity. López-Gómez [15] also established a unilateral global bifurcation theorem. López-Gómez's result indicates that $\mathscr{C}_\mu^\nu$ with each $\nu \in \{+,-\}$ either satisfies Rabinowitz-type global alternative or contains a nontrivial element of complement of kernel space.

Following the Rabinowitz's reflection argument in the proof of [20, Theorem 1.27], Kielhofer [11, Theorem II.5.9] established a unilateral global bifurcation theorem via the conception of odd crossing number. To present the Kielhofer's unilateral global bifurcation theorem, we recall the conception of odd crossing number. Let 0 be an isolated eigenvalue of algebraic multiplicity m of $D_uF(\mu,0)$ for some $\mu \in \mathbb{R}$. It is well known that the number m is an invariant, i.e., the dimension of eigenspace is invariant under perturbation near μ. The set of all perturbed eigenvalues near 0 is called 0-*group*. Further, define $\sigma(\lambda) = 1$ if there are no negative real eigenvalues in the 0-group of $D_uF(\lambda,0)$ and

$$\sigma(\lambda) = (-1)^{m_1+m_2+\cdots+m_k}$$

if $\mu_1,\mu_2,\ldots,\mu_k$ are all negative real eigenvalues in the 0-group having algebraic multiplicities $m_1,m_2,\ldots,m_k$, respectively. From now on, for simplicity, $\sigma(\lambda)$ is called 0-*group index* of λ. If $D_uF(\lambda,0)$ is regular for $\lambda \in (\mu-\delta,\mu)\cup(\mu,\mu+\delta)$ and if $\sigma(\lambda)$ changes at $\lambda=\mu$, then $D_uF(\lambda,0)$ has an *odd crossing number* at $\lambda=\mu$.

If $\dim \mathrm{Ker}(D_uF(\mu,0)) = 1$ and $D_uF(\lambda,0)$ has an odd crossing number at $\lambda=\mu$, Kielhofer [11, Theorem II.5.9] proved that there exist two sub-continua, $\mathscr{C}_\mu^+$ and $\mathscr{C}_\mu^-$, of $\mathscr{C}_\mu$ bifurcating from $(\mu,0)$, such that $\mathscr{C}_\mu^\nu$ with each $\nu \in \{+,-\}$ either satisfies Rabinowitz-type global alternative or contains a pair of points (λ,u) and $(\lambda,-u)$ with $u \neq 0$. If $f(\lambda,u) = \lambda f(u)$ and 0 is the simple eigenvalue of $D_uF(\mu,0)$, Kielhofer's unilateral global bifurcation theorem is just the Rabinowitz's unilateral global bifurcation theorem of [20, Theorem 1.27]. So, Kielhofer's result extends Rabinowitz's unilateral global bifurcation theorem of [20, Theorem 1.27]. As the mentioned above, since the proof of Theorem 1.27 of [20] is insufficient, Kielhofer's argument is also insufficient because he also adopted the Rabinowitz's reflection argument.

The first aim of this work is to establish the Dancer-type unilateral global bifurcation theorem under the assumptions of Kielhofer, which fills the above gap by providing a corrected unilateral global bifurcation theorem. Let $\mathcal{S}$ be the closure of the set of nontrivial solutions of equation (1.1). The following Dancer-type unilateral global bifurcation theorem is our first main result.

Theorem 1.1. *Assume that* $\dim \mathrm{Ker}(D_uF(\mu,0)) = 1$ *for some* $\mu \in \mathbb{R}$ *and* $D_uF(\lambda,0)$ *has an odd crossing number at* $\lambda=\mu$. *Then* $\mathcal{S}$ *possesses two maximal sub-continua* $\mathscr{C}_\mu^\pm$ *emanating from* $(\mu,0)$, *such that either* $\mathscr{C}_\mu^+$ *and* $\mathscr{C}_\mu^-$ *are both unbounded or* $\mathscr{C}_\mu^+ \cap \mathscr{C}_\mu^- \neq \{(\mu,0)\}$.

If $f(\lambda,u)$ has the form of $\lambda f(u)$ and 0 is the simple eigenvalue of $D_uF(\mu,0)$, the conclusion of Theorem 1.1 would degenerate to the famous Dancer-type unilateral global bifurcation theorem from simple eigenvalues [6]. While, $f(\lambda,u)$ has the form of $\lambda f(u)$ and 0 is odd algebraic multiplicity eigenvalue of $D_uF(\mu,0)$, Theorem 1.1 degenerates to the Dancer-type

unilateral global bifurcation theorem from odd algebraic multiplicity eigenvalues [7]. As pointed out by Dancer [7], although the conditions are the same, Dancer-type unilateral global bifurcation conclusion is better than López-Gómez's [15, Theorem 6.4.3].

As one of applications for our unilateral global bifurcation theorem, we next investigate the unilateral global bifurcation phenomenon for an overdetermined elliptic problem in $\mathbb{S}^N \times \mathbb{R}$ and $\mathbb{H}^N \times \mathbb{R}$, where $\mathbb{S}^N$ is the N-dimensional sphere, and $\mathbb{H}^N$ is the N-dimensional hyperbolic space. We consider the following overdetermined elliptic problem

$$\begin{cases} \Delta_g u + \lambda u = 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \\ g(\nabla u, \nu) = \text{const.} & \text{on } \partial\Omega, \end{cases} \tag{1.2}$$

where $\Omega \subset \mathbb{M}^N \times \mathbb{R}$ with $\mathbb{M}^N = \mathbb{S}^N$ or $\mathbb{H}^N$, $N \geq 2$, g denotes the standard metric of $\mathbb{M}^N \times \mathbb{R}$ and Δ_g is the Laplace–Beltrami operator.

When $\mathbb{M}^N = \mathbb{R}^N$, Sicbaldi [24] constructed periodic solutions of (1.2) that are perturbations of a cylinder, which can be seen the first unbounded case counterexample to the following BCN Conjecture.

BCN Conjecture: If Ω is a smooth domain and $\mathbb{R}^N \setminus \overline{\Omega}$ is connected such that problem (1.2) exists a bounded solution, then Ω is either a ball, a half-space, a generalized cylinder $B^k \times \mathbb{R}^{N-k}$ where B^k is a ball in $\mathbb{R}^k$, or the complement of one of them.

In [23], it is shown that such new solutions belong in fact to a smooth local 1-parameter family. Generalizations of such results have been done in the Riemannian manifolds $\mathbb{S}^N \times \mathbb{R}$ and $\mathbb{H}^N \times \mathbb{R}$ [5,16], and in the Euclidean case for some functions f [22]. The boundaries of the domains Ω constructed in [24] are related to the Delaunay surfaces in $\mathbb{R}^N$. The analogy between constant mean curvatures surfaces and overdetermined elliptic problems has inspired a lot of works [9, 14, 21, 25]. Such analogy motivated also the study of overdetermined elliptic problems in the Riemannian manifolds $\mathbb{S}^N \times \mathbb{R}$ and $\mathbb{H}^N \times \mathbb{R}$. It is well known that the Thurston's Geometrization Conjecture proved by G. Perelman in 2003 [17–19]. Since these two manifolds with $N = 2$ represent two of the eight Thurston's 3-dimensional geometries [1], the theory of constant mean curvature surfaces in such ambient spaces are extremely important.

While, we note that bifurcation results in [5,16] are all local. A natural question is whether these local bifurcation results can be extended to the global? Our second main result provides a positive answer to this question.

Theorem 1.2. *Let* $\mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$ *be the space of even* 2π*-periodic* $\mathcal{C}^{2,\alpha}$ *functions of mean zero. There exist two nontrivial branches* $\mathscr{C}^+$ *and* $\mathscr{C}^-$ *in* $\mathcal{V} \times (0, T_0)$ *emanating from* $(0, T_*(N))$*, such that* $\mathscr{C}^\nu \cap (\{0\} \times (0, +\infty)) = \{(0, T_*(N))\}$ *and for any* $(v^\nu, T) \in \mathscr{C}^\nu \setminus \{(0, T_*(N))\}$ *with* $\nu \in \{+, -\}$*, the overdetermined problem* (1.2) *has a positive* T*-periodic solution* $u \in \mathcal{C}^{2,\alpha}(\Omega^\nu)$ *on the modified cylinder*

$$\Omega^\nu = \left\{ (x, t) \in \mathbb{M}^N \times \mathbb{R} : |x| < 1 + v^\nu\left(\frac{2\pi}{T} t\right) \right\},$$

where $\mathcal{V}$ *is an open neighborhoods of the* 0 *in* $\left\{ v \in \mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z}) : v > -1 \right\}$ *for some positive constant* T_0. Moreover, $\mathscr{C}^\nu$ satisfies at least one of the following three properties:

(i) $\mathscr{C}^\nu \cap \partial\mathcal{O} \neq \emptyset$ with $\mathcal{O} = \mathcal{V} \times (0, T_0)$,

(ii) $\mathscr{C}^\nu$ *is unbounded,*

(iii) $\mathscr{C}^\nu$ *contains a point* $(T^*, 0) \in \mathcal{O}$ *with some* $T^* \neq T_*$.

The outline of the rest of this article is as follows. In Section 2, we mainly establish a new Dancer-type unilateral global bifurcation theorem via the so-called 0-group, which ends the proof of Theorem 1.1. In Section 3, we finish the proof of Theorem 1.2 by using the new Dancer-type unilateral global bifurcation Theorem 1.1.

2 Proof of Theorem 1.1

Under the assumptions of Theorem 1.1, the operator F can be rewritten as

$$F(\lambda, u) = u + D_u f(\lambda, 0)u + H(\lambda, u),$$

where $H(\lambda, u)$ is $o(\|u\|)$ for $u \in X$ near 0 uniformly on the bounded λ interval. Since $f : \mathbb{R} \times X \to X$ is a completely continuous operator, $D_u f(\lambda, 0)$ is also a completely continuous operator (see [8] or [13]). It further follows that $H : \mathbb{R} \times X \to X$ is a completely continuous operator.

Let $\mathbb{X} = \mathbb{R} \times X$. Given any $\iota \in \mathbb{R}$ and $0 < s < +\infty$, we consider an open neighborhood of $(\iota, 0)$ in $\mathbb{X}$ defined by

$$\mathbb{B}_s(\iota, 0) = \{(\lambda, u) \in \mathbb{X} : \|u\| + |\lambda - \iota| < s\}.$$

Let X_0 be a closed subspace of X such that

$$X = \operatorname{span}\{w_0\} \oplus X_0,$$

where w_0 is a nonzero element in $\operatorname{Ker}(D_u F(\mu, 0))$. Without loss of generality, we assume that $\|w_0\| = 1$. According to the Hahn–Banach theorem, there exists a linear functional $l \in X^*$ such that

$$l(w_0) = 1 \quad \text{and} \quad X_0 = \{u \in X : l(u) = 0\},$$

where X^* denotes the dual space of X. For any $0 < \eta < 1$, define

$$K_\eta = \{(\lambda, u) \in \mathbb{X} : |l(u)| > \eta\|u\|\}.$$

Obviously, K_η is an open subset of $\mathbb{X}$ consisting of two disjoint components K_η^+ and K_η^- with

$$K_\eta^+ = \{(\lambda, u) \in \mathbb{X} : l(u) > \eta\|u\|\},$$
$$K_\eta^- = \{(\lambda, u) \in \mathbb{X} : l(u) < -\eta\|u\|\}.$$

Clearly, both K_η^+ and K_η^- are convex cones, $K_\eta^- = -K_\eta^+$, and $\nu t w_0 \in K_\eta^\nu$ for every $t > 0$ and each $\nu \in \{+, -\}$.

Applying [15, Lemma 6.4.1] or [3, Lemma 2.2], we have the the following lemma, which localizes the possible solutions of problem (1.1) bifurcating from $(\mu, 0)$.

Lemma 2.1. *For every* $\eta \in (0, 1)$ *there exists a number* $\delta_0 > 0$ *such that for each* $0 < \delta < \delta_0$, *there holds*

$$(\mathcal{S} \backslash \{(\mu, 0)\}) \cap \bar{\mathbb{B}}_\delta(\mu, 0) \subseteq K_\eta,$$

and when

$$(\lambda, u) \in (\mathcal{S} \setminus \{(\mu, 0)\}) \cap \bar{\mathbb{B}}_\delta(\mu, 0)$$

there are $s \in \mathbb{R}$ *and a unique* $y \in X_0$ *such that* $u = sw_0 + y$ *and* $|s| > \eta \|u\|$. *Furthermore, for each* (λ, u), *there holds* $\lambda = \mu + o(1)$ *and* $y = o(s)$ *as* $s \to 0$.

It follows from [11, Theorem II.3.3] that $(\mu, 0)$ is a bifurcation point for equation (1.1), and $\mathcal{S}$ possesses a maximal continuum $\mathscr{C}_\mu$ such that $(\mu, 0) \in \mathscr{C}_\mu$ and $\mathscr{C}_\mu$ either meets at infinity in $\mathbb{R} \times X$, or meets at $(\hat{\mu}, 0)$ with some $\hat{\mu} \neq \mu$. Furthermore, by [15, Lemma 6.4.2] or [3, Lemma 2.3], we have that $\mathscr{C}_\mu$ possesses a subcontinuum in each of the cones $K_\eta^+ \cup \{(\mu, 0)\}$ and $K_\eta^- \cup \{(\mu, 0)\}$ each of which meets $(\mu, 0)$ and $\partial \bar{\mathbb{B}}_\varrho(\mu, 0)$ for all $\varrho > 0$ sufficiently small, which is the local unilateral bifurcation structure of $\mathscr{C}_\mu$.

Proof of Theorem 1.1. For any $\varepsilon > 0$ small enough, let $a = \mu - \varepsilon$ and $b = \mu + \varepsilon$. Since $D_u F(a, 0)$ and $D_u F(b, 0)$ are isomorphism, the isolated zero index formula is well-defined for $I + D_u f(a, 0)$ and $I + D_u f(b, 0)$, which are denoted by $i(I + D_u f(a, 0), 0)$ and $i(I + D_u f(b, 0), 0)$. From the definition of 0-group index we see that

$$i(I + D_u f(a, 0), 0) = \sigma(a)$$

and

$$i(I + D_u f(b, 0), 0) = \sigma(b).$$

Thus, we have that

$$i(I + D_u f(a, 0), 0) \neq i(I + D_u f(b, 0), 0).$$

That is to say

$$\deg(I + D_u f(a, 0), \mathfrak{B}_r(0), 0) \neq \deg(I + D_u f(a, 0), \mathfrak{B}_r(0), 0),$$

where $\mathfrak{B}_r(0) = \{u \in X : \|u\| < r\}$ is an isolating neighborhood of the trivial solution. Applying [4, Theorem 3.1], we obtain that $\mathcal{S}$ possesses two maximal sub-continua $\mathscr{C}_\mu^\pm$ emanating from $(\mu, 0)$, such that either $\mathscr{C}_\mu^+$ and $\mathscr{C}_\mu^-$ are both unbounded or $\mathscr{C}_\mu^+ \cap \mathscr{C}_\mu^- \neq \{(\mu, 0)\}$. □

Note that the unilateral global bifurcation result of [4, Theorem 3.1] is for multiparameter problem. Here we use its special case of single parameter. If f is not globally defined, it is not difficult to get the following result.

Corollary 2.2. *Assume that* $\mathcal{O}$ *is an open subset of* $\mathbb{R} \times X$ *and* F *is defined on* $\mathcal{O}$. *Under the assumptions of Theorem 1.1, either* $\mathscr{C}_\mu^+$ *and* $\mathscr{C}_\mu^-$ *satisfy the alternatives of Theorem 1.1 or at least one of them meets* $\partial\mathcal{O}$.

3 Proof of Theorem 1.2

Let k be the sectional curvature of the manifold $\mathbb{M}^N$ (i.e. $k = 1$ if $\mathbb{M}^N = \mathbb{S}^N$ and $k = -1$ if $\mathbb{M}^N = \mathbb{H}^N$). If we choose spherical coordinates (r, θ), with $\theta \in \mathbb{S}^{N-1}$ and $r \in [0, +\infty)$ if $k < 0$ and $r \in [0, \pi]$ if $k > 0$, the usual metric in $\mathbb{M}^N$ [2, Section II.5, Theorem 1] can be written as

$$g_{\mathbb{M}^N} = \mathrm{d}r^2 + S_k^2(r)\, \mathrm{d}\theta^2$$

where

$$S_k(r) = \begin{cases} \sinh r & \text{if } k = -1, \\ \sin r & \text{if } k = 1. \end{cases}$$

Consider the eigenvalue problem

$$\begin{cases} \Delta_{g_{\mathbb{M}^N}} u + \lambda u = 0 & \text{in } B_1, \\ u = 0 & \text{on } \partial B_1, \end{cases} \tag{3.1}$$

where B_1 is the unit geodesic ball of $\mathbb{M}^N$. It is well known that (3.1) possesses a unique principal eigenvalue λ_1. Let $\widetilde{\phi}_1$ be the positive eigenfunction associated to λ_1 normalized so that $\int_{B_1} \widetilde{\phi}_1^2 \, \mathrm{dvol}_{g_{\mathbb{M}^N}} = 1/2\pi$. Then, if g denotes the standard product metric of $\mathbb{M}^N \times \mathbb{R}$ and $r(x)$ denotes the geodesic distance of $x \in \mathbb{M}^N$ from a fixed point $0 \in \mathbb{M}^N$ (the origin), the function $\phi_1(x,t) = \widetilde{\phi}_1(x)$ is a solution of

$$\begin{cases} \Delta_g \phi_1 + \lambda_1 \phi_1 = 0 & \text{in } C_1^T, \\ \phi_1 = 0 & \text{on } \partial C_1^T, \end{cases}$$

where

$$C_1^T = \Big\{ (x,t) \in \mathbb{M}^N \times \mathbb{R}/T\mathbb{Z} : r(x) < 1 \Big\}.$$

It is easy to see that

$$\int_{C_1^{2\pi}} \phi_1^2 \, \mathrm{dvol}_g = 1. \tag{3.2}$$

For each $v \in \mathcal{C}^{2,\alpha}_{\mathrm{even},0}(\mathbb{R}/2\pi\mathbb{Z})$ with $v(t) > -1$, we set

$$C_{1+v}^T = \left\{ (x,t) \in \mathbb{M}^N \times \mathbb{R}/T\mathbb{Z} : r(x) < 1 + v\left(\frac{2\pi t}{T}\right) \right\}.$$

It follows from [2, 10] that there exists a unique positive function $\phi_v \in \mathcal{C}^{2,\alpha}\big(C_{1+v}^T\big)$ and a constant λ_v such that

$$\begin{cases} \Delta_g \phi_v + \lambda_v \phi_v = 0 & \text{in } C_{1+v}^T, \\ \phi_v = 0 & \text{on } \partial C_{1+v}^T \end{cases} \tag{3.3}$$

and

$$\int_{C_{1+v}^{2\pi}} \phi_v^2 \left(x, \frac{T}{2\pi} t \right) \mathrm{dvol}_g = 1.$$

Define the operator

$$N(v,T) = g(\nabla \phi_v, \omega) \mid_{\partial C_{1+v}^T} - \frac{1}{\mathrm{Vol}_g\big(\partial C_{1+v}^T\big)} \int_{\partial C_{1+v}^T} g(\nabla \phi_v, \omega) \, \mathrm{dvol}_g,$$

where ω denotes the unit normal vector field to ∂C_{1+v}^T. By the rotational symmetry of C_{1+v}^T, it is easy to show that N depends only on the variable t [16]. Set $F(v,T) = N(v,T)\big(\frac{T}{2\pi} t\big)$. Obviously, $F(0,T) = 0$ for any $T > 0$. From [5, Lemma 2.1] we know that F is a C^1 operator in a neighborhood of $(0,T)$ for any fixed $T > 0$.

Let ψ be the unique solution of

$$\begin{cases} \Delta_g \psi + \lambda_1 \psi = 0 & \text{in } C_1^T, \\ \psi = -\partial_r \phi_1 v\big(\frac{2\pi t}{T}\big) & \text{on } \partial C_1^T. \end{cases}$$

Define the function $\widetilde{H}_T(\cdot)$ as follows

$$\widetilde{H}_T(v) = \left(\partial_r \psi + \partial_r^2 \phi_1 v\left(\frac{2\pi}{T} t\right) \right) \Big|_{\partial C_1^T}$$

and set

$$H_T(v) = \widetilde{H}_T(v)\left(\frac{T}{2\pi}t\right).$$

It follows from [16, Proposition 3.2] that the linearization of F with respect to v at the point $(0, T)$ is just H_T.

If $v \in \mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$, its Fourier expansion is

$$v = \sum_{m\geq 1} a_m \cos(mt).$$

Let V_m be the space spanned by the function $\cos(mt)$. It follows from [16, Proposition 4.3] that H_T preserves the eigenspaces V_m. Let $\sigma_m(T)$ be the eigenvalue of H_T associated with the eigenfunction $\cos(mt)$. It is known (see [16]) that

$$\sigma_m(T) = \partial_r c_m(1) + \partial_r^2 \phi_1(1),$$

where c_m is the continuous solution on $[0, 1]$ of

$$\left(\partial_r^2 + (n-1)\frac{C_k(r)}{S_k(r)}\partial_r + \lambda_1\right)c - \left(\frac{2m\pi}{T}\right)^2 c = 0$$

with $c_m(1) = -\partial_r\phi_1(1)$, where

$$C_k(r) = \begin{cases} \cosh r & \text{if } k = -1, \\ \cos r & \text{if } k = 1. \end{cases}$$

It follows from [5, Proposition 2.1] that the function $\sigma_1(T)$ satisfies $\sigma_1'(T) < 0$ for any $T > 0$. Moreover, σ_1 has exactly one zero in $(0, +\infty)$, which is denoted by T_*. Furthermore, by [5, Proposition 2.2], we also know that the linearized operator

$$H_T = D_v F(0, T) : \mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z}) \longrightarrow \mathcal{C}^{1,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$$

is a formally self-adjoint, first order elliptic operator. It preserves the eigenspaces V_m for all m and $T > 0$. Moreover, the kernel of H_{T_m} is just V_m and the eigenvalue associated to the eigenspace V_m has a unique zero which is just T_m. Note that $\sigma_m(T) = \sigma_1(T/m)$, which indicates the property of σ_m can be deduced from the property of σ_1. So we next only consider the case of $m = 1$.

We now present the proof of Theorem 1.2.

Proof of Theorem 1.2. From the property of $\sigma_1(T)$ we know that there exists $T_0 > T_*$ such that $\sigma_1(T) > -1$ for any $T \in (0, T_0)$. We *claim* that $H_T + \mathrm{Id}$ is invertible for any $T \in (0, T_0)$. For any $v \in \mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$ such that $H_T v + v = 0$, it follows from the Fourier expansion $v = \sum_{m\geq 1} a_m \cos(mt)$ and $\sigma_m(T) = \sigma(T/m)$ that

$$(\sigma(T) + 1)\int_{-\pi}^{\pi} v^2 \,\mathrm{d}t \leq \int_{-\pi}^{\pi} (H_T v^2 + v^2)\,\mathrm{d}t = 0.$$

It follows that $v \equiv 0$. Clearly, $H_T + \mathrm{Id}$ is linear continuous. By Banach inverse operator theorem, $H_T + \mathrm{Id}$ is an isomorphism for any $T \in (0, T_0)$.

Define $G : (0, T_0) \times \mathcal{V} \to \mathcal{W}$ by

$$G(T, v) = F(v, T) + v,$$

where $\mathcal{V} \subset \mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$ and $\mathcal{W} \subset \mathcal{C}^{1,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$ are open neighborhoods of the 0 function. Since the operator $H_T + \mathrm{Id}$ is invertible for $T \in (0, T_0)$, $D_v G(T, 0)$ is an isomorphism for all $T \in (0, T_0)$. For $w \in \mathcal{W}$, there exists a unique $v \in \mathcal{V}$ such that $G(\lambda, v) = w$. Let $v = G^{-1}(w)$. Clearly, G^{-1} maps $\mathcal{W}$ into $\mathcal{V}$. Let $R(T, w) = w - G^{-1}(w)$, which maps $(0, T_0) \times \mathcal{W}$ into $\mathcal{W}$ because $\mathcal{V} \subset \mathcal{W}$. Since the embedding of $\mathcal{C}^{2,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z}) \hookrightarrow \mathcal{C}^{1,\alpha}_{\text{even},0}(\mathbb{R}/2\pi\mathbb{Z})$ is compact, $R : (0, T_0) \times \mathcal{W} \to \mathcal{W}$ is compact. Then $F(v, T) = 0$ is equivalent to $R(T, v) = 0$ for all $T \in (0, T_0)$. We see that $D_w R(T, 0)w = \mu w$ is equivalent to $H_\lambda(w) = \mu w/(1 - \mu)$ with $\mu < 1$. It follows that $D_w R(T, 0)$ has the same number of negative eigenvalues as H_T.

We have known that $\dim \mathrm{Ker}(H_{T_*}) = 1$. So we also have that $\dim \mathrm{Ker}(D_w R(T_*, 0)) = 1$. For any $\varepsilon > 0$ small enough, the property of $\sigma(T)$ implies that 0-group index $\sigma(T_* - \varepsilon) = (-1)^0 = 1$ and $\sigma(T_* + \varepsilon) = (-1)^1 = -1$. It further indicates that $D_w R(T, 0)$ has an odd crossing number at $T = T_*$. Applying Theorem 1.1 to $R(T, v) = 0$, we can conclude the desired unilateral global bifurcation result. □

Abstract. A classical result in the theory of stability of nonautonomous linear systems is that the uniform exponential decay of its corresponding transition matrix is equivalent to the uniform asymptotic stability of the trivial solution. The aim of this article is to extend this equivalence for non-exponential decays $h(t)$. In this article we prove that, in some suitable cases, the function $h(t)$ allows the construction of a topological abelian group that makes possible to formulate a more general definition of uniform stability which is equivalent with a decay dominated by $h(t)$. Moreover, we can use this group to establish the necessary elements to develop a theory of h-stable systems. As a first step in this direction, we provide integral conditions on the solutions of a uniformly asymptotically h-stable system.

Keywords: linear nonautonomous systems, uniform asymptotic h-stability, group theory.

2020 Mathematics Subject Classification: 34A30, 34C11, 34D20.

1 Introduction and motivation

1.1 Preliminaries

This article provides new results about the property of uniform asymptotic h-stability of the nonautonomous linear system of ordinary differential equations:

$$\dot{x} = A(t)x \quad \text{for any } t \in J := (a, +\infty), \tag{1.1}$$

where a can be either a real number or $a = -\infty$, $A\colon J \to M_n(\mathbb{R})$ is a piecewise continuous matrix valued function. Moreover, $\Phi(t)$ and $\Phi(t,s) = \Phi(t)\Phi^{-1}(s)$ will denote respectively a fundamental matrix of (1.1) and its corresponding transition matrix. The solution of (1.1) passing through x_0 at time $t = t_0 > a$ will be denoted by $t \mapsto x(t, t_0, x_0) := \Phi(t, t_0)x_0$. For a

given norm $\|\cdot\|$ on $\mathbb{R}^n$ and any matrix $U \in M_n(\mathbb{R})$, the induced operator norm is defined as $\|U\|_{\mathcal{L}} := \sup\{\|Ux\| : \|x\| \leq 1\}$.

The stability and asymptotic stability of the nonautonomous linear systems (1.1) are classic research topics and there exists a myriad of asymptotic stabilities whose classification and description has been carried out in authoritative monographs as [5, 9, 14]. In particular, the uniform asymptotic h-stability is defined as follows:

Definition 1.1. The nonautonomous system (1.1) is *uniformly asymptotically h-stable* if there exist constants $K \geq 1$ and $\alpha > 0$ and a function $h : J \to (0, +\infty)$ such that:

$$\|\Phi(t, t_0)\|_{\mathcal{L}} \leq K \left(\frac{h(t_0)}{h(t)}\right)^{\alpha} \quad \text{for any } t \geq t_0 > a, \tag{1.2}$$

where $h(\cdot)$ is continuous, surjective and strictly increasing.

To the best of our knowledge, the above definition has been introduced by M. Pinto in [13] in a more general context, including the nonlinear case and considering $\alpha = 1$. This definition of stability has been explored by the current research, either by considering a fixed function $h(\cdot)$ such as in the cases of polynomial stability [7] or algebraic dichotomy [11], or by considering a large family of functions, such as in [12].

The previous definition is a particular case of the *uniform stability* and encompasses a wide range of well known stabilities, for example, the classical property of *uniform asymptotic stability*, which is ubiquitous in theoretical and applied research and will be recalled to make this article self contained:

Definition 1.2 ([2, Ch. III.1])**.** The nonautonomous linear system (1.1) is *uniformly stable* if any solution $t \mapsto x(t) := x(t, t_0, x_0)$ satisfies the following property:

a) For each $\varepsilon > 0$ there is a $\delta_\varepsilon > 0$ such that if $\|x(t_0)\| < \delta_\varepsilon$ for some $t_0 \in J$ then $\|x(t)\| < \varepsilon$ for all $t \geq t_0$.

The nonautonomous system (1.1) is *uniformly asymptotically stable* if it is uniformly stable and in addition:

b) There is a $\delta_0 > 0$ such that for all $\varepsilon > 0$ there exists a constant $T_\varepsilon \in (0, +\infty)$ such that if $\|x(t_0)\| < \delta_0$ then $\|x(t)\| < \varepsilon$ for all $t \geq t_0 + T_\varepsilon$.

The proof that the uniform asymptotic stability described in Definition 1.2 is a particular case of the uniform asymptotic h-stability follows from the following results considering $h(t) = e^t$:

Proposition 1.3 ([9, Prop.3.3.1])**.** *The nonautonomous linear system* (1.1) *is uniformly stable if and only if there exists a constant $K \geq 1$ such that:*

$$\|\Phi(t, s)\|_{\mathcal{L}} \leq K \quad \textit{for all } t \geq s > a.$$

Proposition 1.4 ([10, Th.4.11])**.** *The nonautonomous linear system* (1.1) *is uniformly asymptotically stable if and only if it is uniformly exponentially stable, namely, there exist constants $K \geq 1$ and $\alpha > 0$ such that:*

$$\|\Phi(t, s)\|_{\mathcal{L}} \leq K e^{-\alpha(t-s)} \quad \textit{for all } t \geq s > a. \tag{1.3}$$

Another equivalent characterization of uniform asymptotic stability in terms of the transition matrix is given by:

Proposition 1.5. *The nonautonomous linear system* (1.1) *is uniformly asymptotically stable if and only if it is uniformly stable and there exists a constant* $T \in (0, +\infty)$ *such that*

$$\sup_{s\in J} \|\Phi(T+s,s)\|_{\mathcal{L}} < 1. \tag{1.4}$$

The step proving the necessity of the above result can be found as an intermediate step in the proof of Proposition 1.4 given by [2, Ch. III.1] and as Lemma 5 in [6], while the sufficiency step of the is an immediate consequence of Proposition 1.4.

1.2 Novelty of the article and main results

We stress that the equivalence between the ε–δ characterization of uniform asymptotic stability stated in Definition 1.2 and the estimations for the transition matrices given by Propositions 1.4 and 1.5 is a classical topic in stability theory. Nevertheless, a generalization for decays described by $h(\cdot)$ functions has not been addressed and is the aim of this article.

A possible way to study the uniform asymptotic h-stability is to introduce the change of time variables

$$t = h^{-1}(e^{\tilde{t}}) \quad \text{and} \quad \tilde{t} = \log(h(t)) \quad \text{with } \log(h(a^+)) < \tilde{t} < +\infty, \tag{1.5}$$

and the matrix $\Phi_h(\tilde{u})$:

$$\Phi_h(\tilde{u}) = \Phi(h^{-1}(e^{\tilde{u}})) \quad \text{for any } \tilde{u} > \log(h(a^+)). \tag{1.6}$$

These change of variables allow to reinterpret the estimation (1.2) as follows:

$$\|\Phi_h(\tilde{t},\tilde{t}_0)\|_{\mathcal{L}} \le Ke^{-\alpha(\tilde{t}-\tilde{t}_0)} \quad \text{for any } \tilde{t} \ge \tilde{t}_0 > \log(h(a^+)). \tag{1.7}$$

Notice that the right-hand side of the inequalities (1.3) and (1.7) describes a similar exponential decay. Nevertheless, we warn that this analogy could induce the erroneous belief that the uniform asymptotic h-stability can be trivially revisited as a uniform exponential stability via a suitable change of variables. To support this warning, we state that the columns of the transformed matrix $\Phi_h(\cdot)$ are not a basis of solutions and the left side of (1.7) as well as (1.5)–(1.6) do not have an intuitively clear meaning. These issues deserve a meticulous study and a big contribution of this article is to show that any function $h(\cdot)$ allows to construct a topological group $(J,*)$ such that the change of variables described by (1.5) can be seen as the commutative diagrams of isomorphisms of topological groups such that

$$\begin{array}{ccc} (\mathbb{R},+) & \xrightarrow{e} & (\mathbb{R}^+,\cdot) \\ & & \downarrow{\scriptstyle h^{-1}} \\ & & (J,*) \end{array} \quad \text{and} \quad \begin{array}{ccc} (J,*) & \xrightarrow{h} & (\mathbb{R}^+,\cdot) \\ & & \downarrow{\scriptstyle \log} \\ & & (\mathbb{R},+), \end{array}$$

where the isomorphism $h\colon (J,*) \to (\mathbb{R}^+,\cdot)$ verifies $h(t*s) = h(t)h(s)$, which mimics the exponential identity $e^{t+s} = e^t e^s$.

The above described approach will enable to state the main results of this article:

- To provide an ε–δ definition of uniform asymptotic h-stability generalizing the one described in Definition 1.2.
- To generalize the Proposition 1.5 for the uniformly asymptotically h-stable case.

- To deduce integral characterizations for the uniform asymptotic h-stability which generalizes those obtained for the uniform asymptotic stability.

We stress that Definition 1.2 and Proposition 1.5 are stated in term of the additive group $(\mathbb{R}, +)$ whereas its generalization will be carried out in terms of the *additive* structure of $(J, *)$. We stress the originality of this approach, its remarkable simplicity and its potential application for the study of h-dichotomies.

1.3 Structure of the article

In Section 2 we provide examples of systems which are uniformly h-stable but not uniformly asymptotically stable. Section 3 is devoted to the construction the topological group $(J, *)$, an invariant measure on J under the action of this group, and the study of their properties. In Section 4 we state and prove the main results, namely, the generalization of the equivalences between Definition 1.2 and Propositions 1.4 and 1.5 to the uniform h-stability framework. Finally, in Section 5 we generalize, to uniform h-stable systems, a pair of results characterizing the uniform exponentially stable systems in terms integral conditions.

2 Examples of uniform asymptotic h-stability

We will consider simple h-stable scalar equations and use them to show the existence of an equation that is logarithmically stable but not exponentially.

Example 2.1. Given $h : J \to (0, +\infty)$ continuously differentiable, surjective and strictly increasing, together with a constant $\alpha > 0$, let us consider the equation:

$$x' = -\alpha \left(\frac{h'(t)}{h(t)} \right) x,$$

which provides a simple example of h-stability. Indeed, the transition matrix is given by

$$\Phi(t, s) = \left(\frac{h(s)}{h(t)} \right)^{\alpha},$$

and the Definition 1.1 is verified with $K = 1$.

Example 2.2. The above example allows us to construct a nonautonomous linear equation whose solutions $t \mapsto x(t, s, x_0)$ asymptotically approach the origin but are not uniformly exponentially stable. In fact, when considering $h(t) = \log(1 + t)$, the previous example says that the corresponding transition matrix is given by

$$\Phi(t, s) = \left(\frac{\log(1 + s)}{\log(1 + t)} \right)^{\alpha},$$

this system is uniformly asymptotically log-stable and for any $s \in J := (0, +\infty)$ and $x_0 \in \mathbb{R}$ it follows that

$$\lim_{t \to +\infty} \Phi(t, s) x_0 = \lim_{t \to +\infty} \left(\frac{\log(1 + s)}{\log(1 + t)} \right)^{\alpha} x_0 = 0.$$

However, for any pair of positive numbers α and $\beta > 0$, we have the estimation

$$\lim_{t \to +\infty} \log(1 + t) e^{-t^{\frac{\beta}{\alpha}}} = 0.$$

Hence for a fixed $s \in J$ and $K > 1$ there exists t large enough such that

$$\log(1+t)e^{-t\frac{\beta}{\alpha}} < K^{-1}\log(1+s)e^{-s\frac{\beta}{\alpha}},$$

and we can rearrange this inequality to obtain

$$Ke^{\beta(s-t)} < \left(\frac{\log(1+s)}{\log(1+t)}\right)^{\alpha},$$

which shows that the inequality (1.3) is not true for all pairs $t \geq s$ and the uniform exponential stability described by (1.3) cannot be verified.

3 A topological group induced by $h(\cdot)$

The conditions we have given to the function $h(\cdot)$ on Definition 1.1 are enough to carry out a deep study of the solutions of (1.1). In fact, as any continuous bijection between two open intervals is an homeomorphism, the function $h : (a, +\infty) \to (0, +\infty)$ has a continuous inverse $h^{-1}(\cdot)$. Then, we introduce the operation

$$t * s := h^{-1}(h(t)h(s)), \tag{3.1}$$

on $J = (a, +\infty)$, namely, the domain of h. To distinguish $*$ from the usual operations on $\mathbb{R}$, we will denote the integer powers of t as t^{*n}. This operation is associative and commutative, it has an identity element defined by

$$e_* = h^{-1}(1)$$

and each $t \in J$ has an inverse

$$t^{*-1} = h^{-1}\left(\frac{1}{h(t)}\right). \tag{3.2}$$

These properties, alongside the continuity of h and h^{-1}, imply that $(J, *)$, with the standard real open interval topology, is a locally compact abelian topological group.

Example 3.1. Let $h(t) = \log(t)$ on the interval $(1, +\infty)$. The corresponding group operation is

$$t * s = e^{\log(t)\log(s)} = t^{\log(s)} = s^{\log(t)},$$

and the identity on this group is $h^{-1}(1) = e^1 = e$.

It is straightforward to deduce the following properties as a consequence of (3.1) and (3.2):

$$\begin{aligned} h(t*s) &= h(t)h(s) \\ h^{-1}(t) * h^{-1}(s) &= h^{-1}(ts) \\ h(s*t^{*-1}) &= \frac{h(s)}{h(t)}. \end{aligned} \tag{3.3}$$

The first two identities of (3.3) imply that the function $h : J \mapsto \mathbb{R}^+$ is an isomorphism of topological groups between $(J, *)$ and the multiplicative group of positive real numbers $(\mathbb{R}^+, \cdot)$. Due to this isomorphism, we may understand properties of $(J, *)$ by first considering the analogous case on $(\mathbb{R}^+, \cdot)$ and passing from one group to the other by using the functions h and h^{-1}.

Remark 3.2. In the case of uniform exponential stability, namely, when $h(t) = e^t$, this operation becomes $t * s = \log(e^t e^s) = t + s$ and, consequently, the group $(\mathbb{R}, *)$ coincides with the additive group $(\mathbb{R}, +)$.

Remark 3.3. Note that inequality (1.2), which defines uniform asymtptotic h-stability, can be seen from another perspective by using the identity (3.3) as follows:

$$\|\Phi(t,s)\|_{\mathcal{L}} \leq Kh(s * t^{*-1})^{\alpha} \quad \text{for all } t \geq s > a.$$

We also can define a measure μ_* on the interval J, which is invariant under the action of elements of $(J, *)$. This is an absolutely continuous measure whose Radon–Nikodym derivative is the logarithmic derivative of h, that is, for a Borel measurable set $A \subset J$ we define its measure μ_* as

$$\mu_*(A) = \int_A \frac{h'(u)}{h(u)} \mathrm{d}m(u), \tag{3.4}$$

where $m(\cdot)$ is the Lebesgue measure. To see that this is an invariant measure, it is enough to prove that it is invariant for compact intervals, as these sets generate the Borel σ-algebra.

Lemma 3.4. *Given a compact interval $[s,t] \subset J$, its measure is invariant under translation by elements of $(J, *)$, that is, for any $\gamma \in J$*

$$\mu_*([s,t]) = \mu_*([\gamma * s, \gamma * t])$$

Proof. The measure of the interval $[s,t] \subset J$ is

$$\mu_*([s,t]) = \int_s^t \frac{h'(u)}{h(u)} \mathrm{d}m(u) = \log\left(\frac{h(t)}{h(s)}\right). \tag{3.5}$$

Notice that, given any constant $\gamma \in J$, by (3.3) we have

$$\begin{aligned} \mu_*([\gamma * s, \gamma * t]) &= \log\left(\frac{h(\gamma * t)}{h(\gamma * s)}\right) \\ &= \log\left(\frac{h(t)}{h(s)}\right) \\ &= \mu_*([s,t]). \end{aligned}$$

□

Remark 3.5. The identity (3.5) allows an additional characterization of the uniform asymptotic h-stability in terms of the measure μ_* as follows:

$$\|\Phi(t,s)\|_{\mathcal{L}} \leq Ke^{-\alpha\mu_*([s,t])} \quad \text{for all } t \geq s \geq a.$$

Remark 3.6. It will be of interest to understand the behavior of the iterates of elements on $(J, *)$ in the sense

$$\begin{aligned} J \times J &\to J \\ (\gamma, \gamma) &\mapsto \gamma^{*2} := \gamma * \gamma. \end{aligned}$$

Firstly, by using the isomorphism between $(J, *)$ and $(\mathbb{R}^+, \cdot)$, it follows that the n-the power of γ is

$$\gamma^{*n} = h^{-1} \circ h(\gamma^{*n}) = h^{-1}(h(\gamma)^n). \tag{3.6}$$

Secondly, given an element $\gamma > e_*$ we have that $h(\gamma) > 1$, which implies that $h(\gamma)^n \to +\infty$ and $h(\gamma)^{-n} \to 0$ as $n \to +\infty$. This means that any forward orbit of the action $J \to \gamma * J$ approaches $+\infty$ while any backward orbit approaches a.
Analogously, for $\gamma < e_*$ forward orbits approach a while backward orbits approach $+\infty$.

Table 3.1: Some examples for functions $h(\cdot)$ with its respective interval of stability, group operation, and logarithmic derivative.

A useful construction on $\mathbb{R}$ is the partition on intervals $[k, k+1)$ of equal length, where $k \in \mathbb{Z}$. In proofs of exponential stability theory such as [8], this partition allows us to approximate the continuous system (1.1) by a discretization of $\Phi(t,s)$. However, when the decay rate of $\Phi(t,s)$ is given by a function $h(\cdot)$ rather than the exponential function, the notion of length, given by the invariant measure, changes. For this reason, we propose the following partition:

Lemma 3.7. *For any $\gamma \in (e_*, +\infty)$ the intervals $J_k = [\gamma^{*k}, \gamma^{*(k+1)})$ with $k \in \mathbb{Z}$ define a partition of J into sets of constant μ_* measure.*

Proof. The function h^{-1} is strictly increasing and $h(\gamma) > 1$, hence the sequence $\{\gamma^{*k}\}_{k\in\mathbb{Z}}$ which is defined by (3.6), that is, by the identity $\gamma^{*k} = h^{-1}(h(\gamma)^k)$, is strictly increasing, which implies that the intervals J_k are disjoint. It remains to show that the intervals J_k form a covering of J. Without loss of generality we assume that $t \in [e_*, +\infty)$. As discussed in Remark 3.6, for any $t \in [e_*, +\infty)$ there exists $n \in \mathbb{N} \cup \{0\}$ such that $\gamma^{*(n+1)} > t$. Since the inequality $\gamma^{*(n+1)} > t$ is satisfied by a set of natural numbers, there must be a least element of this set, which we call m. The number m is the minimal natural such that $\gamma^{*(m+1)} > t$, hence $\gamma^{*m} \leq t$, that is, $t \in J_m$. □

A noticeable byproduct of the above result is:

Corollary 3.8. *The measure μ_* is σ-finite.*

Example 3.9. In the case corresponding to $h(t) = t$, which defines polynomial stability in [7] and [1], the operation is defined by $t * s = ts$, the domain of h is the interval $(0, +\infty)$ and, for any $\gamma > 1$, the subintervals $\{[1,\gamma), [\gamma,\gamma^2), [\gamma^2,\gamma^3), \ldots\}$, and $\{[\gamma^{-1},1), [\gamma^{-2},\gamma^{-1}), [\gamma^{-3},\gamma^{-2}), \ldots\}$ define a uniform partition of $(0,+\infty)$. Moreover, given a constant $C > 0$ and considering the measure defined by (3.4), we have $\mu_*([C\gamma^k, C\gamma^{k+1})) = \mu_*([\gamma^k, \gamma^{k+1})) = \log(\gamma)$ for any $k \in \mathbb{Z}$.

4 Characterizations of uniform asymptotic *h*-stability

The main result of this work is a characterization of the uniform asymptotic h-stability which emulates and generalizes the equivalence between uniform asymptotic stability with Proposition 1.4 and Proposition 1.5. The group $(J, *)$ introduced in the previous section, as well as its properties, will play an essential role on the proof.

Theorem 4.1. *Given a nonautonomous system (1.1) with a transition matrix $\Phi(t,s)$, the following statements are equivalent:*

i) The system (1.1) is uniformly asymptotically h-stable.

ii) The system (1.1) is uniformly stable and there exists a constant $T \in (e_*, +\infty)$ such that

$$\sup_{s\in J} \|\Phi(T * s, s)\|_{\mathcal{L}} < 1. \tag{4.1}$$

iii) The solutions $x(t) = \Phi(t, t_0)x_0$ of the system (1.1) satisfy the following two properties:

a) For each $\varepsilon > 0$ there is a $\delta_\varepsilon > 0$ such that if $\|x(t_0)\| < \delta_\varepsilon$ for some $t_0 \in J$ then $\|x(t)\| < \varepsilon$ for all $t \geq t_0$.

b) There is a $\delta_0 > 0$ such that for all $\varepsilon > 0$ there exists a constant $T_\varepsilon \in (e_*, +\infty)$ such that if $\|x(t_0)\| < \delta_0$ then $\|x(t)\| < \varepsilon$ for all $t \geq t_0 * T_\varepsilon$.

Proof. We begin with i) $\Rightarrow$ ii): Suppose that the system (1.1) is uniformly asymptotically h-stable. By using (1.2) it follows that an uniformly asymptotically h-stable system always satisfies the bound $\|\Phi(t,s)\|_{\mathcal{L}} \leq K$ since $\frac{h(s)}{h(t)} \leq 1$ for all pairs s, t with $a < s \leq t < +\infty$, that is, for any h an uniformly asymptotically h-stable system is also uniformly stable, due to Proposition 1.3.

Now, note that for all $s \in J$ and $T \in (e_*, +\infty)$, by using (1.2) and (3.3) we have

$$\begin{aligned}\|\Phi(T * s, s)\|_{\mathcal{L}} &\leq K\left(\frac{h(s)}{h(T * s)}\right)^{\alpha} \\ &= K\left(\frac{h(s)}{h(T)h(s)}\right)^{\alpha} \\ &= K\left(\frac{1}{h(T)}\right)^{\alpha},\end{aligned}$$

thus, by choosing $T \in (e_*, +\infty)$ large enough such that $K\left(\frac{1}{h(T)}\right)^{\alpha} < 1$, we obtain (4.1) since the right hand of the above inequality is independent of s.

We proceed to prove ii) $\Rightarrow$ i): Let us consider a pair of values (t, s) such that $a < s \leq t < +\infty$, by following a construction analogue to that of Lemma 3.7, we construct a partition of the interval J into the sets $s * A_n := s * [T^{*n}, T^{*(n+1)})$ for $n \in \mathbb{Z}$. As $\{s * A_n\}_{n\in\mathbb{Z}}$ is a partition of J, there must be an unique integer k such that $t \in s * A_k$. We can then rewrite $\Phi(t, s)$ as

$$\Phi(t,s) = \Phi(t, T^{*k} * s)\Phi(T^{*k} * s, T^{*(k-1)} * s) \cdots \Phi(T * s, s). \tag{4.2}$$

On the other hand, due to inequality (4.1) and the uniform stability of the system, we know that there exists constants $\theta < 1$ and $1 \leq K$ respectively, such that

$$\|\Phi(T * s, s)\|_{\mathcal{L}} < \theta \quad \text{and} \quad \|\Phi(t, T^{*k} * s)\|_{\mathcal{L}} \leq K.$$

Using these two bounds along with the submultiplicative property of the operator norm applied to (4.2), we get

$$\|\Phi(t,s)\|_{\mathcal{L}} \leq K\theta^k = Ke^{-k|\log(\theta)|}, \tag{4.3}$$

where $\log(\theta) = -|\log(\theta)|$ because $\theta < 1$. As the integer k depends on the values of T, t and s, we can bound it by a function of these numbers, to do this we notice that $t \in s * A_k$ is equivalent to the inequalities

$$s * T^{*k} \leq t < s * T^{*(k+1)}. \tag{4.4}$$

For any $\gamma \in J$, the group action on J, $\gamma * (\cdot)$, is an strictly increasing function, as can be seen by noting that $\gamma * (\cdot) = h^{-1}(h(\gamma)h(\cdot))$, where the left hand side is a composition of increasing functions. Hence, the action of s^{*-1} on (4.4) mantains the inequalities

$$T^{*k} \leq t * s^{*-1} < T^{*(k+1)}.$$

By passing the above inequality through the monotone function $u \mapsto \log(h(u))$ combined with the identities (3.2) and (3.3), we get

$$k \log(h(T)) \leq \log\left(\frac{h(t)}{h(s)}\right) < (k+1)\log(h(T)).$$

Notice that $\log\left(\frac{h(t)}{h(s)}\right)\log(h(T))^{-1} - 1 < k$, then by (4.3) and, due to the fact that the exponent $-k|\log(\theta)| < 0$, we deduce

$$\begin{aligned}\|\Phi(t,s)\|_{\mathcal{L}} &\leq K\theta^k \\ &\leq Ke^{-[\log(\frac{h(t)}{h(s)})\log(h(T))^{-1}-1]|\log(\theta)|} \\ &= Ke^{|\log(\theta)|}\left(\frac{h(s)}{h(t)}\right)^{\frac{|\log(\theta)|}{\log(h(T))}},\end{aligned}$$

as this is true for any pair (t,s), we have shown that $\Phi(t,s)$ is uniformly asymptotically h-stable with constants $Ke^{|\log(\theta)|} \geq 1$ and $\frac{|\log(\theta)|}{\log(h(T))} > 0$.

We now prove i) $\Rightarrow$ iii): Suppose that the system (1.1) is uniformly asymptotically h-stable. The property a) of iii) is immediately verfied since, as we said in the step i) $\Rightarrow$ ii), the uniform h-stability implies the uniform stability from Definition 1.2 which is equivalent to iii).

In order to prove that the solutions $x(t)$ satisfy property $b)$, let us consider $\delta_0 = 1$, $T \in (e_*, +\infty)$ and $t_0 \in (a, +\infty)$. Now, if $x(t)$ is a solution of (1.1) such that $\|x_0\| < \delta_0$ and $t \geq T * t_0$ by using the fact that (1.1) is uniformly asymptotically h-stable combined with (3.3) we can deduce that

$$\begin{aligned}\|x(t)\| &= \|\Phi(t, T*t_0)\Phi(T*t_0, t_0)x_0\| \\ &\leq \|\Phi(t, T*t_0)\|_{\mathcal{L}} \cdot \|\Phi(T*t_0, t_0)\|_{\mathcal{L}} \cdot \|x_0\| \\ &\leq K^2\left(\frac{h(t_0)}{h(T*t_0)}\right)^{\alpha}\delta_0 \\ &= K^2\left(\frac{1}{h(T)}\right)^{\alpha}.\end{aligned}$$

As the function h is surjective onto the interval $(0, +\infty)$, for any given $\varepsilon > 0$ we can choose a T_ε such that

$$K^2\left(\frac{1}{h(T_\varepsilon)}\right)^{\alpha} < \varepsilon,$$

which proves property $b)$.

Finally, we need to prove iii) $\Rightarrow$ ii): If (1.1) satisfies iii) then it has property $a)$, which is the uniform stability described by Definition 1.2.

We now prove (4.1). Let δ_0 be as in property $b)$ of statement iii). Given any $0 < \varepsilon < \delta_0/2$ we define $\theta = \varepsilon(2/\delta_0) < 1$. There exists $T_\varepsilon > e_*$ such that

$$\|\Phi(T_\varepsilon * s, s)\|_{\mathcal{L}} = \sup_{\|x\|=1} \frac{2}{\delta_0}\|\Phi(T_\varepsilon * s, s)\frac{\delta_0}{2}x\| < \theta,$$

which proves iii). □

5 Integral conditions

The results proved in the previous sections will allow us to carry out a wider study of the properties of uniform asymptotic h-stability, we will extend two existing results regarding necessary and sufficient conditions for uniform exponential stability. One of these theorems is proved in [9, Th. 3.3.15] in a finite dimensional framework. Besides the case of uniform exponential stability, these results were proved for uniform polynomial stability in [7], within the more general framework of evolutionary processes in Banach spaces.

Theorem 5.1. *A nonautonomous linear system* (1.1) *with a transition matrix* $\Phi(t,s)$ *is uniformly asymptotically h-stable if and only if it is uniformly stable and*

$$\sup_{s\in J}\int_s^{+\infty}\|\Phi(u,s)x\|\mathrm{d}\mu_*(u)<+\infty \quad \textit{for all } x\in\mathbb{R}^n. \tag{5.1}$$

Proof. We begin with the forward direction of the equivalence. Let $\Phi(t,s)$ be a transition matrix of an uniformly asymptotically h-stable system. As a uniformly asymptotically h-stable system is also uniformly stable, we only need to prove (5.1). To do this we can use (1.2) to bound the integral as follows

$$\begin{aligned}\int_s^{+\infty}\|\Phi(u,s)x\|\mathrm{d}\mu_*(u) &\leq K\|x\|\int_s^{+\infty}\left(\frac{h(s)}{h(u)}\right)^{\alpha}\frac{h'(u)}{h(u)}\mathrm{d}m(u)\\ &= K\|x\|h(s)^{\alpha}\int_s^{+\infty}\frac{h'(u)}{h(u)^{\alpha+1}}\mathrm{d}m(u)\\ &= K\alpha^{-1}\|x\|\lim_{t\to+\infty}\left(1-\frac{h(s)^{\alpha}}{h(t)^{\alpha}}\right)\\ &= K\alpha^{-1}\|x\|,\end{aligned}$$

which gives, for each $x\in\mathbb{R}^n$, a finite bound that is independent from s and the property (5.1) is verified.

To prove the backwards direction of the equivalence we will use Theorem 4.1. Given a compact interval $[c,d]\subset J$, the fact that $\Phi(t,s)$ is the transition matrix of an uniformly stable system implies that there exists a constant $K>1$ such that

$$\begin{aligned}rcl\|\Phi(d,c)\|_{\mathcal{L}} &\leq \|\Phi(d,u)\|_{\mathcal{L}}\cdot\|\Phi(u,c)\|_{\mathcal{L}}\\ &\leq K\|\Phi(u,c)\|_{\mathcal{L}} \text{ for } c\leq u\leq d.\end{aligned}$$

Given that the integral in (5.1) has a non-negative integrand we have the inequalities

$$\begin{aligned}+\infty &> \sup_{s\in J}\int_s^{+\infty}\|\Phi(u,s)x\|\mathrm{d}\mu_*(u)\\ &\geq \int_c^d\|\Phi(u,c)x\|\mathrm{d}\mu_*(u)\\ &\geq \int_c^d K^{-1}\|\Phi(d,c)x\|\mathrm{d}\mu_*(u)\\ &= K^{-1}\|\Phi(d,c)x\|\mu_*([c,d]).\end{aligned}$$

As the above inequality is satisfied by all $x\in\mathbb{R}^n$ and $[c,d]\subset J$, the Banach–Steinhaus theorem implies the existence of a constant M such that

$$\mu_*([c,d])K^{-1}\|\Phi(d,c)\|_{\mathcal{L}}\leq M$$

for any compact interval $[c,d] \subset J$.

There exists $T \in (e_*, +\infty)$ large enough such that $\frac{MK}{\mu_*([e_*,T])} < 1$. Then, by the invariance of μ_* under $*$-translations given for intervals in Lemma 3.4 we have:

$$\|\Phi(T*s,s)\|_{\mathcal{L}} \leq \frac{MK}{\mu_*([s,T*s])} = \frac{MK}{\mu_*([e_*,T])} < 1,$$

which due to Theorem 4.1 proves that $\Phi(t,s)$ is uniformly asymptotically h-stable. □

Theorem 5.2. *A nonautonomous system (1.1) with a transition matrix $\Phi(t,s)$ is uniformly asymptotically h-stable if and only if it is uniformly stable and*

$$\sup_{t\in J} \int_a^t \|\Phi(t,u)\|_{\mathcal{L}} \mathrm{d}\mu_*(u) < \infty. \tag{5.2}$$

Proof. We begin with the forward direction of the equivalence. As uniform asymptotic h-stability implies uniform stability, we only need to prove that $\Phi(t,s)$ satisfies (5.2). For any $t \in J = (a, +\infty)$ we replace $\|\Phi(t,s)\|_{\mathcal{L}}$ with its bound (1.2) to obtain the inequality

$$\begin{aligned}
\int_a^t \|\Phi(t,u)\| \mathrm{d}\mu_*(u) &\leq K \int_a^t \left(\frac{h(u)}{h(t)}\right)^{\alpha} \mathrm{d}\mu_*(u) \\
&= K \int_a^t \left(\frac{h(u)}{h(t)}\right)^{\alpha} \frac{h'(u)}{h(u)} \mathrm{d}m(u) \\
&= \frac{K}{h(t)^{\alpha}} \lim_{s\to a^+} \int_s^t h(u)^{\alpha-1} h'(u) \mathrm{d}m(u) \\
&= K\alpha^{-1},
\end{aligned}$$

which proves the first part of the theorem.

Now we prove the backward direction of the equivalence. Let $K > 0$ be the bound of $\|\Phi(t,s)\|_{\mathcal{L}}$ obtained by the uniform stability and $M > 0$ a bound of (5.2). For all $a < s \leq t < +\infty$ it is true that

$$\begin{aligned}
KM &> K \int_s^t \|\Phi(t,u)\|_{\mathcal{L}} \mathrm{d}\mu_*(u) \\
&> \int_s^t \|\Phi(t,u)\|_{\mathcal{L}} \|\Phi(u,s)\|_{\mathcal{L}} \mathrm{d}\mu_*(u) \\
&\geq \int_s^t \|\Phi(t,s)\|_{\mathcal{L}} \mathrm{d}\mu_*(u) \\
&= \log\left(\frac{h(t)}{h(s)}\right) \|\Phi(t,s)\|_{\mathcal{L}}.
\end{aligned} \tag{5.3}$$

The function h is upper unbounded, hence there exists $T \in (e_*, +\infty)$ such that $\log(h(T)) > KM$. Given any $s \in J$, the inequality (5.3) for the pair $(T*s, s)$ is

$$\|\Phi(T*s,s)\|_{\mathcal{L}} \leq \frac{KM}{\log(h(T))} < 1.$$

It follows from Theorem 4.1 that $\Phi(t,s)$ is uniformly h-stable. □

6 Discussion

In this work, we revisited the property of uniform h-stability for nonautonomous linear systems and proved a set of properties emulating the classical results for the uniform asymptotic stability and its equivalence with the uniform exponential one. The main tool was the characterization of h as an isomorphism of topological abelian groups $h : (J, *) \to (\mathbb{R}, \cdot)$ which, in the specific case $h(t) = e^t$ with $(J, *) = (\mathbb{R}, +)$, recovers the uniform exponential stability and its characterizations.

To the best of knowledge, there are few results on stability for nonautonomous linear systems based on group theory. However, the methods we have presented in this paper can be applied to generalize other existing theorems of the theory of exponential stability to uniform asymptotic h-stability. In particular, we have obtained preliminary results in the following topics:

a) The problem of $(\mathcal{B}, \mathcal{D})$-admissibility, that is, if for each $f \in \mathcal{B}$ the system

$$\dot{x} = A(t)x + f(t), \tag{6.1}$$

has a solution $x \in \mathcal{D}$, where $\mathcal{B}$ and $\mathcal{D}$ are suitable function spaces. An affirmative answer to this problem, allows us to give a functional characterization of stability properties of the linear system associated to (6.1).

b) The roughness of uniform asymptotic h-stability, which concerns sufficient smallness conditions for a matrix valued function $B(\cdot)$ such that the system

$$\dot{x} = A(t)x + B(t)x,$$

is uniformly asymptotically h-stable, provided that (1.1) is a uniformly asymptotically h-stable system.

To further emphasize the usefulness of the ideas developed in this article, we will also mention that the function $\frac{h'(t)}{h(t)}$ has been used by other authors to prove theorems regarding h-stability and dichotomy, see for example [7] and [3]. Despite this, the way it relates to the algebraic structure of these problems, such as the fact that it defines an invariant measure, has neither been established nor employed to its further extent in previous works.

Abstract. The main subject of this study is a linear fractional-order differential equation with two delayed terms. By applying the D-decomposition method to the characteristic equation, we present a stability region as a necessary and sufficient condition for the asymptotic stability of the zero solution. Given the relationship between the Caputo fractional derivative and the integer-order derivative, we compare the conditions in this study with the results of the corresponding first-order delay differential equation to demonstrate the validity of the extension.

Keywords: fractional-order differential equation, delay differential equation, two delays, asymptotic stability, stability region.

2020 Mathematics Subject Classification: 34K37, 34K25, 34K20.

1 Introduction

Fractional calculus is a generalization concept of the classical calculus of integer order, including integrals and derivatives of any arbitrary real or complex order. There are several different families of fractional integrals and fractional derivatives, and the potentially useful properties of these definitions have been identified (see [7, 10, 12, 18] and references therein). As the basic theory of fractional calculus improves, its advantages in describing the memory and hereditary properties of processes has been gradually acknowledged. For example, empirical analyses of the transmission dynamics of COVID-19 (see [16, 22]) reveal that models incorporating Caputo fractional-order derivatives demonstrate superior performance in data fitting accuracy and epidemic trend prediction capabilities over their integer-order counterparts. By now, fractional differential equations have become one of the best tools in the areas of fluid flow, rheology, dynamical processes in self-similar and porous structures, electrical networks, and biophysics. Because stability is an important characteristic of the normal operation of a practical system, the stability theory of fractional differential equations have attracted the attention of mathematicians and engineers.

In engineering and natural systems, the time delay in the process of material exchange and information transmission cannot be ignored. The existence of a time delay is usually the source of the instability of the system, which makes the discussion essential on the stability of fractional differential equations with time delay. Moreover, several factors can cause time delays in large or complex systems. In general, secondary factors are often overlooked for the convenience of processing; thus, the system is simplified into a single time-delay system with only the main time-delay parameter. However, for a complex system in which it is difficult to select the factors that cause a time delay, a model with multiple delay parameters should be considered.

The research on fractional differential equations with multiple delays has increased in the last double decades; see, e.g., [1, 6, 9, 20, 21, 23, 24] and references therein. The basic criterion of these studies are based on [6] in which an n-dimensional system of linear fractional differential equations with n^2 different delays was considered. In 2007, Deng et al. [6] established that the zero solution of the system is asymptotically stable if all the roots of the associated characteristic equation have negative real parts. It should be pointed out that the characteristic equation of a linear delay differential equation is a transcendental equation that cannot be solved using algebraic tools, and there are practical difficulties in condition verification.

This study focuses on a linear fractional differential equation with two delays

$$\begin{aligned} {}^{C}\mathrm{D}_0^{\alpha} x(t) &= a x(t-\tau_1) + b x(t-\tau_2), \quad t \geq 0, \\ x(t) &= \phi(t), \quad t \in [-\tau, 0], \quad \tau = \max\{\tau_1, \tau_2\}. \end{aligned} \tag{1.1}$$

Here, $\alpha \in (0,1)$ is a constant and ${}^{C}\mathrm{D}_0^{\alpha}$ is the Caputo fractional differentiation operator of order α defined by

$${}^{C}\mathrm{D}_0^{\alpha} x(t) = \frac{1}{\Gamma(1-\alpha)} \int_0^t \frac{x'(r)}{(t-r)^{\alpha}} dr, \quad t > 0.$$

Parameters a and b are real numbers and τ_1 and τ_2 are positive real numbers. The initial function ϕ is continuous on the interval $[-\tau, 0]$. The main purpose of this study is to investigate the asymptotic behavior of the solutions to (1.1) and present the stability set of (a, b) for the zero solution to be asymptotically stable.

The study on (1.1) with $b = 0$ can be found in [5, 13] and references therein. In 2011, Krol [13] determined the range of parameter a where the zero solution is asymptotically stable.

Theorem A. Let $b = 0$ and $\tau_1 = \tau$. Then, the zero solution to (1.1) is asymptotically stable if and only if

$$-\left(\frac{\pi - \alpha\pi/2}{\tau}\right)^{\alpha} < a < 0.$$

This is stable but not asymptotically stable if and only if

$$a = -\left(\frac{\pi - \alpha\pi/2}{\tau}\right)^{\alpha}.$$

Stability criteria for (1.1) with $\tau_1 = 0$ was studied in [2, 3, 11] and references therein. Especially, Čermák et al. [3] gave the stability set of (a, b) for (1.1) with $\tau_1 = 0$ and $0 < \alpha < 1$, which has been extended for the case $\alpha > 1$ by Čermák et al. [4]. By virtue of their work, we have the following result.

Theorem B. Let $\alpha > 0$, $\tau_1 = 0$, and $\tau_2 = \tau$.

(i) The zero solution to (1.1) is asymptotically stable if and only if $(a,b) \in D$ where D is an open region enclosed by the line $a+b=0$ from above and by the parametric curve

$$a = \frac{\omega^\alpha \sin(\tau\omega + \alpha\pi/2)}{\sin(\tau\omega)}, \quad b = -\frac{\omega^\alpha \sin(\alpha\pi/2)}{\sin(\tau\omega)} \tag{1.2}$$

for $\omega \in ((\pi - \alpha\pi)/\tau, \pi/\tau)$ from below.

(ii) The zero solution to (1.1) is stable but not asymptotically stable if and only if either

$$a+b=0, \quad a \le \frac{(\pi(1-\alpha))^\alpha}{2\tau^\alpha \cos(\alpha\pi/2)},$$

or a and b satisfy (1.2) for an admissible value ω.

Letting $\alpha \to 1^-$, (1.1) becomes the first-order delay differential equation

$$x'(t) = ax(t-\tau_1) + bx(t-\tau_2), \quad t \ge 0. \tag{1.3}$$

When $b=0$ or $\tau_1 = 0$ in (1.3), relevant classical results exist for the asymptotic stability of the zero solution. A simple calculation shows that the asymptotic stability condition in Theorems A and B with $\alpha = 1$ coincides with the result for the corresponding case in (1.3).

Stability criteria for (1.3) can be found in [14, 15, 19, 25]. In [19], Sakata discussed the stability set of (a,b) for (1.3) when $\tau_2 = n\tau_1$, $n = 2, 3$. Here, we present the result for $\tau_2 = 2\tau_1$.

Theorem C. Let $\tau_2 = 2\tau_1 = 2\tau$. Then, the zero solution to (1.3) is asymptotically stable if and only if $(a,b) \in D_1$ where D_1 is an open region enclosed by the line $a+b=0$ from the right and by the parametric curve

$$a = \frac{\omega\cos(2\tau\omega)}{\sin(\tau\omega)}, \quad b = -\frac{\omega\cos(\tau\omega)}{\sin(\tau\omega)}, \quad 0 < \omega < \frac{2\pi}{3\tau}$$

from the left.

In this study, we consider the special case of (1.1) in which $\tau_2 = 2\tau_1$. For simplicity, we denote τ_1 as τ and τ_2 as 2τ. Subsequently, (1.1) is reduced to

$$\begin{aligned} {}^C\mathrm{D}_0^\alpha x(t) &= ax(t-\tau) + bx(t-2\tau), \quad t \ge 0, \\ x(t) &= \phi(t), \quad t \in [-2\tau, 0]. \end{aligned} \tag{1.4}$$

The following theorem is the main result of this study.

Theorem 1.1. *Let $0 < \alpha < 1$, a, b and $\tau > 0$ be real numbers.*

(i) *The zero solution to (1.4) is asymptotically stable if and only if $(a,b) \in D_{0,0}$ where $D_{0,0}$ is an open region enclosed by the line $a+b=0$ from the right and by the parametric curve*

$$a = \frac{\rho^\alpha \sin(\alpha\pi/2 + 2\tau\rho)}{\sin(\tau\rho)}, \quad b = -\frac{\rho^\alpha \sin(\alpha\pi/2 + \tau\rho)}{\sin(\tau\rho)} \tag{1.5}$$

for

$$\rho \in \left(\frac{(1-\alpha)\pi}{3\tau}, \frac{(3-\alpha)\pi}{3\tau} \right)$$

from the left.

(ii) *The zero solution to* (1.4) *is stable but not asymptotically stable if and only if* $a+b=0$ *or* a *and* b *satisfy* (1.5) *for*

$$\rho = \frac{(2-\alpha)\pi}{4\tau} \quad or \quad \rho \in \left[\frac{(2-\alpha)\pi}{2\tau}, \frac{(3-\alpha)\pi}{3\tau}\right).$$

Remark 1.2. We observe that the conditions for parameter a in Theorem 1.1 are the same as those in Theorem A by letting $b=0$, that is, $\tau\rho=(2-\alpha)\pi/2$ in (1.5).

Remark 1.3. As previously mentioned, (1.4) corresponds to (1.3) with $\tau_1=\tau$ and $\tau_2=2\tau$ as $\alpha\to 1^-$. Comparing the conditions of Theorems C and 1.1 (i), the regions for the asymptotic stability of the zero solution are the same if $\alpha=1$.

Remark 1.4. As $\alpha\to 1^+$, (1.4) does not become (1.3) with $\tau_1=\tau$ and $\tau_2=2\tau$ if $x'(0)\neq 0$. Therefore, the case of $\alpha>1$ is out of the scope of the extension of Theorem C that we aim to achieve.

The set of the pair (a,b) that guarantees the asymptotic stability of the zero solution when the fractional order takes different values with a fixed delay is shown in Figure 1.1. Notably, these regions have no inclusion relationships with each other.

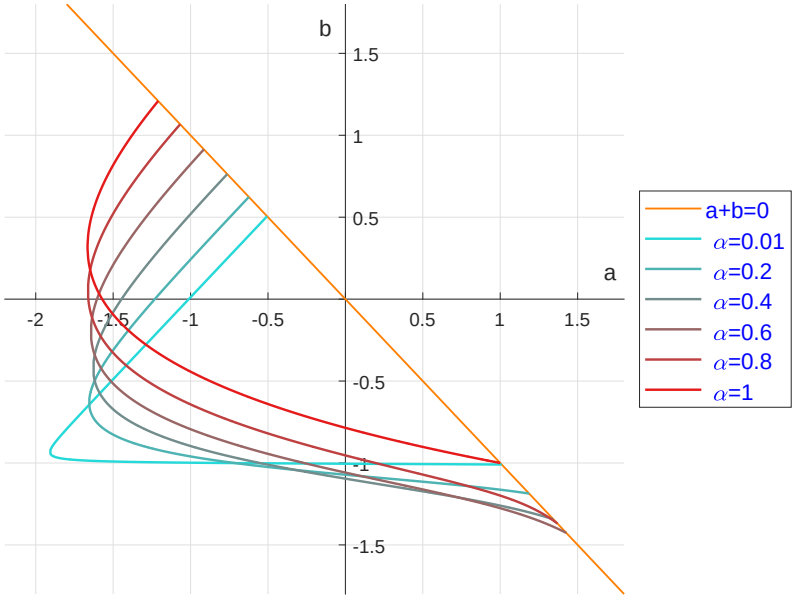

Figure 1.1: Parametric curve (1.5) for $\alpha=0.2,0.4,0.6,0.8,1$, and $\tau=1$.

Remark 1.5. According to [12,18], as $\alpha\to 0^+$, (1.4) is reduced to

$$x(t)-\phi(0)=ax(t-\tau)+bx(t-2\tau), \quad t\geq 0.$$

Figure 1.1 indicates that as $\tau=1$ and $\alpha\to 0^+$, $D_{0,0}$ given in Theorem 1.1 becomes the open triangle region D_0 enclosed by lines $a+b=0$, $b=a+1$, and $b=-1$. We note that D_0 can be regarded as the stability set for the equilibrium $\phi(0)/(1-a-b)$ of the second-order difference equation

$$x(k)-ax(k-1)-bx(k-2)=\phi(0), \quad k=0,1,2,\ldots,$$

where a, b, and $\phi(0)$ are real numbers with $a+b<0$; see, e.g., [8].

The structure of this article is arranged as follows: In the next section, we present the expression for the solutions using the Laplace transform. In Section 3, we provide a detailed analysis of the characteristic equation to present a set of (a,b) in which all the characteristic roots are located in the left half of the complex plane. The proof of the main theorem is completed in Section 4. Finally, we summarize our results in Section 5 and compare them with those of the corresponding first-order differential equation with two delays. The scope for future directions is also provided.

2 Preliminaries

In this section, we introduce some definitions and properties as preliminary for investigating the asymptotic behavior of the solutions to (1.1).

First, we introduce the Laplace transform; see, e.g. [7,10,12,18].

Definition 2.1. The Laplace transform of the function $f:\mathbb{R}_+\to\mathbb{R}$ is defined as

$$\mathcal{L}[f(t)](s)=\mathcal{L}_f(s):=\int_0^\infty e^{-st}f(t)dt,\quad s\in\mathbb{C}.$$

Suppose that $f\in L^1_{loc}(\mathbb{R}_+)$ and there exists $r\geq 0$ such that $|f(t)|\leq ce^{rt}$ for a large t. Then, $\mathcal{L}_f(s)$ exists and is analytic for $\mathrm{Re}(s)>r$. Moreover, if the integral converges at point $s_0\in\mathbb{C}$, then it converges absolutely for $s\in\mathbb{C}$ with $\mathrm{Re}(s)>\mathrm{Re}(s_0)$. The infimum R_f of the real part of s for which the Laplace integral of $f(t)$ converges, is called the abscissa of convergence. Clearly, the Laplace transform is linear. Next, we provide common rules and formulae for the Laplace transform.

Lemma 2.2.

(i) $\mathcal{L}[t^k](s)=\Gamma(k+1)/s^{k+1}$ *for* $k>-1$ *and* $s>0$.

(ii) $\mathcal{L}\big[\int_0^t f(t-u)g(u)du\big](s)=\mathcal{L}_f(s)\mathcal{L}_g(s)$.

(iii) $\mathcal{L}[f^{(n)}(t)](s)=s^n\mathcal{L}_f(s)-\sum_{k=1}^n s^{n-k}f^{(k-1)}(s)$.

(iv) *For* $c\in\mathbb{R}$, *let*

$$f_c(t)=\begin{cases}0, & t<c,\\ f(t-c), & t\geq c.\end{cases}$$

Then, $\mathcal{L}[f_c(t)](s)=e^{-cs}\mathcal{L}_f(s)$.

Definition 2.3. The inverse formula for the Laplace transform is given by

$$f(t)=\mathcal{L}^{-1}[\mathcal{L}_f(s)](t)=\frac{1}{2\pi i}\int_{r-i\infty}^{r+i\infty}e^{ts}\mathcal{L}_f(s)ds.$$

Here, the integral is along the vertical line $\mathrm{Re}(s)=r$ in $\mathbb{C}$ such that $r>R_f$, that is, it is greater than the real part of all the singularities of $\mathcal{L}_f$, and $\mathcal{L}_f$ is bounded on the line.

Next, we establish a representation formula for the solution $x(t)$ to (1.1). Let $X(s)=\mathcal{L}[x(t)](s)$. Then, the Laplace transform of (1.1) becomes

$$s^\alpha X(s)-s^{\alpha-1}\phi(0)=ae^{-\tau_1 s}X(s)+a\int_{-\tau_1}^0\phi(u)e^{-s(\tau_1+u)}du+be^{-\tau_2 s}X(s)+b\int_{-\tau_2}^0\phi(u)e^{-s(\tau_2+u)}du.$$

This implies that

$$X(s) = \frac{s^{\alpha-1}\phi(0) + a\int_{-\tau_1}^{0}\phi(u)e^{-s(\tau_1+u)}du + b\int_{-\tau_2}^{0}\phi(u)e^{-s(\tau_2+u)}du}{s^\alpha - ae^{-\tau_1 s} - be^{-\tau_2 s}}.$$

Let

$$\Phi^{\alpha,\beta}(t) = \mathcal{L}^{-1}\left(\frac{s^{\alpha-\beta}}{s^\alpha - ae^{-\tau_1 s} - be^{-\tau_2 s}}\right)(t).$$

Subsequently, from Lemma 2.2, it follows that

$$\begin{aligned} X(s) &= \phi(0)\mathcal{L}\left(\Phi^{\alpha,1}(t)\right)(s) + a\mathcal{L}\left(\Phi^{\alpha,\alpha}(t)\right)(s)\int_{-\tau_1}^{0}\phi(u)e^{-s(\tau_1+u)}du \\ &\quad + b\mathcal{L}\left(\Phi^{\alpha,\alpha}(t)\right)(s)\int_{-\tau_2}^{0}\phi(u)e^{-s(\tau_2+u)}du \\ &= \phi(0)\mathcal{L}\left(\Phi^{\alpha,1}(t)\right)(s) + a\int_{-\tau_1}^{0}\phi(u)\mathcal{L}\left({\Phi^{\alpha,\alpha}}_{\tau_1+u}(t)\right)(s)du \\ &\quad + b\int_{-\tau_2}^{0}\phi(u)\mathcal{L}\left({\Phi^{\alpha,\alpha}}_{\tau_2+u}(t)\right)(s)du. \end{aligned}$$

Using the inverse Laplace transform of $X(s)$, we obtain the following representation formula for the solution to (1.1):

$$x(t) = \phi(0)\Phi^{\alpha,1}(t) + a\int_{-\tau_1}^{0}\phi(u){\Phi^{\alpha,\alpha}}_{\tau_1+u}(t)du + b\int_{-\tau_2}^{0}\phi(u){\Phi^{\alpha,\alpha}}_{\tau_2+u}(t)du.$$

In particular, we obtain the representation formula for the solution to (1.4):

$$x(t) = \phi(0)\Phi^{\alpha,1}(t) + a\int_{-\tau}^{0}\phi(u){\Phi^{\alpha,\alpha}}_{\tau+u}(t)du + b\int_{-2\tau}^{0}\phi(u){\Phi^{\alpha,\alpha}}_{2\tau+u}(t)du, \tag{2.1}$$

where

$$\Phi^{\alpha,1}(t) = \mathcal{L}^{-1}\left[\frac{s^{\alpha-1}}{s^\alpha - ae^{-\tau s} - be^{-2\tau s}}\right](t), \tag{2.2}$$

$$\Phi^{\alpha,\alpha}{}_c(t) = \mathcal{L}^{-1}\left[\frac{e^{-cs}}{s^\alpha - ae^{-\tau s} - be^{-2\tau s}}\right](t). \tag{2.3}$$

3 Analysis of characteristic equation

The representation formula (2.1) shows that

$$P(s) := s^\alpha - ae^{-\tau s} - be^{-2\tau s} = 0 \tag{3.1}$$

is a characteristic equation associated with (1.4). Therefore, it is essential to analyze the roots of (3.1) in detail. First, we note that $P(0) = -a - b$ and $P(s) > 0$ for s real and sufficiently large. Thus, if $a + b > 0$, then (3.1) has at least one positive root. Moreover, as $\overline{e^z} = e^{\bar{z}}$ for any $z \in \mathbb{C}$, we observe that

$$\overline{P(s)} = \overline{s^\alpha} - \overline{ae^{-\tau s}} - \overline{be^{-2\tau s}} = \bar{s}^\alpha - ae^{-\tau\bar{s}} - be^{-2\tau\bar{s}} = P(\bar{s}).$$

This implies that for any $s \in \mathbb{C}$, $P(s) = 0$ if and only if $P(\bar{s}) = 0$. Based on this property, we consider (3.1) only in the upper half of the complex plane in the following discussion.

Proposition 3.1. *Let $0 < \alpha < 1$, a, b and $\tau > 0$ be real numbers.*

(i) (3.1) *has the root 0 if and only if $a + b = 0$.*

(ii) (3.1) *has a finite number of roots in the domain of $\{s \in \mathbb{C} \mid |\arg(s)| \leq \sigma\}$ for any given $\sigma \in (\pi/2, \pi)$.*

(iii) (3.1) *has a root ρi with $\rho > 0$ if and only if a and b satisfy*

$$a = \frac{\rho^\alpha \sin(\alpha\pi/2 + 2\tau\rho)}{\sin(\tau\rho)}, \quad b = -\frac{\rho^\alpha \sin(\alpha\pi/2 + \tau\rho)}{\sin(\tau\rho)}, \quad \rho \neq \frac{m\pi}{\tau}, \quad m \in \mathbb{N}. \tag{3.2}$$

(iv) (3.1) *has no quadruple roots. Moreover, if $a \neq 0$ and $b > 0$, then* (3.1) *has no double roots on the imaginary axis.*

Proof. (i) This part is obvious.

(ii) Let $s = \rho e^{\theta i}$ be a root of (3.1), where $\rho \geq 0$ and $\theta \in [0, \pi]$. The real and imaginary parts of $P(\rho e^{\theta i}) = 0$ are separated to obtain

$$\rho^\alpha \cos(\alpha\theta) = a\cos(\tau\rho\sin\theta)e^{-\tau\rho\cos\theta} + b\cos(2\tau\rho\sin\theta)e^{-2\tau\rho\cos\theta}, \tag{3.3}$$

$$\rho^\alpha \sin(\alpha\theta) = -a\sin(\tau\rho\sin\theta)e^{-\tau\rho\cos\theta} - b\sin(2\tau\rho\sin\theta)e^{-2\tau\rho\cos\theta}. \tag{3.4}$$

The sum of the squares of (3.3) and (3.4) is

$$\rho^{2\alpha} = e^{-2\tau\rho\cos\theta}\left[a^2 + 2ab\cos(\tau\rho\sin\theta)e^{-\tau\rho\cos\theta} + b^2e^{-2\tau\rho\cos\theta}\right]. \tag{3.5}$$

If $\theta \in [0, \pi/2]$, then

$$e^{-2\tau\rho\cos\theta}\left(a^2 + 2ab\cos(\tau\rho\sin\theta)e^{-\tau\rho\cos\theta} + b^2e^{-2\tau\rho\cos\theta}\right) \leq \left(|a| + |b|\right)^2.$$

This implies that (3.5) is impossible if $\rho > \left(|a| + |b|\right)^{1/\alpha}$. Thus, (3.1) has no roots in the region of

$$\{s \in \mathbb{C} \mid |s| > \left(|a| + |b|\right)^{1/\alpha}, \arg(s) \in [0, \pi/2]\}.$$

Similarly, if $\theta \in (\pi/2, \pi)$, it follows that

$$e^{-2\tau\rho\cos\theta}\left(a^2 + 2ab\cos(\tau\rho\sin\theta)e^{-\tau\rho\cos\theta} + b^2e^{-2\tau\rho\cos\theta}\right) \geq e^{-2\tau\rho\cos\theta}\left(|a| - |b|e^{-\tau\rho\cos\theta}\right)^2.$$

Because there exists a $\rho_1 > 0$ such that

$$\rho^{2\alpha} < e^{-2\tau\rho\cos\theta}\left(|a| - |b|e^{-\tau\rho\cos\theta}\right)^2$$

for all $\rho > \rho_1$, (3.1) has no root in the region of

$$\{s \in \mathbb{C} \mid |s| > \rho_1, \arg(s) \in (\pi/2, \pi)\}.$$

Therefore, there exists a $\bar{\rho}$ such that (3.1) has no root with $|s| > \bar{\rho}$ and $|\arg(s)| \in (\pi/2, \pi)$. Furthermore, if $a + b \neq 0$, then (3.3) does not hold as $\rho \to 0$. Hence, there exists $\underline{\rho} > 0$ such that (3.1) has no roots with $|s| < \underline{\rho}$. Let

$$\Omega = \{s \in \mathbb{C} \mid \underline{\rho} < |s| < \bar{\rho}, \ |\arg(s)| \in [0, \sigma]\}.$$

Because the function P is analytic on Ω, (3.1) has finite number of roots in Ω.

(iii) Let $P(\rho i) = 0$ where $\rho > 0$. Then, (3.3) and (3.4) with $\theta = \pi/2$ become

$$\begin{aligned}\rho^\alpha \cos(\alpha\pi/2) &= a\cos(\tau\rho) + b\cos(2\tau\rho),\\ \rho^\alpha \sin(\alpha\pi/2) &= -a\sin(\tau\rho) - b\sin(2\tau\rho),\end{aligned}$$

namely,

$$a\sin(\tau\rho) = \rho^\alpha \sin(\alpha\pi/2 + 2\tau\rho), \quad b\sin(\tau\rho) = -\rho^\alpha \sin(\alpha\pi/2 + \tau\rho). \tag{3.6}$$

Therefore, $P(\rho i) = 0$ is equivalent to (3.6). If $\sin(\tau\rho) = 0$, then (3.6) yields $\rho = 0$, which is a contradiction. Thus, $\sin(\tau\rho) \neq 0$, that is, $\tau\rho \neq m\pi$ for $m \in \mathbb{N}$; hence, $P(\rho i) = 0$ is equivalent to (3.2).

(iv) Finally, we consider the multiplicity of the roots of (3.1). Let $P'(s) = 0$. Then,

$$\frac{dP}{ds} = \alpha s^{\alpha-1} + a\tau e^{-\tau s} + 2b\tau e^{-2\tau s} = 0. \tag{3.7}$$

Clearly, $s = 0$ is not the root of (3.7). From Part (ii), we observe that if $s = \rho e^{\theta i}$ is a root of (3.7), then $\bar{s} = \rho e^{-\theta i}$ is also a root of (3.7). Eliminating s^α in (3.1) and (3.7) yields

$$a(\tau s + \alpha) + b(2\tau s + \alpha)e^{-\tau s} = 0.$$

Eliminating $e^{-2\tau s}$ in (3.1) and (3.7) yields

$$2\tau s^\alpha + \alpha s^{\alpha-1} - a\tau e^{-\tau s} = 0.$$

Then, we obtain

$$\frac{2\tau s + \alpha}{a\tau s^{1-\alpha}} = e^{-\tau s} = -\frac{a(\tau s + \alpha)}{b(2\tau s + \alpha)}. \tag{3.8}$$

This implies that

$$b(2\tau s + \alpha)^2 = -a^2\tau s^{1-\alpha}(\tau s + \alpha). \tag{3.9}$$

We observe that (3.9) has no positive real root s if $b > 0$. Let $s = \rho e^{\varphi i}$ where $\rho > 0$, $\varphi \in (0, 2\pi)$. Then, we have

$$\begin{aligned}b(4\tau^2\rho^2\cos 2\varphi + 4\alpha\tau\rho\cos\varphi + \alpha^2) &= -a^2\tau\rho^{1-\alpha}\left(\tau\rho\cos((2-\alpha)\varphi) + \alpha\cos((1-\alpha)\varphi)\right),\\ b(4\tau^2\rho^2\sin 2\varphi + 4\alpha\tau\rho\sin\varphi) &= -a^2\tau\rho^{1-\alpha}\left(\tau\rho\sin((2-\alpha)\varphi) + \alpha\sin((1-\alpha)\varphi)\right).\end{aligned}$$

If $\varphi = \pi$, then ρ satisfies

$$\begin{aligned}b(2\tau\rho - \alpha)^2 &= a^2\tau\rho^{1-\alpha}(\alpha - \tau\rho)\cos\alpha\pi,\\ 0 &= a^2\tau\rho^{1-\alpha}(\tau\rho - \alpha)\sin\alpha\pi.\end{aligned}$$

The second equation implies that $\rho = 0$ or $\rho = \alpha/\tau$; however, none satisfies the first equation. Therefore, (3.9) has no negative real root.

Suppose that (3.9) has a root $s = \rho i$. Then, ρ satisfies

$$\begin{aligned}b(\alpha^2 - 4\tau^2\rho^2) &= -a^2\tau\rho^{1-\alpha}\left(\alpha\sin(\alpha\pi/2) - \tau\rho\cos(\alpha\pi/2)\right),\\ 4b\alpha\tau\rho &= -a^2\tau\rho^{1-\alpha}\left(\tau\rho\sin(\alpha\pi/2) + \alpha\cos(\alpha\pi/2)\right).\end{aligned}$$

If $b > 0$, then the second equation does not hold for any $\rho > 0$; hence, (3.9) has no root on the imaginary axis. If $b < 0$, we divide the two equations to obtain

$$\frac{\alpha^2 - 4\tau^2\rho^2}{4\alpha\tau\rho} = \frac{\alpha\sin(\alpha\pi/2) - \tau\rho\cos(\alpha\pi/2)}{\tau\rho\sin(\alpha\pi/2) + \alpha\cos(\alpha\pi/2)}.$$

This implies that

$$F(\rho) := \rho^3 + \frac{3\alpha^2}{4\tau^2}\rho - \frac{\alpha^3}{4\tau^3}\cot\frac{\alpha\pi}{2} = 0.$$

As $F(0) < 0$ and $F'(\rho) > 0$ for $\rho \geq 0$, there is a unique positive root ρ^* for this equation. Therefore, (3.9) contains only one pair of roots $s = \pm\rho^* i$ if $b < 0$.

In summary, (a) if $a \neq 0$ and $b > 0$, (3.1) has no real or purely imaginary double roots; (b) if $a \neq 0$ and $b < 0$, (3.1) has a positive real double root and one pair of purely imaginary double roots, but has no negative real double roots.

Let $P''(s) = 0$. Then,

$$\frac{d^2P}{ds^2} = \alpha(1-\alpha)s^{\alpha-2} + a\tau^2e^{-\tau s} + 4b\tau^2e^{-2\tau s} = 0. \tag{3.10}$$

From (3.7) and (3.10), we obtain

$$e^{-\tau s} = -\frac{a(\tau s + \alpha - 1)}{2b(2\tau s + \alpha - 1)}. \tag{3.11}$$

From (3.8) and (3.11), we obtain

$$\alpha = (2\tau s + \alpha)(\tau s + \alpha). \tag{3.12}$$

Note that (3.12) has only one positive real root and one negative real root. Therefore, (3.1) has a positive real triple root if $b < 0$.

Let $P'''(s) = 0$. Then,

$$\frac{d^3P}{ds^3} = \alpha(1-\alpha)(2-\alpha)s^{\alpha-3} + a\tau^3e^{-\tau s} + 8b\tau^3e^{-2\tau s} = 0. \tag{3.13}$$

From (3.10) and (3.13), we obtain

$$e^{-\tau s} = -\frac{a(\tau s + \alpha - 2)}{4b(2\tau s + \alpha - 2)}. \tag{3.14}$$

From (3.11) and (3.14), we obtain

$$3\tau s + 3\alpha - 2 = (2\tau s + \alpha)(\tau s + \alpha). \tag{3.15}$$

Note that (3.12) and (3.15) have only one common root, $s^* = (2-2\alpha)/(3\tau)$. Substituting s^* into (3.12), we obtain $\alpha^2 - 7\alpha - 8 = 0$. This yields $\alpha = 1$ or $\alpha = -8$. This result is in conflict with $\alpha \in (0,1)$. Therefore, (3.1) has no quadruple root. □

For simplicity, we define the family of parametric curves as follows:

$$\begin{gathered} a = a_m(\rho) := \frac{\rho^\alpha\sin(\alpha\pi/2 + 2\tau\rho)}{\sin(\tau\rho)}, \quad b = b_m(\rho) := -\frac{\rho^\alpha\sin(\alpha\pi/2 + \tau\rho)}{\sin(\tau\rho)}, \\ \Gamma_m : (a_m(\rho), b_m(\rho)), \quad \frac{m\pi}{\tau} < \rho < \frac{(m+1)\pi}{\tau}, \quad m = 0, 1, 2, \ldots \end{gathered} \tag{3.16}$$

Proposition 3.1 (ii) indicates that conjugate complex numbers $\pm\rho i$ with $\rho > 0$ are roots of (3.1) if and only if the pair (a, b) satisfies (3.16). The parametric curve in (1.5) corresponds to a part of the Γ_0.

Lemma 3.2. *Let $m, n \in \mathbb{N}$.*

(i) *Each curve Γ_m intersects with the a-axis at $((-1)^m\rho^\alpha, 0)$ when $\tau\rho = (2-\alpha)\pi/2 + m\pi$; intersects with the b-axis at two points, which are $(0, -\rho^\alpha)$ when $\tau\rho = (2-\alpha)\pi/4 + m\pi$ and $(0, \rho^\alpha)$ when $\tau\rho = (4-\alpha)\pi/4 + m\pi$.*

(ii) *Each curve Γ_{2n} intersects with the line $a + b = 0$ when $\tau\rho = (1-\alpha)\pi/3 + 2n\pi$ and $\tau\rho = (3-\alpha)\pi/3 + 2n\pi$; intersects with the line $a = b$ when $\tau\rho = (2-\alpha)\pi/3 + 2n\pi$.*

(iii) *Each curve Γ_{2n+1} intersects with the line $a + b = 0$ when $\tau\rho = (2-\alpha)\pi/3 + (2n+1)\pi$; intersects with the line $a = b$ when $\tau\rho = (1-\alpha)\pi/3 + (2n+1)\pi$ and $\tau\rho = (3-\alpha)\pi/3 + (2n+1)\pi$.*

(iv) *If $\tau\rho$ tends to $2n\pi$, curves Γ_{2n-1} and Γ_{2n} approach their common asymptotes*

$$l_{2n} : b = -a + \left(\frac{2n\pi}{\tau}\right)^\alpha \cos\left(\frac{\alpha\pi}{2}\right).$$

(v) *If $\tau\rho$ tends to $(2n+1)\pi$, curves Γ_{2n} and Γ_{2n+1} approach their common asymptotes*

$$l_{2n+1} : b = a + \left(\frac{(2n+1)\pi}{\tau}\right)^\alpha \cos\left(\frac{\alpha\pi}{2}\right).$$

Proof. Parts (i), (ii), and (iii) are clear. A direct calculation reveals that

$$\begin{aligned} a_m(\rho) + \cos(\tau\rho) b_m(\rho) &= \frac{\rho^\alpha \sin(\alpha\pi/2 + 2\tau\rho) - \rho^\alpha \cos(\tau\rho)\sin(\alpha\pi/2 + \tau\rho)}{\sin(\tau\rho)} \\ &= \rho^\alpha \cos(\alpha\pi/2 + \tau\rho). \end{aligned}$$

Then, parts (iv) and (v) are obvious. □

Proposition 3.1 indicates that the range of $\tau\rho$ for the curve $\Gamma_{2n}(\rho)$ to lie in the region $\overline{D} := \{(a,b) \in \mathbb{R}^2 \mid a + b \le 0\}$ is

$$\tau\rho \in \left(\frac{(1-\alpha)\pi}{3} + 2n\pi, \frac{(3-\alpha)\pi}{3} + 2n\pi\right) =: J_{2n}$$

and the range of $\tau\rho$ for the curve $\Gamma_{2n+1}(\rho)$ to lie in the region $\overline{D}$ is

$$\tau\rho \in \left((2n+1)\pi, \frac{(2-\alpha)\pi}{3} + (2n+1)\pi\right)$$

for $n \in \mathbb{N}$.

Proposition 3.3. *Let $\alpha \in (0,1)$, $a + b \le 0$, and $m, n \in \mathbb{N}$. Suppose the point (a,b) lies on the curves Γ_m at $\tau = \tau^*$. Then, for $\tau^*\rho \in J_{2n} \cup J_{2n+1}$, the root ρi of (3.1) enters the right half of the complex plane as τ increases from τ^*, where*

$$J_{2n+1} := \left(\frac{(1-\alpha)\pi}{3} + (2n+1)\pi, \frac{(2-\alpha)\pi}{3} + (2n+1)\pi\right).$$

Proof. It suffices to demonstrate that

$$\mathrm{Re}\left(\frac{ds}{d\tau}\right)\Big|_{\substack{s=\rho i \\ \tau=\tau^*}} > 0 \quad \text{for} \quad \tau^*\rho \in J_{2n} \cup J_{2n+1}.$$

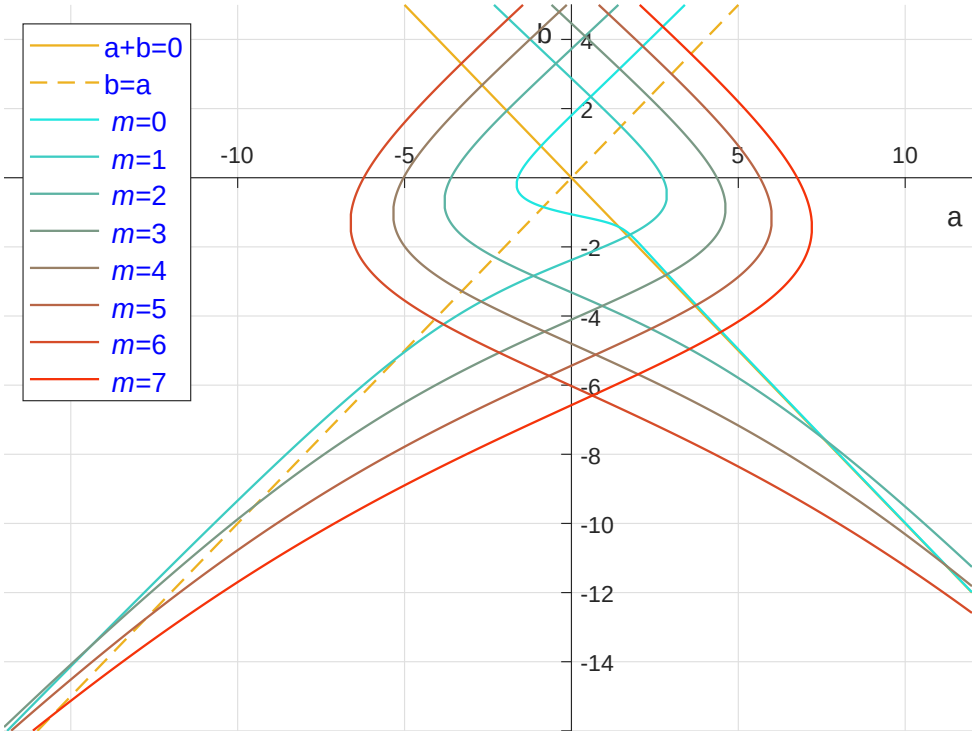

Figure 3.1: The graph of Γ_m for $m \in \{0,1,2,3,4,5,6,7\}$ with $\alpha = 0.6$ and $\tau = 1$.

From (3.1), we have

$$\frac{ds}{d\tau} = -\frac{s(ae^{-\tau s} + 2be^{-2\tau s})}{\alpha s^{\alpha-1} + a\tau e^{-\tau s} + 2b\tau e^{-2\tau s}}. \tag{3.17}$$

Substituting $s = \rho i$, $\tau = \tau^*$, $a = a_m(\rho)$, $b = b_m(\rho)$ into (3.17), we obtain

$$\left.\frac{ds}{d\tau}\right|_{\substack{s=\rho i \\ \tau=\tau^*}} = -\frac{A + Bi}{C + Di}, \tag{3.18}$$

where

$$\begin{aligned}
A &= \rho a_m(\rho)\sin(\tau^*\rho) + 2\rho b_m(\rho)\sin(2\tau^*\rho),\\
B &= \rho a_m(\rho)\cos(\tau^*\rho) + 2\rho b_m(\rho)\cos(2\tau^*\rho),\\
C &= \alpha\rho^{\alpha-1}\cos\left(\frac{(\alpha-1)\pi}{2}\right) + \tau^* a_m(\rho)\cos(\tau^*\rho) + 2\tau^* b_m(\rho)\cos(2\tau^*\rho),\\
D &= \alpha\rho^{\alpha-1}\sin\left(\frac{(\alpha-1)\pi}{2}\right) - \tau^* a_m(\rho)\sin(\tau^*\rho) - 2\tau^* b_m(\rho)\sin(2\tau^*\rho).
\end{aligned}$$

A direct calculation reveals that

$$\begin{aligned}
\mathrm{Re}\left(\frac{ds}{d\tau}\right)\Big|_{\substack{s=\rho i \\ \tau=\tau^*}} \cdot (C^2 + D^2) &= -AC - BD\\
&= \alpha\rho^{\alpha} a_m(\rho)\left(\cos(\tau^*\rho)\cos\left(\frac{\alpha\pi}{2}\right) - \sin(\tau^*\rho)\sin\left(\frac{\alpha\pi}{2}\right)\right)\\
&\quad + 2\alpha\rho^{\alpha} b_m(\rho)\left(\cos(2\tau^*\rho)\cos\left(\frac{\alpha\pi}{2}\right) - \sin(2\tau^*\rho)\sin\left(\frac{\alpha\pi}{2}\right)\right)\\
&= \frac{\alpha\rho^{2\alpha}}{2}\left(3 - \frac{\sin(\alpha\pi + 3\tau^*\rho)}{\sin(\tau^*\rho)}\right).
\end{aligned}$$

Therefore, if we show that

$$f(x) = 3 - \frac{\sin(\alpha\pi + 3x)}{\sin x} > 0 \quad \text{for } x \in J_{2n} \cup J_{2n+1}, \tag{3.19}$$

then the proof will be complete. We only need to consider the behavior of $f(x)$ on the interval $(0, \pi)$ because $f(x)$ is a periodic function with period π and satisfies $\lim_{x\to k\pi^-} f(x) = +\infty$ and $\lim_{x\to k\pi^+} f(x) = -\infty$ for any integer k. First, we obtain $f((r-\alpha)\pi/3) = 3$ for $r = 1, 2, 3$, and

$$\begin{aligned} f'(x) &= \frac{\sin(\alpha\pi + 3x)\cos(x) - 3\cos(\alpha\pi + 3x)\sin(x)}{\sin^2(x)} \\ &= \frac{2\sin(\alpha\pi + 2x) - \sin(\alpha\pi + 4x)}{\sin^2(x)} =: \frac{g(x)}{\sin^2(x)}. \end{aligned}$$

Note that $g((1-\alpha)\pi/3) = 3\sin((1-\alpha)\pi/3) > 0$, $g((2-\alpha)\pi/3) = -3\sin((2-\alpha)\pi/3) < 0$, $g((3-\alpha)\pi/3) = 3\sin((3-\alpha)\pi/3) > 0$, and $g'(x) = 8\sin(x)\sin(\alpha\pi + 3x) = 0$ only at $x = (r-\alpha)\pi/3$ for $r = 1, 2, 3$. Therefore, there only exist two numbers x_1^* and x_2^* with

$$\frac{(1-\alpha)\pi}{3} < x_1^* < \frac{(2-\alpha)\pi}{3} < x_2^* < \frac{(3-\alpha)\pi}{3}$$

such that $g(x_1^*) = g(x_2^*) = 0$. Then we see that the minimum of $f(x)$ on the interval $((1-\alpha)\pi/3, (3-\alpha)\pi/3)$ is $f(x_2^*)$. Next, we will show that $f(x_2^*) > 0$. From $f'(x_2^*) = 0$, we have

$$\sin(\alpha\pi + 3x_2^*)\cos(x_2^*) = 3\cos(\alpha\pi + 3x_2^*)\sin(x_2^*).$$

This yields

$$\sin^2(\alpha\pi + 3x_2^*)\left(1 - \sin^2(x_2^*)\right) = 9\left(1 - \sin^2(\alpha\pi + 3x_2^*)\right)\sin^2(x_2^*).$$

Thus,

$$\left|\frac{\sin(\alpha\pi + 3x_2^*)}{\sin(x_2^*)}\right| = \frac{3}{\sqrt{1 + 8\sin^2(x_2^*)}} < 3,$$

which implies that $f(x_2^*) > 0$. Therefore, we obtain

$$f(x) > 0 \quad \text{for} \quad x \in \left(\frac{(1-\alpha)\pi}{3} + k\pi, \frac{(3-\alpha)\pi}{3} + k\pi\right), \ k \in \mathbb{N}.$$

In other words, (3.19) is satisfied. □

Proposition 3.4. *Let $\alpha \in (0, 1)$, a, b and $\tau > 0$ be constants. Then, all roots of (3.1) are located in the left half of the complex plane if and only if $(a, b) \in D_{0,0}$, where the open region $D_{0,0}$ is bounded by the line $a + b = 0$ and the curve Γ_0 with $\rho \in ((1-\alpha)\pi/3\tau, (3-\alpha)\pi/3\tau)$.*

Proof. The region $\overline{D}$ is divided into an infinite number of regions by the curves Γ_m for $m \in \mathbb{N}$. As shown in Figure 3.2, the open regions that are enclosed by the line $a + b = 0$ and the curves Γ_m are denoted by $D_{h,k}$ with nonnegative integers h and k. It is well established that the number of roots with positive real part of the characteristic equation changes only if the pure imaginary root appears. Then the number of roots of (3.1) with positive real parts does not change in these regions $D_{h,k}$ if the time delay is fixed. Let $N(D_{h,k})$ denote the number of

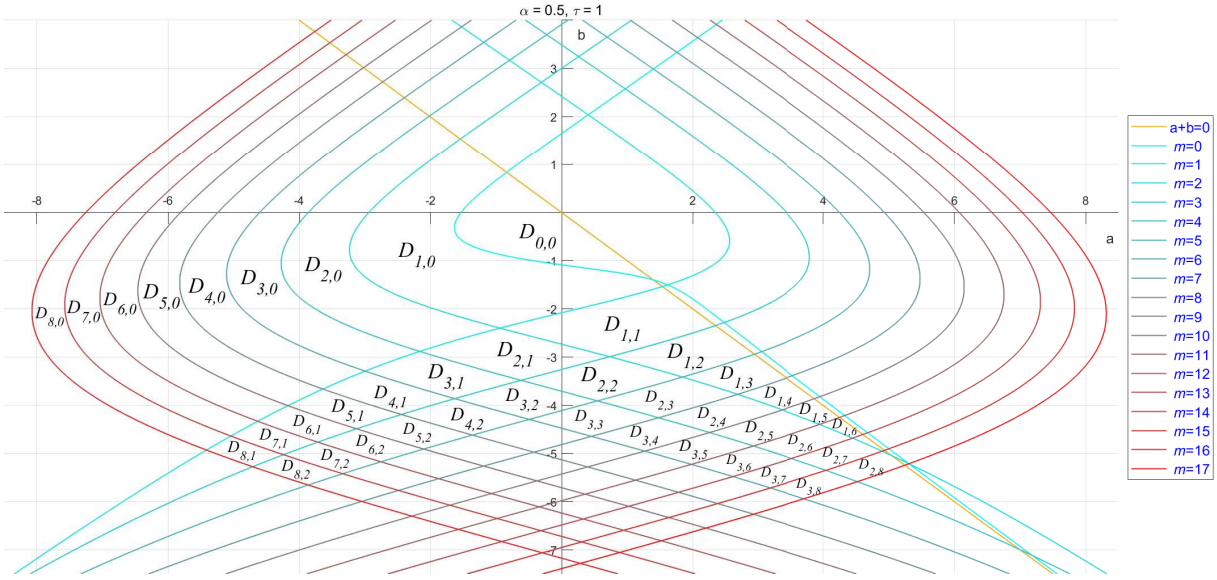

Figure 3.2: The graph of Γ_m for $\alpha = 0.5$, $\tau = 1$.

roots of (3.1) with positive real parts for $(a,b) \in D_{h,k}$. From Theorem A and Lemma 3.2 (i), we see that $N(D_{0,0}) = 0$ and $N(D_{h,k}) > 0$ for $D_{h,k}$ which intersects the a-axis or the b-axis.

Suppose there exists a point (a,b) lies on the common boundary of $D_{1,0}$ and $D_{1,1}$, which is on the curve Γ_1. Especially, we suppose the point (a,b) is close to the common point of Γ_1 and the line $a+b=0$, which guarantees that $\tau^*\rho \in J_1$. From Lemma 3.2 (i), the point (a,b) moves from $D_{1,0}$ into $D_{1,1}$ as τ grows near τ^*. Then, Proposition 3.3 shows that the number of roots of (3.1) with positive real parts increases as the point (a,b) moves from $D_{1,0}$ into $D_{1,1}$. Therefore, $N(D_{1,1}) > N(D_{1,0})$. Similarly, we can prove that $N(D_{1,k+1}) > N(D_{1,k}) > 0$ for any nonnegative integer k.

Suppose there exists a point (a,b) lies on the common boundary of $D_{1,0}$ and $D_{2,0}$, which is on the curve Γ_2. From Lemma 3.2 (i), the point (a,b) moves from $D_{1,0}$ into $D_{2,0}$ as τ grows near τ^*. Then, Proposition 3.3 shows that the number of roots of (3.1) with positive real parts increases as the point (a,b) moves from $D_{1,0}$ into $D_{2,0}$. Therefore, $N(D_{2,0}) > N(D_{1,0})$. Similarly, we can prove that $N(D_{2,k}) > N(D_{1,k})$ for any nonnegative integer k.

By repeating the same argument, we conclude that for any $D_{h,k}$ with $h = 1,2,\ldots$ and $k = 0,1,2,\ldots$, (3.1) has at least one pair of conjugate roots with positive real part. This completes the proof. □

4 Proof of main theorem

To prove that the zero solution to (1.4) is asymptotically stable or stable, we must examine the behavior of the solution to (1.4) given in (2.1) as $t \to \infty$. Because the representation formula (2.1) comprises functions (2.2) and (2.3), the problem is reduced to studying the behavior of the family of functions Φ as $t \to \infty$.

Because function Φ is defined by the inverse Laplace transform, we introduce an integral curve that is commonly used in inverse Laplace transforms. For brevity, denote by $\gamma(\varepsilon,\vartheta)$ the

contour comprising the following parts:

$$\{s \in \mathbb{C} \mid |s| = \varepsilon, \, |\arg(s)| \le \vartheta\}, \quad \{s \in \mathbb{C} \mid |s| \ge \varepsilon, \, |\arg(s)| = \vartheta\},$$

where $\varepsilon > 0$ and $0 < \vartheta \le \pi$.

The following lemma is utilized to compute the inverse Laplace transform of Φ.

Lemma 4.1. *Let $\alpha \in (0,1)$, $\beta \in (0,1]$, $\varepsilon > 0$, $\sigma \in (\pi/2, \pi)$, and $\ell = 0$ or $\ell = \alpha$. Define*

$$w(t) = \frac{1}{2\pi\alpha i} \int_{\gamma(\varepsilon^\alpha, \alpha\sigma)} \frac{z^{\frac{1-\beta}{\alpha}} \exp\left(z^{\frac{1}{\alpha}}(1 + 2\tau/t)\right)}{z \exp\left((2\tau/t) z^{\frac{1}{\alpha}}\right) - at^\alpha \exp\left((\tau/t) z^{\frac{1}{\alpha}}\right) - bt^\alpha} dz.$$

If there exists $K > 0$ such that

$$\left| z \exp\left(\frac{2\tau}{t} z^{\frac{1}{\alpha}}\right) - at^\alpha \exp\left(\frac{\tau}{t} z^{\frac{1}{\alpha}}\right) - bt^\alpha \right| \ge Kt^\ell \left| \exp\left(\frac{2\tau}{t} z^{\frac{1}{\alpha}}\right) \right| \tag{4.1}$$

for all $z \in \gamma(\varepsilon^\alpha, \alpha\sigma)$, then $w(t) = O(t^{-\ell})$ as $t \to \infty$.

Proof. From (4.1), we observe that:

$$\begin{aligned}
|w(t)| &\le \frac{1}{2\pi\alpha} \int_{\gamma(\varepsilon^\alpha, \alpha\sigma)} \frac{\left|z^{\frac{1-\beta}{\alpha}}\right| \left|\exp\left(z^{\frac{1}{\alpha}}(1 + 2\tau/t)\right)\right|}{Kt^\ell \left|\exp\left((2\tau/t) z^{\frac{1}{\alpha}}\right)\right|} |dz| \\
&= \frac{t^{-\ell}}{2\pi\alpha K} \int_{\gamma(\varepsilon^\alpha, \alpha\sigma)} \left|z^{\frac{1-\beta}{\alpha}}\right| \left|\exp\left(z^{\frac{1}{\alpha}}\right)\right| |dz| \\
&= \frac{t^{-\ell}}{2\pi\alpha K} \left(\varepsilon^{1+\alpha-\beta} \int_{-\alpha\sigma}^{\alpha\sigma} \exp\left(\varepsilon \cos\frac{\theta}{\alpha}\right) d\theta + 2 \int_{\varepsilon^\alpha}^{\infty} r^{\frac{1-\beta}{\alpha}} \exp\left(\cos\sigma r^{\frac{1}{\alpha}}\right) dr \right).
\end{aligned}$$

From $\sigma \in (\pi/2, \pi)$, it follows that

$$\begin{aligned}
\int_{\varepsilon^\alpha}^{\infty} r^{\frac{1-\beta}{\alpha}} \exp\left(\cos\sigma r^{\frac{1}{\alpha}}\right) dr &= \frac{\alpha}{(-\cos\sigma)^{1+\alpha-\beta}} \int_{\varepsilon^\alpha}^{\infty} \left(-\cos\sigma r^{\frac{1}{\alpha}}\right)^{\alpha-\beta} \exp\left(\cos\sigma r^{\frac{1}{\alpha}}\right) d\left(-\cos\sigma r^{\frac{1}{\alpha}}\right) \\
&< \frac{\alpha\Gamma(1+\alpha-\beta)}{(-\cos\sigma)^{1+\alpha-\beta}}.
\end{aligned}$$

Therefore, we obtain

$$|w(t)| < \frac{t^{-\ell}}{\pi\alpha K} \left(\alpha\sigma\varepsilon^{1+\alpha-\beta} e^\varepsilon + \frac{\alpha\Gamma(1+\alpha-\beta)}{(-\cos\sigma)^{1+\alpha-\beta}} \right) = O(t^{-\ell}) \quad \text{as } t \to \infty,$$

as desired. □

Proposition 4.2. *Let $0 < \alpha < 1$, $0 < \beta \le 1$.*

(i) *If all the roots of (3.1) are located in the left half-plane, then $\Phi^{\alpha,\beta}(t) = O(t^{\beta-\alpha-1})$ as $t \to \infty$.*

(ii) *If there exists the root 0 of (3.1) and other roots of (3.1) are located in the left half-plane, then $\Phi^{\alpha,\beta}(t) = O(t^{\beta-1})$ as $t \to \infty$.*

(iii) *If all the roots of (3.1) are located in the left half-plane or on the imaginary axis, and those of the roots on the imaginary axis are simple, then $\Phi^{\alpha,\beta}(t)$ is bounded.*

(iv) *If all the roots of* (3.1) *are located in the left half-plane or on the imaginary axis, and those of the roots on the imaginary axis are double, then*

$$\limsup_{t\to\infty}\left|\frac{\Phi^{\alpha,\beta}(t)}{t}\right| = \text{const} > 0. \tag{4.2}$$

(v) *If there are some roots* s_i *of* (3.1) *in the right half-plane, then*

$$\limsup_{t\to\infty}\left|\frac{\Phi^{\alpha,\beta}(t)}{t^2e^{Mt}}\right| = \text{const} > 0, \tag{4.3}$$

where $M = \max_{s_i}\{\mathrm{Re}(s_i)\}$.

Proof. Proposition 3.1 (i) implies that only the finite number of roots of (3.1) satisfy $|\arg(s)| < \sigma$ for $\sigma \in (\pi/2, \pi)$. Then, for $t > 1$, there exist $R > 0$ and $\varepsilon > 0$ with $R > \varepsilon$ such that all the roots of (3.1) are located to the left of $\gamma(R,\sigma)$ and the roots of (3.1) with $|\arg(s)| \le \sigma$ are located to the right of $\gamma(\varepsilon/t, \sigma)$. Subsequently, $\Phi^{\alpha,\beta}(t)$ is expressed as

$$\begin{aligned}\Phi^{\alpha,\beta}(t) &= \frac{1}{2\pi i}\int_{\gamma(R,\sigma)}\frac{s^{\alpha-\beta}e^{ts}}{P(s)}ds\\ &= \frac{1}{2\pi i}\int_{\gamma(R,\sigma)-\gamma(\varepsilon/t,\sigma)}\frac{s^{\alpha-\beta}e^{ts}}{P(s)}ds + \frac{1}{2\pi i}\int_{\gamma(\varepsilon/t,\sigma)}\frac{s^{\alpha-\beta}e^{ts}}{P(s)}ds.\end{aligned}$$

Using the residue theorem, we obtain

$$I_1(t) := \frac{1}{2\pi i}\int_{\gamma(R,\sigma)-\gamma(\varepsilon/t,\sigma)}\frac{s^{\alpha-\beta}e^{ts}}{P(s)}ds = \sum_{k=1}^{N}\mathrm{Res}\left[\frac{s^{\alpha-\beta}e^{ts}}{P(s)}; s_k\right].$$

Here, s_k, $k = 1, 2, \ldots, N$, represent the roots of (3.1) in the area enclosed by $\gamma(R,\sigma) - \gamma(\varepsilon/t, \sigma)$. Proposition 3.1 (iii) implies that

$$\begin{aligned}\frac{s^{\alpha-\beta}}{P(s)} &= a^k_{-3}(s-s_k)^{-3} + a^k_{-2}(s-s_k)^{-2} + a^k_{-1}(s-s_k)^{-1} + a^k_0 + \cdots,\\ e^{ts} &= e^{ts_k}\left(1 + t(s-s_k) + t^2(s-s_k)^2/2! + \cdots\right),\end{aligned}$$

where a^k_j, $j = -3, -2, \ldots$, are complex constants that are not all zero. Hence,

$$I_1(t) = \sum_{k=1}^{N}\left(a^k_{-1} + a^k_{-2}t + \frac{a^k_{-3}}{2!}t^2\right)e^{ts_k}.$$

By changing the variable $s = z^{1/\alpha}/t$, we obtain

$$\begin{aligned}I_2(t) &:= \frac{1}{2\pi i}\int_{\gamma(\varepsilon/t,\sigma)}\frac{s^{\alpha-\beta}e^{ts}}{P(s)}ds\\ &= \frac{1}{2\pi i}\int_{\gamma(\varepsilon/t,\sigma)}\frac{s^{\alpha-\beta}e^{ts}}{s^\alpha - ae^{-\tau s} - be^{-2\tau s}}ds\\ &= \frac{t^{\beta-1}}{2\pi\alpha i}\int_{\gamma(\varepsilon^\alpha,\alpha\sigma)}\frac{z^{\frac{1-\beta}{\alpha}}\exp\left(z^{\frac{1}{\alpha}}(1+2\tau/t)\right)}{z\exp\left((2\tau/t)z^{\frac{1}{\alpha}}\right) - at^\alpha\exp\left((\tau/t)z^{\frac{1}{\alpha}}\right) - bt^\alpha}dz\\ &= t^{\beta-1}w_{\frac{1-\beta}{\alpha},2}(t).\end{aligned}$$

If $a+b=0$, then (3.1) has the root 0. Note that the points in

$$\{s \in \mathbb{C} \mid s = (\varepsilon/t)e^{\theta i},\ \theta \in [-\sigma, \sigma]\}$$

are the closest points of $\gamma(\varepsilon/t,\ \sigma)$ with respect to the root 0. Thus, we have

$$|s^\alpha - ae^{-\tau s} - be^{-2\tau s}| \geq \left| \left(\frac{\varepsilon}{t}\right)^\alpha e^{\alpha\theta i} - a\exp\left(-\frac{\varepsilon\tau}{t}e^{\theta i}\right) - b\exp\left(-\frac{2\varepsilon\tau}{t}e^{\theta i}\right)\right|.$$

Because

$$\lim_{t\to\infty}\left| \left(\frac{\varepsilon}{t}\right)^\alpha e^{\alpha\theta i} - a\exp\left(-\frac{\varepsilon\tau}{t}e^{\theta i}\right) - b\exp\left(-\frac{2\varepsilon\tau}{t}e^{\theta i}\right)\right| t^\alpha = \varepsilon^\alpha,$$

we observe that there exist $\eta_0 > 0$ and $T > 0$ such that

$$|s^\alpha - ae^{-\tau s} - be^{-2\tau s}| \geq \eta_0 t^{-\alpha} \quad \text{for } t > T.$$

By changing the variable $s = z^{1/\alpha}/t$, we obtain

$$\left| \frac{z}{t^\alpha} - a\exp\left(-\frac{\tau}{t}z^{\frac{1}{\alpha}}\right) - b\exp\left(-\frac{2\tau}{t}z^{\frac{1}{\alpha}}\right)\right| \geq \eta_0 t^{-\alpha} \quad \text{for } t > T,$$

namely,

$$\left| z\exp\left(\frac{2\tau}{t}z^{\frac{1}{\alpha}}\right) - at^\alpha\exp\left(\frac{\tau}{t}z^{\frac{1}{\alpha}}\right) - bt^\alpha\right| \geq \eta_0 \left|\exp\left(\frac{2\tau}{t}z^{\frac{1}{\alpha}}\right)\right| \quad \text{for } t > T.$$

Then, from Lemma 4.1 with $\ell = 0$, we obtain

$$I_2(t) = t^{\beta-1}w_{\frac{1-\beta}{\alpha},2}(t) = t^{\beta-1}O(1) = O\big(t^{\beta-1}\big) \quad \text{as } t \to \infty.$$

If $a+b \neq 0$, then (3.1) contains only nonzero roots. Because contour $\gamma(\varepsilon/t,\ \sigma)$ does not contain any root of (3.1), there exists $\eta_1 > 0$ such that

$$|s^\alpha - ae^{-\tau s} - be^{-2\tau s}| \geq \eta_1$$

for all $s \in \gamma(\varepsilon/t,\ \sigma)$. By changing the variable $s = z^{1/\alpha}/t$, we obtain

$$\left| z\exp\left(\frac{2\tau}{t}z^{\frac{1}{\alpha}}\right) - at^\alpha\exp\left(\frac{\tau}{t}z^{\frac{1}{\alpha}}\right) - bt^\alpha\right| \geq \eta_1 t^\alpha \left|\exp\left(\frac{2\tau}{t}z^{\frac{1}{\alpha}}\right)\right|.$$

Then, from Lemma 4.1 with $\ell = \alpha$, it follows that

$$I_2(t) = t^{\beta-1}w_{\frac{1-\beta}{\alpha},2}(t) = t^{\beta-1}O(t^{-\alpha}) = O\big(t^{\beta-\alpha-1}\big) \quad \text{as } t \to \infty.$$

(i) If all the roots of (3.1) are located in the left half-plane, then

$$\Phi^{\alpha,\beta}(t) = I_2(t) = O\big(t^{\beta-\alpha-1}\big) \quad \text{as } t \to \infty.$$

(ii) If there exists the root 0 of (3.1) and the other roots of (3.1) are located in the left half-plane, then

$$\Phi^{\alpha,\beta}(t) = I_2(t) = O\big(t^{\beta-1}\big) \quad \text{as } t \to \infty.$$

(iii) If all the roots of (3.1) are located in the left half-plane or on the imaginary axis, and those roots on the imaginary axis are simple, then

$$\Phi^{\alpha,\beta}(t) = I_1(t) + I_2(t) = \sum_{k=1}^{N_1} a_{-1}^k e^{\pm\rho_k i t} + O\big(t^{\beta-1}\big),$$

which implies that $\Phi^{\alpha,\beta}(t)$ is bounded.

(iv) If all the roots of (3.1) are located in the left half-plane or on the imaginary axis, and those roots on the imaginary axis are double, then

$$\Phi^{\alpha,\beta}(t) = I_1(t) + I_2(t) = \sum_{k=1}^{N_1} \big(a_{-1}^k + a_{-2}^k t\big) e^{\pm\rho_k i t} + O\big(t^{\beta-1}\big) \quad \text{as } t \to \infty.$$

This yields (4.2).

(v) If there are some roots s_i of (3.1) in the right half-plane, then

$$\Phi^{\alpha,\beta}(t) = I_1(t) + I_2(t) = \sum_{k=1}^{N} \big(a_{-1}^k + a_{-2}^k t + a_{-3}^k t^2\big) e^{t s_k} + O\big(t^{\beta-1}\big) \quad \text{as } t \to \infty.$$

This implies (4.3). □

Remark 4.3. The asymptotic behaviors in Proposition 4.2 are fully characterized by Matignon's Theorem 1 in [17]: the algebraic decay $O(t^{-\alpha})$ for stable solutions corresponds to characteristic roots satisfying $|\arg(\lambda)| > \alpha\pi/2$; bounded but non-asymptotically stable solutions on the stability boundary occur when characteristic roots satisfy $|\arg(\lambda)| \geq \alpha\pi/2$ and the geometric multiplicity of a characteristic root with $|\arg(\lambda)| = \alpha\pi/2$ is one; the exponential growth rate e^{Mt} in unstable regimes directly follows from his analysis of $|\arg(\lambda)| \leq \alpha\pi/2$.

We are now ready to prove Theorem 1.1.

Proof of Theorem 1.1. Recall the representation formula (2.1). There exist $A > 0$ and $B > 0$ such that

$$\begin{aligned}\left|a\int_{-\tau}^{0} \phi(u)\Phi^{\alpha,\alpha}{}_{\tau+u}(t)du\right| &\leq |a|\int_{-\tau}^{0} |\phi(u)\Phi^{\alpha,\alpha}{}_{\tau+u}(t)|\,du \\ &\leq |a| \sup_{t-\tau\leq\xi\leq t} |\Phi^{\alpha,\alpha}(\xi)| \int_{-\tau}^{0} |\phi(u)|\,du \\ &= A \sup_{t-\tau\leq\xi\leq t} |\Phi^{\alpha,\alpha}(\xi)|,\end{aligned}$$

and

$$\left|b\int_{-2\tau}^{0} \phi(u)\Phi^{\alpha,\alpha}{}_{2\tau+u}du\right| \leq B \sup_{t-2\tau\leq\xi\leq t} |\Phi^{\alpha,\alpha}(\xi)|.$$

Thus, we have:

$$|x(t)| \leq |\phi(0)\Phi^{\alpha,1}(t)| + A \sup_{t-\tau\leq\xi\leq t} |\Phi^{\alpha,\alpha}(\xi)| + B \sup_{t-2\tau\leq\xi\leq t} |\Phi^{\alpha,\alpha}(\xi)|.$$

Then, from Proposition 4.2, we conclude that:

(i) If all the roots of (3.1) are located in the left half-plane, then

$$x(t) = |\phi(0)|\,O(t^{-\alpha}) + A\cdot O(t^{-1}) + B\cdot O(t^{-1}) \quad \text{as } t \to \infty.$$

Therefore, $x(t) = O(t^{-\alpha})$ if $\phi(0) \neq 0$ and $x(t) = O(t^{-1})$ if $\phi(0) = 0$ as $t \to \infty$.

(ii) If there exists the root 0 of (3.1) and the other roots of (3.1) are located in the left half-plane, then we obtain

$$x(t) = |\phi(0)|\, O(1) + A \cdot O(t^{\alpha-1}) + B \cdot O(t^{\alpha-1}) \quad \text{as } t \to \infty.$$

Therefore, $x(t) = O(1)$ if $\phi(0) \neq 0$ and $x(t) = O(t^{\alpha-1})$ if $\phi(0) = 0$ as $t \to \infty$.

(iii) If all the roots of (3.1) are located in the left half-plane or on the imaginary axis, and those roots on the imaginary axis are simple, then $x(t)$ is bounded.

(iv) If all the roots of (3.1) are located in the left half-plane or on the imaginary axis, and those roots on the imaginary axis are double, then

$$\limsup_{t\to\infty} \left| \frac{x(t)}{t} \right| = \text{const} > 0.$$

(v) If there are some roots s_i of (3.1) in the right half-plane, then

$$\limsup_{t\to\infty} \left| \frac{x(t)}{t^2 e^{Mt}} \right| = \text{const} > 0,$$

where $M = \max_{s_i}\{\mathrm{Re}(s_i)\}$.

Hence, along with Propositions 3.1 and 3.3, Theorem 1.1 holds true. □

5 Conclusion

In this study, we discussed a Caputo-type fractional-order differential equation with two delays

$$^{C}\mathrm{D}_0^{\alpha} x(t) = ax(t-\tau) + bx(t-2\tau), \quad t \geq 0,$$

where $\alpha \in (0,1)$. Using the Laplace transform, we obtained the representation formula of the solution and the associated characteristic equation. From a detailed root analysis of the characteristic equation, we presented a region enclosed by a line and a curve in the ab-plane to guarantee that all the roots of the characteristic equation are located in the left half-plane for given α and τ. Moreover, we proved that the zero solution is asymptotically stable if and only if the pair (a,b) is an interior point of this region, and it is only stable if the pair (a,b) is on the partial boundary of this region. Because the Caputo fractional derivative coincides with the first-order derivative if $\alpha \to 1^-$, we compared Theorem 1.1 and Theorem C, which describes the asymptotic stability of the corresponding first-order delay differential equation. On the one hand, the expression of the set of (a,b) for asymptotic stability is the same if we set $\alpha = 1$ in the criterion of Theorem 1.1. On the other hand, we can judge from Figure 1.1, which shows the regions of asymptotic stability when α takes different values, that there exists no relationship of one set being a subset of another. This implies that the fractional order does not make it easier or more difficult to stabilize the zero solution than the integer order.

The asymptotic stability of two cases will be the focus of our future studies: (1.1) with $\tau_1 = \tau$, $\tau_2 = 3\tau$, and $0 < \alpha < 1$; and (1.4) with $1 < \alpha < 2$. This work aims to confirm the effect of the fractional-order α.

Abstract. This note presents some new criteria for the oscillation of all solutions of the second-order hybrid type delay differential equation

$$(a(t)x'(t))' - p_1(t)x(t) + p_2(t)x^{\alpha}(\sigma(t)) = 0,$$

by making use of a positive solution of the associated linear differential equation

$$(a(t)u'(t))' - p_1(t)u(t) = 0.$$

The results obtained are new and are illustrated by three examples.

Keywords: second-order, hybrid type, delay differential equation, oscillation.

2020 Mathematics Subject Classification: 34C10, 34K11.

1 Introduction

Consider the second-order hybrid type delay differential equation of the form

$$(a(t)x'(t))' - q_1(t)x(t) + q_2(t)x^{\alpha}(\sigma(t)) = 0, \qquad t \geq t_0, \tag{E}$$

where we assume throughout that the following conditions hold:

(H_1) $a \in C^1([t_0,\infty),(0,\infty))$, $q_1,\ q_2 \in C([t_0,\infty),(0,\infty))$, and α is a ratio of odd positive integers;

(H_2) $\sigma \in C^1([t_0,\infty),\mathbb{R})$ with $\sigma'(t) \geq 0$, $\sigma(t) \leq t$, and $\sigma(t) \to \infty$ as $t \to \infty$.

✉Corresponding author. Email: johngraef9@gmail.com

By a *proper solution* of (E), we mean a function $x : [T_x, \infty) \to \mathbb{R}$ that satisfies (E) for all sufficiently large t and $\sup\{|x(t)| : t \geq T\} > 0$ for all $T \geq T_x$. We always assume that equation (E) possesses proper solutions. A solution of (E) is said to be *oscillatory* if it has arbitrarily large zeros, and otherwise it is called *nonoscillatory*. Equation (E) is said to be oscillatory if all its solutions are oscillatory.

Note that if $q_1 = 0$, then (E) reduces to the second order delay differential equation

$$(a(t)x'(t))' + q_2(t)x^{\alpha}(\sigma(t)) = 0, \qquad t \geq t_0, \tag{E$_1$}$$

and if $q_2 = 0$, then we obtain the linear differential equation without a delay

$$(a(t)x'(t))' - q_1(t)x(t) = 0, \qquad t \geq t_0. \tag{E$_2$}$$

Therefore, we may refer to equation (E) as a "hybrid type" differential equation.

Oscillation properties of solutions of second-order nonlinear delay differential equations were first studied in [9]. Since then, there has been a large number of papers regarding the oscillation of delay differential equations of different forms; see, for example, the monographs [1,2,10], the recent papers [3,5,7,8,13,17], and the references cited therein. This is due to the fact that oscillation and delay/advanced phenomena appear in different models arising from real world applications.

Recently in [8], the authors studied oscillation properties of the trinomial differential equation

$$x''(t) - q_1(t)x(\tau(t)) - q_2(t)x(\sigma(t)) = 0, \qquad t \geq t_0, \tag{E$_3$}$$

where $\tau(t) \geq t$ and $\sigma(t) \leq t$ for all $t \geq t_0$. Moreover, in [5,17], the authors presented oscillation criteria for equations of the form

$$(a(t)x'(t))' + q_1(t)x(t) + q_2(t)x(\sigma(t)) = 0, \qquad t \geq t_0, \tag{E$_4$}$$

in case (E$_4$) is in either canonical or noncanonical form. Note that if $a(t) > 0$, $q_1(t) > 0$, and $q_2(t) > 0$ for all $t \geq t_0$, then for any positive solution $x(t)$ of (E$_3$) or (E$_4$), the sign of the second-order derivative becomes

$$x''(t) > 0 \quad \text{or} \quad (a(t)x'(t))' < 0, \quad \text{for } t \geq t_0,$$

and from this it can easily be seen that $x'(t) > 0$ or $x'(t) < 0$ eventually. However, equation (E) includes both of the binomial equations (E$_1$) and (E$_2$) as special cases. Properties of both of these equations have been studied by several authors; see, for example, the monographs [1,2,15] and the references contained therein for details.

It is clear that the solutions spaces of equations (E$_1$) and (E$_2$) are completely different. If we denote by S the set of all nonoscillatory solutions of a considered equation, then for (E$_1$), the set S becomes

$$S = S_1 \cup S_0$$

where positive solutions satisfy

$$x(t) \in S_1 \quad \text{if and only if} \quad x'(t) > 0 \text{ and } (a(t)x'(t))' < 0,$$

and

$$x(t) \in S_0 \quad \text{if and only if} \quad x'(t) < 0 \text{ and } (a(t)x'(t))' < 0.$$

On the other hand, for (E_2), the set S has the structure

$$S = S_0^* \cup S_2^*$$

where positive solutions satisfy

$$x(t) \in S_0^* \quad \text{if and only if} \quad x'(t) < 0 \text{ and } (a(t)x'(t))' > 0,$$

and

$$x(t) \in S_2^* \quad \text{if and only if} \quad x'(t) > 0 \text{ and } (a(t)x'(t))' > 0.$$

Consequently, the structure of the set of nonoscillatory solutions of the hybrid equation (E) with positive and negative parts is unclear.

A method often employed in the study of the oscillation of solutions of trinomial differential equations is to omit one term. If, we omit the negative part of (E), then we are led to the differential inequality

$$\{(a(t)x'(t))' + q_2(t)x^\alpha(\sigma(t))\} \operatorname{sgn} x(t) \geq 0. \tag{E_5}$$

However, it is well known that properties of the corresponding differential equation (E_1) are connected to solutions of a differential inequality in the opposite direction. Similarly, omitting the positive term in (E) gives the differential inequality

$$\{(a(t)x'(t))' - q_1(t)x(t)\} \operatorname{sgn} x(t) \leq 0, \tag{E_6}$$

which is again opposite to the one that we would need. There are only a limited number of papers for equations like (E) with positive and negative parts. In this paper, we use a different approach that overcomes those difficulties caused by the presence of both negative and positive terms in (E). We then use comparison methods to obtain criteria for the oscillation of all solutions of (E). Three examples are provided to illustrate the importance and novelty of our main results.

2 Main results

In this section, we first transform the hybrid equation (E) into the form of a binomial equation, and then use a positive solution of the related auxiliary second-order linear ordinary differential equation

$$(a(t)u'(t))' = q_1(t)u(t), \qquad t \geq t_0. \tag{2.1}$$

Lemma 2.1. *The differential equation* (2.1) *has a positive nonincreasing solution on* $[t_0, \infty)$.

Proof. The proof is similar to Theorem 2.46 of [15] and so the details are omitted. □

Next, using a positive solution $u(t)$ of (2.1), we can obtain the following result.

Lemma 2.2. *Let* $u(t)$ *be a positive decreasing solution of* (2.1) *on* $[t_0, \infty)$. *Then* (E) *can be written in the form*

$$\left(a(t)u^2(t)\left(\frac{x(t)}{u(t)}\right)'\right)' + u(t)q_2(t)x^\alpha(\sigma(t)) = 0, \qquad t \geq t_0. \tag{E_7}$$

Proof. By a direct calculation and using (2.1), we see that

$$\begin{aligned}\frac{1}{u(t)}\left(a(t)u^2(t)\left(\frac{x(t)}{u(t)}\right)'\right)' &= \frac{1}{u(t)}\left(a(t)u(t)x'(t)-a(t)u'(t)x(t)\right)'\\ &= \frac{1}{u(t)}\left(u(t)(a(t)x'(t))'-(a(t)u'(t))'x(t)\right)\\ &= (a(t)x'(t))'-\frac{(a(t)u'(t))'x(t)}{u(t)}\\ &= (a(t)x'(t))'-q_1(t)x(t). \end{aligned} \tag{2.2}$$

Substituting (2.2) into (E) yields the desired result, and completes the proof. □

For the sake of convenience, we define the functions:

$$b(t)=a(t)u^2(t), \qquad B(t)=\int_{t_*}^{t}\frac{1}{a(s)u^2(s)}ds,$$

$$Q(t)=u(t)q_2(t)u^{\alpha}(\sigma(t)), \quad \text{and} \quad z(t)=\frac{x(t)}{u(t)}$$

for $t \geq t_* \geq t_0$. Employing the oscillation-preserving transformation $x(t)=u(t)z(t)$, where u is a positive solution of the differential equation (2.1), we can obtain the following consequence of Lemma 2.2.

Theorem 2.3. *Let $u(t)$ be a positive decreasing solution of (2.1). Then (E) is oscillatory if and only if the differential equation*

$$(b(t)z'(t))'+Q(t)z^{\alpha}(\sigma(t))=0, \qquad t \geq t_0, \tag{2.3}$$

is oscillatory.

For convenience in what follows, we will assume that (2.3) is in canonical form, that is,

$$B(t) \to \infty \quad \text{as } t \to \infty. \tag{2.4}$$

Remark 2.4. If $B(t) < \infty$ so that equation (2.3) is in noncanonical form, define

$$\Omega(t)=\int_{t}^{\infty}\frac{1}{b(s)}ds, \qquad b_1(t)=b(t)\Omega^2(t), \qquad \mu(t)=z(t)/\Omega(t),$$

and

$$Q_1(t)=\Omega(t)Q(t)\Omega^{\alpha}(\sigma(t)).$$

Then equation (2.3) can be written in the canonical form as

$$(b_1(t)\mu'(t))'+Q_1(t)\mu^{\alpha}(\sigma(t))=0, \qquad t \geq t_0. \tag{2.5}$$

The oscillation of (2.5) can then be deduced as for equation (2.3).

Theorem 2.5. *Let (2.4) hold and $u(t)$ be a positive decreasing solution of (2.1). Assume that $z(t)$ is an eventually positive (nonoscillatory) solution of (2.3). Then,*

$$z'(t) > 0 \quad \textit{and} \quad b(t)z'(t))' \leq 0 \tag{2.6}$$

for all $t \geq t_1 \geq t_0$.

Proof. Let $z(t)$ be an eventually positive solution of (2.3), say $z(t) > 0$ and $z(\sigma(t)) > 0$ for $t \geq t_1$ for some $t_1 \geq t_0$. Then from (2.3), we see that $(b(t)z'(t))' \leq 0$ and so $b(t)z'(t) > 0$ or $b(t)z'(t) < 0$ for all $t \geq t_1$.

If $b(t)z'(t) < 0$ for $t \geq t_1$, then

$$b(t)z'(t) \leq b(t_1)z'(t_1) < 0.$$

Dividing the last inequality by $b(t)$ and then integrating from t_1 to t gives

$$z(t) \leq z(t_1) + b(t_1)z'(t_1)\int_{t_1}^{t} \frac{1}{b(s)}ds \to -\infty$$

as $t \to \infty$ by (2.4). This contradicts the positivity of $z(t)$ and proves the theorem. □

Theorem 2.6. *Let* (2.4) *hold and* u *be a positive decreasing solution of* (2.1). *If*

$$\int_{t_1}^{\infty} Q(t)dt = \infty, \tag{2.7}$$

then equation (E) *is oscillatory.*

Proof. Assume, to the contrary, that $x(t)$ is an eventually positive solution of (E), say $x(t) > 0$ and $x(\sigma(t)) > 0$ for $t \geq t_1$ for some $t_1 \geq t_0$. Then, by our transformation, $z(t) = \frac{x(t)}{u(t)}$ is an eventually positive solution of (2.3), say $z(t) > 0$ and $z(\sigma(t)) > 0$ for all $t \geq t_1$. By Theorem 2.5, $z(t)$ is increasing, so by (H_1), we have $z(\sigma(t)) \geq z(\sigma(t_1))$ for $t \geq t_1$. Using this in (2.3) and then integrating the resulting inequality from t_1 to t yields

$$z^{\alpha}(\sigma(t_1))\int_{t_1}^{t} Q(s)ds \leq b(t_1)z'(t_1) - b(t)z'(t) \leq b(t_1)z'(t_1)$$

since $b(t)z'(t)$ is nonnegative. Letting $t \to \infty$ in the last inequality contradicts (2.7). This completes the proof. □

Remark 2.7. The above theorem is independent of α and the delay argument, so it holds for linear, super-linear, and sublinear equations as well as for delay or advanced type equations.

Next, we give two results for the oscillation of equation (E) without condition (2.7) holding.

Theorem 2.8. *Let* (2.4) *hold and* u *be a positive decreasing solution of* (2.1). *If* $\alpha = 1$ *and*

$$\liminf_{t\to\infty} B(\sigma(t))\int_{t}^{\infty} Q(s)ds > \frac{1}{4}, \tag{2.8}$$

then equation (E) *is oscillatory.*

Proof. Assume that $x(t)$ is an eventually positive solution of (E), say $x(t) > 0$ and $x(\sigma(t)) > 0$ for all $t \geq t_1$ for some $t_1 \geq t_0$. Then, proceeding as in the proof of Theorem 2.6, we have $z(t) > 0$, $z(\sigma(t)) > 0$, and condition (2.6) holds for all $t \geq t_1$. Using Corollary 2 in [7], we see that condition (2.8) implies that $z(t)$ is oscillatory. This contradiction completes the proof. □

Theorem 2.9. *Let* (2.4) *hold and* u *be a positive decreasing solution of* (2.1). *If the first order delay differential equation*

$$w'(t) + Q(t)B^{\alpha}(\sigma(t))w^{\alpha}(\sigma(t)) = 0 \tag{2.9}$$

is oscillatory, then equation (E) *is oscillatory.*

Proof. Assume that $x(t)$ is an eventually positive solution of (E), say $x(t) > 0$ and $x(\sigma(t)) > 0$ for $t \geq t_1 \geq t_0$. Proceeding as in the proof of Theorem 2.6, we see that $z(t)$ is a positive solution of (2.3) and (2.6) holds for $t \geq t_1$. Using the monotonicity of $b(t)z'(t) > 0$, we have

$$z(t) \geq \int_{t_1}^{t} \frac{b(s)z'(s)}{b(s)} ds \geq B(t)b(t)z'(t).$$

Using this in (2.3) yields

$$(b(t)z'(t))' + Q(t)B^{\alpha}(\sigma(t))(b(\sigma(t))z'(\sigma(t)))^{\alpha} \leq 0.$$

Let $w(t) = b(t)z'(t) > 0$; then $w(t)$ is a positive solution of the inequality

$$w'(t) + Q(t)B^{\alpha}(\sigma(t))w^{\alpha}(\sigma(t)) \leq 0.$$

By [14, Theorem 1], equation (2.9) also has a positive solution, which is a contradiction. This completes the proof. □

Next, we present some explicit oscillation criteria for equation (E) with the help of the results given in [10] and [16] for $\alpha = 1$, $0 < \alpha < 1$, and $\alpha > 1$.

Corollary 2.10. *Let* (2.4) *hold and* u *be a positive decreasing solution of* (2.1). *If*

$$\liminf_{t\to\infty} \int_{\sigma(t)}^{t} Q(s)B(\sigma(s))ds > \frac{1}{e} \quad \text{for } \alpha = 1, \tag{2.10}$$

or

$$\int_{t_0}^{\infty} Q(t)B^{\alpha}(\sigma(t))dt = \infty \quad \text{for } 0 < \alpha < 1, \tag{2.11}$$

then equation (E) *is oscillatory.*

Proof. Based on results in [10] (see [10, Theorem 2.1.1] and [10, Theorem 3.6.3], we see that conditions (2.10) and (2.11), respectively, imply equation (2.3) is oscillatory. The conclusion then follows from Theorem 2.3. □

Corollary 2.11. *Let* $\alpha > 1$, (2.4) *hold, and* u *be a positive decreasing solution of* (2.1). *Then every solution of* (E) *is oscillatory if any of the following conditions hold:*

(i) $\sigma(t) = t - \tau$, $\tau > 0$, *and there exists* $\lambda > \tau^{-1} \ln \alpha$ *such that*

$$\liminf_{t\to\infty} \left[Q(t)B^{\alpha}(\sigma(t)) \exp(-e^{\lambda t}) \right] > 0; \tag{2.12}$$

(ii) $\sigma(t) = \theta t$, $0 < \theta < 1$ *and there exists* $\lambda > -\ln \alpha / \ln \theta$ *such that*

$$\liminf_{t\to\infty} \left[Q(t)B^{\alpha}(\sigma(t)) \exp(-t^{\lambda}) \right] > 0; \tag{2.13}$$

(iii) $\sigma(t) = t^{\theta}$, $0 < \theta < 1$ *and there exists* $\lambda > -\ln \alpha / \ln \theta$ *such that*

$$\liminf_{t\to\infty} \left[Q(t)B^{\alpha}(\sigma(t)) \exp(-(\ln t)^{\lambda}) \right] > 0. \tag{2.14}$$

Proof. The proof follows from Theorem 3(i), Theorem 4(i), and Theorem 5(i) in [16], respectively, along with Theorem 2.9 above. This proves the corollary. □

Before presenting our final theorem, we define the constants

$$\beta_* = \liminf_{t\to\infty} b(t)B(\sigma(t))B(t)Q(t) \quad \text{and} \quad \lambda_* = \liminf_{t\to\infty} \frac{B(t)}{B(\sigma(t))}.$$

Theorem 2.12. *Let* (2.4) *hold and* u *be a positive decreasing solution of* (2.1). *If* $\alpha = 1$ *and*

$$\beta_* > \begin{cases} 0, & \text{if } \lambda_* = \infty, \\ \frac{d+2-\sqrt{(d+2)^2-4d}}{2d}, & \text{if } \lambda_* < \infty, \end{cases} \tag{2.15}$$

where $d = \ln \lambda_*$, *then equation* (E) *is oscillatory.*

Proof. From Corollary 2 and Theorem 4 in [11], we see that equation (2.3) is oscillatory. The conclusion then follows from Theorem 2.3. □

3 Examples

In this section, we present three examples to show the importance and novelty of the main results.

Example 3.1. Consider the second order hybrid differential equation

$$\left(t^{3/2}x'(t)\right)' - \frac{1}{2\sqrt{t}}x(t) + \frac{q_0}{\sqrt{t}}x(\lambda t) = 0, \qquad t \geq 1, \tag{3.1}$$

where $q_0 > 0$, and $\lambda \in (0,1)$. Here we have $a(t) = t^{3/2}$, $q_1(t) = \frac{1}{2\sqrt{t}}$, $q_2(t) = \frac{q_0}{\sqrt{t}}$, $\alpha = 1$, and $\sigma(t) = \lambda t$.

The auxiliary equation (2.1) becomes

$$(t^{3/2}u'(t))' = \frac{1}{2\sqrt{t}}u(t), \qquad t \geq 1$$

which has the positive decreasing solution $u(t) = 1/t$. Thus, $b(t) = t^{-1/2}$, $B(t) = \frac{2}{3}\left(t^{3/2} - 1\right)$, $Q(t) = q_0/(\lambda t^{5/2})$, and $z(t) = tx(t)$.

The transformed binomial form (2.3) of (3.1) is

$$\left(\frac{1}{\sqrt{t}}z'(t)\right)' + \frac{q_0}{\lambda t^{5/2}}z(\lambda t) = 0, \qquad t \geq 1. \tag{3.2}$$

Condition (2.4) clearly holds and condition (2.8) becomes

$$\liminf_{t\to\infty} \frac{2}{3}\left(\lambda^{3/2}t^{3/2} - 1\right)\int_t^\infty \frac{q_0}{\lambda s^{5/2}}ds > \frac{4}{9}\sqrt{\lambda}q_0,$$

so it holds if $q_0 > \frac{9}{16\sqrt{\lambda}}$. Hence, by Theorem 2.8, equation (3.1) is oscillatory if $q_0 > \frac{9}{16\sqrt{\lambda}}$.

In view of condition (2.10), we see that if

$$q_0 > \frac{3}{2e\sqrt{\lambda}\ln\frac{1}{\lambda}},$$

then equation (3.1) is oscillatory.

For $\lambda = 1/4$, the condition (2.8) becomes $q_0 > 9/8$ and the condition (2.11) becomes $q_0 > 0.796107$. Thus, we see that condition (2.11) is better than (2.8).

Also note that equation (3.1) is of the noncanonical type (since $\int_{t_0}^\infty \frac{1}{a(s)}ds < \infty$) whereas the transformed equation (3.2) is in canonical form. Thus, our results apply to noncanonical equations as well as those in canonical form.

Example 3.2. Consider the second order sub-linear hybrid delay differential equation

$$x''(t) - x(t) + e^{\frac{2t}{3}} x^{\frac{1}{3}}(t-\pi) = 0, \qquad t \geq \pi. \tag{3.3}$$

We have $a(t) = 1$, $q_1(t) = 1$, $q_2(t) = e^{\frac{2t}{3}}$, $\alpha = \frac{1}{3}$, and $\sigma(t) = t - \pi$, so the auxiliary equation is

$$u''(t) - u(t) = 0$$

for which $u(t) = e^{-t}$ is a positive decreasing solution. The transformed equation is

$$\left(e^{-2t} z'(t)\right)' + e^{\frac{-2t}{3} + \frac{\pi}{3}} z^{\frac{1}{3}}(t-\pi) = 0, \qquad t \geq \pi.$$

Simple calculations show that $B(t) \approx \frac{e^{2t}}{2}$, $Q(t) = e^{\frac{-2t}{3} + \frac{\pi}{3}}$ and condition (2.11) becomes

$$\int_{\pi}^{\infty} \frac{e^{\frac{-2t}{3} + \frac{\pi}{3}} e^{\frac{2t}{3}}}{2^{\frac{1}{3}}} dt = \infty,$$

so it holds. Therefore, by Corollary 2.10, equation (3.3) is oscillatory.

Example 3.3. Consider the second order super-linear hybrid delay differential equation

$$x''(t) - x(t) + e^{t^2+2t} x^3(t/2) = 0, \qquad t \geq 1. \tag{3.4}$$

Now $a(t) = 1$, $q_1(t) = 1$, $q_2(t) = e^{t^2+2t}$, $\alpha = 3$, and $\sigma(t) = t/2$. The auxiliary equation is

$$u''(t) - u(t) = 0$$

and $u(t) = e^{-t}$ is a positive decreasing solution. The transformed equation is

$$\left(e^{-2t} z'(t)\right)' + e^{t^2-2t} z^3(t/2) = 0, \qquad t \geq 1.$$

Additional calculations give $b(t) = e^{-2t}$, $B(t) \approx \frac{e^{2t}}{2}$, and $Q(t) = e^{t^2 - t/2}$. Choosing $\lambda = 2$ we see that $2 > \ln 3 / \ln 2$. The condition (2.13) becomes

$$\liminf_{t\to\infty} \left[\frac{1}{8} e^{t^2 - t/2} e^{3t} e^{-t^2}\right] = \infty > 0,$$

so it holds. Therefore, by Corollary 2.11(ii), equation (3.4) is oscillatory.

4 Conclusion

In this paper, we studied the oscillatory properties of hybrid delay differential equations of second-order. This is achieved by transforming the equation under consideration to a binomial type equation. Then by applying the comparison method and integral averaging technique, we established conditions for the oscillation of all solutions. None of the results reported in [5, 8, 17] are applicable to Examples 3.1 or 3.3 since these equations contain both positive and negative parts. Thus, the oscillation results presented here are a significant new contribution to the theory of oscillation of trinomial delay differential equations. In a future work, we plan to extend the results in this paper to equations of the form

$$(a(t)x'(t))' + p_1(t)x(t) - p_2(t)x^{\alpha}(\sigma(t)) = 0,$$

where $\sigma(t) \geq t$.

Abstract. This paper presents a systematic method to address the complete stability problem of delayed neural networks with heterogeneous free parameters. First, we adopt an algebraic method to investigate the complete stability problem with respect to the free delay parameter τ. Then, the stability analysis is extended to the scenario with additional free system parameters, denoted by a vector X. We can investigate the complete root classification for the auxiliary characteristic equation in the entire (X, τ)-space. As a result, we can analytically calculate the number of stability τ-intervals and characterize all classifications of stability property over the whole (X, τ)-space. Finally, we will give a systematic method for determining the stability set in the whole (X, τ)-space. Some representative examples show the effectiveness of the approach.

Keywords: neural networks, time delays, stability, complete root classification.

1 Introduction

During the last four decades, the interest in investigating the stability of neural networks (NNs) has steadily increased since the pioneering work of Hopfield (see [19]). Based on the Hopfield NN model, Marcus and Westervelt incorporated time delays in an NN model (see [32]). Since then, various types of delayed NN models have been proposed, and various issues of these models (including stability, periodic solution, and bifurcation, etc.) have been studied extensively by many researchers (see e.g., [1–3, 7, 12, 15, 16, 18, 20, 23, 28, 40, 42, 44, 45, 47]).

The appearance of delays causes a dynamical system to be infinitely dimensional. Hence, the stability analysis for a time delay system will usually be much more complicated than that for a delay-free system (see e.g., [14, 34, 37]).

✉Corresponding author. Email: xuli_89@163.com

From a practical point of view, besides a time delay, a system usually involves a number of parameters. One can design the system parameters to render the system asymptotically stable (see e.g., [36, 41] for the controller design, [22] for the economic system, [48] for the laser system, and [4] for the biological system).

The stability problem becomes much more complex if the system contains the delay free parameter as well as additional system free parameters (i.e., heterogeneous free parameters).

For delayed NNs, the stability set of delay τ subject to the form $\tau \in [0, \overline{\tau})$ is extensively addressed. Such a $\overline{\tau}$ is termed the delay margin (see [14]), a notion widely used in the field of time-delay systems. See, for instance, [5] and [21] for delayed Hopfield NNs, [9] and [38] for delayed bidirectional associative memory (BAM) NNs, and [8] and [46] for delayed NNs with an annular topology.

Recently, the complete stability problem w.r.t. the delay parameter τ* has been studied for NNs in [24]. It is found therein that a delayed NN may have more than one stability τ-interval including or excluding $\tau = 0$.

Nevertheless, the problem considered in [24] contains only a free delay parameter τ. In this paper, for the delayed NN, we will address the complete stability problem with heterogeneous free parameters, including a delay parameter τ and additional system parameters (throughout this paper, we denote them by a vector X).

It will be interesting to see in this paper that the stability parameter space of a delayed NN may have multiple disjoint parts.

As far as we know, the complete stability problem of delayed NNs with heterogeneous free parameters has not been well investigated. In our opinion, the difficulties in studying this problem mainly come from two aspects:

(i) The free parameter space is multiple-dimensional.

(ii) The free parameters are of heterogeneous types.

To the best of the authors' knowledge, the above two technical points can not be appropriately covered by the existing results for delayed NNs. In order to solve such a complete stability problem, we will develop a systematic approach.

First, for the case where τ is the only free parameter, an algebraic approach will be employed for the complete stability analysis w.r.t. τ of the NN.

Notably, the above approach covers the general case (to be explained in Remark 3.7).

Next, in the scenario where the free parameters contain delay parameter τ plus system parameter vector X, we will employ the discrimination system, a mathematical tool for polynomial algebra. Then, we can obtain the complete root classification (CRC) for the auxiliary characteristic equation.

Consequently, we are able to characterize the stability property over the entire (X, τ)-space. To be more precise, we can calculate the possible number of stability τ-intervals and analytically calculate them.

Combining the abovementioned results, we will develop a systematic method to identify the stability set in the whole (X, τ)-space.

This systematic method can contribute to a more refined design process. It offers a possible "stabilization" way such that a pair of (X, τ) can be found under which a practical NN system can be stable.

*We call the problem of analyzing the stability property along the entire positive τ-axis as the complete stability problem w.r.t. τ (see e.g., [26]).

We will present some examples with different NN architectures and show that all classifications of stability property can be characterized in the entire (X, τ)-space by using our approach. It will be seen in the examples that a very small change of the vector X may make the $NU(\tau)$ distribution ($NU(\tau)$ stands for the number of characteristic roots in $\mathbb{C}_+$) have a structural variation.

This paper is organized as follows. In Section 2, three types of delayed NNs and the corresponding characteristic functions are reviewed. The main results are proposed in Section 3. Illustrative examples are presented in Section 4. Finally, the paper concludes in Section 5.

Notations: Throughout the paper, the following standard notations are used. $\mathbb{R}$ ($\mathbb{R}_+$) is the set of (positive) real numbers. $\mathbb{N}$ stands for the set of non-negative integers. $\mathbb{C}$ represents the set of complex numbers. We use $\mathbb{C}_-$ and $\mathbb{C}_+$ respectively to denote the left half-plane and the right half-plane in $\mathbb{C}$. $\deg(\cdot)$ is the degree of a polynomial. Finally, $\lceil \gamma \rceil$ stands for the smallest integer greater than or equal to γ, where $\gamma \in \mathbb{R}$.

2 Neural network models and characteristic functions

We will review in this section three types of delayed NN models, including the Hopfield NN model, the bidirectional associative memory (BAM) NN model, and the NN model with an annular topology. In recent years, these NN models have attracted much attention.

We will show that the local stability is determined by the corresponding characteristic function $f(\lambda, \tau)$.

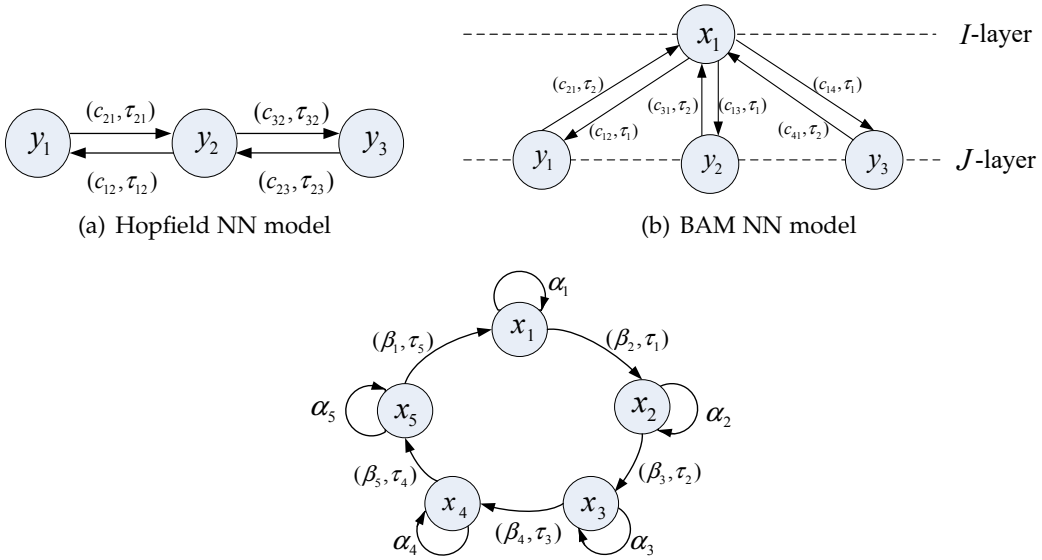
2.1 Delayed Hopfield neural network model

The first model to be recalled in this paper is the delayed Hopfield NN model (see e.g., [5] and [21]):

$$\dot{y}_i(t) = -\mu_i y_i(t) + \sum_{j=1}^{n} c_{ij} f(y_j(t - \tau_{ij})), \qquad i = 1, \ldots, n, \tag{2.1}$$

where $y_i(t)$ stands for the voltage on the input of the i-th neuron at time t; $\mu_i \in \mathbb{R}_+$ is a positive constant; $c_{ij} \in \mathbb{R}$ represents the connection weight of the unit j on the unit i; f is the activation function; $\tau_{ij} \in \mathbb{R}_+ \cup 0$ denotes the signal transmission delay.

Here, we consider a simplified Hopfield NN model, which has three neurons in series (see Fig. 2.1 (a) borrowed from [29]):



$$\begin{cases} \dot{y}_1(t) = -\mu_1 y_1(t) + c_{12} f(y_2(t - \tau_{12})), \\ \dot{y}_2(t) = -\mu_2 y_2(t) + c_{21} f(y_1(t - \tau_{21})) + c_{23} f(y_3(t - \tau_{23})), \\ \dot{y}_3(t) = -\mu_3 y_3(t) + c_{32} f(y_2(t - \tau_{32})), \end{cases} \tag{2.2}$$

where $c_{ij} = 0$ if $i = j$, $f \in C^1$, and $f(0) = 0$.

For the sake of simplicity, we assume that both the loops between neurons have the same sum of delays, i.e., $\tau_{12} + \tau_{21} = \tau_{23} + \tau_{32}$. We denote this value by τ.

It is not hard to see that for NN (2.2), the origin is the equilibrium and the linearization is

$$\begin{cases} \dot{y}_1(t) = -\mu_1 y_1(t) + h_{12} y_2(t - \tau_{12}), \\ \dot{y}_2(t) = -\mu_2 y_2(t) + h_{21} y_1(t - \tau_{21}) + h_{23} y_3(t - \tau_{23}), \\ \dot{y}_3(t) = -\mu_3 y_3(t) + h_{32} y_2(t - \tau_{32}), \end{cases}$$

(a) Hopfield NN model (b) BAM NN model

(c) Annular NN model

Figure 2.1: Architectures of three delayed NN models.

where $h_{ij} = c_{ij}f'(0)$.

The corresponding characteristic function is

$$a_0(\lambda) + a_1(\lambda)e^{-\tau\lambda}, \tag{2.3}$$

where $a_0(\lambda) = \prod_{i=1}^{3}(\lambda+\mu_i)$, $a_1(\lambda) = -(h_{21}h_{12}+h_{23}h_{32})\lambda - h_{21}h_{12}\mu_3 - h_{23}h_{32}\mu_1$. It follows that $\deg(a_0(\lambda)) = 3$ and $\deg(a_1(\lambda)) = 1$.

For such a Hopfield NN model, the coefficients μ_i and h_{ij} are allowed to have free system parameters (as mentioned previously, we denote them by a vector X). In Example 4.1 of this paper, we will choose $X = (h_{21})$ and study the whole stability set in (h_{21},τ)-plane.

2.2 Delayed bidirectional associative memory (BAM) neural network model

Next, we recall the BAM NNs (see e.g., [9] and [38]).

A delayed BAM NN is described by the model

$$\begin{cases} \dot{x}_i(t) = -\mu_i x_i(t) + \sum_{j=1}^{m} c_{ji} f_i(y_j(t-\tau_2)), \\ \dot{y}_j(t) = -\nu_j y_j(t) + \sum_{i=1}^{n} d_{ij} g_j(x_i(t-\tau_1)), \end{cases} \tag{2.4}$$

where $x_i(t)$ and $y_j(t)$ are the state of the neurons in the I-layer and the J-layer at time t, respectively ($i = 1,\dots,n$, $j = 1,\dots,m$, n and m denote the numbers of neurons); f_i and g_j are the activation functions; $c_{ji} \in \mathbb{R}$ and $d_{ij} \in \mathbb{R}$ are the connection weights; τ_1 and τ_2 are the signal transmission delays; $\mu_i \in \mathbb{R}_+$ and $\nu_j \in \mathbb{R}_+$ describe the stability of internal neuron process.

Here, we consider the case where $n = 1$ and $m = 3$ (the architecture of this model is described in Fig. 2.1 (b)).

For simplicity, we redefine $\mu_2 = \nu_1, \mu_3 = \nu_2, \mu_4 = \nu_3$, $c_{21} = c_{11}$, $c_{31} = c_{21}$, $c_{41} = c_{31}$,

$c_{12} = d_{11}$, $c_{13} = d_{12}$, $c_{14} = d_{13}$, $f_2 = g_1$, $f_3 = g_2$, $f_4 = g_3$. Then, the BAM NN model (2.4) reads:

$$\begin{cases} \dot{x}_1(t) = -\mu_1 x_1(t) + c_{21} f_1(y_1(t-\tau_2)) + c_{31} f_1(y_2(t-\tau_2)) + c_{41} f_1(y_3(t-\tau_2)), \\ \dot{y}_1(t) = -\mu_2 y_1(t) + c_{12} f_2(x_1(t-\tau_1)), \\ \dot{y}_2(t) = -\mu_3 y_2(t) + c_{13} f_3(x_1(t-\tau_1)), \\ \dot{y}_3(t) = -\mu_4 y_3(t) + c_{14} f_4(x_1(t-\tau_1)), \end{cases} \tag{2.5}$$

where $f_i \in C^1$ and $f_i(0) = 0, i = 1, 2, 3, 4$.

By letting $u_1(t) = x_1(t-\tau_1), u_2(t) = y_1(t), u_3(t) = y_2(t)$, $u_4(t) = y_3(t)$, and $\tau = \tau_1 + \tau_2$, the BAM NN model (2.5) may be rewritten as the following model

$$\begin{cases} \dot{u}_1(t) = -\mu_1 u_1(t) + c_{21} f_1(u_2(t-\tau)) + c_{31} f_1(u_3(t-\tau)) + c_{41} f_1(u_4(t-\tau)), \\ \dot{u}_2(t) = -\mu_2 u_2(t) + c_{12} f_2(u_1(t)), \\ \dot{u}_3(t) = -\mu_3 u_3(t) + c_{13} f_3(u_1(t)), \\ \dot{u}_4(t) = -\mu_4 u_4(t) + c_{14} f_4(u_1(t)). \end{cases} \tag{2.6}$$

Then, the linearization of the model (2.6) at the equilibrium $(0, 0, 0, 0)$ is

$$\begin{cases} \dot{u}_1(t) = -\mu_1 u_1(t) + h_{21} u_2(t-\tau) + h_{31} u_3(t-\tau) + h_{41} u_4(t-\tau), \\ \dot{u}_2(t) = -\mu_2 u_2(t) + h_{12} u_1(t), \\ \dot{u}_3(t) = -\mu_3 u_3(t) + h_{13} u_1(t), \\ \dot{u}_4(t) = -\mu_4 u_4(t) + h_{14} u_1(t), \end{cases} \tag{2.7}$$

where $h_{ij} = c_{ij} f_j'(0)$.

The corresponding characteristic function is

$$a_0(\lambda) + a_1(\lambda) e^{-\tau\lambda}, \tag{2.8}$$

where $a_0(\lambda) = \lambda^4 + (\mu_1 + \mu_2 + \mu_3 + \mu_4)\lambda^3 + (\mu_1\mu_2 + \mu_3\mu_4 + \mu_1\mu_3 + \mu_1\mu_4 + \mu_2\mu_3 + \mu_2\mu_4)\lambda^2 + (\mu_1\mu_2\mu_3 + \mu_1\mu_2\mu_4 + \mu_1\mu_3\mu_4 + \mu_2\mu_3\mu_4)\lambda + \mu_1\mu_2\mu_3\mu_4$ and $a_1(\lambda) = -(h_{12}h_{21} + h_{13}h_{31} + h_{14}h_{41})\lambda^2 - (h_{12}h_{21}\mu_3 + h_{12}h_{21}\mu_4 + h_{13}h_{31}\mu_2 + h_{13}h_{31}\mu_4 + h_{14}h_{41}\mu_2 + h_{14}h_{41}\mu_3)\lambda - (h_{12}h_{21}\mu_3\mu_4 + h_{13}h_{31}\mu_2\mu_4 + h_{14}h_{41}\mu_2\mu_3)$. It follows that $\deg(a_0(\lambda)) = 4$ and $\deg(a_1(\lambda)) = 2$.

For this BAM NN model, the coefficients μ_i and h_{ij} are allowed to have free system parameters. In Examples 3.12 and 4.2 of this paper, we will choose $X = (h_{12}, h_{21})$ and study the whole stability set in (h_{12}, h_{21}, τ)-space. In Example 4.2, we will also obtain the stability set in the corresponding 4D parameter space.

2.3 Delayed annular neural network model

Finally, we recall the delayed annular NN model (see e.g., [8] and [46]). Now consider the following NN model with five neurons:

$$\begin{cases} \dot{x}_1(t) = -\mu_1 x_1(t) + \alpha_1 f(x_1(t)) + \beta_1 g(x_5(t-\tau_5)), \\ \dot{x}_2(t) = -\mu_2 x_2(t) + \alpha_2 f(x_2(t)) + \beta_2 g(x_1(t-\tau_1)), \\ \dot{x}_3(t) = -\mu_3 x_3(t) + \alpha_3 f(x_3(t)) + \beta_3 g(x_2(t-\tau_2)), \\ \dot{x}_4(t) = -\mu_4 x_4(t) + \alpha_4 f(x_4(t)) + \beta_4 g(x_3(t-\tau_3)), \\ \dot{x}_5(t) = -\mu_5 x_5(t) + \alpha_5 f(x_5(t)) + \beta_5 g(x_4(t-\tau_4)), \end{cases} \tag{2.9}$$

where $x_i(t)$ stands for the voltage on the input of the ith neuron at time t; $\mu_i \in \mathbb{R}_+$ denotes the ratio of the capacitance to the resistance; τ_i represents the signal transmission delay; α_i and β_i are the nonzero connection weights; the activation functions f and g are assumed to satisfy $f, g \in C^1$ and $f(0) = g(0) = 0$.

The above model (2.9) represents the dynamics of a ring of neurons, and the architecture of this model is described in Fig. 2.1 (c).

We now calculate the associated characteristic function.

For NN model (2.9), the origin is the equilibrium and the linearization is

$$\begin{cases} \dot{x}_1(t) = (s_1 - \mu_1)x_1(t) + h_1 x_5(t - \tau_5), \\ \dot{x}_2(t) = (s_2 - \mu_2)x_2(t) + h_2 x_1(t - \tau_1), \\ \dot{x}_3(t) = (s_3 - \mu_3)x_3(t) + h_3 x_2(t - \tau_2), \\ \dot{x}_4(t) = (s_4 - \mu_4)x_4(t) + h_4 x_3(t - \tau_3), \\ \dot{x}_5(t) = (s_5 - \mu_5)x_5(t) + h_5 x_4(t - \tau_4), \end{cases} \tag{2.10}$$

where $s_i = \alpha_i f'(0), h_i = \beta_i g'(0), i = 1, \ldots, 5$.

The corresponding characteristic function is

$$a_0(\lambda) + a_1(\lambda)e^{-\tau\lambda}, \tag{2.11}$$

where $a_0(\lambda) = \prod_{i=1}^{5}(\lambda + \mu_i - s_i)$, $a_1(\lambda) = -\prod_{i=1}^{5}(h_i)$, and $\tau = \sum_{i=1}^{5}\tau_i$. It follows that $\deg(a_0(\lambda)) = 5$ and $\deg(a_1(\lambda)) = 0$.

For such an annular NN model, the coefficients μ_i, s_i, and h_i are allowed to have free system parameters. In Example 4.3 of this paper, we will choose $X = (s_1)$ and study the whole stability set in (s_1, τ)-plane.

2.4 Characteristic function

It is clear that the characteristic functions for abovementioned three types of delayed NNs are subject to the same form

$$f(\lambda, \tau) = a_0(\lambda) + a_1(\lambda)e^{-\lambda\tau}, \tag{2.12}$$

where $a_0(\lambda)$ and $a_1(\lambda)$ ($\deg(a_0(\lambda)) > \deg(a_1(\lambda))$) are polynomials with real coefficients. The coefficients may contain free parameters.

The characteristic function $f(\lambda, \tau)$ is a quasipolynomial, and, unsurprisingly, it also covers many other types of delayed NNs.

The local asymptotic stability of delayed NNs may be analytically determined by the above characteristic function (2.12). More specifically, the delayed NN is locally asymptotically stable if all the characteristic roots are located in the left half-plane $\mathbb{C}_-$.

3 Main results

The complete stability problem w.r.t. the delay parameter τ has been studied for delayed NNs by using a frequency-sweeping approach in a very recent paper (see [24]). It is pointed out that a delayed NN may have more than one stability τ-interval including or excluding $\tau = 0$.

However, the frequency-sweeping approach, as a graphical one, is difficult to apply in the case with additional free system parameters. When a delayed NN has multiple free parameters, we need to study the parameter space and the difficulties mentioned in Introduction arise.

In order to study the complete stability problem of delayed NN with heterogeneous free parameters, we will fulfill a systematic analysis in the whole (X, τ)-space.

More specifically, when τ is the only free parameter, we will adopt an algebraic approach for the complete stability analysis (to be given in Subsection 3.1), and in the case where the free parameters include delay parameter τ plus system parameter vector X, we will adopt a tool for polynomial algebra and develop a method to achieve the CRC of effective W roots (to be given in Subsection 3.2). Finally, we will present a systematic method to detect the stability set in the whole (X, τ)-space (to be given in Subsection 3.3).

3.1 Complete stability problem w.r.t. τ

When τ is the only free parameter, we use $NU(\tau) \in \mathbb{N}$ to denote the number of characteristic roots in $\mathbb{C}_+$. $NU(\tau)$ may increase or decrease only when τ is a critical delay (CD) where the system has a critical imaginary root (CIR) $\lambda = j\omega$, $\omega \in \mathbb{R}$. We call the corresponding pair (λ, τ) a critical pair.

We denote the CIRs as $\lambda_\alpha = j\omega_\alpha$, $\alpha = 0, \ldots, \mathfrak{u} - 1$. Concerning a CIR $\lambda_\alpha = j\omega_\alpha$, the CDs are $\tau_{\alpha,k} = \tau_{\alpha,0} + \frac{2k\pi}{\omega_\alpha}, k \in \mathbb{N}$, where $\tau_{\alpha,0}$ is the minimum CD satisfying

$$e^{-\tau\omega_\alpha j} = -\frac{a_0(j\omega_\alpha)}{a_1(j\omega_\alpha)}. \tag{3.1}$$

For a critical pair $(\lambda_\alpha, \tau_{\alpha,k} > 0)$, the influence of the asymptotic behavior on $NU(\tau)$ can be reflected by the notation $\Delta NU_{\lambda_\alpha}(\tau_{\alpha,k}) \in \mathbb{N}$, representing the variation of $NU(\tau)$ due to λ_α as τ is increased from $\tau_{\alpha,k} - \varepsilon$ to $\tau_{\alpha,k} + \varepsilon$.

First, along the similar idea in [13], we may obtain the following lemma straightforwardly.

Lemma 3.1. *For the characteristic function $f(\lambda, \tau)$ of a delayed NN considered in this paper, there exists a critical imaginary root $\lambda = j\omega \neq 0$ if and only if (iff) the auxiliary characteristic equation $\mathcal{F}(W) = 0$ has a positive real root $W = \omega^2$, where*

$$\begin{aligned} \mathcal{F}(W) &= |a_0(j\omega)|^2 - |a_1(j\omega)|^2 \\ &= (\mathrm{Re}(a_0(j\omega)))^2 + (\mathrm{Im}(a_0(j\omega)))^2 - (\mathrm{Re}(a_1(j\omega)))^2 - (\mathrm{Im}(a_1(j\omega)))^2. \end{aligned} \tag{3.2}$$

Remark 3.2. The application of auxiliary characteristic function can be traced back to [13], with an almost 40-year history. It has been widely used for the stability analysis of time-delay systems. However, the existing methods have the restriction of not being able to address the multiple auxiliary characteristic roots. In the sequel, we will give some results covering the restriction.

For the auxiliary characteristic function (3.2), we are only concerned with the positive real W roots since $W = \omega^2$. Such roots are termed the *effective W roots*, denoted by W_α, $\alpha = 0, \ldots, \mathfrak{u} - 1$, with $W_\alpha = \omega_\alpha^2$. Without any loss of generality, assume that among W_α, there are $q_o \in \mathbb{N}$ ones with odd multiplicities (we denote them by $W_0^o, \ldots, W_{q_o-1}^o$), and $q_e \in \mathbb{N}$ ones with even multiplicities (we denote them by $W_0^e, \ldots, W_{q_e-1}^e$). We label them as:

$$W_0^o > \cdots > W_{q_o-1}^o > 0, \; W_0^e > \cdots > W_{q_e-1}^e > 0. \tag{3.3}$$

For each W_i^o and W_i^e, we use $(\lambda_i^o = j\omega_i^o, \tau_{i,k}^o)$, where $\omega_i^o = \sqrt{W_i^o} > 0$, and $(\lambda_i^e = j\omega_i^e, \tau_{i,k}^e)$, where $\omega_i^e = \sqrt{W_i^e} > 0, k \in \mathbb{N}$, respectively to denote critical pairs. The CDs are $\tau_{i,k}^o = \tau_{i,0}^o + \frac{2k\pi}{\omega_i^o}$ and $\tau_{i,k}^e = \tau_{i,0}^e + \frac{2k\pi}{\omega_i^e}$, respectively.

Lemma 3.3. *For any $\varepsilon > 0$, when W varies slightly near the effective W root of delayed NNs considered in this paper, one of the following three cases must happen:*

Case (1): For a $W = W_i^e$, when W increases from $W_i^e - \varepsilon$ to $W_i^e + \varepsilon$, the $\mathcal{F}(W)$ does not change sign.

Case (2): For a $W = W_i^o$ (i is even), when W increases from $W_i^o - \varepsilon$ to $W_i^o + \varepsilon$, the sign of $\mathcal{F}(W)$ changes from negative to positive.

Case (3): For a $W = W_i^o$ (i is odd), when W increases from $W_i^o - \varepsilon$ to $W_i^o + \varepsilon$, the sign of $\mathcal{F}(W)$ changes from positive to negative.

Proof of Lemma 3.3. In light of Lemma 3.1, it is clear that $\mathcal{F}(W) = 0$ is a polynomial equation. If the polynomial equation has a W_i^e root, the Case (1) is true. For delayed NNs considered in this paper, the characteristic function (2.12) is satisfied with $\deg(a_0(\lambda)) > \deg(a_1(\lambda))$. It can be seen that $\mathcal{F}(W) > 0$ when $W \to \infty$. Hence, Cases (2) and (3) are true. □

Lemma 3.4. *Suppose $\widetilde{W} = (\widetilde{\omega})^2$ is the effective W root of delayed NNs considered in this paper. $(\widetilde{\lambda} = j\widetilde{\omega}, \widetilde{\tau})$ is the critical pair with $f(\widetilde{\lambda}, \widetilde{\tau}) = 0$. As W increases from $\widetilde{W} - \varepsilon$ to $\widetilde{W} + \varepsilon$, we have the following three results.*

(i) $\Delta NU_{j\widetilde{\omega}}(\widetilde{\tau}_k) = 0$ iff the $\mathcal{F}(W)$ does not change sign.

(ii) $\Delta NU_{j\widetilde{\omega}}(\widetilde{\tau}_k) = +1$ iff the sign of $\mathcal{F}(W)$ changes from negative to positive.

(iii) $\Delta NU_{j\widetilde{\omega}}(\widetilde{\tau}_k) = -1$ iff the sign of $\mathcal{F}(W)$ changes from positive to negative.

Proof of Lemma 3.4. First, letting $z = e^{-\lambda\tau}$, we rewrite the characteristic function (2.12) as $p(\lambda, z) = a_0(\lambda) + a_1(\lambda)z$. For each λ, we have a solution of z such that $p(\lambda, z) = 0$. Hence, we can obtain that $z = -a_0(\lambda)/a_1(\lambda)$, denoted by $z(\lambda)$. Here, we suppose $\widetilde{\lambda} = j\widetilde{\omega}$ is a critical imaginary root (calculated by $\mathcal{F}(W) = 0$, $\widetilde{W} = \widetilde{\omega}^2$ is the effective W root). The corresponding critical delays are $\widetilde{\tau}_k = \widetilde{\tau}_0 + \frac{2k\pi}{\widetilde{\omega}}$, where $\widetilde{\tau}_0$ is the minimum critical delay satisfying $z(j\widetilde{\omega}) = e^{-\tau\widetilde{\omega}j} = -a_0(j\widetilde{\omega})/a_1(j\widetilde{\omega})$. It follows that $|z(j\widetilde{\omega})| = 1$.

Next, for a $\widetilde{\lambda}$, it is clear that under a small perturbation $+\varepsilon j$, we hold that $|z(j(\widetilde{\omega} + \varepsilon))| = |a_0(j(\widetilde{\omega} + \varepsilon)/a_1(j(\widetilde{\omega} + \varepsilon)|$. Hence, $|z(j(\widetilde{\omega} + \varepsilon))| - |z(j\widetilde{\omega})| > 0 (< 0)$ iff $|a_0(j(\widetilde{\omega} + \varepsilon))| - |a_1(j(\widetilde{\omega} + \varepsilon))| > 0 (< 0)$, which is the same sign as $\mathcal{F}((\widetilde{\omega} + \varepsilon)^2)$. The above analysis also applies when the small perturbation is $-\varepsilon j$.

Finally, as W increases from $\widetilde{W} - \varepsilon$ to $\widetilde{W} + \varepsilon$ (ω increases from $\widetilde{\omega} - \varepsilon$ to $\widetilde{\omega} + \varepsilon$), in accordance with Section III(B) of [26] and Theorem 1 of [30], we can obtain the value of $\Delta NU_{j\widetilde{\omega}}(\widetilde{\tau}_k)$ by the sign of $|z(j(\widetilde{\omega} + \varepsilon))| - |z(j\widetilde{\omega})|$ and $|z(j(\widetilde{\omega} - \varepsilon))| - |z(j\widetilde{\omega})|$. Then the Lemma 3.4 can be proved. □

Following from Lemma 3.3 and Lemma 3.4, we can obtain the algebraic criterion for the complete stability problem of the delayed NN as follows:

Lemma 3.5. *When $\widetilde{W} = (\widetilde{\omega}_i^+)^2$ ($+$ is "o" or "e") is the effective W root and τ is the only free parameter for the delayed NN considered in this paper, we have the following three results.*

(1) For a $\lambda_i^e = j\widetilde{\omega}_i^e$ ($\widetilde{W} = W_i^e = (\widetilde{\omega}_i^e)^2$), $\Delta NU_{j\widetilde{\omega}_i^e}(\tau_{i,k}^e) = 0$ for all $\tau_{i,k}^e > 0$.

(2) For a $\lambda_i^o = j\widetilde{\omega}_i^o$ ($\widetilde{W} = W_i^o = (\widetilde{\omega}_i^o)^2$) with i is even, $\Delta NU_{j\widetilde{\omega}_i^o}(\tau_{i,k}^o) = +1$ for all $\tau_{i,k}^o > 0$.

(3) For a $\lambda_i^o = j\widetilde{\omega}_i^o$ ($\widetilde{W} = W_i^o = (\widetilde{\omega}_i^o)^2$) with i is odd, $\Delta NU_{j\widetilde{\omega}_i^o}(\tau_{i,k}^o) = -1$ for all $\tau_{i,k}^o > 0$.

(The λ_i^o is also listed in order from largest to smallest, with λ_0^o ($i = 0$) being the largest.)

Remark 3.6. The study on the stability of time-delay systems can be roughly classified into two types, namely a time domain approach and a frequency-domain approach. For the current study by the time-domain approach, the Lyapunov–Krasovskii method [14] is widely used, but it usually yield conservative results and cannot deal with the case when the delay is a free parameter. Besides the Lyapunov-based methods, the CTCR method [35], the direct method [39], and the matrix pencil method [10] can effectively analyze the stability of systems. However, it is difficult to apply these methods to deal with the asymptotic behavior of multiple CIRs.

In this paper, we address the complete stability problem of the delayed NN. Based on the perspective of characteristic root, the stability of systems is studied analytically. The conclusion of our approach is almost non-conservative, and it is very easy to obtain the sufficient and necessary conditions.

Remark 3.7. For the stability analysis of time-delay systems, the asymptotic behavior of multiple CIRs is essential (see e.g., [6, 11, 25, 26, 33]). It was recently pointed out in [25] that the appearance of a multiple and degenerate CIR may cause the system to become 'asymptotically stable' from 'unstable'. As far as we know, in the earlier references of delayed NNs, the case with multiple and/or degenerate CIRs has not been studied. Our method covers the case with multiple and/or degenerate CIRs, as such information is not a technical constraint for Lemma 3.5 (unlike for previous results).

In view of Lemma 3.5, $\Delta NU_{\lambda_\alpha}(\tau_{\alpha,k})$ is a constant belonging to the set $\{-1, 0, +1\}$. Next, we are able to derive the expression of $NU(\tau)$ in view of the root continuity argument.

Theorem 3.8. *Consider a delayed NN under consideration in this paper. For any $\tau > 0$ which is not a critical delay, $NU(\tau)$ for the characteristic equation $f(\lambda, \tau) = 0$ can be explicitly expressed as:*

$$NU(\tau) = NU(+\varepsilon) + \sum_{i=0}^{q_o-1} NU_i^o(\tau), \tag{3.4}$$

$$NU_i^o(\tau) = \begin{cases} 0, \ \tau < \tau_{i,0}^o, \\ 2(-1)^i \left\lceil \frac{\tau - \tau_{i,0}^o}{2\pi/\omega_i^o} \right\rceil, \ \tau > \tau_{i,0}^o, \end{cases} \quad \text{if } \tau_{i,0}^o \neq 0,$$

$$NU_i^o(\tau) = \begin{cases} 0, \ \tau < \tau_{i,1}^o, \\ 2(-1)^i \left\lceil \frac{\tau - \tau_{i,1}^o}{2\pi/\omega_i^o} \right\rceil, \ \tau > \tau_{i,1}^o, \end{cases} \quad \text{if } \tau_{i,0}^o = 0.$$

(In light of Theorem 5.1 in [26], one can calculate the value of $NU(+\varepsilon)$.)

The equilibrium corresponding to the characteristic equation $f(\lambda, \tau) = 0$ is locally asymptotically stable if τ is not a CD and belongs to the set with $NU(\tau) = 0$.

In view of the "$NU(\tau)$ vs. τ" plot, the equilibrium may undergo a Hopf bifurcation (see [17] for the Hopf Bifurcation Theorem) as τ is increased near a CD. The stability interval(s) and bifurcation values of τ can be exhaustively obtained in the whole positive τ-axis.

As mentioned, a delayed NN may contain multiple stability τ-intervals including or excluding $\tau = 0$. Hence, we introduce a notion from [27] that can be applied in the general case.

For the case where τ is the only free parameter, without loss of generality, we assume that the non-empty stability τ-set is subject to the form

$$\tau \in (\underline{\tau}_1, \overline{\tau}_1) \cup \cdots \cup (\underline{\tau}_s, \overline{\tau}_s), \tag{3.5}$$

plus possible $\tau = 0$, with $0 \leq \underline{\tau}_1 < \overline{\tau}_1 < \cdots < \underline{\tau}_s < \overline{\tau}_s$. $\overline{\tau}_s$ is termed the *generalized delay margin*.

Example 3.9. Consider the delayed BAM NN (2.5) with the activation functions $f_i(\cdot) = \tanh(\cdot)$. It is true that $h_{ij} = c_{ij}$. Here, we choose the coefficients as: $\mu_1 = 2.46$, $\mu_2 = 4.5769$, $\mu_3 = 0.8561$, $\mu_4 = 0.9669$, $h_{12} = 4.1$, $h_{13} = -0.3896$, $h_{14} = 2.3488$, $h_{21} = -4.57$, $h_{31} = -2.8466$, and $h_{41} = 0.7057$.

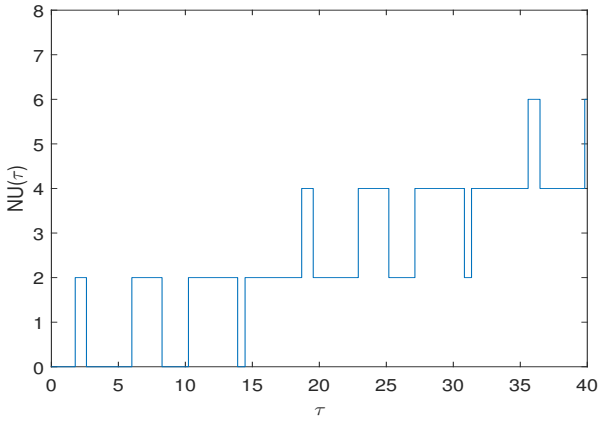
First, we calculate that $NU(0) = 0$ by solving the characteristic equation $f(\lambda, 0) = 0$.

Then, according to Lemma 3.1, we have $\mathcal{F}(W) = W^4 + 28.6674W^3 - 82.5660W^2 - 0.0347W + 69.9926$.

By calculating the roots of equation $\mathcal{F}(W) = 0$, we have two sets of CIRs: $\lambda_0^o = 1.4869j$ (associated with the CDs $\tau_{0,k}^o = 1.7802 + 4.2258k$, $k \in \mathbb{N}$) and $\lambda_1^o = 1.1136j$ (associated with the CDs $\tau_{1,k}^o = 2.6181 + 5.6420k$, $k \in \mathbb{N}$).

Furthermore, we can obtain that $\Delta NU_{\lambda_0^o}(\tau_{0,k}^o) = +1$ and $\Delta NU_{\lambda_1^o}(\tau_{1,k}^o) = -1$ in view of Lemma 3.5. Next, according to Theorem 3.8, we have the "$NU(\tau)$ vs. τ" plot, as shown in Fig. 3.1.

Consequently, we know that the equilibrium is locally asymptotically stable if $\tau \in [0, 1.7802) \cup (2.6181, 6.0059) \cup (8.2602, 10.2317) \cup (13.9022, 14.4575)$ and that a Hopf bifurcation may occur when $\tau = 1.7802$, 2.6181, 6.0059, 8.2602, 10.2317, 13.9022 and 14.4575. To verify the above analysis, we give the simulations for $\tau = 1.2$ (in the first stability τ-interval) in Fig. 3.2 (a), Fig. 3.2 (d) and Fig. 3.3 (a), $\tau = 2.3$ (between the first and the second stability τ-intervals) in Fig. 3.2 (b), Fig. 3.2 (e) and Fig. 3.3 (b), and $\tau = 5$ (in the second stability τ-interval) in Fig. 3.2 (c), Fig. 3.2 (f) and Fig. 3.3 (c).



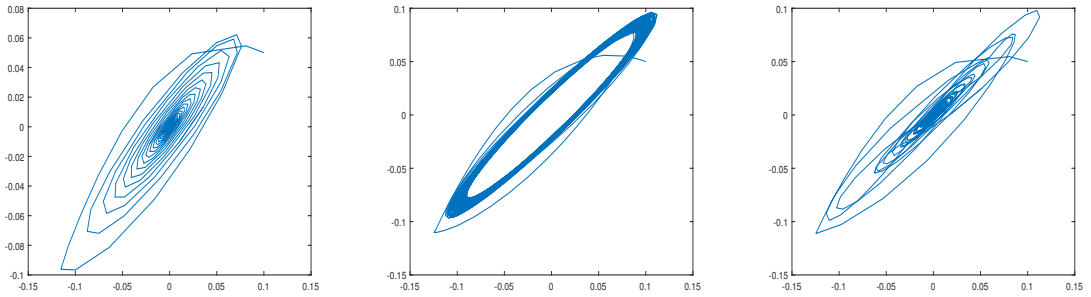


Figure 3.1: $NU(\tau)$ vs. τ for Example 3.9.

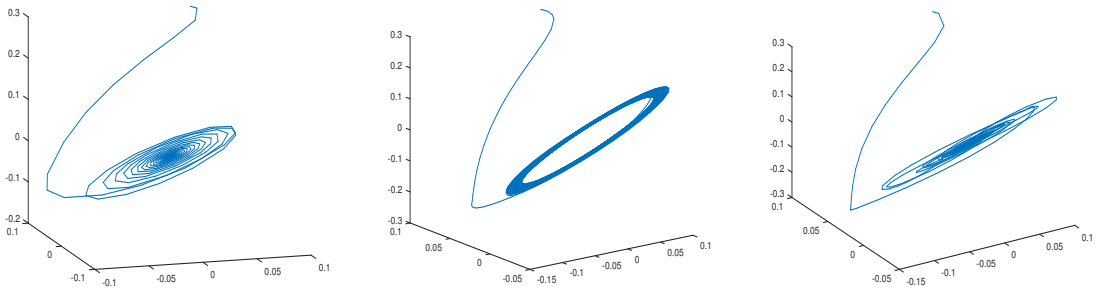
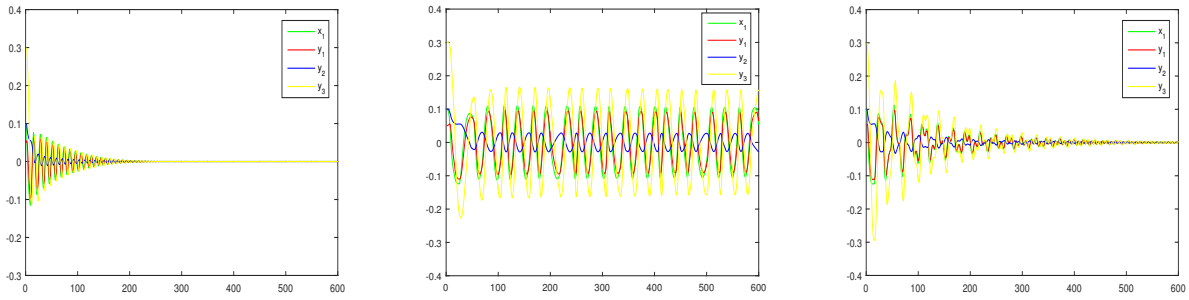


3.2 Complete root classification (CRC) of effective W roots

We proceed to address the scenario with additional free system parameters. In order to appropriately address such a case, we now investigate the real W root classification and the effective W root classification. The real (effective) W root classification refers to the information about the numbers and multiplicities of different real (effective) W roots. The complete root classification (CRC) of real (effective) W roots is the collection of all possible real (effective) W root classifications.

In the sequel, we recall a mathematical tool, termed the *discrimination system* (one may refer to [31] and [43] for details).



(a) $x_1 - y_1$ plane with $\tau = 1.2$ (b) $x_1 - y_1$ plane with $\tau = 2.3$ (c) $x_1 - y_1$ plane with $\tau = 5$

(d) $y_1 - y_2 - y_3$ space with $\tau = 1.2$ (e) $y_1 - y_2 - y_3$ space with $\tau = 2.3$ (f) $y_1 - y_2 - y_3$ space with $\tau = 5$

Figure 3.2: Phase portraits for Example 3.9.

(a) $\tau = 1.2$ (b) $\tau = 2.3$ (c) $\tau = 5$

Figure 3.3: Simulations for Example 3.9.

Let $\mathcal{Q}(z)$ be a polynomial with real coefficients,

$$\mathcal{Q}(z) = \zeta_q z^q + \zeta_{q-1} z^{q-1} + \cdots + \zeta_0, \zeta_q \neq 0. \tag{3.6}$$

The $2q \times 2q$ matrix $M =$

$$\begin{pmatrix}
\zeta_q & \zeta_{q-1} & \zeta_{q-2} & \cdots & \zeta_0 & & & \\
0 & q\zeta_q & (q-1)\zeta_{q-1} & \cdots & \zeta_1 & & & \\
 & \zeta_q & \zeta_{q-1} & \cdots & \zeta_1 & \zeta_0 & & \\
 & 0 & q\zeta_q & \cdots & 2\zeta_2 & \zeta_1 & & \\
 & & & \vdots & \vdots & & & \\
 & & & \zeta_q & \zeta_{q-1} & \zeta_{q-2} & \cdots & \zeta_0 \\
 & & & 0 & q\zeta_q & (q-1)\zeta_{q-1} & \cdots & \zeta_1
\end{pmatrix}$$

is the *discrimination matrix* of $\mathcal{Q}(z)$.

The determinant of the submatrix of M consisting of the first 2α rows and the first 2α columns $(\alpha = 1, \ldots, q)$ is represented by D_α. We call the *discriminant sequence* of $\mathcal{Q}(z)$ as $D = [D_1, \ldots, D_q]$.

In light of the signs of $D_1, \ldots, D_q$, we can obtain the sign list $[\text{sign}(D_1), \ldots, \text{sign}(D_q)]$ (sign(x)= 1(0)[-1] if $x > 0 (= 0)[< 0]$) and then the revised sign list for $\mathcal{Q}(z)$ (see [31] for more details).

Without loss of generality, let $\mathcal{F}(W)$ (3.2) be a qth-order polynomial

$$\mathcal{F}(W) = \psi_q W^q + \psi_{q-1} W^{q-1} + \cdots + \psi_0, \psi_q \neq 0, \tag{3.7}$$

where $\psi_q, \psi_{q-1}, \ldots, \psi_0$ are coefficients. These coefficients are allowed to be functions of the free system parameters denoted by the vector X.

As for the delayed Hopfield NN model where $\deg(a_0(\lambda)) = 3$, the sign list of $\mathcal{F}(W)$ is [sign(D_1),sign(D_2),sign(D_3)]. If sign(D_2) = 0, the revised sign list is [sign(D_1), -1, sign(D_3)]. Otherwise, the revised sign list is exactly the sign list.

As for the delayed BAM NN model where $\deg(a_0(\lambda)) = 4$, the sign list of $\mathcal{F}(W)$ is [sign(D_1),sign(D_2),sign(D_3),sign(D_4)]. If sign(D_i) = 0, $i = 2, 3$, the revised sign list is listed in Table 3.1. Otherwise, the revised sign list is exactly the sign list.

sign(D_i) = 0	The revised sign list
sign(D_2) = 0	[sign(D_1), -1, sign(D_3), sign(D_4)]
sign(D_3) = 0	[sign(D_1), sign(D_2), -1, sign(D_4)]
sign(D_2) = 0 and sign(D_3) = 0	[sign(D_1), -1, -1, sign(D_4)]

Table 3.1: The revised sign list with sign(D_i) = 0, $i = 2, 3$ for the delayed BAM NN model.

As for the delayed annular NN model where $\deg(a_0(\lambda)) = 5$, the sign list of $\mathcal{F}(W)$ is [sign(D_1),sign(D_2),sign(D_3),sign(D_4),sign(D_5)]. If sign(D_i) = 0, $i = 2, 3, 4$, the revised sign list is listed in Table 3.2. Otherwise, the revised sign list is exactly the sign list.

sign(D_i) = 0	The revised sign list
sign(D_2) = 0	[sign(D_1), -1, sign(D_3), sign(D_4), sign(D_5)]
sign(D_3) = 0	[sign(D_1), sign(D_2), -1, sign(D_4), sign(D_5)]
sign(D_4) = 0	[sign(D_1), sign(D_2), sign(D_3), -1, sign(D_5)]
sign(D_2) = 0 and sign(D_3) = 0	[sign(D_1), -1, -1, sign(D_4), sign(D_5)]
sign(D_2) = 0 and sign(D_4) = 0	[sign(D_1), -1, sign(D_3), -1, sign(D_5)]
sign(D_3) = 0 and sign(D_4) = 0	[sign(D_1), sign(D_2), -1, -1, sign(D_5)]
sign(D_2) = 0, sign(D_3) = 0, and sign(D_4) = 0	[sign(D_1), -1, -1, 1, sign(D_5)]

Table 3.2: The revised sign list with sign(D_i) = 0, $i = 2, 3$ for the delayed BAM NN model.

Proposition 3.10 ([43]). *Suppose that the revised sign list of $\mathcal{F}(W)$ has l non-vanishing members and the number of sign changes is v. It follows that the number of distinct real roots of $\mathcal{F}(W)$ is $l - 2v$.*

For example, if the revised sign list for $\mathcal{F}(W)$ is $[1,1,-1]$, then $v=1$, $l=3$, and $\mathcal{F}(W)$ has $l-2v=1$ real W root. If the revised sign list for $\mathcal{F}(W)$ is $[1,1,1,0]$, then $v=0$, $l=3$, and F(W) has $l-2v=3$ distinct real W roots. If the revised sign list for $\mathcal{F}(W)$ is $[1,-1,-1,1,0]$, then $v=2$, $l=4$, and $\mathcal{F}(W)$ has $l-2v=0$ real W root.

Applying the discrimination system to $\mathcal{F}(W)$ (3.7), one can obtain the discriminant sequence $D=[D_1,\ldots,D_q]$ and then the CRC of real W roots.

As earlier mentioned, we are only concerned with the positive real W roots (since $W=\omega^2$), i.e., the effective W roots. We will present a method to examine the CRC of effective W roots.

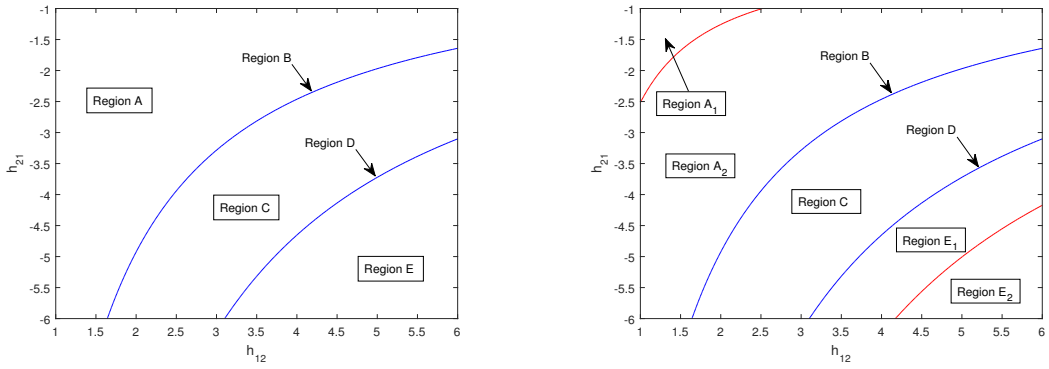
Theorem 3.11. *For the auxiliary characteristic function $\mathcal{F}(W)$ (3.7), consider a region partitioned in view of the CRC of real W roots. If the set $\psi_0=0$ separates this region into some subregions in X space, then the positive real W root classification keeps unchanged in each subregion. Otherwise, in the whole region, the positive real root classification remains unchanged.*

Proof of Theorem 3.11. For $\mathcal{F}(W)$, there exists a root $W=0$ iff $\psi_0=0$. If a point in X space continuously moves in a region partitioned in view of the CRC of real W roots, all the real W roots' signs remain unchanged if it does not cross the set $\psi_0=0$. □

For each region partitioned in accordance with the CRC of real W roots, we can obtain the effective W root classifications. According to Theorem 3.11, for each region not separated (or subregion separated) by the set $\psi_0=0$, we can select any point to solve $\mathcal{F}(W)=0$ and this point represents the effective W root classification for all the points in the region (subregion).

We follow the notations adopted in [43]. For example: "$\{1,1,1,1\}$" stands for four different simple real W roots; "$\{2,1,1\}$" stands for one double real W root plus two simple real W roots; "$\{\ \}$" stands for no real W root. Furthermore, the effective W root classification is represented by $\{\cdot,\ldots,\cdot\}^+$. For example, if a real root classification $\{2,1,1\}$ involves one double *negative* real W root and two different simple *positive* real W roots, it is represented by $\{1,1\}^+$ (two different simple effective W roots).

Example 3.12. Consider the delayed BAM NN of Example 3.9. Here, we choose h_{12} and h_{21} as free system parameters, i.e., $X=(h_{12},h_{21})$. For simplicity, we study the case $(h_{12},h_{21})\in[1,6]\times[-6,-1]$.



First, according to Lemma 3.1, we obtain $\mathcal{F}(W)=W^4+28.6674W^3+(172.4842-(h_{12}h_{21}+2.7666)^2)W^2+((1.6555h_{12}h_{21}+22.8053)(h_{12}h_{21}+2.7666)-(1.8230h_{12}h_{21}+15.1537)^2+229.9256)W+86.8611-(0.8278h_{12}h_{21}+11.4027)^2$.

Then, applying the discrimination system, the discriminant sequence of $\mathcal{F}(W)$ is $[D_1,D_2,D_3,D_4]$, where $D_1=4$, $D_2=8h_{12}^2h_{21}^2+44.2653h_{12}h_{21}+1146.8204$, $D_3=8h_{12}^6h_{21}^6+132.7960h_{12}^5h_{21}^5-316.9872h_{12}^4h_{21}^4+2920.3114h_{12}^3h_{21}^3+114921.2317h_{12}^2h_{21}^2+801885.8568h_{12}h_{21}+8309682.1306$, and $D_4=0.1632h_{12}^{10}h_{21}^{10}+11.7962h_{12}^9h_{21}^9+1602.5531h_{12}^8h_{21}^8+46407.3671h_{12}^7h_{21}^7+418378.3143h_{12}^6h_{21}^6+2094423.4796h_{12}^5h_{21}^5+46116871.4106h_{12}^4h_{21}^4+738951226.2778h_{12}^3h_{21}^3+6714650368.4108h_{12}^2h_{21}^2+40072389757.5584h_{12}h_{21}+111789468423.0607$.

For this example, $D_1>0$, $D_2>0$ (one may easily prove it), D_3 and D_4 may represent different signs w.r.t. $X=(h_{12},h_{21})$. We can obtain the CRC of real W roots and thereby partition the selected domain into five regions, as shown in Fig. 3.4 (a).

Region A with $\{1,1,1,1\}$: $D_3>0\cap D_4>0$; Region B with $\{2,1,1\}$: $D_3>0\cap D_4=0$; Region C with $\{1,1\}$: $(D_3>0\cap D_4<0)\cup(D_3=0\cap D_4<0)\cup(D_3<0\cap D_4<0)$; Region D with $\{2,1,1\}$: $D_3>0\cap D_4=0$; Region E with $\{1,1,1,1\}$: $D_3>0\cap D_4>0$.

Second, the set $\psi_0=0$, i.e., the set $86.8611-(0.8278h_{12}h_{21}+11.4027)^2=0$, corresponds to the red curves in Fig. 3.4 (b).

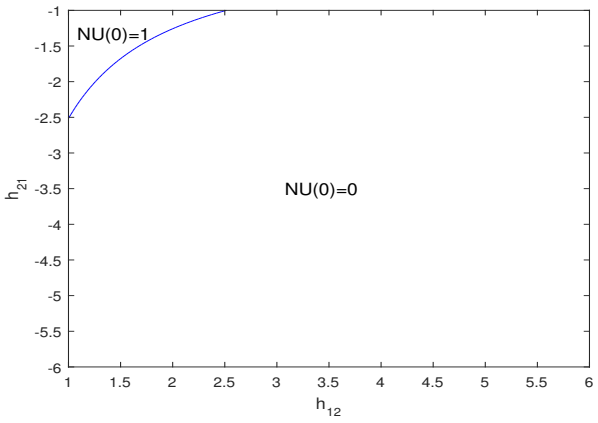
(a) Real W root classifications (b) Effective W root classifications

Figure 3.4: CRCs of real and effective W roots.

Region A is separated by the set $\psi_0 = 0$ into subregions A_1 and A_2, and Region E is separated by the set $\psi_0 = 0$ into subregions E_1 and E_2.

In accordance with Theorem 3.11, we have the following results: Region A_1: $\{1,1,1,1\} \to \{1\}^+$; Region A_2: $\{1,1,1,1\} \to \{\ \}^+$; Region B: $\{2,1,1\} \to \{\ \}^+$; Region C: $\{1,1\} \to \{\ \}^+$; Region D: $\{2,1,1\} \to \{2\}^+$; Region E_1: $\{1,1,1,1\} \to \{1,1\}^+$; Region E_2: $\{1,1,1,1\} \to \{1\}^+$.

Furthermore, we can combine Regions A_2, B, and C into one region, labeled by Region $B^{'}$. Consequently, we may partition the domain into five regions: Regions A_1, $B^{'}$, D, E_1, and E_2. Region D is the boundary between Regions $B^{'}$ and E_1, whose analytic condition is $D_3 > 0 \cap D_4 = 0$.



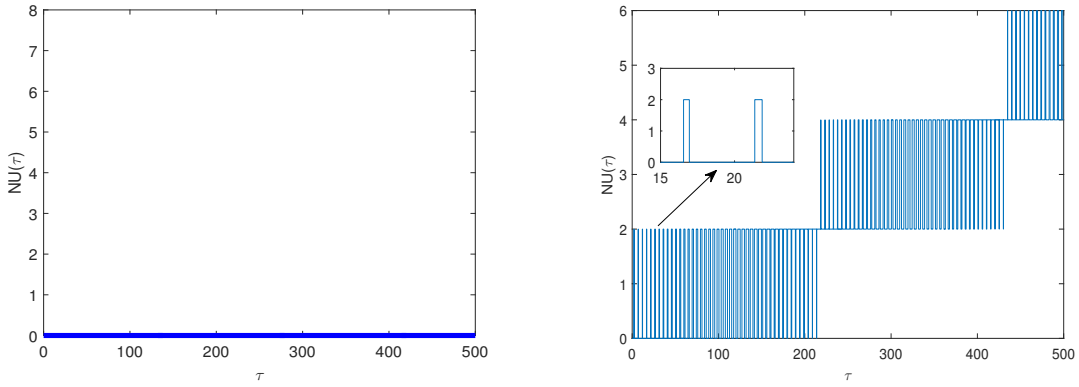


Figure 3.5: $NU(0)$ distribution w.r.t. (h_{12}, h_{21}) for Example 3.12.

Next, based on the equation $f(\lambda, 0) = 0$, $NU(0)$ distribution w.r.t. (h_{12}, h_{21}) is obtained (see Fig. 3.5).

According to the above analysis, we can obtain the following results:

(1) In Region A_1 $(NU(0) = 1)$: As there does not exist an effective W root, the system is not asymptotically stable for any $\tau \in [0, +\infty)$.

(2) In Region $B^{'}$ $(NU(0) = 0)$: As there does not exist an effective W root, the system is delay-independently stable.

(a) $h_{21} = -4.5396$ (b) $h_{21} = -4.5397$

Figure 3.6: $NU(\tau)$ vs. τ for Example 3.12.

(3) On Region D $(NU(0) = 0)$: As there exists a double effective W root, the system is asymptotically stable for all $\tau \geq 0$ except at the CDs.

(4) In Region E_1 $(NU(0) = 0)$: As there exist two simple effective W roots, the system may contain more than one stability τ-interval including $\tau = 0$.

(5) In Region E_2 $(NU(0) = 0)$: As there exists one simple effective W root, the system has only one stability τ-interval of the form $[0, \overline{\tau}_1)$.

For illustrations, we choose a point $(h_{12} = 4.1, h_{21} = -4.5396)$ in Region B' and a point $(h_{12} = 4.1, h_{21} = -4.5397)$ in Region E_1. The corresponding "$NU(\tau)$ vs. τ" plots are shown in Fig. 3.6 (a) and Fig. 3.6 (b), respectively. We can see that the $NU(\tau)$ distribution undergoes a structural variation due to a very small change of h_{21}.

Remark 3.13. The analytic condition for the boundary of different effective W root classifications is available. As the $NU(\tau)$ distribution does not have a structural variation inside a region with identical effective W root classification, we may study the $NU(\tau)$ distribution by employing the parameter-sweeping technique. It is worth noting that such a technique is not for the qualitative test, and hence it is not necessary to set a very fine grid in practice.

3.3 Systematic approach for determining stability set in (X, τ)-space

Based on Theorems 3.8 and 3.11, we now propose a systematic approach to investigate the stability of delayed NNs in the (X, τ)-space, consisting of the following steps.

Step 0: Linearize the delayed NN under consideration at the equilibrium and calculate the characteristic function $f(\lambda, \tau)$. Next, obtain the analytic expression of auxiliary characteristic function $\mathcal{F}(W)$.

Step 1: Obtain the CRC of real W roots in the entire X space with the aid of discrimination system.

Step 2: Determine all possible effective W root classifications in accordance with Theorem 3.11 in the whole X space.

Step 3: Obtain the $NU(0)$ distribution in the X space.

Step 4: Scan the X space. For each point, investigate the complete stability problem w.r.t. τ using Theorem 3.8.

With the steps above, we are able to determine the stability set in the entire (X,τ)-space. Moreover, we can characterize all classifications of stability property in the entire (X,τ)-space.

4 Illustrative examples

In this section, we will give some examples with different NN architectures to illustrate the proposed approach. We adopt the widely-used hyperbolic tangent functions as the activation functions, i.e., $f_i(\cdot)=\tanh(\cdot)$, $g_i(\cdot)=\tanh(\cdot)$, $i=1,2,\ldots,n$. Then, $f_i(0)=g_i(0)=0$ and $f_i'(0)=g_i'(0)=1$, $i=1,2,\ldots,n$.

We will show that an NN with different coefficients can exhibit different classifications of stability property. It is worth mentioning that a very small change of the vector X may make the $NU(\tau)$ distribution have a structural variation, which may alter the classification of stability property. This phenomenon demonstrates the necessity of dividing the parameter space.

Example 4.1. Consider the delayed Hopfield NN (2.2). With the activation functions adopted in this section, it is true that $h_{ij}=c_{ij}$. Here, we choose the coefficients as: $\mu_1=1.4147, \mu_2=1.0102, \mu_3=0.4610, h_{12}=1.5176, h_{23}=-1.4432, h_{32}=0.9080$. We let $X=(h_{21})$.

Step 0: The characteristic function is given by (2.3). In light of Lemma 3.1, we have $\mathcal{F}(W)=W^3+3.2344W^2+(-2.3031h_{21}^2+3.9774h_{21}+0.9674)W-0.4895h_{21}^2+2.5940h_{21}-3.0027$.

Step 1: The discriminant sequence is $[D_1,D_2,D_3]$, where $D_1=3$, $D_2=13.8187h_{21}^2-23.8644h_{21}+15.1182$, and $D_3=48.8657h_{21}^6-253.1688h_{21}^5+490.2890h_{21}^4-623.2539h_{21}^3+742.0196h_{21}^2-443.8572h_{21}+0.0105$.

For this example, $D_1>0$, $D_2>0$ (one may easily prove it), and D_3 may represent different signs w.r.t. h_{21}. We can obtain the CRC of real W roots: (1) {1,1,1} iff $h_{21}\in(-\infty,0.00002373)\cup(1.265628,1.766693)\cup(2.341787,+\infty)$ (where $D_3>0$); (2) {1} iff $h_{21}\in(0.00002373,1.265628)\cup(1.766693,2.341787)$ (where $D_3<0$); (3) {2,1} iff $h_{21}\in\{0.00002373,1.265628,1.766693,2.341787\}$ (where $D_3=0$).

Step 2: When $\psi_0=0$, i.e., $-0.4895h_{21}^2+2.5940h_{21}-3.0027=0$, we can calculate that $h_{21}=1.708129$ or $h_{21}=3.591537$. Hence, the intervals $(1.265628,1.766693)$ and $(2.341787,+\infty)$ are respectively separated into $(1.265628,1.708129)$, $(1.708129,1.766693)$, $(2.341787,3.591537)$, and $(3.591537,+\infty)$.

Furthermore, in light of Theorem 3.11, we can obtain the CRC of effective W roots:

(1) $h_{21}\in(-\infty,1.708129)\cup(3.591537,+\infty)$, $\{1\}^+$;

(2) $h_{21}\in(1.708129,2.341787)$, $\{\ \}^+$;

(3) $h_{21}=\{2.341787\}$, $\{2\}^+$;

(4) $h_{21}\in(2.341787,3.591537)$, $\{1,1\}^+$.

Step 3: We analyze the $NU(0)$ distribution w.r.t. h_{21} by solving the characteristic equation $f(\lambda,0)=0$. We have that when $h_{21}\in(-\infty,2.342233)$, $NU(0)=0$.

In view of the above analysis, we have the following results:

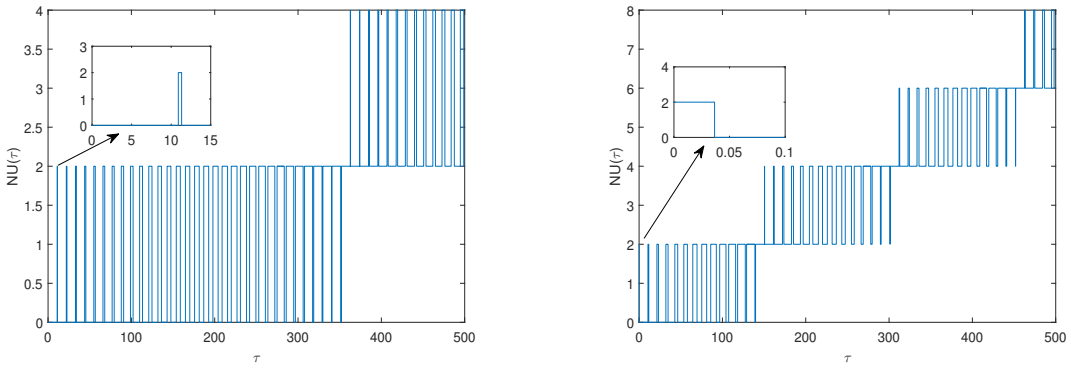
(1) The system contains only 1 stability τ-interval of the form $[0,\overline{\tau}_1)$ iff $h_{21}\in(-\infty,1.708129)$;

(2) The system is delay-independently stable iff $h_{21} \in (1.708129, 2.341787)$;

(3) The system is asymptotically stable for all $\tau \geq 0$ except at the CDs iff $h_{21} = 2.341787$;

(4) The system may contain more than one stability τ-interval including $\tau = 0$ iff $h_{21} \in (2.341787, 2.342233)$;

(5) The system may contain stability τ-interval(s) excluding $\tau = 0$ iff $h_{21} \in (2.342233, 3.591537)$;



(6) The system has no stability τ-interval iff $h_{21} \in (3.591537, +\infty)$.

It can be seen that all classifications of stability property can be characterized in the whole (h_{21},τ)-plane. To illustrate the above results and to show the qualitative change of stability property, we next choose some values of h_{21} and give the detailed results.

At point $h_{21} = 1.70$, the system contains only 1 stability τ-interval $[0, 32.1647)$. At point $h_{21} = 1.71$, the system is delay-independently stable.

At point $h_{21} = 2.342$, the system has 32 stability τ-intervals including $\tau = 0$ and the generalized delay margin is 351.8083. At point $h_{21} = 2.343$, the system has 13 stability τ-intervals excluding $\tau = 0$ and the generalized delay margin is 139.7930. To intuitively show the difference, we give "$NU(\tau)$ vs. τ" plots in Fig. 4.1 (a) and Fig. 4.1 (b), respectively.

At point $h_{21} = 3.59$, the system contains only 1 stability τ-interval $(2.4170, 2.9154)$. At point $h_{21} = 3.60$, no stability τ-interval exists.

(a) $h_{21} = 2.342$ (b) $h_{21} = 2.343$

Figure 4.1: $NU(\tau)$ vs. τ for Example 4.1.

Step 4: We can address the whole (h_{21},τ)-plane and exhaustively determine the stability set. For a clear demonstration, we provide the stability set with $(h_{21}, \tau) \in [-2, 5] \times [0, 50]$ in Fig. 4.2. □

Example 4.2. For the delayed BAM NN (2.5) in Example 3.12, we here choose a domain $(h_{12}, h_{21}) \in [4.1, 4.7] \times [-4.9, -4.57]$ for a clear illustration. Scan the (h_{12}, h_{21})-plane, and for each point we calculate the stability set by using Theorem 3.8. Then we can exhaustively determine the stability set, as shown in Fig. 4.3.

It is interesting to see in Fig. 4.3 that the stability parameter space of the delayed BAM NN has multiple disjoint parts.

Using the approach proposed in Subsection 3.3, we can also obtain the stability set in the corresponding 4-D parameter space, as reflected in Fig. 4.4. We here choose a domain

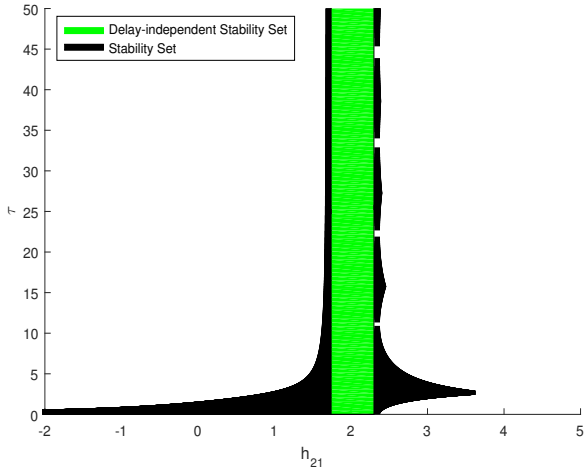


Figure 4.2: Stability set in the (h_{21}, τ)-plane for Example 4.1.

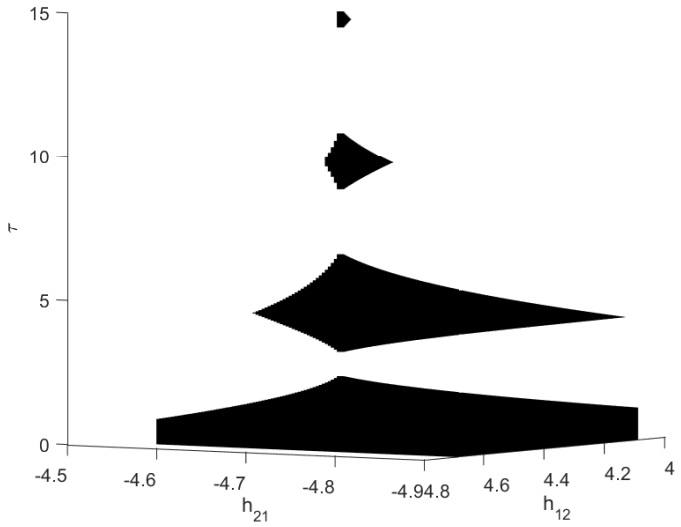

Figure 4.3: Stability set in the (h_{12}, h_{21}, τ)-space for Example 4.2.

$(h_{12}, h_{13}, h_{14}) \in [4.1, 4.2] \times [-0.38, -0.36] \times [2.2, 2.4]$ and the color information represents the generalized delay margin. Here, the maximum generalized delay margin is 14.5923. □

Example 4.3. Consider the delayed annular NN (2.9) with coefficients as in [8] and [46]: $\mu_i = 2, \alpha_i = 1, i = 1, \ldots, 5$, $\beta_1 = 2, \beta_2 = 1, \beta_3 = 1, \beta_4 = 1.3$, and $\beta_5 = -0.5$.

With the activation functions adopted in this section, it is true that $s_i = \alpha_i$ and $h_i = \beta_i$. Here, we let $X = (s_1)$.

Step 0: The characteristic function is given by (2.11). In light of Lemma 3.1, we have that $\mathcal{F}(W) = W^5 + (s_1^2 - 4s_1 + 8)W^4 + (4s_1^2 - 16s_1 + 22)W^3 + (6s_1^2 - 24s_1 + 28)W^2 + (4s_1^2 - 16s_1 + 17)W + s_1^2 - 4s_1 + 2.31$.

Step 1: The discriminant sequence is $[D_1, D_2, D_3, D_4, D_5]$, where $D_1 = 5$, $D_2 = 4s_1^4 - 32s_1^3 + 88s_1^2 - 96s_1 + 36$, $D_3 = 0$, $D_4 = -285.61s_1^4 + 2284.88s_1^3 - 6283.42s_1^2 + 6854.64s_1 - 2570.49$, and $D_5 = -1235.6631s_1^{10} + 24713.2621s_1^9 - 216241.0432s_1^8 + 1087383.5315s_1^7 - 3472213.3222s_1^6 +$

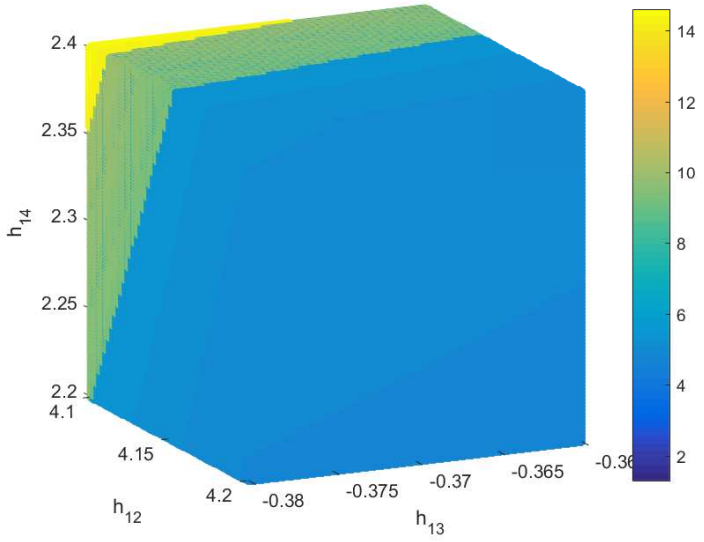

Figure 4.4: Generalized delay margin w.r.t. (h_{12}, h_{13}, h_{14}).

$7344781.4902s_1^5 - 10416639.9667s_1^4 + 9786451.7837s_1^3 - 5838508.1664s_1^2 + 2001774.2285s_1 - 274774.5492$.

For this example, $D_1 > 0$, $D_2 \geq 0$, $D_3 = 0$, $D_4 \leq 0$ (one may easily prove the properties concerning the signs of D_2 and D_4), and D_5 may represent different signs w.r.t. s_1. We can obtain the CRC of real W roots: (1) {1,1,1} iff $s_1 \in (-\infty, 0.3172) \cup (3.6828, +\infty)$ (in the case $D_1 > 0, D_2 > 0, D_3 = 0, D_4 < 0, D_5 < 0$); (2) {1} iff $s_1 \in (0.3172, 3.6828)$ (in the case $D_1 > 0, D_2 > 0, D_3 = 0, D_4 < 0, D_5 > 0$ or $D_1 > 0, D_2 = 0, D_3 = 0, D_4 = 0, D_5 > 0$); (3) {2,1} iff $s_1 \in \{0.3172, 3.6828\}$ (in the case $D_1 > 0, D_2 > 0, D_3 = 0, D_4 < 0, D_5 = 0$).

Step 2: When $\psi_0 = 0$, i.e., $s_1^2 - 4s_1 + 2.31 = 0$, we can calculate that $s_1 = 0.7$ or $s_1 = 3.3$. Hence, the interval $(0.3172, 3.6828)$ is separated into $(0.3172, 0.7)$, $(0.7, 3.3)$, and $(3.3, 3.6828)$.

Furthermore, in light of Theorem 3.11, we can obtain the CRC of effective W roots:

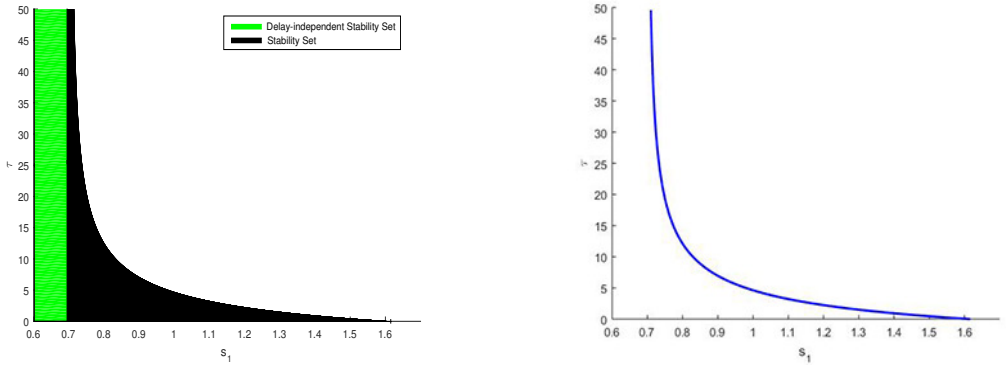
(1) $s_1 \in (0.7, 3.3)$, $\{1\}^+$;

(2) $s_1 \in (-\infty, 0.7) \cup (3.3, +\infty)$, $\{\}^+$.

Step 3: We analyze the $NU(\tau)$ distribution w.r.t. s_1 through solving the characteristic equation $f(\lambda, 0) = 0$. We have that when $s_1 \in (-\infty, 1.6138356)$, $NU(0) = 0$.

In view of the above analysis, we have that there are three classifications of stability property as described below:

(1) The system is delay-independently stable iff $s_1 \in (-\infty, 0.7)$;



(2) The system contains only one stability τ-interval of the form $[0, \overline{\tau}_1)$ iff $s_1 \in (0.7, 1.6138356)$;

(3) The system has no stability τ-interval iff $s_1 \in (1.6138356, +\infty)$.

Step 4: We can study the whole (s_1,τ)-plane and exhaustively determine the stability set. For a clear demonstration, we provide the stability set with $(s_1, \tau) \in [0.6, 1.7] \times [0, 50]$ in Fig. 4.5 (a).

It can be seen that the system has one stability τ-interval iff $s_1 \in (0.7, 1.6138356)$. The boundary of the corresponding stability region is shown in Fig. 4.5 (b).

To illustrate our analysis, we choose some values of s_1 and analyze the stability of the system. We list the details in Table 4.1. □

(a) Stability set (b) Boundary of stability set

Figure 4.5: Stability set and the boundary curve for Example 4.3.

s_1	stability τ-set	s_1	stability τ-set	s_1	stability τ-set
0.69	$[0,+\infty)$	0.99	$[0,4.7956)$	1.61	$[0,0.0139)$
0.71	$[0,49.4106)$	1	$[0,4.6174)$	1.62	ϕ
0.72	$[0,33.4746)$	1.01	$[0,4.4477)$	1.63	ϕ

Table 4.1: Stability τ-set for Example 4.3.

5 Conclusion and future work

In this paper, we considered the stability of delayed neural networks (NNs) with a free delay parameter τ and a free system parameter vector X. As far as we know, the complete stability problem of delayed NNs involving heterogeneous free parameters has not been well investigated.

We proposed a systematic method to investigate the stability in the (X,τ)-space. As a consequence, we can exhaustively determine the stability set in the whole (X,τ)-space. The effectiveness of the approach is illustrated by some numerical examples. It is interesting to see that the stability parameter space of a delayed NN may have multiple disjoint parts.

Based on the research of this paper, we may further investigate more general delayed NNs. In this paper, we focus on the case where the characteristic functions are in the form $f(\lambda,\tau) = a_0(\lambda) + a_1(\lambda)e^{-\tau\lambda}$. A more general form is $f(\lambda,\tau) = a_0(\lambda) + a_1(\lambda)e^{-\tau\lambda} + \cdots + a_q(\lambda)e^{-q\tau\lambda}$, where $a_0(\lambda),\ldots,a_q(\lambda)$, $q \in \mathbb{N}_+$, are polynomials. The stability analysis when $q > 1$ will be much more complicated. In the future, we would extend the approach to such a case.

Communicated by Mihály Kovács

Abstract. We establish that uniformly exponentially stable random dynamical systems on the half line have equivalent dynamics through a C^m-conjugacy. This result was obtained for random differential equations as well as for random dynamical systems with a uniformly exponentially stable linear part.

Keywords: random dynamical systems, topological equivalence, smooth equivalence, Carathéodory differential equations, stochastic differential equations.

2020 Mathematics Subject Classification: 37H05, 37H15, 37C15, 37D05.

1 Introduction

The Hartman–Grobman theorem is a fundamental result in the local theory of dynamical systems. It establishes a connection between the qualitative behavior of a nonlinear system and its linearization around an equilibrium point. The classical theorem states that if a nonlinear system possesses a hyperbolic equilibrium point, then the qualitative behavior of the system near the equilibrium point is topologically equivalent to that of its linearization.

The original theorem was obtained by Philip Hartman [20, 21] and David Grobman [18] independently in the 1960s. It has since become a cornerstone of dynamical systems theory. This theorem provides a powerful tool for analyzing, e.g., stability of nonlinear systems by reducing the problem to the study of linear systems.

It should be mentioned that the standard framework in Hartman–Grobman theory relies on a fundamental assumption about the hyperbolicity of the linearized system. However, when eigenvalues lie on the imaginary axis, the dynamics can undergo significant changes. For this reason, the original paper on the linearization theorem has inspired pioneering work and extensive research, leading to numerous generalizations and extensions.

Speaking about generalizations, it is important to mention results for autonomous systems in Banach spaces [32,35], linearization for nonautonomous problems [28,33,34] and results for Carathéodory-type differential equations in Banach spaces [3].

In recent years, there has been growing interest in extending the Hartman–Grobman theorem to the case of random dynamical systems. These systems incorporate the effects of

✉Corresponding author. Email: iryna.vasylieva@aau.at

stochasticity or randomness into the evolution of dynamical systems (see, e.g., [1,14,17]), and are particularly relevant in modeling real-world phenomena where uncertainties or random perturbations play a significant role. The generalization of the Hartman–Grobman theorem to random dynamical systems aims to establish similar qualitative connections between the behavior of a nonlinear system and its linearization in the presence of random perturbations. The goal is to understand how the stability properties, attractors, and bifurcations of the deterministic system are affected by the stochastic components. Accordingly, extensions of the Hartman–Grobman theorem to random dynamical systems go back to the works by Arnold [1] resulting from Wanner [44]. As in the deterministic case, there are many generalizations of the random linearization theorem, for instance, in [25,26,47], and others.

In linearization theory, a compelling research question revolves around investigating the smoothness properties of the linearization map, since this allows a better understanding of the information that is carried from one system to another. Smooth linearization ensures that invariant manifolds and their geometric structures, such as stable and unstable tangent directions, are consistently preserved. This is important for accurately capturing the flow near fixed points, periodic orbits, or other invariant sets, allowing to study complex dynamics in a simplified framework. This research problem is widely explored in deterministic settings. For example, in [7,37,39] Hölder properties of linearization homeomorphisms were established. The C^1-linearization result for contractions has been obtained in [5,38,46]. Significant contributions in the higher order smoothness within the autonomous context are the results of Sternberg [42,43], who proved that under certain non-resonance conditions the local conjugation between two systems can actually be a C^m map. Later, Belickii [8,9] achieved the same result under assumptions related to the spectrum of the diffeomorphism that defines the dynamics.

The authors in [11] delved into the differentiability properties within a particular case of Palmer's linearization theorem [33], particularly when restricting the problem to the nonnegative real line. Within this framework, sufficient conditions ensuring that the conjugating map is a C^2-preserving orientation diffeomorphism were obtained. These conditions were established under the premise that the linear system was uniformly asymptotically stable. Recent generalizations and improvements of this result were presented in [12].

Like in deterministic scenarios, the smoothness properties of the conjugating map in random dynamical systems were equally intriguing. At this point, it is worth mentioning the paper [4], where conditions for Hölder continuity of the conjugacies on bounded subsets for infinite-dimensional random dynamical systems with a non-invertible linear part were established.

In the paper [6], the Hölder continuity of conjugacy for both maps and flows was established. Notably, the analysis demonstrated that such continuity could be achieved without imposing any nonresonance condition. In [27], a proof of a $C^{1,\beta}$ generalization of the random Hartman–Grobman theorem was presented. Additionally, temperedness for the conjugacy was obtained, further enhancing the understanding of the relationship between random dynamical systems and their associated linearizations.

In [36], stochastic differential equations (SDEs) with non-Gaussian Lévy processes for two-sided time were studied. Topological equivalence between these SDEs and transformed random differential equations (RDEs) with Lévy processes was established. This allowed for a stochastic Hartman–Grobman theorem for the linearization of SDEs to be proved.

The aim of the present paper is to derive sufficient conditions for C^m-linearizations of random dynamical systems on the nonnegative half-line. The advantage of considering the

positive half-line is that no information about the past is required, allowing the focus to be solely on future dynamics. Specifically, the main contribution of the paper can be considered a generalization of the approach proposed in [12] in several directions.

Firstly, in the class of Carathéodory differential equations. Carathéodory-type models include, for instance, random differential equations [1,14] where the time dependence is often irregular and non-smooth, as well as control systems [16] with control functions that are merely measurable in time and not necessarily smooth. The generality of the Carathéodory framework makes it particularly well suited for modeling real-world systems with time-irregular behavior. Within this setting, we not only derived sufficient conditions for the topological equivalence of the nonlinear equation and its linearization, but also provided additional information about the conjugating map. Specifically, we established that the conjugating map is globally Lipschitz and belongs to the class C^m. These results hold for arbitrary (possibly infinite-dimensional) Banach spaces.

Secondly, in the class of random dynamical systems generated by random differential equations, we obtained both global and local C^m-linearization results. These results were derived under the assumption that the underlying Banach space is finite-dimensional and provide the foundation to extend our analysis to the class of random dynamical systems generated by stochastic differential equations (SDEs). To achieve smooth linearization results for random dynamical systems generated by SDEs, we leveraged the connection between random differential equations (RDEs) and SDEs established in [22].

The paper is arranged as follows. In the remaining part of this section, we introduce the basic notations and definitions needed throughout the paper. Section 2 focuses on semilinear Carathéodory equations, where we establish the smooth topological equivalence results, including sufficient conditions for C^m-linearizations and detailed properties of the conjugating map. In Section 3, we apply these results to the setting of random dynamical systems. Specifically, we analyze systems generated by random differential equations (RDEs) and stochastic differential equations (SDEs), leveraging the connection between RDEs and SDEs to derive smooth C^m-linearization results for the corresponding random dynamical systems. The Appendix contains some key theorems used in proving our results.

1.1 Preliminaries

Throughout the paper, let $I \subseteq \mathbb{R}$ be an interval unbounded from above, X be a Banach space equipped with a norm $\|\cdot\|$, $L(X)$ is the space of linear operator on X, and $(\Omega, \mathfrak{F})$ be a measurable space. Moreover, let $\{\|\cdot\|_{t,\omega}\}_{t\in I,\,\omega\in\Omega}$ denote a family of norms on X such that

(i) the mapping $(t,\omega,x) \mapsto \|x\|_{t,\omega}$ is strongly measurable,

(ii) there exists a measurable mapping $\ell : I \times \Omega \to (0,\infty)$ such that $\ell(\cdot,\omega)$ is locally bounded and

$$\frac{1}{\ell(t,\omega)}\,\|x\| \le \|x\|_{t,\omega} \le \ell(t,\omega)\,\|x\| \quad \text{for all } t \in I,\ \omega \in \Omega,\ x \in X. \tag{1.1}$$

Furthermore, for a linear operator $T \in L(X)$ we define

$$\|T\|_{s,t,\omega} := \sup_{\|x\|_{s,\omega}=1} \|Tx\|_{t,\omega} \quad \text{for all } s,t \in I,\ \omega \in \Omega,$$

and obtain $\|Tx\|_{t,\omega} \le \|T\|_{s,t,\omega}\,\|x\|_{s,\omega}$ for all $t,s \in I$ and $x \in X$.

Given this, a function $\mu : I \to X$ is called *bounded* (for $\omega \in \Omega$), if

$$\|\mu\|_\omega := \sup_{t\in I} \|\mu(t)\|_{t,\omega} < \infty.$$

We write $BC_\omega(I, X)$ for the set of all bounded and continuous functions $\mu : I \to X$, which equipped with the norm $\|\cdot\|_\omega$ becomes a Banach space.

We denote $f : I \times X \to Y$ as *Carathéodory function*, Y being another Banach space, provided the following hold:

- $f(\cdot, x) : I \to Y$ is strongly measurable for each $x \in X$ (w.r.t. the Borel σ-algebras on I and X),
- $f(t, \cdot) : X \to Y$ is continuous for almost all $t \in I$.

Let $f : I \times X \times \Omega \to X$ be a mapping such that for every choice of $\omega \in \Omega$ the mapping $f(\cdot, \cdot, \omega) : I \times X \to X$ has the Carathéodory property. Then the equation

$$\dot{x} = f(t, x, \omega) \tag{1.2}$$

is called an *ω-dependent Carathéodory differential equation,* and an absolutely continuous mapping $\phi : J \to X$ is called a *solution* of (1.2) (to the parameter ω), if the mapping $f(\cdot, \phi(\cdot), \omega)$ is locally integrable and the identity

$$\phi(t) = \phi(\tau_0) + \int_{\tau_0}^{t} f(s, \phi(s), \omega)ds \tag{1.3}$$

holds for all $\tau_0, t \in J$, where $J \subseteq I$ is a subinterval. If in addition the mapping ϕ satisfies the condition $\phi(\tau) = \xi$ then we say that ϕ solves the initial value problem for $\tau, \xi \in X$.

The next lemma bridges the integral and differential formulations of solutions to the Carathéodory equation, providing a tool for analyzing these solutions within a functional-analytic framework.

Lemma 1.1. *An absolutely continuous mapping $\phi\colon J \to X$ solves (1.2) if and only if $\dot{\phi}(t) = f(t, \phi(t), \omega)$ for almost all $t \in J$.*

The following theorem presents the results on existence, uniqueness and continuous dependence of solutions on initial values and parameters.

Theorem 1.2 ([2, Thm. 2.4, p. 49], [10])**.** *Let $f : I \times X \times \Omega \to X$ be a mapping such that, for every $\omega \in \Omega$, the mapping $f(\cdot, \cdot, \omega) : I \times X \to X$ satisfies the Carathéodory property. Furthermore, let $l, l_0 : I \to \mathbb{R}_0^+$ be locally integrable functions such that the two estimates*

$$\|f(t, x, \omega) - f(t, \bar{x}, \omega)\| \le l(t)\|x - \bar{x}\|,$$
$$\|f(t, 0, \omega)\| \le l_0(t)$$

hold for almost all $t \in I$ and for all $x, \bar{x} \in X$ and $\omega \in \Omega$.

Then for any $(\tau, \xi, \omega_0) \in I \times X \times \Omega$ the differential equation (1.2) has a unique solution $\phi(\cdot; \tau, \xi, \omega_0) : I \to X$ to the parameter value ω_0, satisfying the initial condition $x(\tau) = \xi$, and the so-defined mapping $\phi(\cdot, \cdot, \cdot, \omega) : I \times I \times X \to X$ is continuous.

The mapping $\varphi : I \times I \times X \times \Omega \to X$ provided by Theorem 1.2 is called a *general solution* of differential equation (1.2). For all $\tau, t_1, t_2 \in I, \xi \in X$ and $\omega \in \Omega$, this mapping satisfies the two-parameter group property

$$\varphi(t_2; \tau, \xi, \omega) = \varphi(t_2; t_1, \varphi(t_1; \tau, \xi, \omega), \omega). \tag{1.4}$$

2 Semilinear Carathéodory equations

In this section, we focus on semilinear Carathéodory differential equations with parameter and investigate their topological equivalence to linear systems. Specifically, we aim to derive sufficient conditions for smooth linearization of class C^m.

Let $I \subseteq \mathbb{R}$ be an interval unbounded from above and $(\Omega, \mathfrak{F})$ be a measurable space, $A_\omega : I \to L(X)$ be locally integrable and $F_\omega : I \times X \to X$ with a given $\omega \in \Omega$.

Consider the system of semilinear Carathéodory differential equations with parameter $\omega \in \Omega$

$$\dot{x} = A_\omega(t)x + F_\omega(t,x). \tag{N}$$

Together with the system (N) consider a linear system

$$\dot{x} = A_\omega(t)x. \tag{L}$$

Lemma 2.1 ([2, Lemma 2.9, p. 56])**.** *Let $\phi_\omega : I \times I \times X \to X$ denote the general solution of the linear equation (L). Then for any $s,t \in I$ the mapping $\Phi_\omega : I \times I \to L(X)$,*

$$\Phi_\omega(t,s) := \phi_\omega(t;s,\cdot),$$

is called the evolution operator of (L) and satisfies the following properties:

(i) each $\Phi_\omega(t,s)$, $s,t \in I$ is an element of the group $GL(X)$ of invertible operators in $L(X)$ and the mapping $\Phi_\omega : I \times I \to GL(X)$ is continuous;

(ii) the identities

$$\begin{aligned} \Phi_\omega(t,t) &= \mathrm{Id}_X, \\ \Phi_\omega(t,s) &= \Phi_\omega(t,r)\Phi_\omega(r,s), \\ \Phi_\omega(t,s)^{-1} &= \Phi_\omega(s,t) \end{aligned}$$

hold for all $r,s,t \in I$.

2.1 Topological linearization

Assume that the following assumptions hold for all $\omega \in \Omega$

(H_1) $A_\omega : I \to L(X)$ is locally integrable and there exist reals $K(\omega) \geq 1$ and $\alpha > 0$ such that

$$\|\Phi_\omega(t,s)\|_{s,t,\omega} \leq K(\omega)e^{-\alpha(t-s)} \quad \text{for all } t,s \in I,\ s \leq t. \tag{2.1}$$

(H_2^0) $F_\omega : I \times X \to X$ is a Carathéodory function and there exist reals $L(\omega), M(\omega) \geq 0$ such that

$$F_\omega(t,0) = 0, \tag{2.2}$$

$$\|F_\omega(t,x)\|_{t,\omega} \leq M(\omega), \tag{2.3}$$

$$\|F_\omega(t,x) - F_\omega(t,\bar{x})\|_{t,\omega} \leq L(\omega)\,\|x - \bar{x}\|_{t,\omega} \tag{2.4}$$

for almost all $t \in I$ and all $x, \bar{x} \in X$.

It is easy to verify that under assumptions (H_1), (H_2^0), the semilinear equation (N) satisfies the assumptions of Theorem 1.2 with $f(t,x,\omega) = A_\omega(t)x + F_\omega(t,x)$, $l(t) := \|A_\omega(t)\| + L(\omega)$ and $l_0(t) = 0$. Then, for every initial condition $x(\tau) = \xi$ and fixed $\omega \in \Omega$ there exists exactly one solution of (N) on I. From now, we denote the general solution of (N) by φ_ω.

Before delving into the main result, let us first introduce some technical lemmas. Throughout the paper, $\tau_0 \in \mathbb{R}$ is fixed and $\tau \in I := [\tau_0, \infty)$.

Lemma 2.2 (the operator $\mathcal{L}_\omega$)**.** *If (H_1) holds, then*

$$\mathcal{L}_\omega : I \times X \to BC_\omega(I,X), \qquad \mathcal{L}_\omega(\tau,\xi) := \Phi_\omega(\cdot,\tau)\xi$$

defines an operator such that $L_\omega(\tau,\cdot)$ is bounded and linear for all $\tau \in I$, $\omega \in \Omega$. Moreover, for all $\omega \in \Omega$ and $\xi \in X$, the following holds:

(i) $(\tau,\xi) \mapsto \mathcal{L}_\omega(\tau,\xi)$ *is continuous,*

(ii) $\mathcal{L}_\omega(\tau,\xi) : I \to X$ *is absolutely continuous.*

Proof. Let $\omega \in \Omega$, $\tau \in I$, and $\xi \in X$. Then $\Phi_\omega(\cdot,\tau)\xi : I \to X$ solves the initial value problem $\dot{x} = A_\omega(t)x$, $x(\tau) = \xi$, and is therefore absolutely continuous.

Without loss of generality, let $\tilde{\tau} \le \tau \le t$. To prove the continuity of the map $(\tau,\xi) \mapsto \mathcal{L}_\omega(\tau,\xi)$, consider the following expression:

$$\begin{aligned}\|\mathcal{L}_\omega(\tau,\xi) - \mathcal{L}_{,\omega}(\tilde{\tau},\xi_0)\|_{t,\omega} &\le \|\Phi_\omega(t,\tau)\xi - \Phi_\omega(t,\tau)\xi_0\|_{t,\omega} + \|\Phi_\omega(t,\tau)\xi_0 - \Phi_\omega(t,\tilde{\tau})\xi_0\|_{t,\omega} \\ &\le K(\omega)e^{-\alpha(t-\tau)}\|\xi - \xi_0\| + \|\Phi_\omega(t,\tau) - \Phi_\omega(t,\tilde{\tau})\|_{t,\omega}\|\xi_0\|.\end{aligned}$$

From the continuous dependence of $\Phi_\omega(t,\tau)$ on the initial time τ, it follows that for any $\varepsilon > 0$, there exists $\delta > 0$ such that if $|\tau - \tilde{\tau}| + \|\xi - \xi_0\| < \delta$, then

$$\|\mathcal{L}_\omega(\tau,\xi) - \mathcal{L}_\omega(\tilde{\tau},\xi_0)\|_{t,\omega} \le K(\omega)\delta + \|\xi_0\|\,\varepsilon \le \tilde{\varepsilon},$$

where $\tilde{\varepsilon}$ can be made arbitrarily small. Therefore, the continuity of $(\tau,\xi) \mapsto \mathcal{L}_\omega(\tau,\xi)$ follows.

Moreover, one has

$$\begin{aligned}\|[\mathcal{L}_\omega(\tau,\xi)](t)\|_{t,\omega} = \|\Phi_\omega(t,\tau)\xi\|_{t,\omega} &\overset{(2.1)}{\le} K(\omega)e^{-\alpha(t-\tau)}\|\xi\|_{\tau,\omega} = K(\omega)e^{-\alpha(t-\tau_0)}e^{\alpha(\tau-\tau_0)}\|\xi\|_{\tau,\omega} \\ &\le K(\omega)e^{\alpha(\tau-\tau_0)}\|\xi\|_{\tau,\omega} \overset{(1.1)}{\le} K(\omega)e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)\|\xi\| \quad \text{for all } \tau_0 \le t \qquad (2.5)\end{aligned}$$

and passing to the supremum over $t \in I$ yields $\|\mathcal{L}_\omega(\tau,\xi)\|_\omega \le K(\omega)e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)\|\xi\|$, which is the claim. □

Lemma 2.3 (the operator $\mathcal{F}_\omega$)**.** *If (H_1) and (H_2^0) hold, then the nonlinear operator*

$$\mathcal{F}_\omega : BC_\omega(I,X) \to BC_\omega(I,X), \qquad \mathcal{F}_\omega(\phi) := \int_{\tau_0}^{\cdot} \Phi_\omega(\cdot,s)F_\omega(s,\phi(s))\,ds \qquad (2.6)$$

is well-defined, and, for all $\phi, \bar{\phi} \in BC_\omega(I,X)$, $\omega \in \Omega$ satisfies

$$\|\mathcal{F}_\omega(\phi) - \mathcal{F}_\omega(\bar{\phi})\|_\omega \le \frac{K(\omega)L(\omega)}{\alpha}\|\phi - \bar{\phi}\|_\omega, \qquad (2.7)$$

$$\|\mathcal{F}_\omega(\phi)\|_\omega \le \frac{K(\omega)M(\omega)}{\alpha}. \qquad (2.8)$$

Proof. Let $\omega \in \Omega$ and $\phi, \bar{\phi} \in BC_\omega(I,X)$. Then $\int_{\tau_0}^{\cdot} \Phi_\omega(\cdot,s)F_\omega(s,\phi(s))\,ds$ solves the linearly inhomogeneous initial value problem $\dot{x} = A_\omega(t)x + F_\omega(t,\phi(t))$, $x(\tau_0) = 0$. Moreover,

$$\begin{aligned}\|\mathcal{F}_\omega(\phi)(t)\|_{t,\omega} &\le \int_{\tau_0}^{t} \|\Phi_\omega(t,\tau)\|_{s,t,\omega}\,\|F_\omega(s,\phi(s))\|_{s,\omega}\,ds \overset{(2.1)}{\le} K(\omega)\int_{\tau_0}^{t} e^{-\alpha(t-s)}\,\|F_\omega(s,\phi(s))\|_{s,\omega}\,ds \\ &\overset{(2.3)}{\le} K(\omega)M(\omega)\int_{\tau_0}^{t} e^{-\alpha(t-s)}\,ds \le \frac{K(\omega)M(\omega)}{\alpha} \quad \text{for all } \tau_0 \le t,\end{aligned}$$

and passing to the supremum over $t \in I$ yields $\mathcal{F}_\omega(\phi) \in BC_\omega(I,X)$.

Furthermore,

$$\begin{aligned}\|\mathcal{F}_\omega(\phi)(t) - \mathcal{F}_\omega(\bar{\phi})(t)\|_{t,\omega} &\le \int_{\tau_0}^{t} \|\Phi_\omega(t,\tau)\|_{s,t,\omega}\,\|F_\omega(s,\phi(s)) - F_\omega(s,\bar{\phi}(s))\|_{s,\omega}\,ds \\ &\overset{(2.1)}{\le} K(\omega)\int_{\tau_0}^{t} e^{-\alpha(t-s)}\,\|F_\omega(s,\phi(s)) - F_\omega(s,\bar{\phi}(s))\|_{s,\omega}\,ds \\ &\overset{(2.4)}{\le} K(\omega)L(\omega)\int_{\tau_0}^{t} e^{-\alpha(t-s)}\,\|\phi(s) - \bar{\phi}(s)\|_{s,\omega}\,ds \\ &\le \frac{K(\omega)L(\omega)}{\alpha}\,\|\phi - \bar{\phi}\|_{\omega} \quad \text{for all } \tau_0 \le t.\end{aligned}$$

Passing to the supremum over $t \in I$ yields (2.7) for all $\phi, \bar{\phi} \in BC_\omega(I,X)$. Finally, $\mathcal{F}(\phi)$ is absolutely continuous. □

Theorem 2.4 (topological linearization of (N))**.** *If* (H_1) *and* (H_2^0) *hold with*

$$K(\omega)L(\omega) < \alpha,$$

then there exists a map $H_\omega : I \times X \to X$ *such that, for every* $\omega \in \Omega$, $s,t \in I$*:*

(i) $H_\omega(t,\cdot)$ *is a homeomorphism on* X *with* $H_\omega(t,0) = 0$*;*

(ii) the linear equation (L) *and the semilinear equation* (N) *are conjugated in the sense that*

$$H_\omega(t,\Phi_\omega(t,s)\cdot) = \varphi_\omega(t,s,H_\omega(s,\cdot));$$

(iii) the operators $H_\omega(t,\cdot)$ *and its inverse are near identity, i.e. for all* $\xi \in X$, $\eta \in X$*:*

$$\|H_\omega(t,\xi) - \xi\|_{t,\omega} \le \frac{K(\omega)M(\omega)}{\alpha} \quad \text{and} \quad \left\|H_\omega(t,\cdot)^{-1}(\eta) - \eta\right\|_{t,\omega} \le \frac{K(\omega)M(\omega)}{\alpha};$$

(iv) the operators $H_\omega(t,\cdot) : X \to X$ *and its inverse satisfy a global Lipschitz condition;*

(v) the operators $H_\omega : I \times X \to X$ *and* $(t,x) \mapsto H_\omega^{-1}(t,\cdot)(x)$ *are continuous.*

We denote H_ω *as a (topological) conjugacy between the semilinear equation* (N) *and its linear part* (L)*.*

Proof. For clarity of presentation, we carry out the proof in four steps.

Step 1. We fix $\tau \in I, \omega \in \Omega$. Let us define $\mathcal{T}_\omega : BC_\omega(I,X) \times X \to BC_\omega(I,X)$ as

$$\mathcal{T}_\omega(\phi;\xi,\tau) := \mathcal{F}_\omega(\phi + \mathcal{L}_\omega(\tau,\xi)), \tag{2.9}$$

where $\mathcal{F}_\omega : BC_\omega(I,X) \to BC_\omega(I,X)$ is introduced in Lemma 2.3 and $\mathcal{L}_\omega : X \to BC_\omega(I,X)$ is introduced in Lemma 2.1. We have

$$\begin{aligned}\|\mathcal{T}_\omega(\phi;\xi,\tau)-\mathcal{T}_\omega(\bar\phi;\xi,\tau)\|_\omega &\overset{(2.9)}{=}\|\mathcal{F}_\omega(\phi+\mathcal{L}_\omega(\tau,\xi))-\mathcal{F}_\omega(\bar\phi+\mathcal{L}_\omega(\tau,\xi))\|_\omega\\ &\overset{(2.7)}{\leq}\frac{K(\omega)L(\omega)}{\alpha}\|\phi-\bar\phi\|_\omega\end{aligned}$$

for all $\phi,\bar\phi\in BC_\omega(I,X)$. Hence, $\mathcal{T}_\omega$ is a contraction uniformly in $\xi\in X$ and in $\tau\in I$ and by uniform contraction principle (Theorem A.4) there is a unique fixed point $\varphi^*_{\tau,\omega}(\xi)\in BC_\omega(I,X)$ of $\mathcal{T}_\omega(\cdot;\xi,\tau)$ for all $\xi\in X$, $\tau\in I$ and the mapping $(\tau,\xi)\mapsto\varphi^*_{\tau,\omega}(\xi)$ is continuous.

Moreover,

$$\begin{aligned}\left\|\mathcal{T}_\omega(\phi;\xi,\tau)-\mathcal{T}_\omega(\phi;\bar\xi,\tau)\right\|_{\tau,\omega} &\overset{(2.9)}{=}\left\|\mathcal{F}_\omega(\phi+\mathcal{L}_\omega(\tau,\xi))-\mathcal{F}_\omega(\phi+\mathcal{L}_\omega(\tau,\bar\xi))\right\|_{\tau,\omega}\\ &\overset{(2.7)}{\leq}\frac{K(\omega)L(\omega)}{\alpha}\left\|\mathcal{L}_\omega(\tau,\xi)-\mathcal{L}_\omega(\tau,\bar\xi)\right\|_{\tau,\omega}\\ &\overset{(2.5)}{\leq}\frac{K^2(\omega)L(\omega)}{\alpha}e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)\left\|\xi-\bar\xi\right\|.\end{aligned}\tag{2.10}$$

This leads us to conclude that $\mathcal{T}_\omega(\phi,\cdot,\tau)$ is Lipschitz with Lipschitz constant $\frac{K^2(\omega)L(\omega)}{\alpha}e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)$. Therefore, the mapping $\xi\mapsto\varphi^*_{\tau,\omega}(\xi)$ is also Lipschitz with Lipschitz constant $\frac{K^2(\omega)L(\omega)e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)}{\alpha-K(\omega)L(\omega)}$.

Furthermore, we show that $\varphi^*_{\tau,\omega}(\xi)$ satisfies the identity

$$\varphi^*_{\tau,\omega}(\xi)=\varphi^*_{r,\omega}(\Phi_\omega(r,\tau)\xi)\tag{2.11}$$

for all $\xi\in X$ and almost all $\tau,r\in I$.

Indeed,

$$\varphi^*_{\tau,\omega}(\xi)=\int_{\tau_0}^t\Phi_\omega(t,s)F_\omega(s,\varphi^*_{\tau,\omega}(\xi)(s)+\Phi_\omega(t,\tau)\xi)\,ds$$

is a unique solution to the initial value problem $\dot x=A_\omega(t)x+F_\omega(t,x+\Phi_\omega(t,\tau)\xi),x(\tau_0)=0$. On the other hand,

$$\begin{aligned}\varphi^*_{r,\omega}(\Phi_\omega(r,\tau)\xi)&=\int_{\tau_0}^t\Phi_\omega(t,s)F_\omega(s,\varphi^*_{r,\omega}(\Phi_\omega(r,\tau)\xi)(s)+\Phi_\omega(t,r)\Phi_\omega(r,\tau)\xi)\,ds\\ &=\int_{\tau_0}^t\Phi_\omega(t,s)F_\omega(s,\varphi^*_{r,\omega}(\Phi_\omega(r,\tau)\xi)(s)+\Phi_\omega(t,\tau)\xi)\,ds\end{aligned}$$

is a unique solution to the same initial value problem. As consequence of uniqueness of solution we obtain the desired result.

Step 2. Let us introduce $H_\omega:I\times X\to X$ and $G_\omega:I\times X\to X$ as follows

$$\begin{aligned}H_\omega(t,\xi)&:=\xi+\int_{\tau_0}^t\Phi_\omega(t,s)F_\omega(s,\varphi^*_{t,\omega}(\xi)(s)+\Phi_\omega(t,s)\xi)\,ds\\ &=\xi+\varphi^*_{t,\omega}(\xi)(t).\\ G_\omega(t,\eta)&:=\eta-\int_{\tau_0}^t\Phi_\omega(t,s)F_\omega(s,\varphi_\omega(s,t,\eta))\,ds.\end{aligned}\tag{2.12}$$

We can show the boundedness of $\xi \mapsto H_\omega(t,\xi) - \xi$ and $\xi \mapsto G_\omega(t,\eta) - \eta$ as follows

$$\begin{aligned}\|H_\omega(t,\xi) - \xi\|_{t,\omega} &\leq \int_{\tau_0}^{t} \|\Phi_\omega(t,s)\|_{s,t,\omega} \left\|F_\omega(s, \varphi^*_{t,\omega}(\xi)(s) + \Phi_\omega(t,s)\xi)\right\|_{s,\omega} ds \\ &\overset{(2.1)}{\leq} K(\omega) \int_{\tau_0}^{t} e^{-\alpha(t-s)} \left\|F_\omega(s, \varphi^*_{t,\omega}(\xi)(s) + \Phi_\omega(t,s)\xi)\right\|_{s,\omega} ds \\ &\overset{(2.3)}{\leq} K(\omega)M(\omega) \int_{\tau_0}^{t} e^{-\alpha(t-s)}\, ds \leq \frac{K(\omega)M(\omega)}{\alpha} \quad \text{for all } \xi \in X,\end{aligned}$$

and respectively,

$$\begin{aligned}\|G_\omega(t,\eta) - \eta\|_{t,\omega} &\leq \int_{\tau_0}^{t} \|\Phi_\omega(t,s)\|_{s,t,\omega} \|F_\omega(s, \varphi_\omega(s,t,\eta)\|_{s,\omega}\, ds \\ &\leq \frac{K(\omega)M(\omega)}{\alpha} \quad \text{for all } \eta \in X.\end{aligned}$$

Now, let us demonstrate the conjugation of (*N*) and (*L*). First, we claim that $H_\omega(t, \Phi_\omega(t,\tau)\xi)$ is differentiable in t. Indeed,

$$H_\omega(t, \Phi_\omega(t,\tau)\xi) = \Phi_\omega(t,\tau)\xi + \int_{\tau_0}^{t} \Phi_\omega(t,s) F_\omega\left(s, \varphi^*_{t,\omega}(\Phi_\omega(t,\tau)\xi)(s) + \Phi_\omega(t,s)\Phi_\omega(t,\tau)\xi\right) ds.$$

The function $\Phi_\omega(t,s)$ is the solution of (*L*), and the conditions in (H_1) guarantee that Φ_ω is differentiable almost everywhere with respect to t for $t \geq s$. Specifically:

$$\frac{d}{dt}\Phi_\omega(t,s) = A_\omega(t)\Phi_\omega(t,s).$$

To analyze the second term, we note that (H_2^0) guarantees that F_ω is sufficiently regular for the integral term to be differentiable. Moreover, $\varphi^*_{t,\omega}(\xi)$ solves (*N*) and depends on t in a smooth way through $\Phi_\omega(t,s)$ and the nonlinearity F_ω. The Lipschitz continuity of F_ω ensures that the solution $\varphi^*_{t,\omega}(\xi)$ is differentiable with respect to t.

Combining all this with the differentiation under the integral Theorem A.7, we can compute the derivative in a direct form:

$$\begin{aligned}\frac{d}{dt}H_\omega(t, \Phi_\omega(t,\tau)\xi) &= \frac{d}{dt}\Phi_\omega(t,\tau)\xi + \frac{d}{dt}\varphi^*_{t,\omega}(\Phi_\omega(t,\tau)\xi)(t) \\ &= A_\omega(t)\left(\Phi_\omega(t,\tau)\xi + \varphi^*_{t,\omega}(\Phi_\omega(t,\tau)\xi)(t)\right) + F_\omega\left(t, H_\omega(t, \Phi_\omega(t,\tau)\xi)\right) \\ &= A_\omega(t)H_\omega(t, \Phi_\omega(t,\tau)\xi) + F_\omega\left(t, H_\omega(t, \Phi_\omega(t,\tau)\xi)\right).\end{aligned}$$

This means that $t \mapsto H_\omega(t, \Phi_\omega(t,\tau)\xi)$ solves the initial value problem:

$$\dot{x} = A_\omega(t)x + F_\omega(t,x), \quad x(\tau) = H_\omega(\tau,\xi).$$

By the uniqueness of the solution (due to Theorem 1.2), we obtain:

$$H_\omega(t, \Phi_\omega(t,\tau)\xi) = \varphi_\omega(t,\tau, H_\omega(\tau,\xi)) \quad \forall\, \xi \in X.$$

In the same way it can be shown that

$$G_\omega(t, \varphi_\omega(t,s,\eta)) = \Phi_\omega(t,s)G_\omega(s,\eta) \quad \text{for all } \eta \in X.$$

Step 3. In order to complete the proof and to show that $H_\omega(t,\cdot)$ is a homeomorphism, we start with the claim that $H_\omega(t,\cdot): X \to X$ is bijective. Indeed, for any $\eta \in X$, we have

$$\begin{aligned} H_\omega(t, G_\omega(t,\varphi_\omega(s,t,\eta))) &\overset{(2.12)}{=} G_\omega(t,\varphi_\omega(t,\tau,\eta)) + \int_{\tau_0}^t \Phi_\omega(t,s)F_\omega(s,\varphi^*_{t,\omega}(G_\omega(s,\varphi_\omega(t,\tau,\eta)))(s) \\ &\quad + \Phi_\omega(t,s)G_\omega(s,\varphi_\omega(t,\tau,\eta)))\,ds \\ &= \varphi_\omega(t,\tau,\eta) - \int_{\tau_0}^t \Phi_\omega(t,s)F_\omega(s,\varphi_\omega(t,\tau,\eta))ds \\ &\quad + \int_{\tau_0}^t \Phi_\omega(t,s)F_\omega(s,\varphi^*_{t,\omega}(G_\omega(s,\varphi_\omega(t,\tau,\eta)))(s) \\ &\quad + \Phi_\omega(t,s)G_\omega(s,\varphi_\omega(t,\tau,\eta)))\,ds. \end{aligned}$$

If we abbreviate by $\nu(t) = \|H_\omega(t, G_\omega(t,\varphi_\omega(s,t,\eta))) - \varphi_\omega(t,\tau,\eta)\|_{t,\omega}$, then we have

$$\begin{aligned} \nu(t) &\le \int_{\tau_0}^t \|\Phi_\omega(t,s)\|_{s,t,\omega}\,\|F_\omega(s,\varphi^*_{t,\omega}(G_\omega(s,\varphi_\omega(t,\tau,\eta)))(s) \\ &\qquad + \Phi_\omega(t,s)G_\omega(s,\varphi_\omega(t,\tau,\eta))) - F_\omega(s,\varphi_\omega(t,\tau,\eta))\|_{s,\omega}ds \\ &\le K(\omega)L(\omega)\int_{\tau_0}^t e^{-\alpha(t-s)}\|\varphi^*_{t,\omega}(G_\omega(s,\varphi_\omega(t,\tau,\eta)))(s) \\ &\qquad + \Phi_\omega(t,s)G_\omega(s,\varphi_\omega(t,\tau,\eta))) - \varphi_\omega(t,\tau,\eta)\|_{s,\omega}\,ds \\ &\le K(\omega)L(\omega)\int_{\tau_0}^t e^{-\alpha(t-s)}\,\|H_\omega(s,\Phi_\omega(t,s)G_\omega(s,\varphi_\omega(t,\tau,\eta)))) - \varphi_\omega(t,\tau,\eta)\|_{s,\omega}\,ds \\ &\le K(\omega)L(\omega)\int_{\tau_0}^t e^{-\alpha(t-s)}\nu(s)\,ds \le \frac{K(\omega)L(\omega)}{\alpha}\sup_{s\in I}\nu(s) \quad \text{for all } t\in I. \end{aligned}$$

Hence, from the above estimate and the assumption $K(\omega)L(\omega) < \alpha$, it follows that $\nu(t) = 0$ for any $t \in I$ and with $t = \tau$, $H_\omega(\tau, G_\omega(\tau,\eta)) = \eta$.

Now we prove that for all $\xi \in X$, it holds that $G_\omega(t, H_\omega(t,\xi)) = \xi$. We have

$$\begin{aligned} &G_\omega(t, H_\omega(t,\Phi_\omega(t,\tau)\xi)) \\ &\quad = H_\omega(t,\Phi_\omega(t,\tau)\xi) - \int_{\tau_0}^t \Phi_\omega(t,s)F_\omega(s,\varphi_\omega(s,t,H_\omega(t,\Phi_\omega(t,\tau)\xi)))\,ds \\ &\quad = \Phi_\omega(t,\tau)\xi + \int_{\tau_0}^t (F_\omega(s,H_\omega(s,\Phi_\omega(s,\tau)\xi)) - F_\omega(s,\varphi_\omega(s,\tau,H_\omega(\tau,\xi))))\,ds \\ &\quad = \Phi_\omega(t,\tau)\xi. \end{aligned}$$

Now, if we set $t = \tau$, then $G_\omega(\tau, H_\omega(\tau,\xi)) = \xi$ holds.

As a consequence, for any $t \in I$, $H_\omega(t,\cdot)\colon X \to X$ is a bijection, and $G_\omega(t,\cdot)\colon X \to X$ is its inverse.

Step 4. In this step, we show that the conjugacy and its inverse satisfy Lipschitz conditions with Lipschitz constants L_H and L_G respectively, where

$$L_G = 1 + \frac{K^2(\omega)L(\omega)}{2\alpha - K(\omega)L(\omega)}, \qquad L_H = 1 + \frac{K^2(\omega)L(\omega)}{2\alpha} + \frac{K^3(\omega)L^2(\omega)e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)}{\alpha(\alpha - K(\omega)L(\omega))}.$$

In order to show the claim for the operator G_ω, we start with additional estimates.

Note that the general solution $\varphi_\omega(\cdot,\tau,\eta)$ of (N) also solves the inhomogeneous equation

$$\dot{x} = A_\omega(t)x + F_\omega(t,\varphi_\omega(t,\tau,\eta)).$$

Hence, by variation of constants formula (Theorem A.2), we have

$$\varphi_\omega(s,t,\eta) = \Phi_\omega(t,s)\eta + \int_s^t \Phi_\omega(t,\tau)F_\omega(\tau,\varphi_\omega(t,\tau,\eta))\,d\tau,$$

so we obtain

$$\begin{aligned}
&\|\varphi_\omega(s,t,\eta) - \varphi_\omega(s,t,\bar{\eta})\|_{t,\omega} \\
&\quad\le \|\Phi_\omega(t,s)(\eta-\bar{\eta})\|_\omega + \int_s^t \|\Phi_\omega(t,\tau)\|_{s,t,\omega}\,\|F_\omega(\tau,\varphi_\omega(t,\tau,\eta)) - F_\omega(\tau,\varphi_\omega(t,\tau,\bar{\eta}))\|_{s,\omega}\,ds \\
&\quad\le K(\omega)e^{-\alpha(t-s)}\|\eta-\bar{\eta}\| + K(\omega)L(\omega)\int_s^t e^{-\alpha(t-\tau)}\|\varphi_\omega(t,\tau,\eta) - \varphi_\omega(t,\tau,\bar{\eta})\|_{t,\omega}\,ds.
\end{aligned}$$

Multiplying both sides by $e^{\alpha(t-s)}$ and using Gronwall's inequality (A.1), gives us

$$\|\varphi_\omega(s,t,\eta) - \varphi_\omega(s,t,\bar{\eta})\|_{t,\omega}\,e^{\alpha(t-s)} \le K(\omega)e^{K(\omega)L(\omega)(t-s)}\|\eta-\bar{\eta}\|.$$

From the estimate above we obtain

$$\|\varphi_\omega(s,t,\eta) - \varphi_\omega(s,t,\bar{\eta})\|_{t,\omega} \le K(\omega)e^{(-\alpha+K(\omega)L(\omega))(t-s)}\|\eta-\bar{\eta}\|. \tag{2.13}$$

Now, using (2.13), we have that

$$\begin{aligned}
\|G_\omega(t,\eta) - G_\omega(t,\bar{\eta})\|_{t,\omega} &\le \|\eta-\bar{\eta}\| + K(\omega)L(\omega)\int_{\tau_0}^t e^{-\alpha(t-s)}\|\varphi_\omega(t,s,\bar{\eta}) - \varphi_\omega(t,s,\eta)\|_{s,\omega}\,ds \\
&\le \|\eta-\bar{\eta}\|\left(1 + K^2(\omega)L(\omega)\int_{\tau_0}^t e^{(-2\alpha+K(\omega)L(\omega))(t-s)}ds\right) \\
&\le \left(1 + \frac{K^2(\omega)L(\omega)}{2\alpha - K(\omega)L(\omega)}\right)\|\eta-\bar{\eta}\| \\
&\le L_G\|\eta-\bar{\eta}\|.
\end{aligned} \tag{2.14}$$

Now we show that H_ω satisfy a global Lipschitz condition. We have

$$\begin{aligned}
&\left\|H_\omega(t,\xi) - H_\omega(t,\bar{\xi})\right\|_{t,\omega} \\
&\le \|\xi-\bar{\xi}\| + K(\omega)L(\omega)\int_{\tau_0}^t e^{-\alpha(t-s)}\left\{\left\|\Phi_\omega(t,s)\xi - \Phi_\omega(t,s)\widetilde{\xi}\right\|_{s,\omega} + \left\|\varphi^*_{t,\omega}(\xi) - \varphi^*_{t,\omega}(\bar{\xi})\right\|_\omega\right\}ds \\
&\le \|\xi-\bar{\xi}\|\left(1 + K^2(\omega)L(\omega)\int_{\tau_0}^t e^{-2\alpha(t-s)}ds\right) + \frac{K(\omega)L(\omega)}{\alpha}\left\|\varphi^*_{t,\omega}(\xi) - \varphi^*_{t,\omega}(\bar{\xi})\right\|_\omega \\
&\le \|\xi-\bar{\xi}\|\left(1 + K^2(\omega)L(\omega)\int_{\tau_0}^t e^{-2\alpha(t-s)}ds\right) + \frac{K^3(\omega)L^2(\omega)e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)}{\alpha(\alpha - K(\omega)L(\omega))}\|\xi-\bar{\xi}\| \\
&\le \left(1 + \frac{K^2(\omega)L(\omega)}{2\alpha} + \frac{K^3(\omega)L^2(\omega)e^{\alpha(\tau-\tau_0)}\ell(\tau,\omega)}{\alpha(\alpha - K(\omega)L(\omega))}\right)\|\xi-\bar{\xi}\| \\
&\le L_H\left\|\xi-\bar{\xi}\right\|.
\end{aligned} \tag{2.15}$$

Based on (2.14) and (2.15), we conclude that $H_\omega(t,\cdot)$ and $G_\omega(t,\cdot)$ are Lipschitz, and therefore uniformly continuous for any $t \in I$.

Moreover, it can be shown that the operator $H_\omega : I \times X \to X$ and its inverse are continuous.

Indeed, from the continuity of the solution of (L), it follows that for any $\varepsilon_1 > 0$ there exists $\delta_1(t_0, \xi_0, \varepsilon_1) > 0 : |t - t_0| + \|\xi - \xi_0\| < \delta_1 \Rightarrow \|\Phi_\omega(t,s)\xi - \Phi_\omega(t_0,s)\xi_0\|_{s,\omega} < \varepsilon_1$.

Thus, at the first step we proved the continuity of the mapping $(t, \xi) \mapsto \varphi^*_{t,\omega}(\xi)$. This means that, for any $\varepsilon_2 > 0$, there exists $\delta_2(t_0, \xi_0, \varepsilon_2) > 0 : |t - t_0| + \|\xi - \xi_0\| < \delta_2 \Rightarrow \left\|\varphi^*_{t,\omega}(\xi) - \varphi^*_{t,\omega}(\xi_0)\right\|_{t,\omega} < \varepsilon_2$.

Without loss of generality, let $\tau_0 \le t_0 \le t$. In order to prove the continuity of the operator H_ω, we consider the following expression

$$\begin{aligned}
H_\omega(t,\xi) - H_\omega(t_0,\xi_0) = \xi - \xi_0 &+ \int_{\tau_0}^{t} \Phi_\omega(t,s)F_\omega(s,\varphi^*_{t,\omega}(\xi)(s) + \Phi_\omega(t,s)\xi)\,ds \\
&- \int_{\tau_0}^{t_0} \Phi_\omega(t_0,s)F_\omega(s,\varphi^*_{t_0,\omega}(\xi_0)(s) + \Phi_\omega(t_0,s)\xi_0)\,ds = \xi - \xi_0 \\
&+ \int_{\tau_0}^{t_0} (\Phi_\omega(t,s) - \Phi_\omega(t_0,s))F_\omega(s,\varphi^*_{t,\omega}(\xi)(s) + \Phi_\omega(t,s)\xi)\,ds \\
&+ \int_{\tau_0}^{t_0} \Phi_\omega(t_0,s)\left(F_\omega(s,\varphi^*_{t,\omega}(\xi)(s) + \Phi_\omega(t,s)\xi)\right. \\
&- \left. F_\omega(s,\varphi^*_{t_0,\omega}(\xi_0)(s) + \Phi_\omega(t_0,s)\xi_0)\,ds\right) \\
&+ \int_{t_0}^{t} \Phi_\omega(t,s)F_\omega(s,\varphi^*_{t,\omega}(\xi)(s) + \Phi_\omega(t,s)\xi)\,ds.
\end{aligned}$$

Let $C = \max\{\|\Phi(t,s)\|_{s,t,\omega} : t,s \in I, t \ge s\}$, then we obtain

$$\begin{aligned}
\|H_\omega(t,\xi) - H_\omega(t_0,\xi_0)\|_{t,\omega} &\le \|\xi - \xi_0\| + M(\omega)\int_{\tau_0}^{t_0} \|\Phi_\omega(t,s) - \Phi_\omega(t_0,s)\|_{s,t,\omega}\,ds \\
&\quad + L(\omega)C\int_{\tau_0}^{t_0} \left\|\varphi^*_{t,\omega}(\xi)(s) - \varphi^*_{t_0,\omega}(\xi_0)(s)\right\|_{t,\omega}\,ds \\
&\quad + M(\omega)C(t - t_0) + L(\omega)C(t_0 - \tau_0)\varepsilon \\
&\le \|\xi - \xi_0\| + (2M(\omega) + L(\omega)\,(\varepsilon_1 + \varepsilon_2))\,C(t_0 - \tau_0) \\
&\quad + M(\omega)C(t - t_0),
\end{aligned}$$

which proves the continuity of H_ω in any $(t_0, \xi_0) \in I \times X$.

In the same way, using the continuity of general solution $\varphi_\omega(s,t,\eta)$ of (N), we know that for any $\varepsilon_3 > 0$ there exists $\delta_3(t_0, \xi_0, \varepsilon_3) > 0 : |t - t_0| + \|\xi - \xi_0\| < \delta_3 \Rightarrow \|\varphi_\omega(s,t,\eta) - \varphi_\omega(s,t_0,\eta_0)\|_{t,\omega} < \varepsilon_3$. Thus,

$$\begin{aligned}
\|G_\omega(t,\eta) - G_\omega(t_0,\eta_0)\|_{t,\omega} \le\ & \|\eta - \eta_0\| + M(\omega)\int_{\tau_0}^{t_0} \|\Phi_\omega(t,s) - \Phi_\omega(t_0,s)\|_{s,t,\omega}\,ds \\
&+ L(\omega)C\int_{\tau_0}^{t_0} \|\varphi_\omega(s,t,\eta) - \varphi_\omega(s,t_0,\eta_0)\|_{t,\omega}\,ds + M(\omega)C(t - t_0) \\
\le\ & \|\eta - \eta_0\| + (L(\omega)\varepsilon_3 + 2M(\omega))C(t_0 - \tau_0) \\
&+ M(\omega)C(t - t_0),
\end{aligned}$$

which completes the proof. □

If we set $\tilde{u} = 0$ in (2.13), we see that $\|\varphi_\omega(t,s,u)\|_{t,\omega} \le K(\omega)e^{(-\alpha + K(\omega)L(\omega))(t-s)}\|u\|$ which leads us to conclude that the trivial solution of the (N) is globally uniformly exponentially stable.

2.2 Smooth linearization

We write $D_2^j F_\omega : I \times X \to L_j(X)$ for the j-th order partial derivative of a mapping $F_\omega : I \times X \to X$ with respect to the second variable. And we substitute the assumption (H_2^0) by the following condition supposed to hold for some $m \in \mathbb{N}$ and all $\omega \in \Omega$:

(H_2^m) $F_\omega : I \times X \to X$ and its partial derivatives $D_2^j F_\omega : I \times X \to L_j(X)$, $1 \leq j \leq m$, are Carathéodory functions and there exist reals $M_j(\omega) \geq 0$ such that

$$\left\| D_2^j F_\omega(t,x) \right\|_{t,\omega} \leq M_j(\omega) \quad \text{for almost all } t \in I, \text{ all } x \in X \text{ and } 0 \leq j \leq m. \tag{2.16}$$

Lemma 2.5 (Differentiation under the integral). *Let $m \in \mathbb{N}$, $U \subseteq X, V \subseteq Y$ be open and $f : U \times V \to X$ be such that $f(\cdot, y)$ is integrable for any $y \in V$. Suppose, that for any $x \in U, y \in V$, there exist derivatives $D_2^j f(x,y)$, and*

$$\left\| D_2^j f(x,y) \right\| \leq g(x)$$

for all $0 \leq j \leq m$, where $g : U \to \mathbb{R}^+$ is integrable. Then the mapping

$$F(y) = \int_U f(x,y)dx$$

is m times differentiable and its j-th derivative is given by

$$D^j F(y) = \int_U D_2^j f(x,y)dx$$

for all $0 \leq j \leq m$.

Theorem 2.6 (C^m-linearization of (N)). *Assume (H_1) and (H_2^m) hold and $K(\omega)M_1(\omega) < \alpha$ for all $\omega \in \Omega$. Then all statements of Theorem 2.4 hold with $H_\omega(t,\cdot)$ being a C^m-diffeomorphism. In the present setting, H_ω is called a C^m-conjugacy between (N) and its linearization (L).*

Note that C^m-conjugacies guarantee that the integral manifolds of (N) are tangential to the invariant linear integral manifolds of (L).

Proof. First, we aim to show that the general solution $\varphi_\omega(s,t,\cdot) : X \to X$ of (N) is m times differentiable with continuous bounded partial derivatives $D_3^j \varphi_\omega : I \times I \times X \to L_j(X)$ for any $\eta \in X$, $s,t \in I$ and $1 \leq j \leq m$.

It is well-known (see, e.g., Theorem 1.16 in [40]) that $\varphi_\omega \in C^m$. Our goal is to show the boundedness of the partial derivatives.

From the fact that φ_ω is the general solution of (N) it follows that, for any $\eta \in X$, the mapping φ_ω satisfies the equation $D_1\varphi_\omega(t,s,\eta) = A_\omega(t)\varphi_\omega(t,s,\eta) + F_\omega(t,\varphi_\omega(t,s,\eta))$. Then,

$$D_1 D_3 \varphi_\omega(t,s,\cdot) = A_\omega(t) D_3\varphi_\omega(t,s,\eta) + D_2 F_\omega(t,\varphi_\omega(t,s,\eta)) D_3\varphi_\omega(t,s,\eta)$$

and, therefore, $D_3\varphi_\omega(\cdot,s,\eta)$ solves the initial value problem $\dot{x} = [A_\omega(t) + D_2F_\omega(t,\varphi_\omega(t,s,\eta))]x$, $x(s) = \mathrm{Id}_X$. Hence, by variation of constants formula we have

$$D_3\varphi_\omega(t,s,\eta) = \Phi_\omega(t,s) + \int_s^t \Phi_\omega(r,s) D_2F_\omega(r,\varphi_\omega(r,s,\eta)) D_3\varphi_\omega(r,s,\eta)\, dr,$$

and we estimate

$$\begin{aligned}\|D_3\varphi_\omega(t,s,\eta)\|_{t,\omega} \leq & \int_s^t \|\Phi_\omega(r,s)\|_{s,t,\omega} \|D_2F_\omega(r,\varphi_\omega(r,s,\eta))\|_{s,\omega} \|D_3\varphi_\omega(r,s,\eta)\|_{s,\omega}\, dr \\ & + \|\Phi_\omega(t,s)\|_{s,t,\omega} \leq K(\omega)e^{-\alpha(t-s)} \\ & + K(\omega)M_1(\omega)\int_s^t e^{-\alpha(r-s)} \|D_3\varphi_\omega(r,s,\eta)\|_{s,\omega}\, dr.\end{aligned}$$

Multiplying both sides by $e^{\alpha(t-s)}$ and using Gronwall's inequality (A.1), gives us

$$\|D_3\varphi_\omega(t,s,\eta)\|_{t,\omega}\, e^{\alpha(t-s)} \leq K(\omega)e^{K(\omega)M_1(\omega)(t-s)}.$$

From the estimate above, we obtain

$$\|D_3\varphi_\omega(t,s,\eta)\|_{t,\omega} \leq K(\omega)e^{(K(\omega)M_1(\omega)-\alpha)(t-s)},$$

and the boundedness of the first-order partial derivative follows. Moreover, the boundedness of higher-order partial derivatives can be demonstrated using the same arguments by induction.

Now our goal is to show that the map $\eta \mapsto G_\omega(t,\eta)$ is C^m.

This follows from the fact that $\varphi_\omega(s,t,\cdot) : X \to X$ is C^m, hypothesis (H_2^m), and from applying Lemma 2.5 to the function $f(t,\eta) = \Phi_\omega(t,s)F_\omega(s,\varphi_\omega(s,t,\eta))$. To justify the application of Lemma 2.5, we observe that

$$\|D_2f(t,\eta)\|_{t,\omega} \leq M_1K^2(\omega)e^{(K(\omega)M_1-2\alpha)(t-s)}.$$

This allows us to conclude the desired statement and to express $D_2G_\omega(t,\eta)$ in explicit form using the chain rule

$$D_2G_\omega(t,\eta) = \mathrm{Id}_X - \int_{\tau_0}^t \Phi_\omega(t,s)D_2F_\omega(s,\varphi_\omega(s,t,\eta))D_3\varphi_\omega(s,t,\eta)\, ds. \tag{2.17}$$

From (H_2^m) and the fact that φ_ω is the general solution of (N), it follows that $D_3\varphi_\omega(s,t,\cdot)$ satisfies the differential equation

$$\dot{x} = A_\omega(t)x + D_2F_\omega(t,\varphi_\omega(s,t,\eta))x, \quad x(s) = \mathrm{Id}_X. \tag{2.18}$$

Combining (2.17) and (2.18) we obtain

$$\begin{aligned}D_2G_\omega(t,\eta) &= \mathrm{Id}_X - \int_{\tau_0}^t \Phi_\omega(t,s)\left(D_1D_3\varphi_\omega(s,t,\eta) - A_\omega(t)D_3\varphi_\omega(s,t,\eta)\right) ds \\ &= \mathrm{Id}_X - \int_{\tau_0}^t D_1\left(\Phi_\omega(t,s)D_3\varphi_\omega(s,t,\eta)\right) ds \\ &= \Phi_\omega(t,\tau_0)D_3\varphi_\omega(\tau_0,t,\eta).\end{aligned} \tag{2.19}$$

From Lemma 2.1, we know that $\Phi_\omega(t,\tau_0) \in GL(X)$ is invertible. Moreover, (2.18) demonstrates that $D_3\varphi_\omega(\tau_0,t,\eta)$ is a transition matrix of $\dot{x} = [A_\omega(t) + D_2F_\omega(t,\varphi_\omega(t,s,\eta))]x$, and hence it is also invertible. Consequently, the invertibility of $D_2G_\omega(t,\eta)$ follows.

Hence, by Theorem A.5, the map $\xi \mapsto G_\omega(t,\xi)$ is a local C^m diffeomorphism for any fixed $t \in I$. As the final step, since we have shown that G_ω is a homeomorphism, therefore it preserves the compactness of sets. Thus, we can apply Theorem A.6 to G_ω, which completes the proof. □

3 Random dynamical systems

In the previous section, we presented a smooth linearization result specifically for semilinear Carathéodory differential equations in general Banach spaces. Our current objective is to apply this result to continuous-time random dynamical systems, considering random differential equations (RDEs) and stochastic differential equations (SDEs).

RDEs and SDEs are complementary approaches commonly used in the study of random dynamical systems. Random differential equations, introduced in, e.g., [1, 41], and systematically treated in [19, 23], provide a pathwise framework for modeling dynamical systems under uncertainty. Their analysis typically relies on existence and uniqueness results for ordinary differential equations with Carathéodory-type vector fields [29]. Stochastic differential equations, on the other hand, offer a probabilistic framework and are well established in both theory and applications [30, 31].

In order to mimic the constructions from [1, 44], we restrict ourselves to finite-dimensional Banach spaces X. Before delving into the details, we first introduce the research object of this section.

A random dynamical system is an object consisting of a measurable dynamical system and a cocycle over this system [1], therefore we begin with a definition of a measurable dynamical system.

Definition 3.1. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space. We call $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$ to be a *measurable dynamical system (MDS)* , if the mapping $\theta_t : \Omega \to \Omega$ satisfies the following conditions:

(i) the mapping $(t, \omega) \mapsto \theta_t\omega$ is measurable;

(ii) the family $(\theta_t)_{t\in I}$ forms a group, i.e. $\theta_0 = \mathrm{Id}_\Omega$ and $\theta_{t+s} = \theta_t \circ \theta_s$, for arbitrary $s, t \in I$;

(iii) the mapping θ_t is $\mathbb{P}$-preserving, i.e., for arbitrary $t \in I$ and $F \in \mathcal{F}$, the identity $\mathbb{P}(\theta_t^{-1}(F)) = \mathbb{P}(F)$ holds.

An MDS $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$ is called *ergodic* if every θ_t- invariant set has probability 0 or 1, i.e. if for all $F \in \mathcal{F}$ satisfying $\theta_t^{-1}(F) = F$ for every $t \in I$ we have either $\mathbb{P}(F) = 0$ or $\mathbb{P}(F) = 1$.

Definition 3.2. A *measurable random dynamical system (RDS)* on X over some given MDS $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$ is a measurable mapping $\psi\colon I \times \Omega \times X \to X$, $(s, \omega, x) \to \psi(s, \omega, x)$ forming a *cocycle* over θ_t, i.e., the mapping $\psi(t, \omega) := \psi(t, \omega, \cdot)$ satisfies

$$\psi(0, \omega) = \mathrm{Id}_X,$$
$$\psi(s + t, \omega) = \psi(t, \theta_s\omega) \circ \psi(s, \omega),$$

for arbitrary $s, t \in I$, and $\omega \in \Omega$.

The random dynamical system ψ is called *linear,* if the mapping $\psi(t, \omega)$ is linear, *continuous,* if the mapping $\psi(\cdot, \omega)$ is continuous. Furthermore, it is called *smooth of class* C^m, if it is continuous, the mapping $\psi(t, \omega)$ is of class C^m and the derivatives are continuous with respect to the (t, x), for arbitrary $t \in I$, $\omega \in \Omega$, and $x \in X$.

Definition 3.3. Let $\Phi : I \times \Omega \to X$ be a linear RDS over an ergodic MDS θ_t. We define the *Lyapunov exponents* of Φ for all $x \in X, x \neq 0$ as

$$\lambda(\omega, x) = \limsup_{t\to\infty} \frac{1}{t} \|\Phi(t, \omega)x\| .$$

We denote the distinct values that $\lambda(\omega, x)$ can take for $x \neq 0$ as

$$-\infty < \lambda_{k(\omega)}(\omega) < \cdots < \lambda_1(\omega).$$

The value $\lambda_1(\omega)$ is called the *top Lyapunov exponent*.

In the setting of the Multiplicative Ergodic Theorem A.8, the sets $U_\lambda := \{x : \lambda(\omega, x) \leq \lambda(\omega)\}$ are linear subspaces of X, $U_i := U_{\lambda_i}$, and they form a filtration (flag of subspaces)

$$\{0\} \subset U_{k(\omega)} \subset \cdots \subset U_1 = X,$$

where

$$\lambda(\omega, x) = \lambda_i(\omega) \iff x \in U_i \setminus U_{i+1}, \quad i = 1, \ldots, k(\omega).$$

We say that $d_i(\omega) := \dim U_i - \dim U_{i+1}$ is the *multiplicity* of $\lambda_i(\omega)$.

In order to apply the results from the previous section to the random dynamical system, we first answer the following questions:

(1) What is the connection between the semilinear Carathéodory differential equations (N) and the corresponding random dynamical system?

(2) How should we choose the new norm depending on both time and randomness in order to achieve our goal?

The answer to the first question is given in the following lemma.

Lemma 3.4. *Let $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$ be a MDS. If φ_ω denotes the general solution of the Carathéodory differential equation (N), then the following statements are equivalent:*

(i) The mapping ψ_ω defined as $\psi_\omega(t, x) := \varphi_\omega(t, 0, x)$ is a measurable RDS over $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$.

(ii) The general solution of (N) satisfies

$$\varphi_\omega(t, \tau, x) = \varphi_{\theta_\tau \omega}(t - \tau, 0, x) \tag{3.1}$$

for arbitrary $\tau, t \in I$ and $x \in X$.

Proof. $(i) \Rightarrow (ii)$: From the cocycle property of RDS we know that

$$\varphi_\omega(s + t, 0, x) = \varphi_{\theta_s \omega}(t, 0, \varphi_\omega(s, 0, x)). \tag{3.2}$$

Moreover, it is well known that the general solution of (N) satisfies the property

$$\varphi_\omega(t_2, t_0, x) = \varphi_\omega(t_2, t_1, \varphi_\omega(t_1, t_0, x)). \tag{3.3}$$

Thus,

$$\varphi_\omega(t, \tau, x) = \varphi_\omega((t - \tau) + \tau, \tau, x) \overset{(3.2)}{=} \varphi_{\theta_\tau \omega}(t - \tau, \tau, \varphi_\omega(\tau, 0, x)) \overset{(3.3)}{=} \varphi_{\theta_\tau \omega}(t - \tau, 0, x).$$

$(ii) \Rightarrow (i)$: In order to prove this implication it is enough to check the cocycle property. Namely,

$$\varphi_\omega(s + t, 0, x) \overset{(3.3)}{=} \varphi_\omega(s + t, s, \varphi_\omega(s, 0, x)) \overset{(3.1)}{=} \varphi_{\theta_s \omega}(t, 0, \varphi_\omega(s, 0, x)),$$

so the lemma follows. □

To address the second question, we introduce a new norm in the following way. In the setting of the Multiplicative Ergodic Theorem A.8, suppose that Φ is a linear RDS with the Lyapunov exponents $\lambda_1(\omega), \dots, \lambda_{k(\omega)}(\omega)$. It is well known from, e.g., [1], that when θ_t is ergodic, $k(\omega)$ and $\lambda_i(\omega)$ are independent of ω. We assume ergodicity for the remainder of this paper.

Let $a > 0$ denote a fixed real constant such that the intervals $[\lambda_i - a, \lambda_i + a]$, $i = 1, \dots, k$, are disjoint. For $\omega \in \tilde{\Omega}$ and $x = x^1 + \cdots + x^{k(\omega)} \in U_1(\omega) \oplus \cdots \oplus U_{k(\omega)}(\omega)$, we define a new norm

$$|x|_\omega = \sqrt{|x^1|_\omega^2 + \cdots + |x^{k(\omega)}|_\omega^2},$$

where $|x^i|_\omega = \left(\int_0^\infty \|\Phi(t,\omega)x^i\|^2 e^{-2(\lambda_i t + at)} dt \right)^{\frac{1}{2}}$ for $x^i \in U_i(\omega)$. For $\omega \notin \tilde{\Omega}$, we set $|x|_\omega = \|x\|$. Then (according to [1,44]) the following properties holds

(i) $|\cdot|_\omega$ is a random norm on X;

(ii) for every $\varepsilon > 0$, there is a measurable mapping $B_\varepsilon : \Omega \to [1, \infty)$ such that, for every $x \in X$, and almost every $\omega \in \tilde{\Omega}$, and $t \in I$,

$$\frac{1}{B_\varepsilon(\omega)}\|x\| \le |x|_\omega \le B_\varepsilon(\omega)\|x\|,$$
$$B_\varepsilon(\omega)e^{-\varepsilon t} \le B_\varepsilon(\theta_t\omega) \le B_\varepsilon(\omega)e^{\varepsilon t};$$

(iii) for almost every $\omega \in \tilde{\Omega}$, $t \in I$, and every $i = 1, \dots, k(\omega)$, $x \in U_i(\omega)$,

$$e^{(\lambda_i - a)t} \le \left|\Phi(t,\omega)|_{U_i(\omega)}\right|_{\omega,\theta_t\omega} \le e^{(\lambda_i + a)t},$$

where $\left|\Phi(t,\omega)|_{U_i(\omega)}\right|_{\omega,\theta_t\omega} := \sup\{|\Phi(t,\omega)x|_{\theta_t\omega} : x \in U_i(\omega), |x|_\omega \le 1\}$.

It is important to note that the constant a is chosen in such a way that $\lambda_i + a$ remains a negative expression for all $i = 1, \dots, k$. In the following, we will focus on the case, when all of Lyapunov exponents of the system are negative, i.e., $\lambda_k < \cdots < \lambda_1 < 0$.

Remark 3.5. *Let Φ be a linear RDS satisfying the Multiplicative Ergodic Theorem A.8 and suppose $\Phi_\omega(t,s)$ is the evolution operator of a linear random differential equation $\dot{x} = A_\omega(t)x$. In this case $(H1)$ holds with $\|x\|_{t,\omega} := |x|_{\theta_t\omega}$, $K(\omega) = 1$ and $\alpha = -\lambda_1 - a$.*

Indeed, in [1,44] is shown that Φ and $\Phi_\omega(t,s)$ are related by

$$\Phi_\omega(t,s) = \Phi(t-s, \theta_s\omega).$$

From estimates in (iii) for $|\Phi(t,\omega)|_{\omega,\theta_t\omega}$, we have

$$\begin{aligned}
|\Phi(t,\omega)x|_{\theta_t\omega} &= \sqrt{|\Phi(t,\omega)x^1|_{\theta_t\omega} + \cdots + |\Phi(t,\omega)x^k|_{\theta_t\omega}} \\
&\le \sqrt{(e^{(\lambda_1+a)t}|x^1|_\omega)^2 + \cdots + (e^{(\lambda_k+a)t}|x^k|_\omega)^2} \\
&\le e^{(\lambda_1+a)t}\sqrt{|x^1|_\omega^2 + \cdots + |x^k|_\omega^2} \\
&\le e^{(\lambda_1+a)t}|x|_\omega,
\end{aligned}$$

and therefore for all $t \in I$

$$|\Phi(t,\omega)|_{\omega,\theta_t\omega} \le e^{(\lambda_1+a)t}. \tag{3.4}$$

Thus,

$$\|\Phi_\omega(t,s)\|_{s,t,\omega} = |\Phi(t-s,\theta_s\omega)|_{\theta_s\omega,\theta_t\omega} = |\Phi(t-s,\theta_s\omega)|_{\theta_s\omega,\theta_{t-s}\theta_s\omega},$$

which together with (3.4) gives us

$$\|\Phi_\omega(t,s)\|_{s,t,\omega} \leq e^{(\lambda_1+a)(t-s)}. \tag{3.5}$$

In the above definition of the family of norms $\|\cdot\|_{t,\omega}$, the function ℓ can be chosen as $\ell(t,\omega) := B_1(\theta_t\omega)$, since $B_1(\theta.\omega)$ is locally bounded for any $\omega \in \tilde{\Omega}$.

3.1 C^m linearization of random dynamical systems

After establishing the connection between random dynamical systems and Carathéodory differential equations, we apply the results of the second section to RDS. To this end, let Φ be a linear random dynamical system on X over the ergodic MDS $(\Omega,\mathcal{F},\mathbb{P},(\theta_t)_{t\in I})$, satisfying conditions of the MET and generated by the following linear equation

$$\dot{x} = A(\theta_t\omega)x. \tag{3.6}$$

Together with Φ we will consider a random dynamical system ψ on X over the ergodic MDS $(\Omega,\mathcal{F},\mathbb{P},(\theta_t)_{t\in I})$, generated by

$$\dot{x} = A(\theta_t\omega)x + F(\theta_t\omega,x). \tag{3.7}$$

Assume that ψ has 0 as a fixed point, i.e. $\psi(t,\omega,0) = 0$ for almost all $t \in I$, $\omega \in \Omega$. Let the "nonlinear" part of ψ be given by $\Psi(t,\omega,x) = \psi(t,\omega,x) - \Phi(t,\omega)x$.

While the validity of $(H1)$ has already been shown, to satisfy the remaining hypotheses, it is necessary to impose additional conditions on the random dynamical system.

(H_3^0) Assume that for almost all $t \in I$, $\omega \in \Omega$ and all $x, \bar{x} \in X$, there exist reals $L, M \geq 0$ such that

$$|\Psi(t,\omega,x)|_{\theta_t\omega} \leq M \tag{3.8}$$

$$|\Psi(t,\omega,x) - \Psi(t,\omega,\bar{x})|_{\theta_t\omega} \leq L|x-\bar{x}|_\omega. \tag{3.9}$$

Then the following theorem establishes the connection between a random dynamical system ψ and its linearization.

Theorem 3.6 (Topological linearization of RDS)**.** *Assume that the linear random dynamical system Φ, generated by (3.6), satisfies the assumptions of the MET A.8 and has negative Lyapunov exponents. Assume that the nonlinear part Ψ of a RDS ψ, generated by (3.7), satisfies (H_3^0). If $L \leq \alpha$, then the RDS ψ and Φ are topologically equivalent, i.e. there is a measurable mapping $h : \Omega \times X \to X$ with the following properties:*

(i) $h(\omega) = h(\omega,\cdot)$ is a homeomorphism on X with $h(\omega,0) = 0$ for almost all $\omega \in \Omega$;

(ii) $h(\omega)$ maps ω-orbits of Φ onto ω-orbits of ψ in the sense that for every $\omega \in \Omega$, arbitrary $t \in I$ and $x \in X$

$$h(\omega) \circ \Phi(t,\omega)x = \psi(t,\omega,h(\omega,x));$$

(iii) h has property of being near identity, i.e. for all $\xi, \eta \in X$

$$|h(\omega,\xi)-\xi|_{\theta_t\omega} \le \frac{M}{\alpha} \quad \textit{and} \quad |h^{-1}(\omega,\eta)-\eta|_{\theta_t\omega} \le \frac{M}{\alpha},$$

where $\alpha = -\lambda_1 - a > 0$.

Proof. Applying Theorem 2.4 ω-by-ω to the system (3.7) with Ω replaced by $\tilde{\Omega}$ will yield a mapping $h : \Omega \times I \times X \to X$, defined as follows

$$\begin{cases} h(\omega,\xi) = \xi + \int_0^t \Phi(t-s,\theta_s\omega)\Psi(s,\theta_s\omega,\varphi^*_{\theta_t\omega}(\xi)(s) + \Phi(t-s,\theta_s\omega)\xi)\,\mathrm{d}s, \quad \omega \in \tilde{\Omega}, \\ h(\omega,\xi) = 0, \quad \omega \notin \tilde{\Omega}, \end{cases} \tag{3.10}$$

with the inverse

$$\begin{cases} h^{-1}(\omega,\eta) = \eta - \int_0^t \Phi(t-s,\theta_s\omega)\Psi(s,\theta_s\omega,\psi(s,\omega,\eta))\,\mathrm{d}s, \quad \omega \in \tilde{\Omega}, \\ h(\omega,\eta) = 0, \quad \omega \notin \tilde{\Omega}, \end{cases} \tag{3.11}$$

such that statements (i) and (ii) holds.

Let us check that the homeomorphism defined in (3.10) and its inverse are near identity. Indeed, it is easy to verify that

$$\begin{aligned} |h^{-1}(\omega,\eta)-\eta|_{\theta_t\omega} &\overset{(3.11)}{\le} \int_0^t |\Phi(t-s,\theta_s\omega)|_{\theta_s\omega,\theta_t\omega}|\Psi(s,\theta_s\omega,\psi(s,\omega,x))|_{\theta_t\omega}\,ds \\ &\overset{(3.5)}{\le} \int_0^t e^{(\lambda_1+a)(t-s)}|\Psi(s,\theta_s\omega,\psi(s,\omega,x))|_{\theta_t\omega}\,ds \overset{(3.12)}{\le} M\int_0^t e^{(\lambda_1+a)(t-s)}\,ds \\ &\le \frac{M}{-\lambda_1-a}. \end{aligned}$$

Using the same arguments, we obtain

$$|h(\omega,\xi)-\xi|_{\theta_t\omega} \le \frac{M}{-\lambda_1-a}. \qquad \square$$

Theorem 3.7 (Smooth linearization of RDS)**.** *Assume that the linear random dynamical system Φ generated by (3.6) satisfies the assumptions of the MET A.8, has negative Lyapunov exponents. Assume further that all partial derivatives $D_2^j\Psi : I \times \Omega \times X \to L_j(X)$, $1 \le j \le m$ satisfy Carathéodory property, and, moreover, there exist reals $M_j \ge 0$ such that*

$$|D_2^j\Psi(\omega,x)|_{\theta_t\omega} \le M_j \quad \textit{for almost all } t \in I, \omega \in \Omega, \textit{ all } x \in X, 0 \le j \le m, \tag{3.12}$$

and $M_1 \le \alpha$, $\alpha = -\lambda_1 - a$, $\alpha > 0$, then all statements of the previous theorem hold and $h(\omega,\cdot)$ is a C^m-diffeomorphism.

Proof. It suffices to demonstrate that the homeomorphism (3.10) is C^m. To do this we express the $D_2h(\omega,\cdot)^{-1}$ in a direct form, using the same arguments as in Theorem 2.6 :

$$D_2h(\omega,\cdot)^{-1} = \Phi(t,\omega)D_3\psi(s,\omega,\cdot).$$

Applying Theorem [1, Thm. 2.2.2, p. 60], we see that the determinant $\det D\psi(t,\omega,x)$ satisfies Liouville's equation:

$$\det D\psi(t,\omega,x) = \exp\int_0^t \operatorname{trace} D\Psi(\theta_s\omega,\psi(s,\omega,x))\,\mathrm{d}s.$$

Moreover, the linear part of RDS satisfies:

$$\det \Phi(t,\omega) = \exp \int_0^t \operatorname{trace} \Phi(t-s,\theta_s\omega)\, \mathrm{d}s.$$

Therefore, $\det(\Phi(t,\omega)D_3\psi(s,\omega,\eta)) > 0$ for any $t \in I$, $\omega \in \Omega$ which gives us the invertibility of $D_2h^{-1}(\omega,\eta)$ and the theorem follows. □

The assurance of the existence and smallness of a Lipschitz constant, as required in the last theorem, is, of course, not guaranteed in general. Therefore, we will adjust the nonlinear part of the vector fields by cutting them off when they exceed a certain threshold. This will bring us to the local linearization result, which is more suitable to stochastic systems and can be applied in the next section.

For deriving local results from global ones we consider a random dynamical system ψ having a fixed point at the origin. Our objective is to construct a new random dynamical system, denoted as $\tilde{\psi}$, which faithfully reproduces the behavior of ψ within a localized random neighborhood of origin. To make this construction easier, we use the insights from the following lemmas.

Lemma 3.8 ([44, Lemma 4.2, p. 6262])**.** *Let $L_0 > 0$, $(\Omega,\mathcal{F},\mathbb{P},(\theta_t)_{t\in I})$ denote a measurable dynamical system, and consider a measurable mapping $F : \Omega \times X \to X$ such that $F(\omega,\cdot)$ is continuous with $F(\omega,0) = 0$ for all $\omega \in \Omega$. If*

$$\lim_{(x,y)\to(0,0)} \frac{\|F(\omega,x) - F(\omega,y)\|}{\|x-y\|} = 0 \tag{3.13}$$

and

$$\sup_{\|x\|\le c,\|y\|\le c, x\neq y} \frac{\|F(\omega,x) - F(\omega,y)\|}{\|x-y\|} \in L^1(\Omega,\mathcal{F},\mathbb{P}) \tag{3.14}$$

hold for some $c > 0$, then there are measurable mappings $\sigma : \Omega \to (0,c]$, $L : \Omega \to \mathbb{R}^+$ and $\tilde{F} : \Omega \times X \to X$, as well as a θ_t-invariant set $\hat{\Omega} \in \mathcal{F}$ with $\mathbb{P}(\hat{\Omega}) = 1$ such that the following holds:

(i) if we define the random neighborhood of 0 by

$$U(\omega) := \{x \in X : \|x\| < \sigma(\omega)\}, \tag{3.15}$$

then the identity $F(\omega,x) = \tilde{F}(\omega,x)$ holds for all $\omega \in \hat{\Omega}$ and $x \in U(\omega)$. Additionally, we have $\tilde{F}(\omega,x) = 0$ for $\omega \in \Omega \setminus \hat{\Omega}$ and $x \in X$;

(ii) for arbitrary $\omega \in \hat{\Omega}$ and $x,y \in X$ we have

$$|\tilde{F}(\omega,x) - \tilde{F}(\omega,y)|_\omega \le L(\omega)|x-y|_\omega \quad \text{and} \quad |\tilde{F}(\omega,x)|_\omega \le L(\omega)c,$$

as well as $\int_0^1 L(\theta_s\omega)ds \le L_0$;

(iii) for all $\omega \in \hat{\Omega}$ and $a,b \in \mathbb{R}$ with $a \le b$ the estimate $\inf_{a\le t\le b} \sigma(\theta_t\omega) > 0$ holds, i.e., the mapping $\sigma(\theta_t\omega)$ is locally bounded away from 0.

Lemma 3.9 ([44, Prop. 4.3, p. 264])**.** *Assume we are given a continuous random dynamical system ψ on X over the ergodic measurable dynamical system $(\Omega,\mathcal{F},\mathbb{P},(\theta_t)_{t\in I})$ with fixed point 0, which is generated by the random differential equation (3.7). If $\|A\| \in L^1(\Omega,\mathcal{F},\mathbb{P})$, $F(\omega,0) = 0$ and*

$$\lim_{(x,y)\to(0,0)} \frac{\|F(\omega,x) - F(\omega,y)\|}{\|x-y\|} = 0$$

for all $\omega \in \Omega$, then the following holds

(i) There is a θ_t-invariant set $\hat{\Omega} \in \mathcal{F}$ with $\mathbb{P}(\hat{\Omega}) = 1$, as well as a measurable mapping $\sigma : \Omega \to \mathbb{R}^+$ and a continuous random dynamical system $\tilde{\psi}(t,\omega,x) = \Phi(t,\omega)x + \tilde{\Psi}(t,\omega,x)$ over $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$ satisfying (H_3^0), as well as

$$\psi(t,\omega,x) = \tilde{\psi}(t,\omega,x) \tag{3.16}$$

for $\omega \in \hat{\Omega}$, $x \in U(\omega)$ and $t \in I_{\max}(\omega,x) := \{0, t_{\max}(\omega,x)\}$, where $U(\omega)$ is defined in (3.15) and

$$t_{\max}(\omega,x) := \sup\{t \in I : \psi(\tau,\omega,x) \in U(\theta_\tau\omega) \quad \text{for all } 0 \le \tau \le t\} \ge 0. \tag{3.17}$$

(ii) For every $\omega \in \hat{\Omega}$ we have $\lim_{x\to 0} t_{\max}(\omega,x) = \infty$. In particular, this implies that for every choice of $\omega \in \hat{\Omega}$ and $\tau_0 \in I$ the existence of a neighborhood $U_{\tau_0}(\omega) \subset X$ of the origin such that the equality (3.16) holds for all $t \in (0,\tau_0)$ and $x \in U_{\tau_0}(\omega)$.

Lemma 3.10. *If the conditions of Lemma 3.9 holds, then the nonlinear part $\tilde{\Psi}$ of the newly defined local random dynamical system $\tilde{\psi}$ satisfies the assumptions contained in (H_3^0) with Ω replaced by $\hat{\Omega}$.*

Proof. Let $\tilde{\Phi}_\omega(t,s)$ denote the evolution operator of the linear random differential equation $\dot{x} = A(\theta_t\omega)x$. The correspondence between the linear random dynamical system $\Phi(t-s,\theta_s\omega)$ and $\tilde{\Phi}_\omega(t,s)$ shown in Remark 3.5, together with (3.4) implies

$$|\tilde{\Phi}_\omega(t,s)|_{\theta_s\omega,\theta_t\omega} = |\Phi(t-s,\omega)|_{\theta_s\omega,\theta_t\omega} \le e^{(\lambda_1+a)(t-s)} \tag{3.18}$$

for arbitrary $s \le t, \omega \in \hat{\Omega}$.

Let $\tilde{F}$ denote the mapping guaranteed by Lemma 3.8. Since $\tilde{\psi}(t,\omega,x)$ solves the initial value problem $\dot{x} = A(\theta_t\omega)x + \tilde{F}(\theta_t\omega,x)$, $x(0) = x$, from the variation of constants formula we have

$$\tilde{\psi}(t,\omega,x) = \tilde{\Phi}_\omega(t,0)x + \int_0^t \tilde{\Phi}_\omega(t,s)\tilde{F}(\theta_s\omega,\tilde{\psi}(s,\omega,x))ds,$$

and therefore

$$\tilde{\Psi}(t,\omega,x) = \int_0^t \tilde{\Phi}_\omega(t,s)\tilde{F}(\theta_s\omega,\tilde{\Phi}_\omega(s,0)x + \tilde{\Psi}(s,\omega,x))ds,$$

for arbitrary $t \in I$, $x \in X$ and $\omega \in \hat{\Omega}$. This implies the estimate

$$\begin{aligned}
|\tilde{\Psi}(t,\omega,x)|_{\theta_t\omega} &\le \int_0^t |\tilde{\Phi}_\omega(t,s)|_{\theta_s\omega,\theta_t\omega}|\tilde{F}(\theta_s\omega,\tilde{\Phi}_\omega(s,0)x + \tilde{\Psi}(s,\omega,x))|_{\theta_s\omega}\, ds \\
&\le c\int_0^t e^{(\lambda_1+a)(t-s)}L(\theta_s\omega)\, ds \le ce^{(\lambda_1+a)}\int_0^1 L(\theta_s\omega)ds \\
&\le L_0 ce^{(\lambda_1+a)},
\end{aligned}$$

for any $t \in [0,1]$, $\omega \in \hat{\Omega}$ and $x \in X$.

Now, our aim is to verify the Lipschitz condition. For any $t \in [0,1]$, $\omega \in \hat{\Omega}$ and $x, \bar{x} \in X$ we have:

$$\begin{aligned}
&|\tilde{\Psi}(t,\omega,x) - \tilde{\Psi}(t,\omega,\bar{x})|_{\theta_t\omega} \\
&\le \int_0^t |\tilde{\Phi}_\omega(t,s)|_{\theta_s\omega,\theta_t\omega}|\tilde{F}(\theta_s\omega,\tilde{\Phi}_\omega(s,0)x + \tilde{\Psi}(s,\omega,x)) - \tilde{F}(\theta_s\omega,\tilde{\Phi}_\omega(s,0)\bar{x} + \tilde{\Psi}(s,\omega,\bar{x}))|_{\theta_s\omega}\, ds \\
&\le c\int_0^t e^{(\lambda_1+a)(t-s)}L(\theta_s\omega)(|\tilde{\Phi}_\omega(s,0)(x-\bar{x})|_{\theta_s\omega}\, ds + |\tilde{\Psi}(s,\omega,x) - \tilde{\Psi}(s,\omega,\bar{x})|_{\theta_s\omega})\, ds.
\end{aligned}$$

Denote by $\vartheta(t) := e^{-(\lambda_1+a)t}|\tilde{\Psi}(s,\omega,x) - \tilde{\Psi}(s,\omega,\bar{x})|_{\theta_s\omega}$. Then the last estimation can be expressed as follows

$$\begin{aligned}\vartheta(t) &\leq \int_0^t e^{-(\lambda_1+a)s} L(\theta_s\omega)|\tilde{\Phi}_\omega(s,0)|_{\omega,\theta_s\omega}|x-\bar{x}|_\omega\, ds + \int_0^t L(\theta_s\omega)\vartheta(s)\, ds \\ &\leq |x-\bar{x}|_\omega \int_0^t L(\theta_s\omega)\, ds + \int_0^t L(\theta_s\omega)\vartheta(s)\, ds.\end{aligned}$$

By applying Gronwall's inequality, we obtain

$$\begin{aligned}\vartheta(t) &\leq |x-\bar{x}|_\omega \int_0^t L(\theta_s\omega)\, ds + \int_0^t |x-\bar{x}|_\omega L(\theta_s\omega)\left(\int_0^s L(\theta_\tau\omega)\, d\tau\right) e^{\int_s^t L(\theta_\tau\omega)\, d\tau}\, ds \\ &\leq |x-\bar{x}|_\omega (L_0 + L_0^2 e^{L_0}),\end{aligned}$$

for any $s,t \in [0,1], s \leq t$, $x, \bar{x} \in X$ and $\omega \in \hat{\Omega}$.

Finally, we obtain

$$|\tilde{\Psi}(t,\omega,x) - \tilde{\Psi}(t,\omega,\bar{x})|_{\theta_t\omega} \leq e^{\lambda_1+a}(L_0 + L_0^2 e^{L_0})|x-\bar{x}|_\omega,$$

which completes the proof. □

Now, we are able to formulate a local C^m result as well.

Theorem 3.11 (Local topological linearization of RDS)**.** *Let ψ be a given continuous random dynamical system on X over the ergodic metric dynamical system $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$ with fixed point 0, generated by the random differential equation (3.7). And and Φ be a linear random dynamical system on X, generated by the random differential equation (3.6). If Φ satisfies MET, has negative Lyapunov exponents, $F(\omega,0) = 0$ and*

$$\lim_{(x,y)\to(0,0)} \frac{\|F(\omega,x) - F(\omega,y)\|}{\|x-y\|} = 0$$

for all $\omega \in \Omega$, then the newly defined local random dynamical system $\tilde{\psi}$ and Φ are topologically equivalent on $I_{\max}(\omega,x) := (0, t_{\max})$ in the sense of Theorem 3.6 for all $x \in U(\omega)$ and $\omega \in \hat{\Omega}$, where $t_{\max}$ defined in (3.17) and $U(\omega)$ defined in (3.15).

Theorem 3.12 (Local smooth linearization of RDS)**.** *If the assumptions of Theorem 3.11 hold and additionally there exist reals $M_j \geq 0$ such that all partial derivatives $D_2^j F : \hat{\Omega} \times U(\omega) \to L_j(U(\omega))$, $1 \leq j \leq m$ satisfy*

$$|D_2^j F(\omega,x)|_{\theta_t\omega} \leq M_j \quad \text{for almost all } t \in I_{\max},\ \omega \in \hat{\Omega}, \text{ all } x \in U(\omega) \text{ and } 0 \leq j \leq m, \tag{3.19}$$

then random dynamical system $\tilde{\psi}$ and Φ are C^m-topologically equivalent on $I_{\max}$.

Remark 3.13. *The proof of both above Theorems 3.11 and 3.12 follow from the application of the Theorems 3.6 and 3.7 respectively to the new random dynamical system $\tilde{\psi}$ with X restricted to $U(\omega)$ and I restricted to $I_{\max}(\omega,x)$.*

3.2 C^m linearization of stochastic differential equations

In this section, we establish a local correspondence between a random dynamical system, generated by a stochastic differential equation, and its linearization by using conjugate transformations and applying previously established local linearization results. Assume that X is a finite dimensional Banach space. We will also need the following notations borrowed from [24]. For $k \in \mathbb{N}, \delta \in (0,1]$, denote by $C_b^{k,\delta}$ the set of functions $f : X \to X$ which have partial derivatives $D^i f$ of order up to $|\alpha| \leq k$, are linearly bounded and for which the derivatives of order k are δ-Hölder continuous. In other words,

$$\sup_{x\in X} \frac{|f(x)|}{1+|x|} + \sum_{|\alpha|=1}^{k} \sup_{x\in X} |D^\alpha f(x)| + \sum_{|\alpha|=k} \sup_{\substack{x,\bar{x}\in X \\ x\neq\bar{x}}} \frac{|D^\alpha f(x) - D^\alpha f(\bar{x})|}{|x-\bar{x}|^\delta} < \infty.$$

In order to obtain an SDE result, the approach of [22] plays a key role for us. Specifically, the next two theorems demonstrate the feasibility of a suitable random stationary coordinate transformation (cohomology) that establishes a connection between cocycles of stochastic and random differential equations.

Theorem 3.14 ([22, Thm. 3.1, p. 140])**.** *If $f_1, \ldots, f_k \in C_b^{2,\delta}$ satisfy $\sum_{i=1}^k f_i^j \frac{\partial f_i}{\partial x_j} \in C_b^{2,\delta}$, then there exists a random flow of diffeomorphisms $\Phi : I \times X \times \Omega \to X$ such that the following properties hold:*

(i) for any $(\eta, \tau) \in X \times I$ the process $\Phi(x,\tau)$ satisfies the stochastic integral equation

$$\Phi_t(x,\tau) = x + e^{-\tau} \sum_{i=1}^{k} \int_{-\infty}^{t} e^s f_i(\Phi_s(x,\tau)) \circ dW_s^i; \tag{3.20}$$

(ii) if

$$H_t = \Phi_t(\cdot, t), \tag{3.21}$$

$$\Gamma_t = \frac{\partial}{\partial \tau} \Phi_t(\cdot, t), \tag{3.22}$$

then H is a stationary cocycle of diffeomorphisms, Γ is a stationary random field, and for any $x \in X$ the processes $H(x)$ and $\Gamma(x)$ satisfy the SDE

$$dH_t(x) = \sum_{i=1}^{k} f_i(H_t(x)) \circ dW_t^i + \Gamma_t(x)dt;$$

(iii) for $x \in X$, $\Gamma(x)$ satisfies the stochastic integral equation

$$\Gamma_t(x) = -(H_t(x) - x) + e^{-t} \sum_{i=1}^{k} \int_{-\infty}^{t} e^s \frac{\partial}{\partial x} f_i(H_t(x)) \Gamma_s(x) \circ dW_s^i.$$

Theorem 3.15 ([22, Thm. 3.2, p. 142])**.** *If $f_0 \in C_b^{1,\delta}$ and $f_1, \ldots, f_k \in C_b^{2,\delta}$ satisfy $\sum_{i=1}^k f_i^j \frac{\partial f_i}{\partial x_j} \in C_b^{2,\delta}$, then the following holds for the random vector field $g : \Omega \times X \to X$,*

$$g(\cdot, y) := \frac{\partial}{\partial y} H_0^{-1}(y)[f_0(H_0(y)) + \Gamma_0(y)],$$

with H and Γ given by the previous theorem:

(i) *the random differential equation*

$$dy_t = g(\theta_t \cdot, y_t)dt$$

generates a random cocycle of diffeomorphism Ψ*;*

(ii) *the SDE*

$$dx_t = f_0(x_t)dt + \sum_{i=1}^{k} f_i(x_t) \circ dW_t^i$$

generates a random cocycle of diffeomorphism Φ*;*

(iii) Φ *and* Ψ *are conjugate with cohomology* H_0*, i.e., for* $t \in I$, $\omega \in \Omega$

$$\Phi_t(\omega) = H_0(\theta_t\omega, \cdot) \circ \Psi(\omega) \circ H_0^{-1}(\omega, \cdot).$$

Remark 3.16. *It is important to note the following. Consider Theorems 3.14 and 3.15 in the context of a higher degree of smoothness for the vector fields* $f_1, \dots, f_k$*. Specifically, suppose* $f_1, \dots, f_k \in C_b^{m+1,\delta}$*, and* $\sum_{i=1}^{m} f_i^j \frac{\partial f_i}{\partial x_j} \in C_b^{m+1,\delta}$*. Then* Φ *and, consequently,* H *are* C^m *diffeomorphisms.*

This fact is a direct consequence of applying the following Theorem 3.17 to system (3.20).

Theorem 3.17 ([1, Thm. 2.3.32, p. 93])**.** *If* $f_0 \in C_b^{m,\delta}$ *and* $f_1, \dots, f_k \in C_b^{m+1,\delta}$ *satisfy* $\sum_{i=1}^{k} f_i^j \frac{\partial f_i}{\partial x_j} \in C_b^{m,\delta}$*, then the classical Stratonovich stochastic differential equation*

$$dx_t = f_0(x_t)dt + \sum_{j=1}^{k} f_j(x_t) \circ dW_t^j$$

generates a unique C^m *random dynamical system over the filtered dynamical system describing a Brownian motion.*

Transitioning between SDEs and RDEs through coordinate changes must maintain the principles of a multiplicative ergodic theory, such as Lyapunov exponents and Oseledets spaces. The following proposition demonstrates that these properties are indeed preserved, given that the coordinate change fulfills specific integrability criteria.

Lemma 3.18 ([22, Prop. 5.1, p. 156])**.** *Let* $\Phi : I \times \Omega \to X$ *be a linear cocycle such that*

$$\sup_{0\le t\le 1} \log^+ \|\Phi(t,\omega)\| \in L^1(\Omega, \mathcal{F}, \mathbb{P}), \qquad \sup_{0\le t\le 1} \log^+ \left\|\Phi^{-1}(t,\omega)\right\| \in L^1(\Omega, \mathcal{F}, \mathbb{P}).$$

If $H : \Omega \times X \to X$ *is a random linear mapping satisfying*

(i) $t \mapsto H(\theta_t\omega)$ *is continuous for every* $\omega \in \Omega$*,*

(ii) *one has the integrability condition*

$$\sup_{0\le t\le 1} \log^+ \|H(\theta_t\omega)\| \in L^1(\Omega, \mathcal{F}, \mathbb{P}), \qquad \sup_{0\le t\le 1} \log^+ \left\|H^{-1}(\theta_t\omega)\right\| \in L^1(\Omega, \mathcal{F}, \mathbb{P}),$$

then

$$\Psi(t,\omega) = H(\theta_t\omega, \cdot) \circ \Psi(t,\omega) \circ H^{-1}(\omega, \cdot)$$

for any $t \in I$ *and almost all* $\omega \in \Omega$ *defines a linear cocycle which satisfies MET.* Ψ *possesses the same Lyapunov exponents as* Φ*. If* $U_1, \dots, U_k$ *are the Oseledets spaces of* Φ*, then the Oseletets spaces of* Ψ *are given by* $HU_1, \dots, HU_k$*.*

Following the preliminary discussions, we establish a local C^m-linearization result for random dynamical systems (RDS) generated by stochastic differential equations (SDEs).

Theorem 3.19 (Local smooth linearization of SDEs)**.** *Let the vector fields $f_0 \in C_b^{m,\delta}$ and $f_1, \dots, f_k \in C_b^{m+1,\delta}$ satisfy $f_i(0) = 0$, $i = 0, \dots, k$, and additionally assume*

$$\sum_{i=1}^{k} \sum_{j=1}^{d} f_i^j \frac{\partial f_i}{\partial x_j} \in C_b^{m+1,\delta}.$$

If the random dynamical system Φ generated by the linear stochastic differential equation

$$dx_t = \frac{\partial}{\partial x} f_0(0) x_t \, dt + \sum_{i=1}^{k} \frac{\partial}{\partial x} f_i(0) x_t \circ dW_t^i \tag{3.23}$$

satisfies MET with negative Lyapunov exponents, then it is C^{m-1}-topologically equivalent to the RDS ψ generated by the stochastic differential equation

$$dx_t = f_0(x_t) \, dt + \sum_{i=1}^{k} f_i(x_t) \circ dW_t^i \tag{3.24}$$

for all $x \in X$, $t \in I$ and almost all $\omega \in \Omega$.

Proof. To prove the theorem, first, we need to conjugate the nonlinear SDE (3.24) with the corresponding random differential equation.

In order to do this, let us construct Γ and H and for $y \in X$ define the random field $g : \Omega \times X \to X$ according to Theorems 3.14, 3.15 by

$$g(\cdot, x) = \frac{\partial}{\partial x} H_0^{-1}(x)(f_0(H_0(y)) + \Gamma_0(y)).$$

The random differential equation induced by g has 0 as a fixed point by our hypothesis and construction and is differentiable. Let

$$A = \frac{\partial}{\partial x} g.$$

Denote by ψ^0 the RDS generated by g, and by Φ^0 the RDS generated by

$$dx_t = A(\theta_t \cdot) x_t \, dt.$$

By the construction, the RDS ψ is conjugated to ψ^0 via the cohomology H, and the RDS Φ generated by (3.23) is conjugated to Φ^0 via $\frac{\partial H}{\partial x}$.

Now we turn to the application of the local linearization result (Theorem 3.11) to the newly obtained systems ψ^0 and Φ^0. In order to do this, we have to check the assumptions of Theorem 3.11.

By the construction of Γ and H, and the smoothness properties of f_i for $0 \leq i \leq k$, it follows that all required properties for g are satisfied. Moreover, from Lemma 3.18 and the construction of H, it follows that Φ^0 satisfies the integrability condition of the MET. Therefore, by applying the local linearization theorem, we conclude that Φ and ψ^0 are topologically equivalent via C^m-diffeomorphism h.

With all the groundwork laid, we now proceed to conclude that random dynamical systems Φ and ψ are topological equivalent via the C^{m-1}-diffeomorphism

$$\tilde{h} = \frac{\partial}{\partial x} H_0(\theta_t \omega, \cdot) \circ h \circ H_0^{-1}(\omega, \cdot)$$

for all $x \in X$, $t \in I$, and almost all $\omega \in \Omega$. □

A Appendix

This appendix contains all the essential results and lemmas used throughout the paper to support the proofs of our results. It is organized into two logical parts: deterministic and random.

In the deterministic part, we start with Gronwall's Lemma, which is fundamental for estimating the growth of solutions of differential equations.

Throughout, X, Y denote Banach spaces.

Lemma A.1 (Gronwall's inequality [2, Lemma 2.5, p. 53], [10]). *Suppose we are given a nonempty interval I, a point $\tau \in I$ and let $\alpha, u : I \to \mathbb{R}$ be continuous with α non-decreasing. If for fixed $\beta > 0$ the inequality*

$$u(t) \leq \alpha(t) + \int_\tau^t \beta u(s) ds$$

holds, then

$$u(t) \leq \alpha(t) e^{\beta(t-\tau)} \quad \text{for all } t \in I. \tag{A.1}$$

Theorem A.2 (Variation of Constants Formula [2, Thm. 2.10, p. 58], [15]). *Consider the system*

$$\dot{x} = A_\omega(t)x + F_\omega(t, x), \tag{A.2}$$

where $A_\omega \colon I \to L(X)$ and $F_\omega \colon I \times X \to X$ are locally integrable. Then the solution $\varphi(t, s, \xi)$ of (A.2) is given by the variation of constants formula:

$$\varphi(t, s, \xi) = \Phi_\omega(t, s)\xi + \int_s^t \Phi_\omega(t, \tau) F_\omega(\tau, \varphi(\tau, s, \xi))\, d\tau,$$

which is valid for all $(t, s, \xi) \in I \times I \times X$.

Now we present the well-known fixed point theorem of Banach and some related results.

Theorem A.3 (Banach's Fixed Point Theorem [2, Thm. B.1, p. 114], [45]). *If $\mathcal{T} \colon X \to X$ a contraction, i.e. there exists $0 \leq c < 1$ such that*

$$\|\mathcal{T}(x) - \mathcal{T}(\bar{x})\| \leq c \|x - \bar{x}\| \quad \text{for all } x, \bar{x} \in X,$$

then there exists exactly one fixed point $\varphi \in X$ of $\mathcal{T}$.

Theorem A.4 (Uniform Contraction Principle [13, Thm. 2.2, p. 25]). *Suppose $U \subseteq X$, $V \subseteq Y$ are open, let $\bar{U}$ denote the closure of U and $m \in \mathbb{N}_0$. If $\mathcal{T} \in C^m(\bar{U} \times V, X)$, is a uniform contraction, i.e. there exists a $0 \leq c < 1$ such that*

$$\|\mathcal{T}(x, y) - \mathcal{T}(\bar{x}, y)\| \leq c \|x - \bar{x}\| \quad \text{for all } x, \bar{x} \in \bar{U} \text{ and } y \in V,$$

then the unique fixed point $\varphi(y)$ of $\mathcal{T}(\cdot, y)$ in $\bar{U}$ satisfies $\varphi \in C^m(V, X)$.

Theorem A.5 (Local Inverse Mapping Theorem [45, Thm. 4.F, p. 172]). *Let $U \subseteq X, x_0 \in U$ and $f : U \to Y$ be a C^m mapping for $m \in \mathbb{N}$. Then f is a local C^m-diffeomorphism at x_0 if and only if $Df(x_0)$ is bijective.*

Theorem A.6 (Global Inverse Mapping Theorem [45, Thm. 4.G, p. 174]). *Let $f : X \to Y$ be a local C^m-diffeomorphism for $m \in \mathbb{N}$ at every point of X. Then f is a C^m-diffeomorphism if and only if f is proper.*

Theorem A.7 (Differentiation under the integral [40, Thm. A.5, p. 263]). *Let $U \subseteq X, V \subseteq Y$ be open and $f : U \times V \to X$ be such that $f(\cdot, y)$ is integrable for any $y \in V$. Suppose, that for any $x \in U, y \in V$, there exist derivative $D_2 f(x,y)$, and*

$$\|D_2 f(x,y)\| \leq g(x),$$

where $g : U \to \mathbb{R}^+$ is integrable. Then the mapping

$$F(y) = \int_U f(x,y)dx$$

is differentiable with derivative is given by

$$DF(y) = \int_U D_2 f(x,y)dx.$$

Now let us turn to a key result in random dynamical systems: the fundamental Oseledets's multiplicative ergodic theorem (MET).

In the following we will write $\log^+(x) = \max\{0, \log(x)\}$ for any $x \in X$. For a probability space $(\Omega, \mathcal{F}, \mathbb{P})$, we denote by $L^1(\Omega, \mathcal{F}, \mathbb{P})$ the space of all integrable measurable functions.

Theorem A.8 (Multiplicative Ergodic Theorem, half line, continuous time [1, Thm. 3.4.1, p. 134]). *Let Φ be a linear cocycle over an ergodic MDS $(\Omega, \mathcal{F}, \mathbb{P}, (\theta_t)_{t\in I})$. Assume that*

$$\sup_{0\leq t\leq 1} \log^+ \|\Phi(t,\omega)\| \in L^1(\Omega, \mathcal{F}, \mathbb{P}), \qquad \sup_{0\leq t\leq 1} \log^+ \left\|\Phi^{-1}(t,\omega)\right\| \in L^1(\Omega, \mathcal{F}, \mathbb{P}). \tag{A.3}$$

Then there exist a forward invariant set $\tilde{\Omega} \in \mathcal{F}$ of full measure such that for every $\omega \in \tilde{\Omega}$ the following statements hold:

(i) There exist $k(\omega)$ numbers $\lambda_1(\omega) > \cdots > \lambda_{k(\omega)}(\omega)$ and the invariant splitting $X = U_1(\omega) \oplus \cdots \oplus U_{k(\omega)}(\omega)$ such that

$$\begin{aligned} k(\theta_t\omega) &= k(\omega), \\ \lambda_i(\theta_t\omega) &= \lambda_i(\omega) \quad \text{for all } i \in \{1, 2, \ldots, k(\omega)\}, \\ d_i(\theta_t\omega) &= d_i(\omega) \quad \text{for all } i \in \{1, 2, \ldots, k(\omega)\}, \end{aligned}$$

where $d_i(\omega) := \dim U_i(\omega)$.

(ii) Put $V_{k(\omega)+1}(\omega) := 0$ and for $i = 1, \ldots, k(\omega)$

$$V_i(\omega) := U_i(\omega) \oplus \cdots \oplus U_{k(\omega)}(\omega)$$

so that

$$V_{k(\omega)}(\omega) \subset \cdots \subset V_i(\omega) \subset \cdots \subset V_1(\omega)$$

defines a filtration on X. Then for each $x \in X \setminus \{0\}$ the Lyapunov exponent

$$\lambda(\omega, x) := \lim_{t\to\infty} \frac{1}{t} \log \|\Phi(t,\omega)x\|$$

exists and

$$\lambda(\omega, x) = \lambda_i(\omega) \iff x \in V_i(\omega) \setminus V_{i+1}(\omega),$$

i.e.

$$V_i(\omega) = \{x \in X : \lambda(\omega, x) \leq \lambda_i(\omega)\}.$$

(iii) For all $x \in X \setminus \{0\}$

$$\lambda(\theta_t\omega, \Phi(t,\omega)x) = \lambda(\omega, x),$$

whence

$$\Phi(t,\omega)V_i(\omega) \subset V_i(\theta_t\omega) \quad \text{for all } i \in \{1, 2, \ldots, k(\omega)\}.$$

Acknowledgements

The author thanks the supervisor, Christian Pötzsche, for his guidance, support, and helpful feedback. Special thanks are due to the mentor, Maximillian Engel, for his advice and encouragement. The author also gratefully acknowledges the reviewers for their time, careful reading, and valuable comments.

Abstract. We correct and update a result of R. G. D. Richardson [*Amer. J. Math.* **40**(1918), 283–316] dealing with the separation of zeros of the real and imaginary parts of non-real eigenfunctions of non-definite Sturm–Liouville eigenvalue problems. We then extend it to the case where the weight function is allowed to be identically zero on a subinterval that excludes the end-points and study the behavior of the zeros of the real and imaginary parts when the end-points are included. Examples are given illustrating the sharpness of the results along with open questions.

Keywords: Sturm–Liouville, eigenvalues, non-definite, complex ghosts, oscillations, zeros, separation theorem

2020 Mathematics Subject Classification: 34B24, 34B09, 34C10.

1 Introduction

We consider the Sturm–Liouville eigenvalue problem with real piecewise continuous coefficients over an interval $[a, b]$,

$$-y'' + q(x)y = \lambda r(x)y, \tag{1.1}$$

$$y(a) = y(b) = 0. \tag{1.2}$$

in the non-definite case, [11], i.e., this is essentially the case where the quadratic forms induced by the two operators on the left and on the right are sign-indefinite on their domains. The more general equation

$$-(p(x)y')' + q(x)y = \lambda r(x)y$$

where $p(x)$ is of one sign may be reduced to (1.1) by means of a Liouville transformation, and so leads to no new results. Thus, we shall restrict ourselves to the formulation (1.1) in this paper.

Tacit assumptions and notation

In the sequel we will always assume that the eigenvalue problem (1.1)–(1.2) is non-definite and has at least one pair of non-real eigenvalues, usually denoted by $\lambda, \bar{\lambda} \in \mathbf{C}$. The problem of the actual *existence* of non-real eigenvalues for problems of this type is difficult and very few results exist in this direction, see, e.g., [1,14]. Given a non-real eigenvalue of (1.1)–(1.2), an associated non-real eigenfunction will be denoted by $y = \varphi + i\psi$, where φ, ψ are its, normally unspecified, real and imaginary parts. A non-real eigenfunction will be called a complex ghost state or a *complex ghost*, for short [11]. Hereinafter, all solutions will be assumed non-trivial unless otherwise specified. In addition, since Im $\lambda \neq 0$ we will always assume that, unless otherwise specified, Im $\lambda > 0$. This is always possible as we can replace λ by $\bar{\lambda}$ and y by $\bar{y}$ in (1.1). Insofar as tacit assumptions are concerned we will always assume that $q, r \in L^1(a,b)$, so that solutions of initial value problems associated with (1.1) over $[a,b]$ exist and are unique in the Carathéodory sense, [4], i.e., $y, y' \in AC[a,b]$ and (1.1) holds a.e. in $[a,b]$.

The following original result is essentially stated in Richardson [13], see also [9,11].

Theorem 1.1 ([13, Theorem X])**.** Let r be continuous in $[a,b]$. If $r(x)$ changes its sign precisely once in (a,b) then the roots of the real and imaginary parts of any complex ghost separate one another.

A discussion of Theorem 1.1 is necessary. First, it was understood at the time of Richardson's paper (as it is now in classical Sturmian cases, such as in Sturm's separation theorem) that the expression *separate one another* meant that between any two consecutive zeros of one solution there is always exactly one zero (of any other independent solution) that is distinct from either of the two original zeros. It is unlikely that Richardson had in mind the possibility that the weight function, $r(x)$, could be identically zero in a subinterval, however the latter possibility does change the result(s). To be clear, in this paper, the statement that two continuous functions f, g have zeros that separate one another on $[a,b]$ means that between any two consecutive zeros of one there is exactly one zero of the other that is different from either of the other two.

We will show below that Theorem 1.1 as stated is, in general, not true (see e.g., Example 3.2 and Figure 3.1 below). This was alluded to in [9] but without discussion. It is true if one excludes the endpoints as one of the two zeros in question, i.e., we are dealing only with interior zeros. However, counterexamples can be found in cases where the endpoints are included (see the examples at the end of this article). Indeed, we show in Remark 2.11 that if $r(x)$ is identically zero in a right-neighborhood of $x = a$ that includes the endpoint, then Theorem 1.1 is false. In fact, we go further and show in Lemma 2.1 below, that the statement in Theorem 1.1 cannot be true if the endpoints are included (if even the weight function never vanishes identically in any subinterval). As a result, Richardson's Theorem X in [13] must be replaced by something like Theorem 2.10. Indeed, in Theorem 2.10 we show that the single turning point or zero required in Theorem 1.1 may be replaced by an *interval of zeros* without affecting the conclusion.

In addition, we will find conditions under which given two consecutive zeros (one of which is an endpoint) of either the real (or imaginary) part of a complex ghost there is or there isn't a zero of the imaginary (or real) part. In this sense, this paper continues a study of the zeros of the real and imaginary parts of such ghosts, research that began with [9,10,12,13] and continued with [7,8] and the results therein.

Remark 1.2. We note that Theorem 1.1 appears to be exceptional in the sense that it has no apparent equivalent in the two turning point case (with a weight function that does not vanish

identically in a subinterval). For example, in [8] there are examples showing that the interior zeros of the real and imaginary parts of non-real eigenfunctions may not separate one another.

2 Main results

First, we show that Theorem 1.1 cannot be true if one or more end-points are included in its conclusion.

Lemma 2.1. There is no non-trivial complex ghost whose real and imaginary parts have zeros that separate one another on an interval that includes the endpoints of $[a, b]$.

Proof. Without loss of generality we may assume that the endpoint in question is $x = a$. Assuming the contrary, let $y = \varphi + \psi i$ be a non-trivial complex ghost where φ satisfies $\varphi(a) = 0$ and $\varphi(x_0) = 0$ where x_0 is a zero of φ larger than $x = a$. Then, by hypothesis, $\psi(x)$ has a unique zero t_0 in (a, x_0). Now $\psi(a) = \psi(t_0) = 0$, thus, by assumption $\varphi(x_1) = 0$ for some unique $x_1 \in (a, t_0)$. Since $\varphi(a) = \varphi(x_1) = 0$ there must be a unique zero $t_1 \in (a, x_1)$ of ψ. Continuing in this way we see that the now infinite sequence of zeros x_i, t_i must accumulate at $x = a$. On the other hand the theorem of the mean then implies that both $\varphi'(a) = 0$ and $\psi'(a) = 0$. Thus, $y'(a) = 0$ and so y is the trivial solution, a contradiction. □

Lemma 2.2. Let λ be a non-real eigenvalue of (1.1)–(1.2) and $y = \varphi + i\psi$ be a corresponding eigenfunction. Then φ, ψ are linearly independent over $[a, b]$.

Proof. Assume the contrary. Then $\psi = \mu\varphi$ where $\mu \in \mathbf{C} \setminus 0$. Since $y = (1 + i\mu)\varphi$ satisfies (1.1) we get that $-\varphi'' + q\varphi = \lambda r\varphi$. Since the left side of the previous equation is real and $\operatorname{Im}\lambda \neq 0$ we find that $r(x)\varphi(x) \equiv 0$ on $[a, b]$. Since, by hypothesis, (1.1)–(1.2) is non-definite, $r(x)$ cannot be identically zero and so there is an interval $J \subset [a, b]$ on which $r(x) > 0$, say. Thus, $\varphi(x) \equiv 0$ on J. Hence $\psi(x) \equiv 0$ on J so that $y \equiv 0$ on J. This, however, violates the uniqueness of solutions of an initial value problem with initial conditions on a point of J. This contradiction proves the lemma. □

Lemma 2.3. Let $c > a$, r be piecewise continuous on (a, c) and $r(x) < 0$ there. In addition, let $r(x) \equiv 0$ on $[c, d] \subset (a, b)$ and $r(x) > 0$ and continuous on (d, b). Then, for any complex ghost y of (1.1),

$$G(x) \equiv \int_a^x r|y|^2 \, dt, \qquad x \in [a, b], \tag{2.1}$$

is of one sign in (a, b), in fact, $G(x) < 0$, for all $x \in (a, b)$.

Proof. Since $r(x) < 0$ on $(a, c) \subseteq (a, d)$, by hypothesis, then $G(x) < 0$ too, as an eigenfunction cannot vanish identically on an interval unless it is identically zero there. Assume, on the contrary, that there is a smallest point $x_1 \in (a, b)$ with $G(x_1) = 0$. Since $G(x)$ must change its sign around x_1 it follows that $x_1 \in [d, b)$.

Next, observe that $G(x_1) = G(b) = 0$ and $G \in C^1(d, b)$. (Note that $G(b) = 0$ for complex ghosts, see [9, Theorem 1]. Hence there exists $\eta \in (d, b)$ such that $r(\eta)|y(\eta)|^2 = 0$, i.e., $y(\eta) = 0$. Consider the boundary problem (1.1) subject to the boundary conditions $y(\eta) = y(b) = 0$. This new eigenvalue problem admits our complex ghost y as an eigenfunction corresponding to the same non-real eigenvalue. Thus, this problem must be non-definite on $[\eta, b]$, i.e., $r(x)$ must change its sign on this interval, but this is a contradiction as $r(x) > 0$ there. Hence no such x_1 can exist. This completes the proof. □

The next result is an immediate consequence of Lemma 2.3.

Corollary 2.4. If $r(x) > 0$ on (a,c), $r(x) \equiv 0$ on $[c,d] \subset (a,b)$, and $r(x) < 0$ on (d,b), then $G(x) > 0$ on (a,b).

Proof. Replace λ by $-\lambda$ and r by $-r$ in Lemma 2.3 so that the eigenfunction does not change. □

Corollary 2.5 ([13, Theorem X])**.** If $r(x)$ is not identically zero in any right interval of a and $r(x)$ has a unique zero around which $r(x)$ changes sign in (a,b), then $G(x)$ is of one sign in (a,b).

Proof. This is the case where $c = d$ in Lemma 2.3 so either Lemma 2.3 or Corollary 2.4 applies. □

Corollary 2.6. Let $c > a$, r be piecewise continuous on (a,c) and $r(x) < 0$ there. In addition, let $r(x) \equiv 0$ on $[c,d] \subset (a,b)$ and $r(x) > 0$ and continuous on (d,b). Then, for any $x \in (a,b)$, the function $H(x) = \int_x^b r|y|^2\,dt$ is of one sign on (a,b), i.e., $H(x) > 0$ on (a,b).

Proof. This is an application of Lemma 2.3 and the fact that $\int_a^b r|y|^2\,dx = 0$ must hold for any complex ghost. □

Lemma 2.7. Let $y = \varphi + i\psi$ be a complex ghost. Then, for any two points $x_1, x_2 \in [a,b]$ we have,

$$\left[\varphi'\psi - \varphi\psi'\right]\Big|_{x_1}^{x_2} = \operatorname{Im}\lambda \int_{x_1}^{x_2} r|y|^2\ dx.$$

Proof. Let $y = \varphi + i\psi$ be a complex ghost. Then, from (1.1), we find that (suppressing the variables for simplicity of exposition),

$$-\varphi'' + (q - r\operatorname{Re}\lambda)\varphi = -(\operatorname{Im}\lambda)\ r\ \psi, \tag{2.2}$$
$$-\psi'' + (q - r\operatorname{Re}\lambda)\psi = (\operatorname{Im}\lambda)\ r\ \varphi, \tag{2.3}$$

where $\operatorname{Im}\lambda \neq 0$ by hypothesis. For any two points $x_1, x_2 \in [a,b]$ a simple Sturmian argument applied to (2.2) and (2.3) now yields,

$$\left[\varphi'\psi - \varphi\psi'\right]\Big|_{x_1}^{x_2} = \operatorname{Im}\lambda \int_{x_1}^{x_2} r|y|^2\ dx. \tag{2.4}$$

From (2.4) since $y(a) = 0$ is equivalent to $\varphi(a) = \psi(a) = 0$ we get that, for any $x \in [a,b]$,

$$\varphi'(x)\psi(x) - \varphi(x)\psi'(x) = \operatorname{Im}\lambda \int_a^x r|y|^2\ dt = (\operatorname{Im}\lambda)\ G(x). \tag{2.5}$$

By Lemma 2.3 and Corollary 2.4 $G(x)$ is of one sign only on (a,b) (depending on the sign of $r(x)$ on (a,c)). □

The next lemma is an application of classical folklore so a proof is given for the sake of completeness.

Lemma 2.8. Let $q, r \in C[a,b]$, and for some $c > a$, let $r(x) < 0$ on (a,c), $r(x) \equiv 0$ on $[c,d] \subset (a,b)$ and $r(x) > 0$ and continuous on (d,b). Let φ, ψ be two non-trivial solutions of the system (2.2) and (2.3). If the zeros of φ (or ψ) have a point of accumulation $x_0 \in (a,b)$, then the non-real eigenfunction, y, satisfies $y(x_0) = 0$. In addition, the end-points, $x = a, b$, cannot be points of accumulation of either φ or ψ.

Proof. By fundamental existence theorems we know that the continuity of the coefficients q, r implies that both solutions $\varphi, \psi \in C^2(a,b)$ (whenever they exist, or whenever there are non-real eigenvalues).

If possible let $x_0 \in (a,b)$ be a point of accumulation of φ and let $x_n \to x_0$ be an infinite sequence of zeros of φ accumulating at x_0. Then, by continuity, $\varphi(x_0) = 0$. On the other hand, $\varphi \in C^1$ so that $0 = (\varphi(x_n) - \varphi(x_0))/(x_n - x_0) = \varphi'(\xi_n)$ holds for all n for some ξ_n between x_0 and x_n. There follows that $\xi_n \to x_0$ as well and thus, since $\varphi \in C^1$, $\varphi'(x_0) = 0$. Since $\varphi \in C^2$ we get that $0 = (\varphi'(\xi_n) - \varphi'(x_0))/(\xi_n - x_0) = \varphi''(\zeta_n)$ for some ζ_n between ξ_n and x_0. Since $\zeta_n \to x_0$ there follows that $\varphi''(x_0) = 0$. From this and (2.2) we obtain, $r(x_0)\psi(x_0) = 0$ (as $\operatorname{Im}\lambda > 0$, by hypothesis.)

So, $\psi(x_0) = 0$ whenever $r(x_0) \neq 0$. On the other hand, if $r(x) \equiv 0$ on some subinterval $[c,d] \subset (a,b)$ where, in addition, $x_0 \in [c,d]$, then, using (2.2) and (2.3), we get that both φ, ψ are solutions of the same equation, namely, $-z'' + (q - r\operatorname{Re}\lambda)z = 0$, where $x \in [c,d]$. Thus either φ, ψ are linearly dependent, in which case $\varphi(x_0) = 0 = \psi(x_0)$ is immediate, or they are linearly independent, in which case Sturm's Separation Theorem implies the interlacing of the zeros of φ, ψ and thus, once again we must have $\psi(x_0) = 0$. Therefore, in any case we must have $\psi(x_0) = 0$. Finally, $\varphi(x_0) = \psi(x_0) = 0$ is equivalent to $y(x_0) = 0$ as was to be shown.

The same argument applies to ψ so that all its interior zeros are isolated as well.

If either $x_0 = a$ or $x_0 = b$ is an accumulation point of φ, we proceed as follows: Assume that $x = a$ is such a point. Since $y'(a) \neq 0$ (as y is non-trivial) at least one, maybe both, of $\varphi'(a), \psi'(a)$ are non-zero. We may assume that $\varphi'(a) \neq 0$ (or else if $\varphi'(a) = 0$, then $\psi'(a) \neq 0$ and we can apply the following argument to ψ as $\psi(a) = 0$). Applying the argument in the second paragraph of the proof of Lemma 2.8 above, we can conclude that $\varphi'(a) = 0$, which is a contradiction. Hence $x = a$ cannot be a point of accumulation of φ (similarly for ψ). If $x = b$ a similar argument applies whose proof is omitted. □

Corollary 2.9. Let q, r be continuous on $[a,b]$. For some $c > a$, let $r(x) < 0$ on $[a,c)$, $r(x) \equiv 0$ on $[c,d] \subset (a,b)$, and $r(x) > 0$ on $(d,b]$. Then the interior zeros of any solution φ of (2.2)–(2.3) are isolated.

Proof. Since we are dealing with interior zeros, by Lemma 2.8 if there is such an accumulation point x_0 of φ that satisfies $a < x_0 < b$, then it must also satisfy $y(x_0) = 0$ where $y = \varphi + i\psi$ is an eigenfunction of (1.1)–(1.2). Thus, $y(a) = y(x_0) = y(b) = 0$. Note that if $x_0 \in (a,d]$ then $r(x) \leq 0$ in which case the boundary problem (1.1) subject to the boundary condition $y(a) = y(x_0) = 0$ must have a non-real eigenvalue which isn't possible as the eigenvalue problem on $(a,x_0]$ is now right-definite. On the other hand, if $x_0 \in [d,b)$ then $r(x) > 0$ in $[d,b)$ and so in $[x_0,b)$. Hence, the problem (1.1) subject to the boundary condition $y(x_0) = y(b) = 0$ must have also have a non-real eigenvalue which isn't possible as this problem is also right-definite. Thus all interior zeros of φ are isolated. □

Theorem 2.10. Let $q, r \in C[a,b]$, and for some $c > a$, let $r(x) < 0$ on (a,c), $r(x) \equiv 0$ on $[c,d] \subset (a,b)$ and $r(x) > 0$. Then the interior zeros of the real and imaginary part of a complex ghost separate one another.

Proof. Since, by Lemma 2.8, the interior zeros of φ are isolated, we let $x_1 < x_2 \in (a,b)$ be two consecutive zeros of $\varphi(x)$ where, without loss of generality, we may take it that $\varphi(x) > 0$ in (x_1,x_2). (If φ is negative, we replace φ by $-\varphi$ and ψ by $-\psi$ in what follows.) Assume, if possible, that $\psi(x) \neq 0$ in $[x_1,x_2]$.

Since $r(x) < 0$ in (a, c), Lemma 2.3 implies that $G(x) < 0$ in (a, b). Assume, if possible, that $\psi(x) > 0$ in $[x_1, x_2]$. Using (2.5) we get, for $x_1 \leq x \leq x_2$,

$$\left(\frac{\varphi}{\psi}\right)' = \frac{\operatorname{Im}\lambda}{\psi^2(x)}\, G(x) < 0. \tag{2.6}$$

Thus, $0 = \varphi(x_1)/\psi(x_1) > \varphi(x)/\psi(x)$ which is impossible. Hence, $\psi(x) > 0$ in $[x_1, x_2]$ cannot hold, i.e., $\psi(x)$ must vanish somewhere in $[x_1, x_2]$. A similar argument holds in the case where $\psi(x) < 0$ in $[x_1, x_2]$ as from (2.6), $\varphi(x)/\psi(x) > \varphi(x_2)/\psi(x_2) = 0$, which is also impossible.

Now we show that $\psi(x_1)\psi(x_2) \neq 0$. Assuming, if possible, that $\psi(x_1) = 0$, then $y(x_1) = 0$ as well. Since $y(a) = y(x_1) = 0$ and y is a non-real eigenfunction, (1.1) must be non-definite on $[a, x_1]$, so $r(x)$ cannot have a fixed sign there. Therefore, we must have that $x_1 \in (d, b]$ (see the hypotheses on $r(x)$). Once again the problem (1.1), subject to the boundary conditions $y(x_1) = 0, y(b) = 0$, must be non-definite. But this is impossible since $r(x) < 0$ on (d, b). This contradiction implies that $\psi(x_1) \neq 0$. A similar argument applies to the case where $\psi(x_2) = 0$, and we leave this to the reader.

It follows from the preceding argument that $\psi(x) = 0$ somewhere in (x_1, x_2), say, at $x = t_1$. We take it that t_1 is the smallest such zero, so that $\psi(x) \neq 0$ in (t_1, t_2). However, since $\varphi(x) \neq 0$ in $[t_1, t_2]$, a modification of (2.6) using (2.5), gives

$$\left(\frac{\psi}{\varphi}\right)' = -\frac{\operatorname{Im}\lambda}{\varphi^2(x)}\, G(x) > 0, \tag{2.7}$$

from which we obtain a contradiction as before, as ψ/φ must be increasing in (t_1, t_2), yet ψ vanishes at the end-points. This contradiction shows that between any two consecutive interior zeros of φ, the function ψ has a unique zero. □

Remark 2.11. This extends and corrects Theorem 1.1 from a single turning point (or a zero around which $r(x)$ changes sign) to an interval of zeros. The condition that, for some $c > a$, $r(x) \neq 0$ on (a, c) is necessary. This is because if r vanishes identically in some subinterval of $[a, c]$ containing $x = a$, the separation property of the roots fails as φ, ψ must be linearly dependent on account of (2.4) applied to said interval.

Lemma 2.12. Let $G(x) < 0$ for all $x \in (a, b)$. Let $\varphi'(a) > 0$, (resp. $\varphi'(a) < 0$) and let $x_0 \in (a, b)$ be the smallest zero of $\varphi(x)$.

1. If $\psi'(a) > 0$, then $\psi(x) > 0$ in $(a, x_0]$ (resp. if $\psi'(a) < 0$, then $\psi(x) < 0$ in $(a, x_0]$)
2. If $\psi'(a) < 0$, then $\psi(x) = 0$ exactly once in (a, x_0) (resp. if $\psi'(a) > 0$, then $\psi(x) = 0$ exactly once in (a, x_0))
3. If $\psi'(a) = 0$, then one of the first two cases must occur.

Proof. By Lemma 2.8 we can let x_0, where $a < x_0 < b$, be the smallest zero of φ (assuming there is a zero at all). Since $\varphi'(a) > 0$ and x_0 is the smallest zero of $\varphi(x)$, then $\varphi(x) > 0$ on (a, x_0). Assume, for the moment that $\psi(x_0) \leq 0$. Geometrical considerations give us that $\varphi'(x_0)\psi(x_0) \geq 0$. Applying (2.5) with $x = x_0$ we obtain a contradiction. Thus, it must be the case that $\psi(x_0) > 0$.

There are now three possibilities, each of which may occur (see Example 3.2, Example 3.3 and Example 3.4, below).

Case 1. Let $\psi'(a) > 0$. Then ψ increases in a right-neighborhood of $x = a$ and we will show that $\psi(x) \neq 0$ in (a, x_0), so that $\psi(x) > 0$ there.

For assume, on the contrary, that $\psi(x_1) = 0$ at some smallest point x_1 where $a < x_1 < x_0$ and $\psi(x) > 0$ for $a < x < x_1$. From (2.5) we know that

$$\varphi'(x_1)\psi(x_1) - \varphi(x_1)\psi'(x_1) = \operatorname{Im}\lambda \int_a^{x_1} r|y|^2 \, dx < 0,$$

which gives a contradiction since $\varphi(x_1) > 0$ and $\psi'(x_1) < 0$ (note that $\psi'(x_1) = 0$ is excluded from the previous display). Hence, in this case, $\psi(x) \neq 0$ whenever $a < x < x_0$, i.e., $\psi(x) > 0$ in $(a, x_0]$.

Case 2. Let $\psi'(a) < 0$. In this case, ψ decreases in a right neighborhood of $x = a$ and so $\psi(x)$ must be negative. On the other hand $\psi(x_0) > 0$ and so $\psi(x_3) = 0$ at some smallest point $x = x_3$, where $a < x_3 < x_0$ and $\psi(x) < 0$ on (a, x_3). Note that ψ cannot vanish again for $x > x_3$ for, if $\psi(x_4) = 0$, where $x_3 < x_4 < x_0$, then this would violate the separation of internal zeros property in Theorem 2.10 as $\varphi(x) > 0$ in $[x_3, x_4]$.

Case 3. Let $\psi'(a) = 0$. This final case is shown by noting that $\psi(x)$ must be of one sign in a right-neighborhood of $x = a$ after which one of the proofs in cases 1 and 2 must apply, depending on the sign.

The alternative ("respective") result is handled from the first by replacing y by $-y$, or φ, ψ by $-\varphi, -\psi$, a transformation which keeps (2.4) invariant, and the eigenvalue the same. □

Corollary 2.13. Let $G(x) < 0$ for all $x \in (a, b)$. Let $\psi'(a) < 0$, and let $x_0 \in (a, b)$ be the smallest zero of $\psi(x)$.

1. If $\varphi'(a) > 0$, then $\varphi(x) > 0$ in (a, x_0)
2. If $\varphi'(a) < 0$, then $\varphi(x) = 0$ exactly once in (a, x_0)
3. If $\varphi'(a) = 0$, then one of the first two cases must occur.

Proof. Replace $y = \varphi + i\psi$ by $iy = -\psi + i\varphi$ which is another eigenfunction satisfying (1.1)–(1.2) and apply the lemma to this eigenfunction. Observe that this change of variable also keeps (2.4) invariant. □

Remark 2.14. Observe that the proof of Lemma 2.12 fails if $x_0 = b$ as then $G(b) = 0$ so that the right-hand side of (2.5) is zero.

Remark 2.15. Note that if $\psi'(a) = 0$, then one of Case 1, 2 above must apply, i.e., either ψ increases or decreases in a right neighborhood of $x = a$. In either case we have the same results. See Example 3.2 for an application of Corollary 2.13(1) and Example 3.3 for an application of Lemma 2.12 (2).

Results analogous to Lemma 2.12 and Corollary 2.13 may be formulated in the event that information is available at the right endpoint. Two samples follow, others may be readily formulated using the change of variables in Lemma 2.12 and Corollary 2.13. We sketch the proofs.

Lemma 2.16. Let $G(x) < 0$ for all $x \in (a, b)$. Let $\varphi'(b) < 0$, (resp. $\varphi'(b) > 0$) and let $x_0 \in (a, b)$ be the largest zero of $\varphi(x)$.

1. If $\psi'(b) > 0$, then $\psi(x) < 0$ in (x_0, b) (resp. if $\psi'(b) < 0$, then $\psi(x) > 0$ in (x_0, b))

2. If $\psi'(b) < 0$, then $\psi(x) = 0$ exactly once in (x_0, b) (resp. if $\psi'(b) > 0$, then $\psi(x) = 0$ exactly once in (x_0, b))

3. If $\psi'(b) = 0$, then one of the first two cases must occur.

Proof. Let $a < x_0 < b$ be the largest zero at which φ vanishes (again, assuming there is a zero at all). Since $\varphi'(b) < 0$ and x_0 is the largest zero of $\varphi(x)$, then $\varphi(x) > 0$ on (x_0, b). Assume, for the moment that $\psi(x_0) > 0$. Geometrical considerations give us that $\varphi'(x_0)\psi(x_0) \geq 0$. Applying (2.5) with $x = x_0$ we obtain a contradiction. Thus, it must be the case that $\psi(x_0) \leq 0$. On the other hand, if $\psi(x_0) = 0$, then the left hand side of (2.5) is zero (at $x = x_0$) while the right hand is non-zero. This contradiction proves that $\psi(x_0) < 0$.

Case 1. Let $\psi'(b) > 0$. Then ψ increases in a left-neighborhood of $x = b$ and we will show that $\psi(x) \neq 0$ in (x_0, b), so that $\psi(x) < 0$ there.

For assume, on the contrary, that $\psi(x_1) = 0$ at some largest point x_1 where $x_0 < x_1 < b$ and $\psi(x) < 0$ for $x_1 < x < b$. From (2.5) we know that

$$\varphi'(x_1)\psi(x_1) - \varphi(x_1)\psi'(x_1) = \operatorname{Im}\lambda \int_a^{x_1} r|y|^2 \, dx < 0,$$

which gives a contradiction since $\varphi(x_1) > 0$ and $\psi'(x_1) < 0$ (note that $\psi'(x_1) = 0$ is excluded from the previous display). Hence, in this case, $\psi(x) \neq 0$ whenever $x_0 < x < b$, i.e., $\psi(x) < 0$, $x \in (x_0, b)$.

Case 2. If $\psi'(b) < 0$ then ψ decreases and is positive in a left-neighborhood of $x = b$. However, since $\psi(x_0) < 0$, it follows that $\psi(x_5) = 0$ for some $x_0 < x_5 < b$, where x_5 is taken to be the largest (in fact, the only) such zero, i.e., $\psi(x) > 0$ in (x_5, b). If possible, assume that $\psi(x)$ vanishes again at $x = x_6$, where now $x_0 < x_6 < x_5$. This now violates the separation of zeros property in Theorem 2.10 as these are internal zeros and φ is not zero there.

Case 3. This is shown as in the corresponding cases in the above lemmas, so the proofs are left to the reader. □

Corollary 2.17. Let $G(x) < 0$ for all $x \in (a, b)$. Let $\psi'(b) > 0$, and let $x_0 \in (a, b)$ be the largest zero of $\psi(x)$.

1. If $\varphi'(b) > 0$, then $\varphi(x) < 0$ in (x_0, b).

2. If $\varphi'(b) < 0$, then $\varphi(x) = 0$ exactly once in (x_0, b).

3. If $\varphi'(b) = 0$, then one of the first two cases must occur.

Proof. Consider the eigenfunction $iy = -\psi + i\varphi$ as before. □

We recall that if $G(x) > 0$, analogous results may be obtained by replacing λ by $-\lambda$ and r by $-r$ in the above theorems and lemmas as the eigenfunction remains the same although the non-real eigenvalue is the negative of the original one corresponding to a different weight function, r.

3 Examples

In the examples that follow the coefficients q, r appearing in (1.1) are piecewise continuous rather than continuous, this is not a real lack of generality as one expects the same results holding in this slightly weaker case of piecewise continuity as continuous functions on $[a,b]$ are dense in $L(a,b)$. Thus, solutions of problems with piecewise continuous coefficients may be approximated arbitrarily closely by a differential equation with continuous coefficients.

In this section we shall make use of the following result,

Lemma 3.1 ([10, Theorem 4.2.1])**.** Let $p(x) > 0$ a.e. on $[a,b]$, $q \in L(a,b)$ and $r(x)$ is a real-valued function defined on $[a,b]$ and such that $r(x)$ takes both signs on some subsets of positive measure. Then the eigenvalue problem

$$-(p(x)y')' + q(x)y = \lambda r(x)y, \qquad y(a) = y(b) = 0, \tag{3.1}$$

possesses at most a finite number of non-real eigenvalues. If we let M the number of pairs of distinct non-real eigenvalues of (3.1), N the number of distinct negative eigenvalues of (3.1) with $r(x) \equiv 1$, which we know is finite by classical Sturm–Liouville theory, [6, §5.8, Theorem 2], then $M \leq N$.

Example 3.2. As an application of Lemma 2.3 and the second conclusion in Lemma 2.12, consider the eigenvalue problem for the equation

$$-y''(x) - q\,y(x) = \lambda\,\mathrm{sgn}(x)y(x), \qquad y(-1) = 0,\ y(1) = 0.$$

where $\lambda \in \mathbf{C}$, $q > 0$ is a constant, and $\mathrm{sgn}(x) = -1$ for $x \leq 0$ and $\mathrm{sgn}(x) = 1$ for $x > 0$. Its eigenfunctions are given by

$$f(x) = \begin{cases} \sin\left(\sqrt{-q-\lambda}\ (1+x)\right), & -1 \leq x \leq 0 \\ \sin\left(\sqrt{-q-\lambda}\right)\cos\left(x\sqrt{-q+\lambda}\right) + \dfrac{\sqrt{-q-\lambda}\,\cos\left(\sqrt{-q-\lambda}\right)\sin\left(x\sqrt{-q+\lambda}\right)}{\sqrt{-q+\lambda}}, & 0 \leq x \leq 1 \end{cases}$$

where the $\lambda \in \mathbf{C}$ satisfy the dispersion relation, see [3],

$$\sqrt{-z-q}\,\cos(\sqrt{-z-q})\sin(\sqrt{z-q}) + \sqrt{z-q}\,\cos(\sqrt{z-q})\sin(\sqrt{-z-q}) = 0. \tag{3.2}$$

This problem always has a doubly infinite sequence of real eigenvalues along with a finite number of complex eigenvalues, [11, 13], one of which is, in the case where $q = 40$, $\lambda \approx 26.9376 + 6.9215i$. Writing $y = \varphi + \psi i$, the graphs of φ, ψ, and $G(x)$ are reproduced above.

Example 3.3. consider the initial value problem for the equation

$$-y''(x) - (7 + \lambda x)y(x) = 0, \qquad y(-1) = 0,\ y(1) = 0,$$

where $\lambda \in \mathbf{C}$, is solvable in terms of Airy functions, so that if $y'(-1) = 1$, then the solution is

$$\frac{\left(-\mathrm{AiryAi}\left(\frac{\lambda-7}{\lambda^{\frac{2}{3}}}\right)\mathrm{AiryBi}\left(-\frac{\lambda x+7}{\lambda^{\frac{2}{3}}}\right) + \mathrm{AiryBi}\left(\frac{\lambda-7}{\lambda^{\frac{2}{3}}}\right)\mathrm{AiryAi}\left(-\frac{\lambda x+7}{\lambda^{\frac{2}{3}}}\right)\right)\pi}{\lambda^{\frac{1}{3}}}.$$

The associated Dirichlet problem on $[-1,1]$, i.e.,

$$y(-1) = 0 = y(1)$$

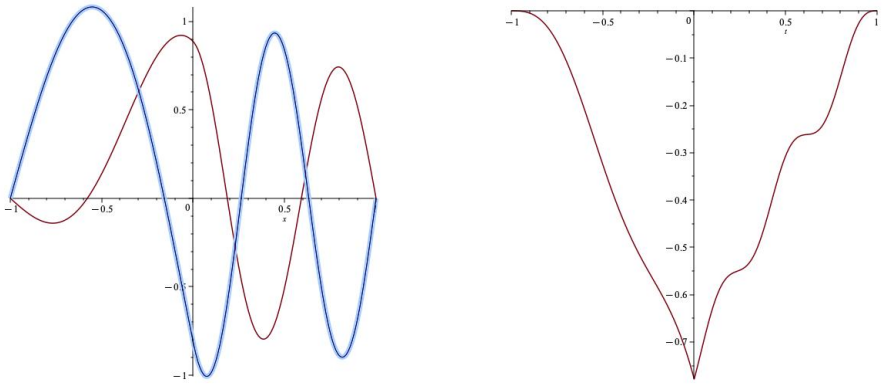

Figure 3.1: Here, φ is the left-most curve of the graph on the left, ψ being the other. The graph on the right is that of $G(x)$.

then gives a doubly infinite sequence of real eigenvalues along with a finite number of complex eigenvalues, [11,13], one of which is $\lambda \approx 12.3076i$.

Now, let $y(-1) = 0$, $y'(-1) = 1 - i$. Of course, the spectrum is the same but the eigenfunctions differ slightly. In this case, the eigenfunctions take the form,

$$y = -\frac{\mathrm{AiryBi}\left(\frac{\lambda-7}{\lambda^{\frac{2}{3}}}\right) \cdot \alpha \cdot \mathrm{AiryAi}\left(-\frac{\lambda\cdot x+7}{\lambda^{\frac{2}{3}}}\right)}{\mathrm{AiryAi}\left(\frac{\lambda-7}{\lambda^{\frac{2}{3}}}\right)} + \alpha \cdot \mathrm{AiryBi}\left(-\frac{\lambda\cdot x+7}{\lambda^{\frac{2}{3}}}\right)$$

where

$$\alpha = \frac{(i-1)\cdot \mathrm{AiryAi}\left(\frac{\lambda-7}{\lambda^{\frac{2}{3}}}\right)\pi}{\lambda^{\frac{1}{3}}}.$$

The plots of the real and imaginary parts of y are given below in Figure 3.2 and the qualitative behavior of these functions is in conformity with the conclusions obtained in Lemma 2.12 (2) and Lemma 2.16 (1).

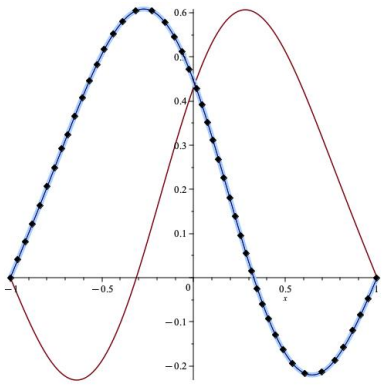

Figure 3.2: Here, φ is the upper curve on the left.

Example 3.4. In this example we exhibit the oscillations in the more general case where the weight function vanishes on an interval, rather than just a point, as in [13].

Here, the piecewise continuous weight function r is given by

$$r(x) = \begin{cases} 1, & \text{if } -2 \le x < -1, \\ 0, & \text{if } -1 \le x < 1. \\ -1, & \text{if } 1 \le x \le 2. \end{cases}$$

and $q(x) = q > 0$, is a constant function. In order to simplify the notation, the Dirichlet problem is defined by considering (1.1) (with q there replaced by $-q$ and r by $-r$) subject to $y(-2) = 0 = y(2)$. Of course, this changes the sign of $G(x)$ in general, if we wish to maintain $\operatorname{Im}\lambda > 0$.

In the following we use the following simplified notation: $\sin\sqrt{q-\lambda} = \sin(\sqrt{q-\lambda})$, $\sin 2\sqrt{q} = \sin(2\sqrt{q})$, $\sin\sqrt{q-\lambda}x = \sin(\sqrt{q-\lambda}x)$ etc.

Thus, the solution of the problem satisfying $y(-2) = 0$, $y'(-2) = 1$ is given by

$$y(x) = \frac{\sin 2\sqrt{q-\lambda}}{\sqrt{q-\lambda}} \left(\cot\ 2\sqrt{q-\lambda} \sin\sqrt{q-\lambda}\, x + \cos\sqrt{q-\lambda}\, x \right),$$

for $-2 \le x \le -1$.

On the other hand, on the interval $-2 \le x < 1$, the solution y is given by,

$$y(x) = \frac{1}{\sqrt{q-\lambda}} \left(\{A - B\} \sin\sqrt{q}x \right) + C\cos\sqrt{q}x$$

where

$$\begin{aligned} A &= \frac{(\sin\sqrt{q-\lambda}\,\sqrt{q}\cot\sqrt{q} + \sqrt{q-\lambda}\cos\sqrt{q-\lambda})\cot\sqrt{q}}{\sqrt{q}\csc\sqrt{q}}, \\ B &= \sin\sqrt{q-\lambda}\csc\sqrt{q}, \\ C &= \frac{1}{\sqrt{q}\sqrt{q-\lambda}\csc\sqrt{q}} \sin\sqrt{q-\lambda}\sqrt{q}\cot\sqrt{q} + \sqrt{q-\lambda}\cos\sqrt{q-\lambda}. \end{aligned}$$

Finally, the expression for y on $1 \le x \le 2$ is given by

$$\begin{aligned} y(x) = &\left(\frac{1}{\sqrt{q+\lambda}\sqrt{q}\sqrt{q-\lambda}} \left\{ A' + B' \right\} \right) \sin\sqrt{q+\lambda}x \\ &+ \left(\frac{1}{\sqrt{q+\lambda}\sqrt{q}\sqrt{q-\lambda}} \left\{ C' + D' \right\} \right) \cos\sqrt{q+\lambda}x \end{aligned} \tag{3.3}$$

where

$$\begin{aligned} A' &= \sqrt{q+\lambda}\sqrt{q}\sin\sqrt{q+\lambda}\cos 2\sqrt{q}\sin\sqrt{q-\lambda} \\ &\quad + \sqrt{q-\lambda}\sqrt{q+\lambda}\sin\sqrt{q+\lambda}\sin 2\sqrt{q}\cos\sqrt{q-\lambda}, \\ B' &= \sqrt{q}\sqrt{q-\lambda}\cos\sqrt{q+\lambda}\cos\sqrt{q-\lambda}\cos 2\sqrt{q} \\ &\quad - q\ \cos\sqrt{q+\lambda}\sin\sqrt{q-\lambda}\sin 2\sqrt{q}, \\ C' &= \sqrt{q}\sqrt{q+\lambda}\cos\sqrt{q+\lambda}\cos 2\sqrt{q}\sin\sqrt{q-\lambda} \\ &\quad + \sqrt{q+\lambda}\sqrt{q-\lambda}\cos\sqrt{q+\lambda}\sin 2\sqrt{q}\cos\sqrt{q-\lambda}, \\ D' &= q\sin 2\sqrt{q}\sin\sqrt{q+\lambda}\sin\sqrt{q-\lambda} \\ &\quad - \sqrt{q}\cos 2\sqrt{q}\sqrt{q-\lambda}\cos\sqrt{q-\lambda}\sin\sqrt{q+\lambda}. \end{aligned}$$

The dispersion relation for the eigenvalues of this non-definite problem is given by setting $y(2) = 0$ in (3.3) and solving for $\lambda \in \mathbf{C}$. Using the Maple© subroutine *RootFinding* we find a non-real eigenvalue $\lambda \approx 6.29625i$ in the case where $q = 8$. It appears as if $G(x) < 0$ in this

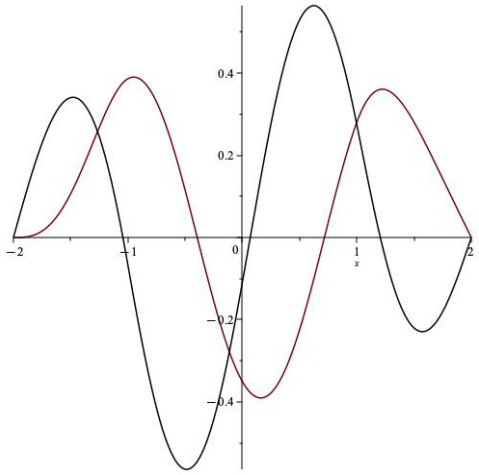

Figure 3.3: Here, the left-most curve is φ, the real part.

case in which case Lemma 2.16 (1) applies.

Example 3.5. Returning to Example 3.2 above,

$$-y''(x) - q\,y(x) = \lambda\,\mathrm{sgn}(x)y(x), \qquad y(-1) = 0,\ y(1) = 0.$$

where now $q = \pi^2/4 + 2$, we get a non-real eigenvalue pair $\lambda \approx \pm 3.8741i$.

Writing $y = \varphi + \psi i$, the graphs of φ, ψ, and $G(x)$ are reproduced below,

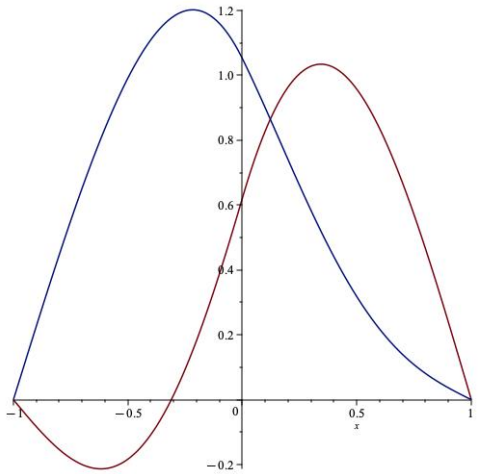

Figure 3.4: Here, φ is the left-most curve of the graph on the left, ψ being the other. Note the positivity of the real part in $(-1, 1)$. Again, $G(x) < 0$, here.

4 Sturm theory for non-real eigenfunctions

In this section the word "eigenvalue" refers to a non-real eigenvalue of (1.1)–(1.2) and all questions here, unless otherwise specified, refer to the case where the weight function has a unique turning point around which $r(x)$ changes sign. For example, we can ask:

1. Under what conditions does there necessarily exist an eigenfunction whose real or imaginary part does not vanish in (a,b)?

   Now, (1.1)–(1.2) always has a finite number of pairs of non-real eigenvalues by Lemma 3.1, so this is a sensible question. In Example 3.3 there is a complex ghost whose real and imaginary part both have a zero in (a,b). In this case, a simple calculation shows that $M = 1$ in Lemma 3.1, and thus there can only be at most one pair of non-real eigenvalues. Since this eigenvalue is one of the only possible pairs of eigenvalues of the problem, the answer is negative in this case.

   On the other hand, in Example 3.5, for $q = \pi^2/4 + 2$ we have an eigenvalue pair $\lambda \approx \pm 3.8741i$ with an eigenfunction having a real part that is seemingly positive in $(-1,1)$. Once again, $M = 1$ in Lemma 3.1 and thus this is the only non-real pair.

   In relation to 1) above, we can ask for a weaker result, that is,

2. Can a non-real eigenfunction $y(x,\lambda)$ vanish for some $x \in (a,b)$?

   Generally speaking this cannot occur in the case of one turning point such as in Richardson [13] or, more generally, as in Theorem 2.10. This is because of the separation of the interior zeros of the real and imaginary parts of the eigenfunction.

   However, the possibility of a non-real eigenfunction vanishing in the interior of an interval may be true in the case of two turning points as the results in [8] show. There, an example of a non-definite problem with two turning points was found in which a non-real eigenfunction vanished as a function of x inside (a,b). The result is therefore likely true in the case of more than two turning points, but this has not been verified yet. In [9] it was shown that if the weight function has n turning points, then any non-real eigenfunction can vanish at most $n-1$ times in (a,b).

3. Under what conditions can we infer the existence of an eigenfunction, corresponding to an eigenvalue of largest modulus, that does not vanish in (a,b)?

   In the case of one turning point or as in Theorem 2.10 this is clear as eigenfunctions cannot vanish in the interior because of the separation property. In particular, see Example 3.5 where we have only one-non-real pair. This statement is then reminiscent of the Perron–Frobenius Theorem [5] in the finite dimensional (matrix) case. (See Corollary 3.2 in [12] for a related result.) Since our boundary value problem always has a finite number of pairs of non-real eigenvalues by Lemma 3.1, this too is a ponderable question. To what extent is it true in cases where there are multiple turning points?

Abstract. This study investigates the theoretical and practical aspects of fourth-order elastic beam equations characterized by variable coefficients and influenced by combined nonlinearities. The equations under consideration arise naturally in the context of high-order differential problems encountered in material science, particularly in the study of phase transitions. The research focuses on establishing the existence and multiplicity of solutions for these equations, which involve both concave and convex nonlinearities. Using advanced mathematical techniques, such as variational methods and critical point theory, the study provides rigorous proofs for the existence of solutions under specific conditions. A central result is the application of Bonanno's local minimum theorem, which ensures the existence of at least one solution. Moreover, the research shows that by imposing additional algebraic conditions, particularly the classical Ambrosetti–Rabinowitz condition, the presence of two distinct solutions can be guaranteed. Beyond this, critical point theorems from Averna and Bonanno are employed to demonstrate scenarios where three solutions are possible.

Keywords: multiple solutions, fourth-order equation, critical point, variational methods.

1 Introduction

Elastic beam equations, particularly those of fourth order, represent a cornerstone of modern theoretical and applied mechanics. These equations are invaluable in modeling the behavior of elastic materials and structures under various forces, enabling scientists and engineers to predict deformation, stability, and stress distribution with high precision. Fourth-order elastic

✉Corresponding author. Email: sh.heidarkhani@razi.ac.ir

equations are especially important because they incorporate effects that lower-order models neglect, such as bending and torsion, and account for variability in material properties and external forces. The significance of fourth-order differential equations extends across multiple disciplines. In structural engineering, these equations are essential for analyzing the deflection and stability of beams and plates, forming the theoretical basis for the design of buildings, bridges, and other critical infrastructures. The pioneering work of Timoshenko and Gere [21] introduced a comprehensive framework for understanding elastic stability, which remains relevant for modern engineering practices. In materials science, fourth-order equations play a central role in studying phase transitions phenomena where materials shift between states, such as from liquid to solid, under controlled conditions. This is particularly important for developing advanced materials in industries such as aerospace and automotive, where performance and reliability are critical. These equations' ability to model real-world conditions, including variable coefficients and nonlinear behaviors, makes them indispensable for tackling complex scientific and engineering challenges. Despite their utility, solving fourth-order elastic equations is a mathematically challenging task. These equations often involve nonlinearities, such as concave and convex effects, which significantly complicate the solution process. Nonlinearities arise in real-world scenarios where material responses to stress are non-proportional to the applied force. For example, when a beam experiences large deformations, the relationship between load and deflection becomes nonlinear. Variable coefficients add another layer of complexity, representing changes in material properties or external conditions over space or time. Traditional analytical methods frequently fall short in addressing these issues, necessitating the use of advanced techniques such as variational methods and critical point theory. These tools provide a rigorous framework for proving the existence and uniqueness of solutions to higher-order differential equations. A key aspect of this study is the application of variational methods to solve fourth-order elastic equations. These methods involve reformulating differential equations into problems of finding critical points of associated functionals. This approach is particularly advantageous for addressing the nonlinearities and boundary conditions inherent in these equations. Bonanno's local minimum theorem [3] and the Ambrosetti-Rabinowitz condition [1] are instrumental in this context, as they provide conditions under which solutions exist. The Palais–Smale condition, a cornerstone of variational calculus, ensures that functionals possess the compactness properties needed to identify critical points. Furthermore, Sobolev spaces offer a robust mathematical framework for handling boundary conditions and variable coefficients with precision. Research by Averna and Bonanno [2] has demonstrated the power of variational methods in proving not only the existence but also the multiplicity of solutions. These results highlight the ability of fourth-order elastic equations to model a range of physical phenomena, from stable configurations to unstable states. The practical implications of this research are vast, spanning both theoretical and applied domains. In materials science, understanding the multiplicity of solutions allows for the prediction of material behavior under different conditions. For instance, during a phase transition, multiple solutions may correspond to distinct physical states, such as stable and unstable configurations. This insight is critical for designing materials with tailored properties, such as high-performance alloys or composites. In structural engineering, these equations inform the design of beams, plates, and other structural elements to ensure safety and reliability. For example, aerospace engineers rely on these models to optimize the design of lightweight yet robust materials for aircraft and spacecraft. By predicting behaviors such as buckling, vibration, and resonance, fourth-order elastic equations provide the tools needed to address the demands of modern engineering.

In this paper, we are going to establish the existence result for the following problem

$$\begin{cases} (p(t)z'')'' - (q(t)z')' + r(t)z = \lambda h(t, z(t)) + \mu g(t, z(t)), \quad t \in [0,1], \\ z(a) = z(b) = 0, \\ z''(a) = z''(b) = 0 \end{cases} \tag{$P^{h,g}$}$$

where $\lambda > 0$, $\mu \geq 0$, h, g are continuous functions, $p \in C^2[0,1]$, $q \in C^1[0,1]$, $r \in C[0,1]$ are regular functions with $p = \operatorname{ess\,inf}_{[0,1]} p > 0$. We aim to advance the understanding of fourth-order elastic equations by addressing both their theoretical and practical challenges. Specifically, we seek to: 1. Establish the existence of solutions using variational methods and critical point theory. 2. Explore conditions that lead to the multiplicity of solutions, highlighting the influence of nonlinearities and variable coefficients.

The remainder of this paper is organized as follows. Section 2 introduces the necessary mathematical preliminaries, including definitions, theorems, and frameworks that form the foundation of the analysis. Section 3 examines the existence of a single solution, employing foundational techniques such as the Palais–Smale condition. Section 4 extends the discussion to explore conditions under which multiple solutions arise, with particular attention to nonlinearities and coefficient variations. Section 5 addresses special cases, such as when specific parameters are set to zero, providing additional insights into the behavior of these equations. Finally, the study concludes with a discussion of the implications of the findings and potential directions for future research.

For additional information, we recommend consulting sources such as [7, 9, 11, 13, 14, 22]. For example, Bonanno et al. in [9] applied multiple critical points theorems to demonstrate the existence of two non-trivial solutions for equation ($P^{h,g}$), in the case $\mu = 0$.

2 Preliminaries

For relevant notations and foundational results, we direct the reader to references [17, 19]. Let E be represent a real Banach space. A functional $I : \mathrm{E} \to \mathbb{R}$, which is continuously Gâteaux differentiable, is said to satisfy the *Palais–Smale condition* (shortened as (PS)-condition) if every sequence $\{z_n\}$ such that $\{I(z_n)\}$ is bounded and $\lim_{n\longrightarrow\infty} \|I'(z_n)\|_{\mathrm{E}^*} = 0$, has a convergent subsequence. This condition is crucial in the framework of variational methods, as it ensures that critical points of λ, correspond to solutions of the associated boundary value problem.

Now, consider two continuously Gâteaux differentiable functions $\Phi, \Psi : \mathrm{E} \longrightarrow \mathbb{R}$ and the functional

$$I = \Phi - \Psi.$$

Let $s_1, s_2 \in [-\infty, \infty]$ with $s_1 < s_2$. The functional I is said to satisfy the *Palais–Smale condition with bounds s_1 and s_2* (denoted ${}^{[s_1]}(\mathrm{PS})^{[s_2]}$-condition) if any sequence $\{z_n\}$ such that $\{I(z_n)\}$ is bounded, $\lim_{n\longrightarrow\infty} \|I'(z_n)\|_{\mathrm{E}^*} = 0$ and $s_1 < \Phi(z_n) < s_2$ for each $n \in \mathbb{N}$, has a convergent subsequence.

When $s_1 = -\infty$ and $s_2 = \infty$, this condition reduces to the classical (PS)-condition. If $s_1 = -\infty$ and $s_2 \in \mathbb{R}$, it is referred to as the $(\mathrm{PS})^{[s_2]}$-condition. Similarly, when $s_1 \in \mathbb{R}$ and $s_2 = \infty$, it is denoted as ${}^{[s_1]}(\mathrm{PS})$-condition. Indeed, if Φ and Ψ be two continuously Gâteaux differentiable functionals defined on a real Banach space E and fix $s \in \mathbb{R}$. The functional $I = \Phi - \Psi$ is said to verify the Palais–Smale condition cut off upper at r (in short $(\mathrm{PS})^{[s]}$) if any sequence $\{z_n\}_{n\in\mathbb{N}}$ in E such that $\{I(z_n)\}$ is bounded, $\lim_{n\longrightarrow\infty} \|I'(z_n)\|_{\mathrm{E}^*} = 0$ and

$\Phi(z_n) < s$ for each $n \in \mathbb{N}$, has a convergent subsequence. Furthermore, if I satisfies the ${}^{[s_1]}(\mathrm{PS})^{[s_2]}$-condition, it automatically satisfies the ${}^{[\varrho_1]}(\mathrm{PS})^{[\varrho_2]}$-condition for all $\varrho_1, \varrho_2 \in [-\infty, \infty]$ such that $s_1 \leq \varrho_1 < \varrho_2 \leq s_2$.

Notably, if I adheres to the classical (PS)-condition, it also satisfies ${}^{[\varrho_1]}(\mathrm{PS})^{[\varrho_2]}$-condition for any $\varrho_1, \varrho_2 \in [-\infty, \infty]$ with $\varrho_1 < \varrho_2$.

The following four theorems will be utilized in proving the results of this paper.

Theorem 2.1 ([5, Theorem 2.3]). *Let* E *be a real Banach space and let* $\Phi, \Psi : \mathrm{E} \longrightarrow \mathbb{R}$ *be two continuously Gâteaux differentiable functions such that* $\inf_{z \in \mathrm{E}} \Phi(z) = \Phi(0) = \Psi(0) = 0$. *Assume that there exist* $s > 0$ *and* $\bar{z} \in \mathrm{E}$, *with* $0 < \Phi(\bar{z}) < s$, *such that*

(a_1) $$\frac{\sup_{\Phi(z) \leq s} \Psi(z)}{s} < \frac{\Psi(\bar{z})}{\Phi(\bar{z})},$$

(a_2) *for each* $\lambda \in \left(\dfrac{\Phi(\bar{z})}{\Psi(\bar{z})}, \dfrac{s}{\sup_{\Phi(z) \leq s} \Psi(z)} \right)$ *the functional* $I_\lambda = \Phi - \lambda \Psi$ *satisfies* $(\mathrm{PS})^{[s]}$*-condition.*

Then, for each

$$\lambda \in \Lambda_s = \left(\frac{\Phi(\bar{z})}{\Psi(\bar{z})}, \frac{s}{\sup_{\Phi(z) \leq s} \Psi(z)} \right)$$

there exists $z_{0,\lambda} \in \Phi^{-1}(0, s)$ *such that* $I'_\lambda(z_{0,\lambda}) = 0$ *and* $I_\lambda(z_{0,\lambda}) \leq I_\lambda(z)$ *for each* $z \in \Phi^{-1}(0, s)$.

Theorem 2.2. *[5, Theorem 3.2] Let* E *be a real Banach space,* $\Phi, \Psi : \mathrm{E} \longrightarrow \mathbb{R}$ *be two continuously Gâteaux differentiable functionals such that* Φ *is bounded from below and* $\Phi(0) = \Psi(0) = 0$. *Fix* $s > 0$ *and assume that, for each*

$$\lambda \in \left(0, \frac{s}{\sup_{z \in \Phi^{-1}(-\infty, s)} \Psi(z)} \right),$$

the functional $I_\lambda = \Phi - \lambda \Psi$ *satisfies* (PS)*-condition and it is unbounded from below. Then, for each*

$$\lambda \in \left(0, \frac{s}{\sup_{z \in \Phi^{-1}(-\infty, s)} \Psi(z)} \right),$$

the functional I_λ *admits two distinct critical points.*

Theorem 2.3 ([2, Theorem A]). *Let* E *be a reflexive real Banach space,* $\Phi : \mathrm{E} \longrightarrow \mathbb{R}$ *a continuously Gâteaux differentiable and sequentially weakly lower semicontinuous functional whose Gâteaux derivative admits a continuous inverse on* E^*, *and* $\Psi : \mathrm{E} \longrightarrow \mathbb{R}$ *a continuously Gâteaux differentiable functional whose Gâteaux derivative is compact. Assume that*

(b_1) $\lim_{\|z\| \longrightarrow \infty} (\Phi(z) + \lambda \Psi(z)) = \infty$ *for each* $\lambda \in [0, \infty)$,

(b_2) *there is* $s \in \mathbb{R}$ *such that*

$$\inf_{\mathrm{E}} \Phi < s$$

and

$$\varphi_1(s) < \varphi_2(s)$$

where

$$\varphi_1(s) = \inf_{z \in \Phi^{-1}(-\infty, s)} \frac{\Psi(z) - \inf_{\overline{\Phi^{-1}(-\infty, s)}^{w}} \Psi}{s - \Phi(z)},$$

$$\varphi_2(s) = \inf_{z\in\Phi^{-1}(-\infty,s)} \sup_{v\in\Phi^{-1}[s,\infty)} \frac{\Psi(z)-\Psi(v)}{\Phi(v)-\Phi(z)},$$

and $\overline{\Phi^{-1}(-\infty,s)}^{w}$ *is the closure of* $\Phi^{-1}(-\infty,s)$ *in the weak topology.*

Then, for each $\lambda \in \left(\frac{1}{\varphi_2(s)}, \frac{1}{\varphi_1(s)}\right)$, *the functional* $\Phi+\lambda\Psi$ *has at least three critical points in* E.

It is important to note that $\varphi_1(s)$ in Theorem 2.3 may equal 0. In such cases, and in similar situations both here and later, we will interpret $\frac{1}{0}$ as ∞.

We will also utilize the following two theorems related to critical points.

Theorem 2.4 ([4, Theorem 1.1]). *Let* E *be a reflexive real Banach space, and let* $\Phi, \Psi : \mathrm{E} \longrightarrow \mathbb{R}$ *be two sequentially weakly lower semicontinuous and Gâteaux differentiable functions. Assume that* Φ *is (strongly) continuous and satisfies*

$$\lim_{\|z\|\longrightarrow\infty} \Phi(z) = \infty.$$

Assume also that there exist two constants s_1 *and* s_2 *such that*

(c_1) $\inf_{\mathrm{E}} \Phi < s_1 < s_2$,

(c_2) $\varphi_1(s_1) < \varphi_2^*(s_1,s_2)$,

(c_3) $\varphi_1(s_2) < \varphi_2^*(s_1,s_2)$, *where* φ_1 *is defined as in Theorem 2.3 and*

$$\varphi_2^*(s_1,s_2) = \inf_{z\in\Phi^{-1}(-\infty,s_1)} \sup_{v\in\Phi^{-1}[s_1,s_2)} \frac{\Psi(z)-\Psi(v)}{\Phi(v)-\Phi(z)}.$$

Then, for each

$$\lambda \in \left(\frac{1}{\varphi_2^*(s_1,s_2)}, \min\left\{\frac{1}{\varphi_1(s_1)}, \frac{1}{\varphi_1(s_2)}\right\}\right),$$

the functional $\Phi+\lambda\Psi$ *admits at least two critical points which lie in* $\Phi^{-1}(-\infty,s_1]$ *and* $\Phi^{-1}[s_1,s_2)$, *respectively.*

It is worth noting that Theorems 2.3 and 2.4 are based on Ricceri's variational principle [20]. For further details, readers are encouraged to consult [6], where Theorems 2.1 and 2.2 were employed to prove the existence of at least one and two solutions for elliptic Dirichlet problems with variable exponents. Similarly, in [10], Theorems 2.3 and 2.4 were utilized to establish the existence of at least two and three solutions for a boundary value problem on the half-line. Additionally, reference [12, 15, 16] demonstrates how Theorems 2.1 through 2.4 were applied to guarantee the existence of solutions for boundary value problems.

In this section, we present fundamental notations and supporting results to incorporate equation ($P^{h,g}$) into a variational framework. Let E denote the Sobolev space $W^{2,2}([0,1]) \cap W_0^{1,2}([0,1])$, equipped with the norm

$$\|z\| = \left(\|z''\|_2^2 + \|z'\|_2^2 + \|z\|_2^2\right)^{\frac{1}{2}} \tag{2.1}$$

for every $z \in \mathrm{E}$ where $\|\cdot\|_2$ is the usual norm in $L^2[a,b]$. It is well known that $\|\cdot\|$ is induced by the inner product

$$\int_a^b \left(z''(t)v''(t) + z'(t)v'(t) + z(t)v(t)\right) \mathrm{d}t$$

for every $z, v \in \mathrm{E}$.

We highlight the following Poincaré-type inequalities, which can be found in the works of [18].

Proposition 2.5. *For every $z \in \mathrm{E}$, if $k = \frac{1}{\pi^2}$, one has*

$$\|z^{(i)}\|_2^2 \leq k^{j-i}\|z^{(j)}\|_2^2, \quad i = 0,1, \quad j = 1,2 \ \text{ with } i < j. \tag{2.2}$$

Now, defining p^- as previously mentioned, and letting $q^- = \operatorname{ess\,inf}_{[0,1]} q$ and $r^- = \operatorname{ess\,inf}_{[0,1]} r$, we will examine the following set of conditions based on the signs of these quantities:

(H_1) $p^- > 0, q^- \geq 0, r^- \geq 0,$

(H_2) $p^- > 0, q^- < 0, r^- \geq 0$ and $p^- + q^- k > 0,$

(H_3) $p^- > 0, q^- \geq 0, r^- < 0$ and $p^- + r^- k > 0,$

(H_4) $p^- > 0, q^- < 0, r^- < 0$ and $p^- + q^- k + r^- k > 0.$

Additionally, take into account the following condition:

(H) $\min\{p^- + q^- k,\ p^- + r^- k,\ p^- + q^- k + r^- k\} > 0.$

Put

$$\sigma = \min\{p^-,\ p^- + q^- k,\ p^- + r^- k,\ p^- + q^- k + r^- k\}.$$

Clearly, assuming the condition (H) implies that $\sigma > 0$. Furthermore, a simple calculation reveals the following result.

Proposition 2.6. *Condition (H) is satisfied if and only if at least one of the conditions (H_1) through (H_4) is met.*

We will now introduce a useful norm, which is equivalent to $\|\cdot\|$ and still ensures that E remains a Hilbert space. Therefore, for the fixed values of p, q and r mentioned earlier, we define the function $N : \mathrm{E} \to \mathbb{R}$ as follows

$$N(z) = \int_0^1 (p(t)|z''(t)|^2 + q(t)|z'(t)|^2 + r(t)|z(t)|^2)\mathrm{d}t$$

holds for any $z \in \mathrm{E}$. We have the following proposition, which will be helpful in confirming that $\sqrt{N(\cdot)}$ is a norm equivalent to the standard one.

Proposition 2.7 ([9, Proposition 2.3])**.** *Assume (H) holds. Then, there exits $m > 0$ such that*

$$N(z) \geq m\|z\|^2 \tag{2.3}$$

for any $z \in \mathrm{E}$, with $m = \frac{\sigma}{1+k+k^2}$. Moreover, one has

$$N(z) \geq \sigma\|z''\|_2^2 \tag{2.4}$$

for any $z \in \mathrm{E}$.

Proposition 2.8 ([9, Proposition 2.4])**.** *Assume that condition (H) is satisfied and define*

$$\|\cdot\|_{\mathrm{E}} = \sqrt{N(\cdot)}$$

for any $z \in \mathrm{E}$. Then, $\|\cdot\|_{\mathrm{E}}$ is a norm equivalent to the usual one defined in (2.2) and $(\mathrm{E}, \|\cdot\|_{\mathrm{E}})$ is a Hilbert space.

Now, assuming again (H), put

$$\delta = \sqrt{\sigma} = \left(\min\{p^-,\ p^- + q^- k,\ p^- + r^- k,\ p^- + q^- k + r^- k\}\right)^{\frac{1}{2}}.$$

The constant δ is well-defined, given that $\sigma > 0$ holds under condition (H).

The following proposition will be useful in the next section.

Proposition 2.9 ([9, Proposition 2.5]). *Assume that (H) holds. One has*

$$\|z\|_\infty \leq \frac{1}{2\pi\delta}\|z\|_{\mathrm{E}}$$

for any $z \in \mathrm{E}$.

Definition 2.10. A function $z \in \mathrm{E}$ is called a weak solution of problem $(P^{h,g})$, if

$$\int_0^1 \left(p(t)z''(t)v''(t) + q(t)z'(t)v'(t) + r(t)z(t)v(t)\right)\mathrm{d}t - \lambda\int_0^1 h(t,z(t))\mathrm{d}t - \mu\int_0^1 g(t,z(t))\mathrm{d}t = 0$$

holds for any $v \in \mathrm{E}$.

Put

$$H(t,m) = \int_0^m h(t,x)\mathrm{d}x \quad \text{for any } (t,m) \in [0,1]\times\mathbb{R}$$

and

$$G(t,m) = \int_0^m g(t,x)\mathrm{d}x \quad \text{for any } (t,m) \in [0,1]\times\mathbb{R}.$$

We define the functionals Φ and Ψ for each $z \in \mathrm{E}$, as follows

$$\Phi(z) = \frac{1}{2}\|z\|_{\mathrm{E}}^2 \tag{2.5}$$

and

$$\Psi(z) = \int_0^1 H(t,z(t))\mathrm{d}t + \frac{\mu}{\lambda}\int_0^1 G(t,z(t))\mathrm{d}t \tag{2.6}$$

and we put

$$I_\lambda(z) = \Phi(z) - \lambda\Psi(z)$$

for every $z \in \mathrm{E}$.

Proposition 2.11 ([9, Proposition 2.6]). *Function $z \in \mathrm{E}$ is a generalized solution of $(P^{h,g})$ if only if $z \in \mathrm{E}$ is a critical point of I_λ.*

We need the following Proposition for existence our main results.

Proposition 2.12. *Let $S : \mathrm{E} \longrightarrow \mathrm{E}^*$ be the operator defined by*

$$S(z)(v) = \int_0^1 \left(p(t)z''(t)v''(t) + q(t)z'(t)v'(t) + r(t)z(t)v(t)\right)\mathrm{d}t$$

for every $z, v \in \mathrm{E}$. Then, S admits a continuous inverse on E^*.

Proof. It is obvious that

$$S(z)(z) = \int_0^1 \left(p(t)|z''(t)|^2 + q(t)|z'(t)|^2 + r(t)|z(t)|^2\right) \mathrm{d}t = \|z\|_{\mathrm{E}}.$$

This follows that S is coercive. Owing to our assumptions on the data, one has

$$\langle S(z) - S(v), z - v\rangle \geq C\|z - v\|_{\mathrm{E}}^2 > 0$$

for some $C > 0$, for every $z, v \in \mathrm{E}$, which means that S is strictly monotone. Moreover, since E is reflexive, for $z_n \longrightarrow z$ strongly in E as $n \to +\infty$, one has $S(z_n) \to S(z)$ weakly in E^* as $n \to \infty$. Hence, S is demicontinuous, so by [23, Theorem 26.A(d)], the inverse operator S^{-1} of S exists and it is continuous. Indeed, let e_n be a sequence of E^* such that $e_n \to e$ strongly in E^* as $n \to \infty$. Let z_n and u in E such that $S^{-1}(e_n) = z_n$ and $S^{-1}(e) = z$. Taking into account that S is coercive, one has that the sequence z_n is bounded in the reflexive space E. For a suitable subsequence, we have $z_n \to \hat{z}$ weakly in E as $n \to \infty$, which concludes

$$\langle S(z_n) - S(z), z_n - \hat{z}\rangle = \langle e_n - e, z_n - \hat{z}\rangle = 0.$$

Note that if $z_n \to \hat{z}$ weakly in E as $n \to +\infty$ and $S(z_n) \to S(\hat{z})$ strongly in E^* as $n \to +\infty$, one has $z_n \to \hat{z}$ strongly in E as $n \to +\infty$, and since S is continuous, we have $z_n \to \hat{z}$ weakly in E as $n \to +\infty$ and $S(z_n) \to S(\hat{z}) = S(z)$ strongly in E^* as $n \to +\infty$. Hence, taking into account that S is an injection, we have $z = \hat{z}$. □

3 Existence of one solution

In this section, we address the existence of a solution for the problem ($P^{h,g}$).

First, put

$$B = \frac{1}{2}\left(\frac{4096}{27}p^- + \frac{64}{9}q^- + \frac{13}{20}r^-\right)$$

and

$$D = \frac{1}{2}\left(\frac{4096}{27}p^+ + \frac{64}{9}q^+ + \frac{13}{20}r^+\right)$$

where p^+, q^+ and r^+ are the ess sup in $[0,1]$ of the functions p, q and r respectively. For ease of reference, we define

$$G^\theta = \int_0^1 \max_{|m|\leq\theta} G(t,m)\mathrm{d}t \quad \text{for each } \theta > 0$$

and

$$G_\sigma = \inf_{t\in[0,1]} G(t,\sigma) \quad \text{for each } \sigma > 0.$$

If g is sign-changing, then clearly $G^\theta \geq 0$ and $G_\sigma \leq 0$.

To achieve our objective, we will fix two positive constants θ and σ, and set

$$\underline{\delta}_{\lambda,g} = \min\left\{\frac{2\delta^2\pi^2\theta^2 - \lambda\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t}{G^\theta}, \frac{D\sigma^2 - \lambda\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t}{G_\sigma}\right\}$$

and

$$\overline{\delta}_{\lambda,g} = \min\left\{\underline{\delta}_{\lambda,g},\ \frac{1}{\max\left\{0, \frac{1}{2\delta^2\pi^2}\limsup_{|m|\longrightarrow\infty}\frac{G(t,m)}{|m|^2}\right\}}\right\}, \tag{3.1}$$

where we read $\epsilon/0 = +\infty$, so that, for instance, $\overline{\delta}_{\lambda,g} = +\infty$ when

$$\limsup_{|m|\longrightarrow\infty}\frac{G(t,m)}{|m|^2} \leq 0$$

and $G_\sigma = G^\theta = 0$.

Theorem 3.1. *Assume that there exist two positive constants θ and σ with the property*

$$\sqrt{\frac{D}{2}}\frac{\sigma}{\pi\delta} < \theta$$

such that

(A_1) $h(t,v) \geq 0$ *for each* $(t,v) \in \left([0,\frac{3}{8}) \cup (\frac{5}{8},1]\right) \times \mathbb{R}$,

(A_2) $\frac{\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t}{\theta^2} < \frac{2\delta^2\pi^2}{D}\frac{\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t}{\sigma^2}$,

(A_3) $\min_{t\in[0,1]}\limsup_{|m|\longrightarrow\infty}\frac{H(t,m)}{|m|^2} \in (-\infty,0]$.

Then, for each

$$\lambda \in \Lambda = \left(\frac{D\sigma^2}{\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t}, \frac{2\delta^2\pi^2\theta^2}{\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t}\right)$$

and for each function $g : [0,1]\times\mathbb{R} \longrightarrow \mathbb{R}$ satisfying the condition

$$\limsup_{|m|\longrightarrow\infty}\frac{G(t,m)}{|m|^2} \in (-\infty,0], \tag{3.2}$$

there exists $\overline{\delta}_{\lambda,g} > 0$ given by (3.1) such that for each $\mu \in [0,\overline{\delta}_{\lambda,g})$, the problem ($P^{h,g}$) admits at least one solution z_λ in E *such that*

$$|z_\lambda(t)| < \theta.$$

Proof. The objective is to apply Theorem 2.1 to address the problem ($P^{h,g}$). To do this, we consider the functionals Φ and Ψ as given in 2.5 and 2.6, respectively. We aim to show that these functionals satisfy the necessary conditions outlined in Theorem 2.1. It is well-known that both functionals are well-defined Gâteaux differentiable, and one has

$$\Psi'(z)(v) = \int_0^1 h(t,z(t))v(t)\,\mathrm{d}t + \frac{\mu}{\lambda}\int_0^1 g(t,z(t))v(t)\,\mathrm{d}t$$

and

$$\Phi'(z)(v) = \int_0^1 \left(p(t)z''(t)v''(t) + q(t)z'(t)v'(t) + r(t)z(t)v(t)\right)\mathrm{d}t$$

for every $z, v \in \mathrm{E}$. Furthermore, Φ and Ψ are C^1-functions. By utilizing the definition of Φ, it follows that

$$\lim_{\|z\|_{\mathrm{E}} \to +\infty} \Phi(z) = +\infty,$$

which implies that Φ is coercive. Furthermore, proposition 2.12 guarantees that Φ has a continuous inverse on E^*. Therefore, we can conclude that the regularity condition on Φ and Ψ, required in Theorem 2.1 are satisfied. The critical points of the functional I_λ in E correspond precisely to the generalized solutions of the considered problem ($P^{h,g}$). To establish the existence of a critical point I_λ in E, we verify that the regularity conditions on Φ and Ψ, as outlined in Theorem 2.1, are indeed fulfilled. It is crucial to note that the operator I_λ is a $C^1(\mathrm{E}, \mathbb{R})$ functional on E, and the critical points of I_λ correspond to weak solutions of the problem ($P^{h,g}$). Furthermore, for $\lambda > 0$, the functional I_λ is coercive. Indeed, since $\mu < \delta_\lambda$ we can fix t such that

$$\limsup_{|m| \longrightarrow \infty} \frac{G(t,m)}{|m|^2} \in (-\infty, 0]$$

and $\mu t < 2\pi^2\delta^2$. Consequently, there exists a positive constant ι such that

$$G(t,m) \leq tm^2 + \iota$$

for each $(t,m) \in [0,1] \times \mathbb{R}$. Now, we fix

$$0 < \varepsilon < \frac{4\pi^2\delta^2}{\lambda}\left(\frac{1}{2} - \mu t \frac{1}{4\pi^2\delta^2}\right).$$

Based on the assumption (A_3) there is a bounded function ϕ_ε such that

$$H(t,m) \leq \varepsilon m^2 + \phi$$

for each $(t,m) \in [0,1] \times \mathbb{R}$. It follows that, for each $z \in \mathrm{E}$, we have

$$\begin{aligned}
\Phi(z) - \lambda\Psi(z) &= \frac{1}{2}\|z\|_{\mathrm{E}}^2 - \lambda\left(\int_0^1 H(t, z(t))\mathrm{d}t + \frac{\mu}{\lambda}\int_0^1 G(t, z(t))\mathrm{d}t\right) \\
&\geq \frac{1}{2}\|z\|_0^2 - \lambda\left(\varepsilon\frac{1}{4\pi^2\delta^2}\|z\|_{\mathrm{E}}^2 + \phi\right) - \mu\left(t\frac{1}{4\pi^2\delta^2}\|z\|_{\mathrm{E}}^2 + \iota\right) \\
&\geq \left(\frac{1}{2} - \lambda\varepsilon\frac{1}{4\pi^2\delta^2} - \mu t\frac{1}{4\pi^2\delta^2}\right)\|z\|_{\mathrm{E}}^2 - \lambda\phi - \mu\iota
\end{aligned}$$

and thus

$$\lim_{\|z\|_{\mathrm{E}} \longrightarrow \infty} \Phi(z) - \lambda\Psi(z) = \infty,$$

which means the functional $I_\lambda = \Phi - \lambda\Psi$ is coercive. Thus, by [3, Proposition 2.1] the functional $I_\lambda = \Phi - \lambda\Psi$ verifies $(\mathrm{PS})^{[s]}$-condition for each $s > 0$ and so the condition (a_2) of Theorem 2.1 is verified. Fix $\lambda \in (0, \lambda^*)$, thus

$$\frac{\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t + \frac{\mu}{\lambda}G_\sigma}{D\sigma^2} > \frac{1}{\lambda}.$$

Put $s = 2\delta^2\pi^2\theta^2$ and

$$w_\sigma(t) = \begin{cases} -\dfrac{64\sigma}{9}\left(t^2 - \dfrac{3}{4}t\right), & \text{if } t \in [0, \frac{3}{8}), \\ \sigma, & \text{if } t \in [\frac{3}{8}, \frac{5}{8}] \\ -\dfrac{64\sigma}{9}\left(t^2 - \dfrac{5}{4}t + \dfrac{1}{4}\right), & \text{if } t \in (\frac{5}{8}, 1]. \end{cases}$$

Clearly, $w_\sigma \in \mathrm{E}$. Obviously, one has

$$\begin{aligned}
&\left(\frac{4096}{27}p^- + \frac{64}{9}q^- + \frac{13}{20}r^-\right)\sigma^2 \\
&\quad \le \int_0^{\frac{3}{8}} p(t)\frac{16384}{81}\sigma^2 \mathrm{d}t + \int_{\frac{5}{8}}^1 p(t)\frac{16384}{81}\sigma^2 \mathrm{d}t + \int_0^{\frac{3}{8}} q(t)\left(-\frac{64\sigma}{9}\left(2t - \frac{3}{4}\right)\right)^2 \mathrm{d}t \\
&\qquad + \int_{\frac{5}{8}}^1 q(t)\left(-\frac{64\sigma}{9}\left(2t - \frac{5}{4}\right)\right)^2 \mathrm{d}t + \int_0^{\frac{3}{8}} r(t)\left(-\frac{64\sigma}{9}\left(t^2 - \frac{3}{4}t\right)\right)^2 \mathrm{d}t \\
&\qquad + \int_{\frac{5}{8}}^1 r(t)\left(-\frac{64\sigma}{9}\left(t^2 - \frac{5}{4}t + \frac{1}{4}\right)\right)^2 \mathrm{d}t + \int_{\frac{3}{8}}^{\frac{5}{8}} r(t)\sigma^2 \mathrm{d}t \\
&\quad = \int_0^1 (p(t)|z''(t)|^2 + q(t)|z'(t)|^2 + r(t)|z(t)|^2)\mathrm{d}t \\
&\quad = \|w_\sigma\|_{\mathrm{E}}^2 \le \left(\frac{4096}{27}p^+ + \frac{64}{9}q^+ + \frac{13}{20}r^+\right)\sigma^2.
\end{aligned}$$

Then, we have $\Phi(0) = \Psi(0) = 0$ and

$$\frac{1}{2}\left(\frac{4096}{27}p^- + \frac{64}{9}q^- + \frac{13}{20}r^-\right)\sigma^2 \le \Phi(w_\sigma) = \frac{1}{2}\|w_\sigma\|_{\mathrm{E}}^2 \le \frac{1}{2}\left(\frac{4096}{27}p^+ + \frac{64}{9}q^+ + \frac{13}{20}r^+\right)\sigma^2.$$

By using condition (A_1), we have

$$\begin{aligned}
\Psi(w_\sigma) &= \int_0^1 H(t, w_\sigma(t))\mathrm{d}t + \frac{\mu}{\lambda}\int_0^1 G(t, w_\sigma(t))\mathrm{d}t \\
&\ge \int_{\frac{3}{8}}^{\frac{5}{8}} H(t, \sigma)\mathrm{d}t + \frac{\mu}{\lambda}G_\sigma.
\end{aligned}$$

Thus, by the assumption

$$\sqrt{\frac{D}{2}}\frac{\sigma}{\pi\delta} < \theta,$$

we have $0 < \Phi(w_\sigma) < s$. Owing to Proposition 2.9, one has

$$\|z\|_\infty \le \frac{1}{2\pi\delta}\|z\|_{\mathrm{E}} \le \frac{1}{2\pi\delta}\sqrt{2s} = \theta,$$

hence, we have

$$\sup_{\Phi(z)<s} \Psi(z) \le \int_0^1 \max_{|m|\le\theta} H(t, m)\mathrm{d}t + \frac{\mu}{\lambda}G^\theta.$$

Therefore, we have

$$\begin{aligned}
&\frac{\sup_{z\in\Phi^{-1}(-\infty,s]}\Psi(z)}{s} \\
&\quad = \frac{\sup_{z\in\Phi^{-1}(-\infty,s]}\left(\int_0^1 H(t, z(t))\mathrm{d}t + \frac{\mu}{\lambda}\int_0^1 G(t, z(t))\mathrm{d}t\right)}{s} \\
&\quad \le \frac{\int_0^1 \max_{|m|\le\theta} H(t, m)\mathrm{d}t + \frac{\mu}{\lambda}G^\theta}{2\delta^2\pi^2\theta^2}
\end{aligned} \tag{3.3}$$

and

$$\begin{aligned}\frac{\Psi(w_\sigma)}{\Phi(w_\sigma)} &\geq \frac{\int_0^1 H(t,w(t))\mathrm{d}t + \frac{\mu}{\lambda}\int_0^1 G(t,w(t))\mathrm{d}t}{D\sigma^2} \\ &\geq \frac{\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t + \frac{\mu}{\lambda}G_\sigma}{D\sigma^2}.\end{aligned} \tag{3.4}$$

Since

$$\mu < \frac{2\delta^2\pi^2\theta^2 - \lambda\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t}{G^\theta},$$

we have

$$\frac{\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t + \frac{\mu}{\lambda}G^\theta}{2\delta^2\pi^2\theta^2} < \frac{1}{\lambda}.$$

Furthermore,

$$\mu < \frac{D\sigma^2 - \lambda\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t}{G_\sigma},$$

this means

$$\frac{\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t + \frac{\mu}{\lambda}G_\sigma}{D\sigma^2} > \frac{1}{\lambda}.$$

Then,

$$\frac{1}{2\delta^2\pi^2}\frac{\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t + \frac{\mu}{\lambda}G^\theta}{\theta^2} < \frac{1}{\lambda} < \frac{\int_{\frac{3}{8}}^{\frac{5}{8}} H(t,\sigma)\mathrm{d}t + \frac{\mu}{\lambda}G_\sigma}{D\sigma^2}. \tag{3.5}$$

Hence, from (3.3)–(3.5), the condition (a_1) of Theorem 2.1 is fulfilled. Since

$$\lambda \in \left(\frac{\Phi(w_\sigma)}{\Psi(w_\sigma)}, \frac{s}{\sup_{\Phi(z)\leq s}\Psi(z)}\right),$$

Theorem 2.1 with $\bar{z} = w$ guarantees the existence of a local minimum point z_λ for the functional I_λ such that $0 < \Phi(z_\lambda) < s$ and so z_λ is a nontrivial solution of the problem ($P^{h,g}$) such that

$$|z_\lambda(t)| < \theta. \qquad \square$$

Remark 3.2. We note that the preceding theorem also holds for a Carathéodory function h alongside $p \in W^{2,1}([0,1])$, $q \in W^{1,1}([0,1])$ and $r \in L^\infty([0,1])$. It is evident that, in this context, the solutions are generalized (see [8]).

We will now illustrate Theorem 3.1 by providing the following example.

Example 3.3. We consider the following problem

$$\begin{cases} z^{(4)} - z'' + z = \lambda h(z(t)) + \mu g(z(t)), & t \in [0,1], \\ z(0) = z(1) = 0, \\ z''(0) = z''(1) = 0 \end{cases} \tag{3.6}$$

where

$$h(m) = \begin{cases} 5m^4, & \text{for any } m \in (-\infty, 1), \\ \dfrac{5}{m}, & \text{for any } m \in [1, +\infty) \end{cases}$$

and

$$g(m) = \begin{cases} 2m, & \text{for any } m \in (-\infty, 1), \\ \dfrac{2}{m}, & \text{for any } m \in [1, +\infty). \end{cases}$$

Based on the expressions for h and g, we can conclude that

$$H(m) = \begin{cases} m^5, & \text{for each } m \in (-\infty, 1), \\ 5\ln(m) + 1, & \text{for each } m \in [1, +\infty) \end{cases}$$

and

$$G(m) = \begin{cases} m^2, & \text{for each } m \in (-\infty, 1), \\ 2\ln(m) + 1, & \text{for each } m \in [1, +\infty). \end{cases}$$

Through straightforward calculations, we derive $\delta = 1$ and $D = \frac{86111}{1080}$. Hence, $\lim_{|m|\longrightarrow\infty} \frac{H(m)}{|m|^2} = 0$, thus (A_3) is holds. Choose $\theta = 10^{-2}$, and $\sigma = 1$. Since

$$\frac{\int_0^1 \max_{|m|\leq\theta} H(m)\mathrm{d}t}{\theta^2} = \frac{1}{10^6} < \frac{540\pi^2}{86111} = \frac{2\delta^2\pi^2}{D}\frac{\int_{\frac{3}{8}}^{\frac{5}{8}} H(\sigma)\mathrm{d}t}{\sigma^2},$$

therefore, if condition (A_2) is satisfied, all the requirements of Theorem 3.1 are met. Consequently, it follows that for each

$$\lambda \in \left(\frac{86111}{270}, 2\pi^2 \times 10^6\right)$$

and since

$$\limsup_{|m|\longrightarrow\infty} \frac{G(,m)}{|m|^2} \in (-\infty, 0]$$

it follows that for each

$$\mu \in \left[0, \min\left\{\frac{2\pi^2 \times 10^{-4} - \lambda 10^{-10}}{10^{-4}}, \frac{86111}{1080} - \frac{\lambda}{4}\right\}\right)$$

the problem (3.6) admits at least one solution z_λ in E such that

$$|z_\lambda(t)| < 10^{-2}.$$

4 Existence of two solutions

Applying Theorem 2.2, we obtain the following results:

Theorem 4.1. *Assume that there exist two positive constants θ and σ with the property*

$$\sqrt{\frac{D}{2}}\frac{\sigma}{\pi\delta} < \theta$$

and

(A_4) *there exist $\nu > 2$ and $R > 0$ such that*

$$0 < \nu H(t, m) \leq mh(t, m) \tag{4.1}$$

for each $|m| \geq R$ and for each $t \in [0, 1]$.

Then, for each

$$\lambda \in \left(0, \frac{2\delta^2\pi^2\theta^2}{\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t}\right),$$

and for each function $g : [0,1] \times \mathbb{R} \longrightarrow \mathbb{R}$ *satisfying the condition* (A_4), *there exists* $\delta_\lambda > 0$ *for each* $\mu \in [0, \delta_\lambda[$, *the problem* ($P^{h,g}$) *admits at least two solutions* z_1 *and* z_2 *in* E *such that*

$$|z_1(t)| < \theta.$$

Proof. Our objective is to utilize Theorem 2.2 in the context of the space E, and the functionals Φ and Ψ as outlined in the proof of Theorem 3.1. Additionally, the functional I_λ adheres to the (PS)-condition. Indeed, assume that $\{z_k\}_{k\in\mathbb{N}} \subset \mathrm{E}$ such that $\{I_\lambda(z_k)\}_{k\in\mathbb{N}}$ is bounded and $I'_\alpha(z_k) \longrightarrow 0$ as $k \longrightarrow +\infty$. Then, there exists a positive constant C_0 such that $|I_\lambda(z_k)| \leq C_0$ for each $k \in \mathbb{N}$. Therefore, we infer to deduce from the definition of I'_λ and the assumption (A_4), for k large enough, we get

$$\begin{aligned} C_0 + C_1\|z_n\|_{\mathrm{E}} \geq \nu I_\lambda(z_n) - I'_\lambda(z_n)(z_n) &= \left(\frac{\nu}{2} - 1\right)\|z_n\|_{\mathrm{E}}^2 \\ &\quad - \lambda\int_0^1 \left(\nu H(t,z_n(t)) - h(t,z_n(t))\, z_n(t)\mathrm{d}t\right. \\ &\quad - \mu\int_0^1 \left(\nu G(t,z_n(t)) - g(t,z_n(t))\, z_n(t)\mathrm{d}t\right. \\ &\geq \left(\frac{\nu}{2} - 1\right)\|z_n\|_{\mathrm{E}}^2 \end{aligned}$$

for some $C_1 > 0$. Since $\nu > 2$, this implies that $\{z_k\}_{k\in\mathbb{N}}$ is bounded. Consequently, since E is a reflexive Banach space, we have, up to a subsequence, $z_k \rightharpoonup z$ in E, $z_k \to z$ in $L^2([0,1])$ and $z_k \to z$ a.e. on $[0,1]$. By $I'_\lambda(z_k) \to 0$ and $z_k \rightharpoonup z$ in E, we obtain

$$\left(I'_\lambda(z_k) - I'_\lambda(z)\right)(z_k - z) \to 0.$$

From the continuity of h and g, we have

$$\int_0^1 \left(h(t,z_k(t)) - h(t,z(t))\right)(z_k(t) - z(t))\mathrm{d}t \to 0$$

and

$$\int_0^1 \left(g(t,z_k(t)) - g(t,z(t))\right)(z_k(t) - z(t))\mathrm{d}t \to 0.$$

Thus

$$0 = \lim_{k\to+\infty}\left(I'_\lambda(z_k) - I'_\lambda(z)\right)(z_k - z) \geq \lim_{k\to+\infty}\|z_k - z\|_{\mathrm{E}}^2.$$

So $\|z_k - z\|_{\mathrm{E}} \to 0$ as $k \to +\infty$, which implies that $\{z_k\}$ converges strongly to u in E. Therefore, I_λ satisfies the Palais–Smale condition. Additionally, by incorporating the condition (4.1), there are constants $a_1, a_2, a_3, a_4 > 0$ such that

$$H(t,z) \geq a_1|z|^\nu - a_2 \quad \text{and} \quad G(t,z) \geq a_3|z|^\nu - a_4$$

for each $(t,z) \in [0,1] \times \mathbb{R}$. Now, by selecting any $z \in \mathrm{E} \setminus \{0\}$, we have

$$\begin{aligned} I_\lambda(z) &= (\Phi + \lambda\Psi)(z) \\ &= \frac{1}{2}\|z\|_{\mathrm{E}}^2 - \lambda\int_0^1 H(t,z(t))\mathrm{d}t - \mu\int_0^1 G(t,z(t))\mathrm{d}t \\ &\leq \frac{1}{2}\|z\|_{\mathrm{E}}^2 - \lambda a_1\frac{1}{2^\nu\pi^\nu\delta^\nu}\|z\|_{\mathrm{E}}^\nu - \mu a_3\frac{1}{2^\nu\pi^\nu\delta^\nu}\|z\|_{\mathrm{E}}^\nu + \lambda a_2 + \mu a_4. \end{aligned}$$

Given that $\nu > 2$, this condition ensures that I_λ is unbounded from below. Consequently, all the requirements of Theorem 2.2 are satisfied. Thus, for each

$$\lambda \in \left(0, \frac{2\delta^2\pi^2\theta^2}{\int_0^1 \max_{|m|\leq\theta} H(t,m)\mathrm{d}t}\right),$$

the functional I_λ admits two distinct critical points that are solutions of the problem $(P^{h,g})$. □

Remark 4.2. In Theorem 2.1, if either $h(t,0) \neq 0$ for some $t \in [0,1]$ or $g(t,0) \neq 0$ for some $t \in [0,1]$ or if both conditions are satisfied, then Theorem 4.1 guarantees the existence of two nontrivial solutions for the problem $(P^{h,g})$. if neither $h(t,0) \neq 0$ and $g(t,0) \neq 0$ is satisfied for any $t \in [0,1]$, the second solution z_2 to the problem $(P^{h,g})$ may be trivial. However, there is still at least one nontrivial solution.

Remark 4.3. Using similar arguments as presented in the proof of [5, Theorem 3.5], the nontrivial nature of the second solution guaranteed by Theorem 4.1 can also be established in the scenario where $h(t,0) = 0$ for each $t \in [0,1]$. This requires an additional condition at zero: namely, there exists a non-empty open set $D \subseteq [0,1]$ and a subset $B \subset D$ with positive Lebesgue measure such that

$$\limsup_{m\longrightarrow 0^+} \frac{\operatorname{ess\,inf}_{t\in B} H(t,m)}{|m|^2} = \infty \quad \text{and} \quad \liminf_{m\longrightarrow 0^+} \frac{\operatorname{ess\,inf}_{t\in D} H(t,m)}{|m|^2} > -\infty.$$

5 Another multiplicity result for the case $\mu = 0$

In this section, we discuss the existence of at least two and three solutions for the problem $(P^{h,g})$ when $\mu = 0$. To do this, we define

$$F^c = \int_0^1 \max_{|m|\leq c} H(t,m)\mathrm{d}t$$

and

$$F_c = \left(\frac{1}{4}\right) \inf_{t\in[0,1]} H(t,c)$$

for each $c > 0$.

Theorem 5.1. *Assume that there exist two positive constants $\bar\theta$ and $\bar\sigma$ such that*

$$\sqrt{\frac{D}{2}}\frac{\bar\sigma}{\pi\delta} < \bar\theta \tag{5.1}$$

and suppose that the assumptions (A_1) and (A_3) in Theorem 3.1 hold. Moreover, assume that

(A_5) $\frac{F^{\bar\theta}}{\bar\theta^2} < \frac{2\delta^2\pi^2}{D}\frac{F_{\bar\sigma}-F^{\bar\theta}}{\bar\sigma^2}$.

Then, for each

$$\lambda \in \left(\frac{D\bar\sigma^2}{F_{\bar\sigma} - F^{\bar\theta}}, \frac{2\delta^2\pi^2\bar\theta^2}{F^{\bar\theta}}\right),$$

the problem $(P^{h,g})$ in the case $\mu = 0$ admits at least three solutions in E.

Proof. Put $I_\lambda = \Phi + \lambda\Psi$, where

$$\Phi(z) = \frac{1}{2}\|z\|_{\mathrm{E}}^2 \tag{5.2}$$

and

$$\Psi(z) = -\int_0^1 H(t, z(t))\mathrm{d}t$$

for each $z \in \mathrm{E}$. Standard arguments demonstrate that the functionals Φ and Ψ are Gâteaux differentiable. The Gâteaux derivatives at a point $z \in \mathrm{E}$ are expressed as follows

$$\Phi'(z)(v) = \int_0^1 z'(t)v'(t)\mathrm{d}t + \int_0^1 \delta(t)(z(t))v(t)\mathrm{d}t$$

and

$$\Psi'(z)(v) = -\int_0^1 h(t, z(t))v(t)\mathrm{d}t$$

for each $z, v \in \mathrm{E}$, respectively. Therefore, a critical point of the functional $\Phi + \lambda\Psi$ corresponds to a solution of equation ($P^{h,g}$) when $\mu = 0$. Our goal is to apply Theorem 2.3 to the functionals Φ and Ψ. The Functional Φ is sequentially weakly lower semicontinuous, and, as discussed in Section 2, Φ is continuously Gâteaux differentiable Moreover, Proposition 2.12 indicates that its Gâteaux derivative has a continuous inverse on E^*. The functional $\Psi : \mathrm{E} \longrightarrow \mathbb{R}$ is well defined, continuously Gâteaux differentiable, and its Gâteaux derivative is compact. Thus, we need to verify that Φ and Ψ satisfy conditions (c_1) and (c_2) as stated in Theorem 2.3. We will now fix $0 < \varepsilon < \frac{2\pi^2\delta^2}{\lambda}$. From the assumption (A_3) there is a function $\phi_\varepsilon : [0,1] \longrightarrow \mathbb{R}$ with $\phi_\varepsilon(t) < \infty$ for each $t \in [0,1]$ such that

$$H(t, \xi) \leq \varepsilon\xi^2 + \phi_\varepsilon(t)$$

for each $(t, \xi) \in [0,1]$. It can be concluded that for each $z \in \mathrm{E}$

$$\begin{aligned}
\Phi(z) + \lambda\Psi(z) &= \frac{1}{2}\|z\|_{\mathrm{E}}^2 - \lambda\int_0^1 H(t, z(t))\mathrm{d}t \\
&\leq \frac{1}{2}\|z\|_{\mathrm{E}}^2 - \lambda\varepsilon\frac{1}{4\pi^2\delta^2}\|z\|_{\mathrm{E}}^2 - \lambda\int_0^1 \phi_\varepsilon(t)dt \\
&= \left(\frac{1}{2} - \lambda\varepsilon\frac{1}{4\pi^2\delta^2}\right)\|z\|_{\mathrm{E}}^2 - \lambda\int_0^1 \phi_\varepsilon(t)dt
\end{aligned}$$

and thus

$$\lim_{\|z\|_{\mathrm{E}} \longrightarrow \infty}(\Phi(z) + \lambda\Psi(z)) = \infty,$$

which means the functional $I_\lambda = \Phi + \lambda\Psi$ is coercive. Now, it remains to show that (c_2) of Theorem 2.3 is fulfilled. Let $\bar{s} = 2\delta^2\pi^2\bar{\theta}^2$ and

$$\bar{w}_{\bar{\sigma}}(t) = \begin{cases} -\frac{64\bar{\sigma}}{9}\left(t^2 - \frac{3}{4}t\right), & \text{if } t \in \left[0, \frac{3}{8}\right), \\ \bar{\sigma}, & \text{if } t \in \left[\frac{3}{8}, \frac{5}{8}\right] \\ -\frac{64\bar{\sigma}}{9}\left(t^2 - \frac{5}{4}t + \frac{1}{4}\right), & \text{if } t \in \left(\frac{5}{8}, 1\right]. \end{cases}$$

Clearly $w \in \mathrm{E}$. Therefore, we can conclude that

$$B\bar{\sigma}^2 \leq \Phi(\bar{w}_{\bar{\sigma}}) \leq D\bar{\sigma}^2.$$

Thus by (5.1), $\Phi(w_\sigma) > \bar{s}$. Moreover

$$\Psi(\bar{w}_{\bar{\sigma}}) = -\int_0^1 H(t, \bar{w}_{\bar{\sigma}})\mathrm{d}t \leq -\int_{\frac{3}{8}}^{\frac{5}{8}} H(t, \bar{\sigma})\mathrm{d}t = -F_{\bar{\sigma}}.$$

For each $z \in \mathrm{E}$ such that $\Phi(z) < \bar{s}$, we obtain

$$\sup_{t\in[0,1]} |z(t)| \leq \bar{\theta}.$$

Thus,

$$\sup_{z\in\Phi^{-1}(-\infty,\bar{s})} \Psi(x) \leq \int_0^1 \max_{|m|\leq\bar{\theta}} H(t, m)\mathrm{d}t = F^{\bar{\theta}}. \tag{5.3}$$

Through straightforward calculations and based on the definition of $\varphi(\bar{s})$, we find that since $\Phi(0) = \Psi(0) = 0$ and $\overline{\Phi^{-1}(-\infty, \bar{s})}^{w} = \Phi^{-1}(-\infty, \bar{s})$, it follows that By simple calculations and from the definition of $\varphi(\bar{s})$, since $\Phi(0) = \Psi(0) = 0$ and $\overline{\Phi^{-1}(-\infty, \bar{s})}^{w} = \Phi^{-1}(-\infty, \bar{s})$, one has

$$\begin{aligned}\varphi_1(\bar{s}) &= \inf_{z\in\Phi^{-1}(]-\infty,\bar{s}[)} \frac{\Psi(z) - \inf_{\overline{\Phi^{-1}(-\infty,\bar{s})}^{w}} \Psi}{\bar{s} - \Phi(z)} \leq \frac{-\inf_{\overline{\Phi^{-1}(-\infty,\bar{s})}^{w}} \Psi}{\bar{s}} \\ &\leq \frac{\int_0^1 \max_{|m|\leq\bar{\theta}} H(t, m)\mathrm{d}t}{2\delta^2\pi^2\bar{\theta}^2} = \frac{F^{\bar{\theta}}}{2\delta^2\pi^2\bar{\theta}^2}.\end{aligned}$$

Alternatively, according to (5.3), one can conclude that

$$\begin{aligned}\varphi_2(\bar{s}) &= \inf_{z\in\Phi^{-1}(-\infty,\bar{s})} \sup_{v\in\Phi^{-1}[\bar{s},\infty)} \frac{\Psi(z) - \Psi(v)}{\Phi(z) - \Phi(v)} \geq \inf_{z\in\Phi^{-1}(-\infty,\bar{s})} \frac{\Psi(z) - \Psi(\bar{w}_{\bar{\sigma}})}{\Phi(\bar{w}_{\bar{\sigma}}) - \Phi(z)} \\ &\geq \frac{\inf_{z\in\Phi^{-1}(-\infty,\bar{s})} \Psi(z) - \Psi(\bar{w}_{\bar{\sigma}})}{\Phi(\bar{w}_{\bar{\sigma}}) - \Phi(z)} \\ &\geq \frac{-\int_0^1 \max_{|m|\leq\bar{\theta}} H(t, m)\mathrm{d}t + \int_{\frac{3}{8}}^{\frac{5}{8}} H(t, \bar{\sigma})\mathrm{d}t}{\Phi(w_\sigma) - \Phi(z)} \\ &\geq \frac{F_{\bar{\sigma}} - F^{\bar{\theta}}}{D\sigma^2}.\end{aligned}$$

Consequently, from (A_5), we derive

$$\varphi_1(\bar{s}) < \varphi_2(\bar{s}).$$

Thus, based on Theorem 2.3, while also considering that

$$\frac{1}{\varphi_2(\bar{s})} \leq \frac{D\sigma^2}{F_{\bar{\sigma}} - F^{\bar{\theta}}}$$

and

$$\frac{1}{\varphi_1(\bar{s})} \geq \frac{2\delta^2\pi^2\bar{\theta}^2}{F^{\bar{\theta}}},$$

we arrive at the intended conclusion. □

Remark 5.2. When the assumption (A_5) of Theorem 5.1 is satisfied, straightforward calculations demonstrate that the condition

(A_6) $\frac{F^{\bar{\theta}}}{2\delta^2\pi^2\bar{\theta}^2} < \frac{F_{\bar{\sigma}}}{D\bar{\sigma}^2}$

implies (A_5) of Theorem 5.1. Therefore, if the conditions (5.1) and (A_5) are satisfied, then for each

$$\lambda \in \left(\frac{D\bar{\sigma}^2}{F_{\bar{\sigma}}}, \frac{2\delta^2\pi^2\bar{\theta}^2}{F^{\bar{\theta}}}\right),$$

the problem $(P^{h,g})$ in the case $\mu = 0$ admits at least three solutions.

We now apply Theorem 2.4, which will later be used to establish the existence of multiple solutions for the problem $(P^{h,g})$ when $\mu = 0$, without relying on assumption (A_3).

Theorem 5.3. *Assume that there exist three positive constants $\bar{\theta}_1$, $\bar{\sigma}$ and $\bar{\theta}_2$ with*

$$\bar{\theta}_1 < \sqrt{\frac{B}{2}}\frac{\bar{\sigma}}{\pi\delta} \tag{5.4}$$

and

$$\sqrt{\frac{D}{2}}\frac{\bar{\sigma}}{\pi\delta} < \bar{\theta}_2 \tag{5.5}$$

in a manner that satisfies the assumption (A_4) in Theorem 2.3 and

(A_7) $\frac{1}{2\delta^2\pi^2}\max\left\{\frac{F^{\bar{\theta}_1}}{\bar{\theta}_1^2}, \frac{F^{\bar{\theta}_2}}{\bar{\theta}_2^2}\right\} < \frac{F_{\bar{\sigma}}}{D\bar{\sigma}^2}$.

Then, for each

$$\lambda \in \Lambda = \left(\frac{D\bar{\sigma}^2}{F_{\bar{\sigma}}}, \min\left\{\frac{2\delta^2\pi^2\bar{\theta}_1^2}{F^{\bar{\theta}_1}}, \frac{2\delta^2\pi^2\bar{\theta}_2^2}{F^{\bar{\theta}_2}}\right\}\right),$$

the problem $(P^{h,g})$ in the case $\mu = 0$ admits at least two solutions $z_{1,\lambda}$ and $z_{2,\lambda}$ such that $|z_{1,\lambda}(t)| < \bar{\theta}_1$ and $|z_{2,\lambda}(t)| < \bar{\theta}_2$.

Proof. Put

$$\overline{h}(t,\epsilon) = \begin{cases} h(t,-\bar{\theta}_2) & \text{if } [0,1]\times(-\infty,\bar{\theta}_2), \\ h(t,\epsilon) & \text{if } [0,1]\times[-\bar{\theta}_2,\bar{\theta}_2], \\ h(t,\bar{\theta}_2) & \text{if } [0,1]\times(\bar{\theta}_2,\infty). \end{cases}$$

Clearly, $\overline{h} : [0,1]\times\mathbb{R} \longrightarrow \mathbb{R}$ is a continuous function. Now put $\overline{H}(t,m) = \int_0^m \overline{h}(t,\epsilon)\mathrm{d}\epsilon$ for each $(t,m) \in [0,1]\times\mathbb{R}$ and take E and Φ as given in (5.2), and

$$\Psi(z) = -\int_0^1 \overline{H}(t,z(t))\mathrm{d}t$$

for each $z \in \mathrm{E}$. Our goal is to apply Theorem 2.4 to Φ and Ψ. It is well known that $\lim_{\|z\|_{\mathrm{E}}\longrightarrow\infty}\Phi(z) = \infty$ and Ψ is a differentiable functional whose differential at the point $z \in \mathrm{E}$ is

$$\Psi'(z)(v) = -\int_0^1 \overline{h}(t,z(t))v(t)\mathrm{d}t$$

for any $v \in \mathrm{E}$ as well as it is sequentially weakly lower semicontinuous. Furthermore $\Psi' : \mathrm{E} \longrightarrow \mathrm{E}^*$ is a compact operator. Therefore, it suffices to demonstrate that Φ and Ψ meet the criteria (c_1), (c_2) and (c_3) outlined in Theorem 2.4. Let

$$\bar{s}_1 = 2\delta^2\pi^2\bar{\theta}_1^2, \quad \bar{s}_2 = 2\delta^2\pi^2\bar{\theta}_2^2$$

and $w \in \mathrm{E}$ in a manner similar to the proof of Theorem 2.4, we note that under the assumptions (5.4) and (5.5), it follows that $\bar{s}_1 < \Phi(w_\sigma) < \bar{s}_2$ and $\inf_{\mathrm{E}} \Phi < \bar{s}_1 < \bar{s}_2$. Furthermore, by applying the reasoning used in the proof of Theorem 5.1 and considering Remark 5.2, we arrive at

$$\varphi_1(\bar{s}_1) \leq \frac{\int_0^1 \max_{|m|\leq\bar{\theta}_1} \overline{H}(t,m)\mathrm{d}t}{2\delta^2\pi^2\bar{\theta}_1^2} = \frac{F^{\bar{\theta}_1}}{2\delta^2\pi^2\bar{\theta}_1^2},$$

$$\varphi_1(\bar{s}_2) \leq \frac{\int_0^1 \max_{|m|\leq\bar{\theta}_2} \overline{H}(t,m)\mathrm{d}t}{2\delta^2\pi^2\bar{\theta}_2^2} = \frac{F^{\bar{\theta}_2}}{2\delta^2\pi^2\bar{\theta}_2^2}$$

and

$$\varphi_2^*(\bar{s}_1,\bar{s}_2) \geq \frac{F_{\bar{\sigma}}}{D\bar{\sigma}^2}.$$

Therefore, based on (A_7), the conditions (c_2) and (c_3) of Theorem 2.4 are satisfied. As a result, we can conclude from Theorem 2.4 that for each $\lambda \in \Lambda$, the problem

$$\begin{cases} -z'' + \alpha(t)z' + \delta(t)z = \lambda\overline{h}(t,z(t)) + \mu\overline{g}(t,z(t)), & t \in [0,1], \\ z(a) = z(b) = 0 \end{cases}$$

admits at least two solutions $z_{1,\lambda}$ and $z_{2,\lambda}$ such that $|z_{1,\lambda}(t)| < \bar{\theta}_1$ and $|z_{2,\lambda}(t)| < \bar{\theta}_2$. Noting that these solutions also satisfy the problem $(P^{h,g})$ when $\mu = 0$, we can draw the conclusion. □

In this section, we will provide some observations regarding our results.

Remark 5.4. In Theorems 5.1 and 5.3, we examined the critical points of the functional I_λ, which is naturally linked to the problem $(P^{h,g})$ when $\mu = 0$. It is important to note that, in general, I_λ can be unbounded from below in the space E. For instance, consider the scenario where $h(t) = 1 + |t|^{v-2}t$ for each $t \in \mathbb{R}$ with $v > 2$. In this case, for any fixed $z \in \mathrm{E}\backslash\{0\}$ and $\iota \in \mathbb{R}$, we can derive

$$\begin{aligned} I_\lambda(\iota z) &= \frac{1}{2}\|\iota z\|_{\mathrm{E}}^2 - \lambda\int_0^1 H(\iota z(t))\mathrm{d}t \\ &\leq \frac{\iota^2}{2}\|z\|_{\mathrm{E}}^2 - \lambda\frac{1}{2\pi\delta}\|z\|_{\mathrm{E}} - \lambda\frac{1}{2^v\pi^v\delta^v}\|z\|_{\mathrm{E}}^v \longrightarrow -\infty \end{aligned}$$

as $\iota \longrightarrow \infty$. Thus, direct minimization cannot be used to locate the critical points of I_λ.

Remark 5.5. If h is non-negative, Theorem 5.3 provides a bifurcation result where the pair $(0,0)$ is included in the closure of the set:

$$\left\{(z_\lambda,\lambda) \in \mathrm{E}\times(0,\infty) : z_\lambda \text{ is a non-trivial solution of } (P^{h,g}),\ \mu = 0\right\} \subset \mathrm{E}\times\mathbb{R}.$$

Indeed, if λ goes to zero, by Theorem 5.3 we have that $\bar{\theta}_i \longrightarrow 0$, $i = 1, 2$ and since $|z_{i,\lambda}(t)| < \bar{\theta}_i$, $i = 1, 2$, there exist two sequences $\{t_j\}$ in E and $\{\lambda_j\}$ in $\mathbb{R}^+$ (here $t_j = z_{\lambda_j}$) such that

$$\lambda_j \longrightarrow 0^+ \quad \text{and} \quad \|t_j\|_{\mathrm{E}} \longrightarrow 0,$$

as $j \longrightarrow \infty$. Moreover, since f is nonnegative, $\Psi(z) < 0$ for each $z \in \mathbb{R}$ and thus

$$(0, \lambda^*) \ni \lambda \mapsto I_\lambda(z_\lambda)$$

is strictly decreasing. Hence, for each $\lambda_1, \lambda_2 \in (0, \lambda^*)$, with $\lambda_1 \neq \lambda_2$, solutions z_{λ_1} and z_{λ_2} ensured by Theorem 2.4 are different.

Remark 5.6. As noted in [18, Remark 3.10], if h is non-negative, the solutions guaranteed by Theorems 5.1 and 5.3 are also non-negative.

Abstract. This paper establishes the existence of positive weak solutions for a class of semipositone Kirchhoff-type problems involving nonlocal operators and anisotropic Φ-Laplacians. By combining variational methods with careful asymptotic analysis, we prove that for sufficiently small $a > 0$, the problem admits a positive solution. Our results extend previous work on semipositone problems to the nonlocal Kirchhoff setting, overcoming challenges arising from the interplay between the nonlocal term and the indefinite nonlinearity.

Keywords: Kirchhoff type problem, semipositone nonlinearity, Orlicz–Sobolev spaces, variational methods, positive solutions.

2020 Mathematics Subject Classification: 35J92, 35J20, 46E30, 35D30, 35B09.

1 Introduction

Semipositone problems, where the nonlinearity satisfies $\hbar(0) < 0$ (see (1.2)), arise naturally in many physical and biological contexts, including population dynamics with harvesting and chemical reaction processes. These problems present substantial mathematical challenges compared to their positone counterparts, as the standard techniques based on sub-super solutions often fail due to the lack of a natural subsolution at zero (see [2–5,7–15,19–23,26,30]).

In 2021, Figueiredo, Massa and Santos [16], proved the existence of positive solution for the semipositone problem

$$\begin{cases} -M(\int_Y |\nabla u|^2 dx)\Delta u = \hbar(u) - a & \text{in } Y, \\ u(x) > 0 & \text{in } Y, \\ u = 0 & \text{on } \partial Y, \end{cases} \tag{1.1}$$

✉Corresponding author. Emails: razani@sci.ikiu.ac.ir (A. Razani), giovany@unb.br (G. M. Figueiredo)

where $Y \subset \mathbb{R}^N$ is a smooth bounded domain, M, f are continuous nonnegative functions and $a > 0$ and small enough. They generalize the classical superlinear and sublinear problems. Recently, Razani and Figueiredo [30] studied a Dirichlet semipositone anisotropic p-Laplacian problem.

In this work, we investigate the existence of positive solutions for a class of nonlocal elliptic problems of Kirchhoff type with semipositone nonlinearities. Specifically, we consider:

$$\begin{cases} -\Gamma\left(\int_Y \Phi(u)dx\right)\Delta_\Phi u = \hbar(u) - \varepsilon & \text{in } Y, \\ u > 0 & \text{in } Y, \\ u = 0 & \text{on } \partial Y, \end{cases} \tag{1.2}$$

where Δ_Φ denotes the Φ-Laplacian operator, a generalization of the p-Laplacian that arises in the study of non-Newtonian fluids and nonlinear elasticity. The term $\Gamma(\int \Phi(u)dx)$ introduces a nonlocal dependence on the solution, modeling phenomena where the system's behavior at a point depends on its global state.

Here we assume $Y \subset \mathbb{R}^N$ is a smooth bounded domain, $\varepsilon > 0$ and $\hbar : [0; +\infty) \to \mathbb{R}$ is a continuous function where

($\hbar_1$) $0 = \hbar(0) = \min_{t\in 0,+\infty)} \hbar(t)$.

($\hbar_2$) $\lim_{t\to 0^+} \frac{\hbar(t)}{\phi(t)t} = 0$.

($\hbar_3$) There is $q \in (m, l^\star)$ such that

$$\lim_{|t|\to+\infty} \frac{|\hbar(t)|}{|t|^{q-1}} < +\infty.$$

($\hbar_4$) There are $\theta > m$ and $t_0 > 0$ such that

$$\theta H(t) \le \hbar(t)t, \quad \text{for all } t \ge t_0,$$

where $H(t) = \int_0^t \hbar(\tau)d\tau$ is the primitive of $\hbar$.

Notice that

$$\Delta_\Phi(u) = \operatorname{div}(\phi(|\nabla u|)\nabla u)$$

where $\Phi(t) := \int_0^{|t|} \phi(s)sds$ and ϕ satisfies the following conditions:

(φ_1) $\phi : \mathbb{R}^+ \to \mathbb{R}^+$ is a C^1-function.

(φ_2) $\phi(t), (\phi(t)t)' > 0,\ t > 0$

(φ_3) There exists $l, m \in (1, N)$ with $m \in [l, l^\star)$ and $l^\star = \frac{lN}{N-l}$ such that

$$l \le \frac{\Phi'(t)t}{\Phi(t)} \le m, \qquad \forall t > 0$$

(φ_4) There exists $\bar{l}, \overline{m} > 0$ such that

$$\bar{l} \le \frac{\Phi''(t)t}{\Phi'(t)} \le \overline{m}, \quad \text{for all } t > 0.$$

Assume $\Gamma : [0, +\infty) \to \mathbb{R}^+$ is an increasing and continuous function and $\Gamma(t) \ge m_0 > 0$ for all $t \in [0, +\infty)$. We set $\digamma(t) = \int_0^t \Gamma(\tau)d\tau$ and we assume

(Γ_0) $\liminf_{t\to 0} \frac{F(t)}{t} > 0$.

(Γ_∞) There exists $\theta_1 \in (1,\theta)$ such that $\limsup_{t\to+\infty} \frac{F(t)}{t^{\theta_1}} < \infty$.

(Γ_{AR}) There exists $\theta > 1,\ D, \beta > 0$ such that

$$\theta F(t) - \Gamma(t)t \geq \beta t - D \quad \text{for every } t \geq 0,$$

Definition 1.1. A function $u \in W_0^{1,\Phi}(\mathrm{Y})$ is called a weak solution of problem (1.2) if:

(i) u is continuous and positive in Y;

(ii) For every test function $\varphi \in W_0^{1,\Phi}(\mathrm{Y})$, the following identity holds:

$$\Gamma\left(\int_{\mathrm{Y}} \Phi(u)\,dx\right)\int_{\mathrm{Y}} \phi(|\nabla u|)\nabla u\cdot\nabla\varphi\,dx = \int_{\mathrm{Y}} \big(\hbar(u)-\varepsilon\big)\varphi\,dx,$$

where $\hbar$ and Γ satisfy the assumptions stated above.

The mathematical study of semipositone problems was initiated by Castro, Castro, and Shivaji [13], who revealed fundamental differences from positone problems, including the breakdown of symmetry properties and more complex solution structures. Subsequent works [4,5,12] developed various techniques to handle these challenges, particularly for local operators. For problems of Kirchhoff type, recent progress has been made in [2,16,27,29], but the semipositone case with general Φ-Laplacian operators remains largely unexplored.

Our work makes several significant contributions:

- We extend the existence theory for semipositone problems to the nonlocal Kirchhoff setting with anisotropic Φ-Laplacian operators.
- We develop new estimates to handle the interplay between the nonlocal coefficient Γ and the semipositone nonlinearity.
- We establish precise threshold values for the parameter ε that guarantee existence of positive solutions.
- Our framework accommodates both degenerate and non-degenerate cases of the Kirchhoff term.

The proof strategy combines variational methods in Orlicz–Sobolev spaces with careful asymptotic analysis. Key challenges include:

- Establishing the mountain pass geometry despite the semipositone nature of the problem.
- Deriving uniform L^∞ estimates independent of the parameter ε.
- Handling the nonlocal coefficient's effect on the compactness properties.
- Ensuring positivity of solutions through delicate comparison arguments.

Our results generalize and extend previous works in several directions, including [5] (local Φ-Laplacian case), [16] (Kirchhoff Laplacian), and [30] (anisotropic semipositone problems). The techniques developed here may be applicable to other nonlocal problems with indefinite nonlinearities.

The paper is organized as follows: Section 2 introduces the necessary framework of Orlicz–Sobolev spaces. Section 3 establishes existence for an auxiliary problem, while Section 4 completes the proof of our main result through careful asymptotic analysis and positivity arguments.

2 Preliminaries on Orlicz–Sobolev spaces

This section provides the necessary background on Orlicz and Orlicz–Sobolev spaces, which serve as the functional framework for our analysis. We recall fundamental definitions, key properties, and essential embedding results that will be crucial for our subsequent arguments. For a comprehensive treatment of these topics, we refer to the standard references [1] and [28].

We begin by recalling key properties of the Orlicz–Sobolev space $W^{1,\Phi}(Y)$, which becomes a Banach space when equipped with the standard norm

$$\|u\|_{1,\Phi} = \|u\|_{\Phi} + \|\nabla u\|_{\Phi}. \tag{2.1}$$

Its subspace $W_0^{1,\Phi}(Y)$, defined as the completion of $C_0^\infty(Y)$ under this norm, inherits these Banach space properties. Crucially, both spaces are separable and reflexive when Φ and its conjugate $\widetilde{\Phi}$ satisfy the Δ_2-condition. This condition further characterizes convergence in $L_\Phi(Y)$: a sequence $\{u_n\}$ converges to u if and only if

$$\int_Y \Phi(|u_n - u|)dx \to 0. \tag{2.2}$$

Three fundamental inequalities govern these spaces:

1. **Poincaré inequality**: There exists $\Lambda > 0$ such that for all $u \in W_0^{1,\Phi}(Y)$,

$$\int_Y \Phi(|u|)dx \leq \Lambda \int_Y \Phi(|\nabla u|)dx. \tag{2.3}$$

   This implies $\|u\| := \|\nabla u\|_\Phi$ is an equivalent norm on $W_0^{1,\Phi}(Y)$, which we adopt hereafter.

2. **Sobolev embedding**: There exists $S_N > 0$ such that

$$\|u\|_{\Phi_*} \leq S_N \|u\|, \tag{2.4}$$

   ensuring the continuous embedding $W_0^{1,\Phi}(Y) \hookrightarrow L_{\Phi_*}(Y)$. For bounded domains, this embedding becomes compact if the N-function B satisfies the growth condition

$$\limsup_{|t|\to\infty} \frac{B(t)}{\Phi_*(t)} = 0. \tag{2.5}$$

3. **Structural assumptions**: For our analysis, we assume $\phi(s) = \varphi(s)s$ and define

$$\Phi(t) = \int_0^{|t|} \varphi(s)s\,ds, \tag{2.6}$$

   extended continuously at $t = 0$. Under conditions (φ_1), (φ_2), (φ_3), both Φ and $\widetilde{\Phi}$ become N-functions satisfying the Δ_2-condition, as established in [17].

Lemma 2.1 (Growth estimates). *Under assumptions (φ_1) and (φ_2), define the comparison functions*

$$\zeta(t) = \min\{t^l, t^m\} \quad \text{and} \quad \kappa(t) = \max\{t^l, t^m\}, \quad t \geq 0.$$

Then the following estimates hold:

(i) Scaling property: For all $\rho, t \geq 0$,

$$\zeta(\rho)\Phi(t) \leq \Phi(\rho t) \leq \kappa(\rho)\Phi(t).$$

(ii) Norm control: For any $u \in L_\Phi(\mathrm{Y})$,

$$\zeta(\|u\|_\Phi) \leq \int_{\mathrm{Y}} \Phi(|u|)dx \leq \kappa(\|u\|_\Phi).$$

Lemma 2.2 (Convergence criterion). *Assume (φ_1), (φ_2), (φ_3) hold and $\mathrm{Y} \subset \mathbb{R}^N$ is a smooth bounded domain. Let $u \in W_0^{1,\Phi}(\mathrm{Y})$ and $\{u_n\}$ be a bounded sequence in $W_0^{1,\Phi}(\mathrm{Y})$ satisfying*

$$\begin{aligned}\int_{\mathrm{Y}} \Bigg(\Gamma\left(\int_{\mathrm{Y}} \Phi(u_n)dx\right) \phi(|\nabla u_n|)\nabla u_n \\ - \Gamma\left(\int_{\mathrm{Y}} \Phi(u)dx\right) \phi(|\nabla u|)\nabla u \Bigg) \cdot \nabla(u_n - u)\, dx \to 0.\end{aligned} \tag{2.7}$$

Then $u_n \to u$ strongly in $W_0^{1,\Phi}(\mathrm{Y})$.

The proof follows from [5, Lemma 2.2].

Lemma 2.3 (Regularity result). *Under assumptions (φ_1), (φ_2), (φ_3), (φ_4), let $h \in L^\infty(\mathrm{Y})$ and $u \in W_0^{1,\Phi}(\mathrm{Y})$ be a weak solution of*

$$\begin{cases} -\Gamma\left(\int_{\mathrm{Y}} \Phi(u)dx\right) div(\phi(|\nabla u|)\nabla u) = h & \text{in } \mathrm{Y}, \\ u = 0 & \text{on } \partial\mathrm{Y}. \end{cases}$$

Then:

- *$u \in C^{1,\alpha}(\overline{\mathrm{Y}})$ for some $\alpha > 0$ depending on $\bar{l}$ and $\overline{m}$*
- *There exists $K = K(\|h\|_\infty, \bar{l}, \overline{m}, \mathrm{Y}) > 0$ such that $|u|_{1,\alpha} \leq K$*
- *$K \to 0$ as $\|h\|_\infty \to 0$*

The proof follows from the regularity results in [24, 25].

Definition 2.4 (Differential inequality). For $u, v \in W_0^{1,\Phi}(\mathrm{Y})$, we say that

$$-\Gamma\left(\int_{\mathrm{Y}} \Phi(u)dx\right) \Delta_\Phi u \leq -\Gamma\left(\int_{\mathrm{Y}} \Phi(v)dx\right) \Delta_\Phi v \quad \text{in } \mathrm{Y}$$

if for all $w \in W_0^{1,\Phi}(\mathrm{Y})$ with $w \geq 0$,

$$\Gamma\left(\int_{\mathrm{Y}} \Phi(u)dx\right) \int_{\mathrm{Y}} \phi(|\nabla u|)\nabla u \cdot \nabla w\, dx \leq \Gamma\left(\int_{\mathrm{Y}} \Phi(v)dx\right) \int_{\mathrm{Y}} \phi(|\nabla v|)\nabla v \cdot \nabla w\, dx.$$

Lemma 2.5 (Comparison principle). *Let $u, v \in W_0^{1,\Phi}(\Upsilon)$ satisfy*

$$\Gamma\left(\int_\Upsilon \Phi(u)dx\right)\int_\Upsilon \phi(|\nabla u|)\nabla u\cdot\nabla w\,dx \le \Gamma\left(\int_\Upsilon \Phi(v)dx\right)\int_\Upsilon \phi(|\nabla v|)\nabla v\cdot\nabla w\,dx$$

for all nonnegative $w \in W_0^{1,\Phi}(\Upsilon)$. Then $u \le v$ in Υ.

Proof. Consider $(u-v)^+ \in W_0^{1,\Phi}(\Upsilon)$. On the set $\Upsilon_1 = \{x \in \Upsilon : u(x) - v(x) \ge 0\}$, we have:

$$\int_{\Upsilon_1}\langle\Gamma\left(\int_\Upsilon \Phi(u)dx\right)\phi(|\nabla u|)\nabla u - \Gamma\left(\int_\Upsilon \Phi(v)dx\right)\phi(|\nabla v|)\nabla v, \nabla(v-u)\rangle dx \le 0.$$

By strict convexity of Φ, this implies $\nabla(u-v) = 0$ a.e. in Υ_1. Since $(u-v)^+ = 0$ on $\partial\Upsilon$, we conclude $u \le v$ in Υ. □

The following maximum principle was established by Guedda et al. [18]:

Theorem 2.6 (Maximum principle). *Let $\Upsilon \subset \mathbb{R}^N$ be a smooth bounded domain and $u \in C^1(\Upsilon)$ a nonnegative function satisfying*

$$-\Delta_\Phi u \ge 0 \quad \text{in } \Upsilon. \tag{2.8}$$

Then

- *If $u \ne 0$, then $u > 0$ in Υ*
- *For $u \in C^1(\Upsilon \cup \{x_0\})$ with $u(x_0) = 0$ at $x_0 \in \partial\Upsilon$, the normal derivative satisfies $\frac{\partial u}{\partial \nu}(y) \ge c > 0$ for all $y \in \partial\Upsilon$.*
- *In particular, for $u \in C^1(\overline{\Upsilon})$ with $u = 0$ on $\partial\Upsilon$, there exists $c > 0$ such that $\frac{\partial u}{\partial \nu}(y) \ge c$ for all $y \in \partial\Upsilon$.*

3 Auxiliary problem and functional framework

We begin by defining the modified nonlinearity $\hbar_\varepsilon : \mathbb{R} \to \mathbb{R}$:

$$\hbar_\varepsilon(t) = \begin{cases} \hbar(t) - \varepsilon & \text{if } t \ge 0, \\ -\varepsilon(t+1) & \text{if } t \in [-1,0], \\ 0 & \text{if } t \le -1, \end{cases}$$

where $0 < \varepsilon < 1$ and $-\varepsilon = \min_{t\in\mathbb{R}} \hbar_\varepsilon(t)$. This leads us to study the auxiliary problem:

$$\begin{cases} -\Gamma\left(\int_\Upsilon \Phi(u)dx\right)\Delta_\Phi u = \hbar_\varepsilon(u) & \text{in } \Upsilon, \\ u > 0 & \text{in } \Upsilon, \\ u = 0 & \text{on } \partial\Upsilon. \end{cases} \tag{3.1}$$

The corresponding energy functional $I_\varepsilon : W_0^{1,\Phi}(\Upsilon) \to \mathbb{R}$ is defined by:

$$I_\varepsilon(u) = F\left(\int_\Upsilon \Phi(|\nabla u|)dx\right) - \int_\Upsilon H_\varepsilon(u)dx,$$

where H_ε is the primitive of $\hbar_\varepsilon$:

$$H_\varepsilon(t) = \begin{cases} H(t) - \varepsilon t & \text{if } t \geq 0, \\ -\frac{\varepsilon}{2}(1-(t+1)^2) & \text{if } t \in [-1,0], \\ \frac{\varepsilon}{2} & \text{if } t \leq -1. \end{cases}$$

The functional I_ε is Fréchet differentiable and I'_ε is given by

$$\langle I'_\varepsilon(u), v\rangle = \Gamma\left(\int_Y \Phi(|\nabla u|)dx\right)\int_Y \phi(|\nabla u|)\nabla u \nabla v dx - \int_Y \hbar_\varepsilon(u)v dx,$$

for all $v \in W_0^{1,\Phi}(Y)$.

Lemma 3.1 (Mountain Pass Geometry)**.** *There exist constants $r, \varepsilon_1 > 0$ such that for any $\rho \in (0,r)$ and $\|u\| = \rho$, we have:*

- *$I_\varepsilon(u) \geq \alpha(\rho) > 0$ for all $\varepsilon \in (0,\varepsilon_1)$.*
- *The constants r and ρ are independent of $\varepsilon \in (0,\varepsilon_1)$.*

Proof. Notice that $H_\varepsilon(t) \leq \frac{1}{\Lambda}\Phi(t) + C\frac{|t|^q}{q} + \frac{\varepsilon}{2}$ for all $t \in \mathbb{R}$ and some $C > 0$. Also by (Γ_0) one can have $\Gamma(t) \geq C_2 t$. Therefore

$$\begin{aligned} I_\varepsilon(u) &= \Gamma\left(\int_Y \Phi(|\nabla u|)dx\right) - \int_Y H_\varepsilon(u)dx \\ &\geq \Gamma\left(\int_Y \Phi(|\nabla u|)dx\right) - \frac{C}{q}\int_Y |u|^q dx - \frac{\varepsilon}{2}|Y| \\ &\geq \zeta(\|u\|) - \frac{C}{q}\int_Y |u|^q dx - \frac{\varepsilon}{2}|Y|, \end{aligned}$$

where ζ was given in Lemma 2.1. Thus, there is $C_1 > 0$ verifying

$$I_\varepsilon(u) \geq \zeta(\|u\|) - \frac{C}{q}\int_Y |u|^q dx - \frac{\varepsilon}{2}|Y|.$$

Taking $\|u\| = \rho$ with ρ small enough and using Lemma 2.1, we get

$$I_\varepsilon(u) \geq \rho^m(1 - C_1\rho^{q-m}) - \frac{\varepsilon}{2}|Y|.$$

Now, we fix $\varepsilon_1 = \varepsilon_1(\rho, q, m) > 0$ and $r > 0$ such that

$$\rho^m(1 - C_1\rho^{q-m}) - \frac{\varepsilon}{2}|Y| \geq \frac{\rho^m(1 - C_1\rho^{q-m})}{2} > 0,$$

for all $\varepsilon \in (0,\varepsilon_1)$ and $\rho \in (0,r)$.

From this, $I_\varepsilon(u) \geq \alpha > 0$ if $\|u\| = \rho$ where $\alpha := \frac{\rho^m(1-C_1\rho^{q-m})}{2}$. □

Lemma 3.2 (Mountain Pass Condition)**.** *For each $\varepsilon \in (0,\varepsilon_1)$, there exists $v \in W_0^{1,\Phi}(Y)$ with $\|v\| > \rho$ and $I_\varepsilon(v) < 0$.*

Proof. Let $\varphi \in C_0^\infty(\Upsilon)$ be a function verifying

$$\varphi > 0, \text{ in } \Upsilon \text{ and } \|\varphi\| = 1.$$

Note that for all $t > 1$,

$$\begin{aligned} I_\varepsilon(t\varphi) &= \digamma\left(\int_\Upsilon \Phi(|\nabla t\varphi|)dx\right) - \int_\Upsilon H_\varepsilon(t\varphi)dx \\ &= \digamma\left(\int_\Upsilon \Phi(|\nabla t\varphi|)dx\right) - \int_\Upsilon H_\varepsilon(t\varphi)dx + \varepsilon\int_\Upsilon t\varphi dx. \end{aligned}$$

By $(\hbar_4)$, there are $A_1, B_1 > 0$ verifying

$$H(t) \geq A_1|t|^\theta - B_1, \text{ for all } t \in \mathbb{R}. \tag{3.2}$$

and By (Γ_∞) there exists $C, D > 0$ such that $\digamma(t) \leq Ct^{\theta_1} + D$ for $t \geq 0$. The last inequality together with Lemma 2.1 leads to

$$\begin{aligned} I_\varepsilon(t\varphi) &\leq C\kappa(t)\kappa(\|\varphi\|) - \varepsilon_1 t^\theta \int_\Upsilon \varphi^\theta dx + ta\|\varphi\|_1 + (D + B_1)|\Upsilon| \\ &\leq Ct^m - \varepsilon_1 t^\theta \|\varphi\|_\theta^\theta + ta\|\varphi\|_1 + (D + B_1)|\Upsilon|. \end{aligned}$$

where κ was given in Lemma 2.1. Since $\theta > m$ and $\varepsilon \in (0, \varepsilon_1)$, we can fix $t_0 > 1$ large enough so that $I_\varepsilon(v) < 0$, where $v = t_0\varphi \in W_0^{1,\Phi}(\Upsilon)$. □

3.1 Compactness and existence results

Lemma 3.3 (Palais–Smale Condition)**.** *The functional I_ε satisfies the Palais–Smale condition for all $a > 0$.*

Proof. Let $\{u_n\}$ be a sequence in $W_0^{1,\Phi}(\Upsilon)$ such that $\{I_\varepsilon(u_n)\}$ is bounded and $I'_\varepsilon(u_n) \to 0$. Hence, there exists $n_0 \in \mathbb{N}$ such that $|\langle I'_\varepsilon(u_n), u_n\rangle| \leq \|u_n\|$ for $n > n_0$. Thus,

$$\begin{aligned} -\|u_n\| &\leq \langle I'_\varepsilon(u_n), u_n\rangle \\ &= \Gamma\left(\int_\Upsilon \Phi(|\nabla u_n|)dx\right)\int_\Upsilon \phi(|\nabla u_n|)\nabla u_n \nabla u_n dx - \int_\Upsilon \hbar_\varepsilon(u_n)u_n dx \\ &\leq \theta\digamma\left(\int_\Upsilon \Phi(|\nabla u_n|)dx\right) + \beta\left(\int_\Upsilon \Phi(|\nabla u_n|)dx\right) - D - \int_\Upsilon \hbar_\varepsilon(u_n)u_n dx, \end{aligned}$$

so

$$-\|u_n\| - \theta\digamma\left(\int_\Upsilon \Phi(|\nabla u_n|)dx\right) - \beta\left(\int_\Upsilon \Phi(|\nabla u_n|)dx\right) + D \leq -\int_\Upsilon \hbar_\varepsilon(u_n)u_n dx. \tag{3.3}$$

On the other hand, as there exists $K > 0$ such that $|I_\varepsilon(u_n)| \leq K$ for all $n = 1, 2, \ldots$, it follows that

$$\digamma\left(\int_\Upsilon \Phi(|\nabla u_n|)dx\right) - \int_\Upsilon H_\varepsilon(u_n)dx \leq K, \quad \text{for all } n \in \mathbb{N}. \tag{3.4}$$

This implies that

$$\digamma\left(\int_\Upsilon \Phi(|\nabla u|)dx\right) - \frac{1}{\theta}\int_\Upsilon \hbar_\varepsilon(u_n)u_n dx + \frac{1}{\theta}M|\Upsilon| \leq K, \quad \text{for all } n \in \mathbb{N}. \tag{3.5}$$

This shows

$$F\left(\int_Y \Phi(|\nabla u|)dx\right) - \frac{1+\beta}{\theta}\|u_n\| \leq K - \frac{1}{\theta}\left(M|Y| + D\right),$$

for n large enough, which is a contradiction. This shows that $\{u_n\}$ is bounded in $W_0^{1,\Phi}(Y)$. Thus, without loss of generality, we may assume that $u_n \rightharpoonup u$ in $W_0^{1,\Phi}(Y)$ and since that $B(t) = |t|^q$ verifies (2.5), we get $u_n \to u$ in $L^q(Y)$, $m < q < l^*$. By conditions of $\hbar$,

$$\int_Y \hbar_\varepsilon(u_n)(u_n - u)dx \to 0.$$

Since

$$\begin{aligned} o_n &= I'_\varepsilon(u_n)(u_n - u) \\ &= \Gamma\left(\int_Y \Phi(|\nabla u_n|)dx\right)\int_Y \phi(|\nabla u_n|)\nabla u_n \nabla(u_n - u)dx - \int_Y \hbar_\varepsilon(u_n)(u_n - u)dx \end{aligned}$$

we have

$$\Gamma\left(\int_Y \Phi(|\nabla u_n|)dx\right)\int_Y \phi(|\nabla u_n|)\nabla u_n \nabla(u_n - u)dx \to 0. \tag{3.6}$$

The weak convergence $u_n \rightharpoonup u$ in $W_0^{1,\Phi}(Y)$ yields

$$\Gamma\left(\int_Y \Phi(|\nabla u|)dx\right)\int_Y \phi(|\nabla u|)\nabla u \nabla(u_n - u)dx \to 0. \tag{3.7}$$

This implies that

$$\int_Y \left\{\Gamma\left(\int_Y \Phi(|\nabla u_n|)dx\right)\phi(|\nabla u_n|)\nabla u_n - \Gamma\left(\int_Y \Phi(|\nabla u|)dx\right)\phi(|\nabla u|)\nabla u\right\}\nabla(u_n - u)dx \to 0.$$

This shows $u_n \to u$ in $W_0^{1,\Phi}(Y)$ by Lemma 2.2. □

Lemma 3.4 (Existence of solutions). *For $\varepsilon \in (0, \varepsilon_1)$, problem (1.2) has a solution $u_\varepsilon \in W_0^{1,\Phi}(Y)$ with $I_\varepsilon(u_\varepsilon) \leq C(\varepsilon_1, \theta, m, |Y|)$.*

Proof. The verification of the Mountain Pass Geometry (Lemma 3.1), linking condition (Lemma 3.2), and Palais–Smale condition (Lemma 3.3) allows us to apply the Mountain Pass Theorem [6], yielding for each $a \in (0, \varepsilon_1)$ a critical point $u_\varepsilon \in W_0^{1,\Phi}(Y)$ at level $d_\varepsilon > 0$, where d_ε is the Mountain Pass level associated with I_ε.

Now, letting $\phi \in C_0^\infty(Y), \phi \geq 0$, $t > 0$ and using (3.2), we obtain

$$\begin{aligned} I_\varepsilon(t\phi) &= F\left(\int_Y \Phi(|\nabla t\phi|)dx\right) - \int_Y H_\varepsilon(t\phi)dx \\ &\leq C\kappa(t)\kappa(\|\Phi\|) - \varepsilon_1\int_Y (t\phi)^\theta dx + B_1|Y| + \int_Y \varepsilon t\phi dx \end{aligned}$$

for all $\varepsilon \in (0, \varepsilon_1)$. Then

$$I_\varepsilon(t\phi) \leq C_1\kappa(t) - C_2 t^\theta + C_3 t + C_4,$$

where $C_1 = \kappa(\|\phi\|), C_2 = A_1\|\phi\|_\theta^\theta, C_3 = \varepsilon_1\|\phi\|_1$ and $C_4 = B_1|Y|$. Setting $h(t) = C_1\kappa(t) - C_2 t^\theta + C_3 t + C_4$, we find

$$d_\varepsilon \leq \max\{I_\varepsilon(t\phi), t \geq 0\} \leq \max_{t\geq 0} h(t) = C(\varepsilon_1, m, \theta, |Y|) > 0.$$

Thus $I_\varepsilon(u_\varepsilon) \leq C(\varepsilon_1, m, \theta, |Y|)$. □

Lemma 3.5 (Uniform boundedness). *There exists $K = K(\varepsilon_1, q, m, \theta, |\mathrm{Y}|) > 0$ such that $\|u_\varepsilon\| \leq K$ for all $\varepsilon \in (0, \varepsilon_1)$.*

Proof. Notice that

$$\begin{aligned}
C(\varepsilon_1, m, \theta, |\mathrm{Y}|) &\geq I_\varepsilon(u_\varepsilon) - \frac{1}{\theta} I'_\varepsilon(u_\varepsilon)u_\varepsilon \\
&= \digamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right) - \int_{\mathrm{Y}} H_\varepsilon(u_\varepsilon)dx \\
&\quad - \frac{1}{\theta}\left(\Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right)\int_{\mathrm{Y}} \phi(|\nabla u_\varepsilon|)|\nabla u_\varepsilon|^2 dx - \int_{\mathrm{Y}} \hbar_\varepsilon(u_\varepsilon)u_\varepsilon dx\right) \\
&= \left(\digamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right) - \frac{1}{\theta}\Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right)\int_{\mathrm{Y}} \phi(|\nabla u_\varepsilon|)|\nabla u_\varepsilon|^2 dx\right) \\
&\quad - \left(\int_{\mathrm{Y}} H_\varepsilon(u_\varepsilon)dx - \frac{1}{\theta}\int_{\mathrm{Y}} \hbar_\varepsilon(u_\varepsilon)u_\varepsilon dx\right) \\
&\geq \left(\digamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right) - \frac{m}{\theta}\Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right)\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right) \\
&\quad - \left(\int_{\mathrm{Y}} H_\varepsilon(u_\varepsilon)dx - \frac{1}{\theta}\int_{\mathrm{Y}} \hbar_\varepsilon(u_\varepsilon)u_\varepsilon dx\right) \\
&\geq \frac{1}{\theta}\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx - \frac{1}{\theta}D - \frac{M}{\theta}|\mathrm{Y}|.
\end{aligned}$$

Now the Δ_2-condition combines with the last inequality to gives

$$\|u_\varepsilon\| \leq K \quad \text{for all } \varepsilon \in (0, \varepsilon_1),$$

for some $K = K(\varepsilon_1, q, m, \theta, |\mathrm{Y}|)$. □

3.2 Regularity and positivity

Lemma 3.6 (L^∞-regularity). *There exists $\varepsilon_2 \in (0, \varepsilon_1)$ such that:*

- *$u_\varepsilon \in L^\infty(\mathrm{Y})$ for all $\varepsilon \in (0, \varepsilon_2)$.*
- *$\|u_\varepsilon\|_\infty \leq C$ uniformly for $\varepsilon \in (0, \varepsilon_2)$.*

Proof. To establish the uniform L^∞ bound, consider any sequence $\varepsilon_j \to 0^+$ with corresponding solutions $u_j := u_{\varepsilon_j} \in W_0^{1,\Phi}(\mathrm{Y})$. Our proof proceeds in three steps:

1. Compactness: Since $\{u_j\}$ is bounded in $W_0^{1,\Phi}(\mathrm{Y})$ by Lemma 3.5, the subcritical growth of $\hbar$ and the compact embedding $W_0^{1,\Phi}(\mathrm{Y}) \hookrightarrow L^q(\mathrm{Y})$ (for $q < l^*$) yield a subsequence (still denoted $\{u_j\}$) converging strongly to some $u \in W_0^{1,\Phi}(\mathrm{Y})$.

2. Regularity transfer: Each u_j satisfies the equation

$$-\Gamma\left(\int_{\mathrm{Y}} \Phi(u_j)\right)\Delta_\Phi u_j = \hbar(u_j) - \varepsilon_j.$$

The right-hand side remains bounded in $L^s(\mathrm{Y})$ for some $s > 1$ due to the growth condition on $\hbar$ and the uniform $W_0^{1,\Phi}$ bounds.

3. Bootstrap: Applying the regularity arguments from [31, Theorem 3.1], we obtain uniform L^∞ estimates:

$$\|u_j\|_{L^\infty(\mathrm{Y})} \leq C(\|\hbar(u_j)\|_{L^s} + \|\varepsilon_j\|_\infty + 1) \leq C',$$

where C' depends only on the structural constants and is independent of j. □

Lemma 3.7 (Lower bound). *There exist $\varepsilon_3 \in (0, \varepsilon_2)$ and $\delta > 0$ such that $\|u_\varepsilon\|_\infty \geq \delta$ for all $\varepsilon \in (0, \varepsilon_3)$.*

Proof. If u_ε is a solution of (1.2), then

$$\Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right) \int_{\mathrm{Y}} \phi(|\nabla u_\varepsilon|)\nabla u_\varepsilon \nabla \phi dx = \int_{\mathrm{Y}} \hbar_\varepsilon(u_\varepsilon)\phi dx$$

for all $\phi \in W_0^{1,\Phi}(\mathrm{Y})$. For $\phi = u_\varepsilon$

$$\int_{\mathrm{Y}} \hbar_\varepsilon(u_\varepsilon)u_\varepsilon dx = \Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx\right) \int_{\mathrm{Y}} \phi(|\nabla u_\varepsilon|)|\nabla u_\varepsilon|^2 dx \geq ml \int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx.$$

By Δ_2-condition,

$$\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx \to 0 \quad \text{as } \varepsilon \to 0 \quad \Longleftrightarrow \quad \|u_\varepsilon\| \to 0 \quad \text{as } \varepsilon \to 0.$$

Since $I_\varepsilon(u_\varepsilon) \geq \alpha$ for all $\varepsilon \in (0, \varepsilon_2)$, there exists $\varepsilon_3 \in (0, \varepsilon_2)$ and $\alpha_0 > 0$ such that

$$\int_{\mathrm{Y}} \Phi(|\nabla u_\varepsilon|)dx \geq \alpha_0, \quad \text{for all } \varepsilon \in (0, \varepsilon_3). \tag{3.8}$$

Thus,

$$\int_{\mathrm{Y}} \hbar_\varepsilon(u_\varepsilon)u_\varepsilon dx \geq lm\alpha =: A > 0, \quad \text{for all } \varepsilon \in (0, \varepsilon_3).$$

There exists $C > 0$ such that

$$|\hbar_\varepsilon(t)| \leq C(|t|^q + \phi(|t|)|t|) + \varepsilon, \quad \text{for all } t \in \mathbb{R} \text{ and for all } \varepsilon \in (0, \varepsilon_3).$$

Therefore

$$\begin{aligned} A &\leq \int_{\mathrm{Y}} (C(|u_\varepsilon|^q + \phi(|u_\varepsilon|)|u_\varepsilon|) + \varepsilon|u_\varepsilon|)dx \\ &\leq (C(\|u_\varepsilon\|_\infty^q + \phi(\|u_\varepsilon\|_\infty)|u_\varepsilon|) + \varepsilon\|u_\varepsilon\|_\infty). \end{aligned}$$

Thus $\|u_\varepsilon\|_\infty \geq \delta$ for some $\delta > 0$ for all $\varepsilon \in (0, \varepsilon_3)$, decreasing ε_3 if necessary. □

4 Existence of positive solution

The study of positive solutions for semipositone problems has long been challenging due to the lack of natural subsolutions at zero. When combined with nonlocal Kirchhoff-type operators and anisotropic Φ-Laplacian nonlinearities, these problems present intricate mathematical structures that require novel analytical approaches. In this section, we establish our principal existence result, which not only extends classical semipositone theory but also provides new insights into the interplay between nonlocal effects and anisotropic operators.

Theorem 4.1 (Existence of positive solutions)**.** *Under the structural conditions:*

(S1) Regularity and growth assumptions on ϕ ((φ_1)–(φ_4)),

(S2) Nonlocal term properties ((Γ_0), (Γ_∞), (Γ_{AR})),

(S3) Nonlinearity behavior ($(\hbar_1)$–$(\hbar_4)$),

there exists a critical threshold $\varepsilon^\star > 0$ such that for all $\varepsilon \in (0, \varepsilon^\star)$, the semipositone Kirchhoff-type problem (1.2) admits at least one positive weak solution $u_\varepsilon \in W_0^{1,\Phi}(Y)$. Moreover, the solution satisfies:

(i) $u_\varepsilon \in C^{1,\alpha}(\overline{Y})$ for some $\alpha > 0$.

(ii) $\inf_K u_\varepsilon > 0$ for any compact $K \subset Y$,

(iii) Uniform bounds $\delta \leq \|u_\varepsilon\|_\infty \leq C$ independent of ε,

Proof. First, we prove that the solution u_ε is positive for $\varepsilon \in (0, \varepsilon_3)$, decreasing ε_3 if necessary. Indeed, let $\{\varepsilon_g\} \in (0, \varepsilon_3)$ be a sequence with $\varepsilon_j \to 0$ as $j \to \infty$, and let u_j be a solution of (1.2) with $\varepsilon = \varepsilon_j$. Setting $\hbar_j(u_j) = \hbar_{\varepsilon_j}(u_j)$, we have

$$\begin{cases} -\Gamma(\int_Y \Phi(u_j)dx)\Delta_\Phi(u_j) = \hbar_j(u_j) & \text{in } Y, \\ u_j = 0 & \text{on } \partial Y. \end{cases}$$

By Lemma 3.6, there is $C > 0$ such that $\|u_j\|_\infty \leq C$ for all $j \in \mathbb{N}$, then $\|\hbar_j(u_j)\|_\infty \leq C_1$ for all $j\mathbb{N}$ and some $C_1 > 0$. Thereby, by Lemma 2.3, $u_j \in C^{1,\beta}(\overline{Y})$ for some $\beta \in (0,1)$, and

$$|u_j|_{1,\beta} \leq \Gamma(\|\hbar_j(u_j)\|_\infty) \leq M_2, \quad \text{for all } j \in \mathbb{N} \text{ and for some } M_2 > 0.$$

From compactness embedding $C^{1,\beta}(\overline{Y}) \hookrightarrow C^{1,\tau}(\overline{Y})$ for $\tau \in (0, \beta)$, there exists a subsequence for $\{u_j\}$, still denoted by $\{u_j\}$, and $u \in C^{1,\tau}(\overline{Y})$ such that $u_j \to u$ in $C^{1,\tau}(\overline{Y})$.

Now we estimate

$$-\Delta_\Phi u_j = \frac{\hbar_j(u_j)}{\Gamma(\int_Y \Phi(v_j)dx)} \geq \frac{-\varepsilon_j}{h_{\varepsilon_3}}$$

Assume v_j is the solution of

$$\begin{cases} -\Delta_\Phi(v_j) = k_j := \frac{-\varepsilon_j}{h_{\varepsilon_3}} & \text{in } Y, \\ v_j = 0 & \text{on } \partial Y, \end{cases}$$

where $k_j = \min\{\hbar_j(t), t \in \mathbb{R}\} = -\varepsilon_j \to 0^-$ as $j \to \infty$. Then $u_j, v_j \in W_0^{1,\Phi}(Y)$ and

$$-\Delta_\Phi v_j \leq -\Delta_\Phi u_j$$

and by comparison principle

$$v_j \leq u_j \quad \text{in } Y, \text{ for all } j \in \mathbb{N}. \tag{4.1}$$

On the other hand, as $k_j \to 0$, the Lemma 2.3 gives

$$\|v_j\|_\infty \to 0. \tag{4.2}$$

Then, (4.1) combines with (4.2) to give $u \geq 0$ in Y. Notice that

- $\nabla u_j \to \nabla u$ uniformly in $\overline{\mathrm{Y}}$,
- $\int_{\mathrm{Y}} \Phi(|\nabla u_j|)dx \to \int_{\mathrm{Y}} \Phi(|\nabla u|)dx$ and then

$$\Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_j|)dx\right) \to \Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u|)dx\right),$$

- $\{\hbar_j(u_j)\}$ is bounded in $L^s(\mathrm{Y})$, $s > 1$,
- $\hbar_j(u_j) \rightharpoonup z$ in $L^s(\mathrm{Y})$,
- $\hbar_j(u_j(x)) \to \hbar_0(u(x))$ a.e. $x \in \mathrm{Y}$,

where $\hbar_0(t) = \hbar(t)$ if $t \geq 0$, and $\hbar_0(t) = 0$ if $t < 0$. Thus $z = \hbar_0(u)$, and for any $\phi \in C_0^\infty(\mathrm{Y})$,

$$\begin{aligned}\Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u|)dx\right)\int_{\mathrm{Y}} \phi(|\nabla u|)\nabla u\nabla\phi dx &= \lim_{j\to+\infty} \Gamma\left(\int_{\mathrm{Y}} \Phi(|\nabla u_j|)dx\right)\int_{\mathrm{Y}} \phi(|\nabla u_j|)\nabla u_j\nabla\phi dx \\ &= \lim_{j\to+\infty}\int_{\mathrm{Y}} \hbar_j(u_j)\phi dx \\ &= \int_{\mathrm{Y}} z\phi dx,\end{aligned}$$

consequently

$$\begin{cases} -\Delta_\Phi(u) = \frac{z}{\Gamma\left(\int_{\mathrm{Y}} \Phi(u)dx\right)} & \text{in } \mathrm{Y}, \\ u \geq 0 & \text{in } \mathrm{Y}, \\ u = 0 & \text{on } \partial\mathrm{Y}. \end{cases}$$

As $\|u_j\|_\infty \geq C_0$ for all $j \in \mathbb{N}$, we derive that $\|u_j\|_\infty \geq C_0$, and so $u \neq 0$. As $z \geq 0$, by Theorem 2.6,

$$u > 0, \quad \text{in } \mathrm{Y} \quad \text{and} \quad \frac{\partial u}{\partial \eta} < 0 \quad \text{on } \partial\mathrm{Y}$$

and by

$$u_j \to u \quad \text{in } C^{1,\tau}(\overline{\mathrm{Y}})$$

we have $u_j(x) > 0$, $x \in \mathrm{Y}$, for j large enough. Decreasing ε_3 if necessary, the above analysis guarantee that u_ε is positive for $\varepsilon \in (0, \varepsilon_3)$. □

Conclusion

In this work, we have established the existence of positive weak solutions for a class of semipositone Kirchhoff-type problems involving nonlocal operators and anisotropic Φ-Laplacians. By employing variational methods in the framework of Orlicz–Sobolev spaces, we successfully overcame the challenges posed by three key features of the problem:

- The semipositone nature of the nonlinearity ($\hbar(0) < 0$).
- The nonlocal Kirchhoff term $\Gamma(\int \Phi(u)dx)$.
- The anisotropic behavior of the Φ-Laplacian operator.

Our main result (Theorem 4.1) demonstrates that for sufficiently small positive values of the parameter ε, the problem admits at least one positive solution. The proof combined mountain pass techniques with careful asymptotic analysis and delicate estimates to handle the interaction between the nonlocal term and the indefinite nonlinearity.

Several interesting directions for future research emerge from this work:

- Investigation of multiplicity results for positive solutions.
- Extension to more general nonlocal operators.
- Study of critical growth cases in this framework.
- Analysis of related parabolic versions of the problem.

The methods developed in this paper may be applicable to other classes of nonlocal problems with indefinite nonlinearities, particularly those arising in mathematical physics and biology where such structural features naturally occur.

Abstract. In this paper we obtain the interior optimal $C^{1,\alpha}$ regularity of weak solutions for the following quasilinear elliptic equations with Orlicz growth in divergence form

$$-\operatorname{div} a(x,Du) = -\operatorname{div}\mathbf{F}+f \quad \text{in } \Omega\subset\mathbb{R}^n,$$

including the following two special models

$$-\operatorname{div}\left((ADu\cdot Du)^{\frac{p-2}{2}}ADu\right) = -\operatorname{div}\mathbf{F}+f$$

and

$$-\operatorname{div}\left((ADu\cdot Du)^{\frac{p-2}{2}}\ln^{\theta}\left(1+(ADu\cdot Du)^{\frac{1}{2}}\right)ADu\right) = -\operatorname{div}\mathbf{F}+f$$

for $\theta>0$, $n\geq 2$, $\mathbf{F}(x)\in C^{0,\sigma_0}(\Omega)$ for some $\sigma_0\in(0,1)$ and $f\in L^q_{loc}(\Omega)$ with $n<q\leq\infty$, where the symmetric matrix $A(x)$ of coefficients is a Hölder continuous function satisfying the uniformly elliptic condition. Moreover, we would like to remark that this work can be viewed as a continuation and follow-up to the works [4,33,34].

Keywords: $C^{1,\alpha}$, regularity, divergence, weak solutions, Orlicz, quasilinear, elliptic.

1 Introduction

In this paper we are mainly concerned with the interior optimal $C^{1,\alpha}$ regularity estimates for weak solutions of the following quasilinear elliptic equations with Orlicz growth in divergence form

$$-\operatorname{div} a(x,Du) = -\operatorname{div}\mathbf{F}+f \quad \text{in } \Omega\subset\mathbb{R}^n, \tag{1.1}$$

✉Corresponding author. Email: yfp@shu.edu.cn

where $n \geq 2$, $f \in L^q(\Omega)$ for $n < q \leq \infty$, $\mathbf{F}(x) \in C^{0,\sigma_0}(\Omega)$ for some $\sigma_0 \in (0,1)$ and the vector field $a(x,\xi) : \Omega \times \mathbb{R}^n \to \mathbb{R}^n$ is C^1-regular in the variable ξ satisfying

$$|a(x,\xi)| + \left|D_\xi a(x,\xi)\right| |\xi| \leq C\varphi(|\xi|), \tag{1.2}$$

$$D_\xi a(x,\xi)\eta \cdot \eta \geq C\varphi'(|\xi|)|\eta|^2, \tag{1.3}$$

$$|a(x_1,\xi) - a(x_2,\xi)| \leq w\left(|x_1 - x_2|\right)\varphi(|\xi|). \tag{1.4}$$

Here $w : [0,+\infty) \to [0,+\infty)$ belongs to $C^{0,\sigma}\left([0,+\infty)\right)$ for some $\sigma \in (0,1)$, $w(0) = 0$ and the function $\varphi(t) : [0,+\infty) \to [0,+\infty)$ belongs to $C^1\left([0,+\infty)\right)$ satisfying

$$0 < i_a := \inf_{t>0} \frac{t\varphi'(t)}{\varphi(t)} \leq \sup_{t>0} \frac{t\varphi'(t)}{\varphi(t)} =: s_a < \infty. \tag{1.5}$$

Actually, the two special models of (1.1) are the nonhomogeneous p-Laplacian equation with varying coefficients in divergence form

$$-\operatorname{div}\left((ADu \cdot Du)^{\frac{p-2}{2}} ADu\right) = -\operatorname{div}\mathbf{F} + f$$

and the nonhomogeneous p-Laplacian equation with varying coefficients and the logarithmic growth in divergence form

$$-\operatorname{div}\left((ADu \cdot Du)^{\frac{p-2}{2}} \ln^\theta\left(1 + (ADu \cdot Du)^{\frac{1}{2}}\right) ADu\right) = -\operatorname{div}\mathbf{F} + f$$

for $\theta > 0$.

It is well-known that the classical elliptic p-Laplacian equation

$$-\operatorname{div}\left(|Du|^{p-2} Du\right) = f$$

can be derived from the variational problem

$$\mathcal{P}(u,\Omega) := \min_{v-g \in W_0^{1,p}(\Omega)} \mathcal{P}(v,\Omega),$$

where

$$\mathcal{P}(v,\Omega) := \int_\Omega \left(\frac{1}{p}|\nabla v|^p - fv\right) dx \quad \text{for any } v \in W^{1,p}(\Omega).$$

Then $\mathcal{P}(v,\Omega)$ attains its minimum at a unique function u, which implies u is the weak solution of elliptic p-Laplacian equation with the boundary condition $u = g$ on $\partial\Omega$, satisfying

$$\int_\Omega \left[\,|Du|^{p-2} Du \cdot D\phi - f\phi\right] dx = 0 \quad \text{for any } \phi \in W_0^{1,p}(\Omega).$$

In reality, the nonlinear elliptic and parabolic PDEs can be derived from many important practical problems among the natural sciences: nonlinear elasticity mechanics and dynamic glaciology, non-Newtonian fluid mechanics, turbulent flows of a gas in porous media, thermodynamics and so on. At the same time, they can also come from some financial and economic problems and simultaneously the solutions of the nonlinear PDEs and their properties illustrate the features of these problems. Since the structure models in some real financial products and the option price can be reduced to some nonlinear PDE boundary problems, it is useful to adopt the existing theory and methods of PDEs as a fundamental approach to the study of the

financial and economic theory (see [22]). For these reasons it is very meaningful and useful for us to study various kinds of regularity estimates for the nonlinear elliptic and parabolic PDEs with different coefficients and domain conditions. There have been a wide research activities [5, 6, 8–10, 17, 23, 25] on L^p-type estimates for weak solutions of elliptic quasilinear equations of p-Laplacian type with different coefficient and domain assumptions. On the other hand, Duzaar, Kuusi and Mingione [19, 20, 24] also made a deep study of sharp local a priori estimates and regularity results for solutions to

$$-\operatorname{div} a(x, Du) = \mu,$$

whose prototype is the elliptic p-Laplacian equation with coefficients and the right-hand side measure μ

$$-\operatorname{div}\left(\gamma(x)\,|Du|^{p-2}\,Du\right) = \mu.$$

Moreover, Cianchi and Maz'ya [12–14] proved global Lipschitz regularity and sharp estimates for weak solutions of

$$\operatorname{div}\left(\varphi'\left(|\nabla u|\right)\nabla u\right) = f \quad \text{in } \Omega \tag{1.6}$$

with the condition (1.5). Meanwhile, Baroni [7] proved pointwise gradient estimates via linear Riesz potentials for solutions to the following nonlinear elliptic equations with the right-hand side measure

$$\operatorname{div}\left(\varphi'\left(|\nabla u|\right)\nabla u\right) = \mu.$$

The theory of $C^{1,\alpha}$ regularity estimates for weak solutions of the elliptic p-Laplacian equation

$$-\operatorname{div}\left(|Du|^{p-2}\,Du\right) = 0 \tag{1.7}$$

is well-known. Evans, Lewis, Tolksdorf, Uhlenbeck and Ural'ceva (see [21, 26, 29–31] and references therein) have studied the theory of $C^{1,\alpha}$ regularity estimates for weak solutions of the elliptic p-Laplace equation (1.7) and the more general cases with variable coefficients. Moreover, Wang [32] used compactness methods to give a different proof of the interior $C^{1,\alpha}$ regularity for weak solutions of (1.7). In addition, Colombo and Mingione [15, 16] obtained the interior $C^{1,\alpha}$ regularity of weak solutions for a class of variational problems whose model is given by the functional

$$w \mapsto \int \left(|Dw|^p + a(x)\,|Dw|^q\right) dx.$$

A longstanding conjecture in elliptic regularity theory inquires whether a $W^{1,p}$ function whose p-Laplacian is bounded is locally of class $C^{p'} = C^{1,\frac{1}{p-1}}$. Recently, Araújo, Teixeira and Urbano [2] proved the planar counterpart of $C^{p'}$-regularity in the plane that weak solutions of the elliptic degenerate p-Laplacian equation

$$-\operatorname{div}\left(|Du|^{p-2}\,Du\right) = f(x) \quad \text{in } \Omega \subset \mathbb{R}^2$$

with a bounded source $f \in L^\infty$ are locally of class $C^{p'} = C^{1,\frac{1}{p-1}}$, in which they gave the precise control on a new oscillation of weak solutions in terms of the magnitude of its gradient and then improved $C^{1,\alpha}$ regularity estimates by geometric iteration. Moreover, we would like to remark that this regularity in [2] is optimal. Subsequently, Araújo, Teixeira and Urbano [3] solved the $C^{p'}$-regularity conjecture for weak solutions of the degenerate elliptic p-Laplacian equation in higher dimensions $n > 2$. Very recently, Araújo and Zhang [4] established the

interior optimal sharp $C^{1,\alpha}$ estimates for weak solutions of quasilinear elliptic equations of p-Laplacian type with varying coefficients

$$-\operatorname{div} a(x, Du) = f \quad \text{in } \Omega \subset \mathbb{R}^n,$$

where $n \geq 2$, $f \in L^q(\Omega)$ for $n < q \leq \infty$ and the vector field $a(x,\xi) : \Omega \times \mathbb{R}^n \to \mathbb{R}^n$ is C^1-regular in the variable ξ satisfying the following structural assumptions

$$\begin{aligned} |a(x,\xi)| + \left|D_\xi a(x,\xi)\right| |\xi| &\leq C|\xi|^{p-1}, \\ D_\xi a(x,\xi)\eta \cdot \eta &\geq C|\xi|^{p-2}|\eta|^2, \\ |a(x_1,\xi) - a(x_2,\xi)| &\leq w\left(|x_1 - x_2|\right) |\xi|^{p-1} \end{aligned}$$

with $w \in C^{0,\sigma}(\Omega)$ for some $\sigma \in (0,1)$, $w(0) = 0$ and $f \in L^q(\Omega)$. Additionally, Ding, Zhang and Zhou [18] then studied the optimal $C^{1,\alpha}$ estimates for the elliptic $p(x)$-Laplacian equation

$$\operatorname{div}\left(a(x)\,|Du|^{p(x)-2}\,Du\right) = \operatorname{div} \mathbf{h}(x) + f(x) \quad \text{in } \Omega.$$

Just recently Teixeira [28] undertook further research of the p-degenerate elliptic equations in a heterogeneous medium

$$-\operatorname{div} a(x, Du) = f(x, u, Du) \quad \text{in } \Omega,$$

which cover the following degenerate-elliptic nonhomogeneous PDE of the general form

$$-\operatorname{div}\left(|Du|^{p-2}\,Du\right) = f(x, u, Du) \quad \text{in } \Omega.$$

For the sake of convenience, we first elaborate on some definitions and fundamental results about the general Orlicz spaces, which have been widely used in the area of analysis as one of the most natural generalizations of Sobolev spaces (see [1,27]). A function $\Phi : [0,+\infty) \to [0,+\infty)$ is said to be a Young function if it is convex and $\Phi(0) = 0$. Moreover, a Young function Φ is called an N-function if $0 < \Phi(t) < \infty$ for $t > 0$ and

$$\lim_{t\to+\infty} \frac{\Phi(t)}{t} = \lim_{t\to 0+} \frac{t}{\Phi(t)} = +\infty.$$

Additionally, we call that a Young function Φ belongs to Δ_2 if there exists a positive constant K such that

$$\Phi(2t) \leq K\Phi(t) \quad \text{for any } t > 0.$$

Furthermore, we say that a Young function Φ belongs to ∇_2 if there exists a number $\theta > 1$ such that

$$\Phi(t) \leq \frac{\Phi(\theta t)}{2\theta} \quad \text{for any } t > 0.$$

Definition 1.1 (see [1]). *The Orlicz class $K^\Phi(\Omega)$ is the set of all measurable functions $g : \Omega \to \mathbb{R}$ satisfying*

$$\int_\Omega \Phi(|g|)dx < \infty.$$

The Orlicz space $L^\Phi(\Omega)$ is the linear hull of $K^\Phi(\Omega)$. Furthermore, we define $W^{1,\Phi}(\Omega)$ as

$$W^{1,\Phi}(\Omega) := \left\{u \in L^\Phi(\Omega) \mid Du \in L^\Phi(\Omega)\right\}.$$

The space $W_0^{1,\Phi}(\Omega)$ is the closure of $C_0^\infty(\Omega)$ in $W^{1,\Phi}(\Omega)$.

In this paper we define

$$\Phi(t) := \int_0^t \varphi(\tau)d\tau \quad \text{for } t \geq 0. \tag{1.8}$$

Then from (1.5) it is easy to check that

$$\varphi(t) \text{ is strictly increasing and continuous over } [0, +\infty], \tag{1.9}$$

and

$$\Phi(t) \text{ is increasing over } [0, +\infty]. \tag{1.10}$$

As usual, the solutions of (1.1) are taken in a weak sense. We now state the definition of weak solutions.

Definition 1.2. A function $u \in W^{1,\Phi}_{loc}(\Omega)$ is a local weak solution of of (1.1) in Ω if

$$\int_\Omega \left[a(x, Du) \cdot D\phi - \mathbf{F} \cdot D\phi - f\phi\right] dx = 0$$

holds for any $\phi \in C_0^\infty(\Omega)$.

A direct example

$$v(x) = \frac{p-1}{p}|x|^{\frac{p}{p-1}} = \frac{p-1}{p}|x|^{1+\frac{1}{p-1}} \quad \text{for } p > 1,$$

which satisfies the elliptic p-Laplacian equation

$$\operatorname{div}\left(|Dv|^{p-2}\, Dv\right) = n,$$

shows that if the optimal regularity for the elliptic p-Laplacian equations is $C^{1,\alpha}$, then we can get to know that α is surely smaller than $\frac{1}{p-1}$. In particular, in [34] the authors proved that weak solutions for a class of the homogeneous quasilinear elliptic equations

$$\operatorname{div}\left(\varphi'\left(|\nabla u|\right)\nabla u\right) = 0 \quad \text{in } \Omega \tag{1.11}$$

with $f, w \equiv 0$ are locally $C^{1,\alpha}$ for some $\alpha \in (0,1)$ depending on n, i_a, s_a. Following the same approach as Definition 3 of the article [28], we define the maximal C^{1,α_m} regularity for weak solutions of (1.11) as corresponding to the maximal $\alpha_m \in (0,1]$, where α_m is given by

$$\alpha_m := \sup\left\{\alpha \in (0,1) \mid h \text{ belongs to } C^{1,\alpha}_{loc}(\Omega) \text{ for every local weak solution } h \in W^{1,\Phi}_{loc}(\Omega) \text{ of (1.11) with the condition (1.5)}\right\}.$$

Furthermore, in [33] authors have also extended the corresponding results in [34] to the non-uniformly nonlinear elliptic equations.

Now let us state the main result of this work.

Theorem 1.3. *Assume that the conditions (1.2)–(1.5) hold and let $u \in W^{1,\Phi}_{loc}(\Omega)$ be a local weak solution of (1.1). Then we have $u \in C^{1,\alpha}_{loc}(\Omega)$ for some $\alpha \in (0,1)$, where*

$$\alpha := \min\left\{\alpha_m - \epsilon, \alpha_{\sigma, i_a, s_a, q}\right\} \tag{1.12}$$

for any positive number ϵ less than α_m, and

$$\alpha_{\sigma,i_a,s_a,q} := \begin{cases} \min\left\{\sigma,\sigma_0,1-\dfrac{n}{q}\right\}\cdot\min\left\{1,\dfrac{1}{s_a}\right\} & \text{if } n<q<\infty, \\ \min\{\sigma,\sigma_0\}\cdot\min\left\{1,\dfrac{1}{s_a}\right\} & \text{if } q=\infty. \end{cases} \tag{1.13}$$

Moreover, for every $\Omega' \subset\subset \Omega$, the following estimates

$$\sup_{\substack{x,y\in\Omega' \\ x\neq y}} \frac{|u(x)-u(y)|}{|x-y|^{\alpha}} \leq C \tag{1.14}$$

and

$$\sup_{\substack{x,y\in\Omega' \\ x\neq y}} \frac{|Du(x)-Du(y)|}{|x-y|^{\alpha}} \leq C \tag{1.15}$$

hold, where C is a positive constant depending on $n, i_a, s_a, \alpha, \sigma, \sigma_0$, $\|u\|_{W^{1,\Phi}_{loc}(\Omega)}$, $\|w\|_{C^{0,\sigma}_{loc}(\Omega)}$, $[\boldsymbol{F}]_{C^{0,\sigma_0}_{loc}(\Omega)}$, $\|f\|_{L^q_{loc}(\Omega)}$ and dist $(\Omega',\partial\Omega)$.

2 Auxiliary lemmas

In the following, we will introduce several auxiliary lemmas, which will be employed in the proof of the conclusions stated in Theorem 1.3. Moreover, we stress the point that the proof is much influenced by the papers [2–4, 11]. Let us first state a crucial lemma under present assumptions on the function $\varphi(t)$.

Lemma 2.1. *If $\varphi(t)$ satisfies (1.5), then we find that*

$$\theta^{i_a}\varphi(t) \leq \varphi(\theta t) \leq \theta^{s_a}\varphi(t) \quad \text{for } \theta \geq 1 \tag{2.1}$$

and

$$C\theta^{i_a-1}\varphi'(t) \leq \varphi'(\theta t) \leq C\theta^{s_a-1}\varphi'(t) \quad \text{for } \theta \geq 1. \tag{2.2}$$

Proof. Firstly, (1.5) implies that

$$\frac{i_a}{\theta t} \leq \frac{\varphi'(\theta t)}{\varphi(\theta t)} \leq \frac{s_a}{\theta t} \quad \text{for any } t>0,$$

which implies that

$$\int_1^{\theta} \frac{i_a}{\theta t}d\theta \leq \frac{1}{t}\ln\left[\frac{\varphi(\theta t)}{\varphi(t)}\right] = \int_1^{\theta}\frac{\varphi'(\theta t)}{\varphi(\theta t)}d\theta \leq \int_1^{\theta}\frac{s_a}{\theta t}d\theta.$$

So, we can get the desired estimate (2.1)

$$\theta^{i_a}\varphi(t) \leq \varphi(\theta t) \leq \theta^{s_a}\varphi(t) \quad \text{for } \theta \geq 1.$$

On the other hand, by using (1.5) again we deduce that

$$i_a\frac{\varphi(\theta t)}{\theta t} \leq \varphi'(\theta t) \leq s_a\frac{\varphi(\theta t)}{\theta t} \quad \text{for any } t>0$$

and

$$i_a \frac{\varphi(t)}{t} \le \varphi'(t) \le s_a \frac{\varphi(t)}{t} \quad \text{for any } t > 0,$$

which imply, thanks to (2.1), that

$$\frac{i_a}{s_a}\theta^{i_a-1}\varphi'(t) \le i_a \frac{\theta^{i_a}\varphi(t)}{\theta t} \le \varphi'(\theta t) \le s_a \frac{\theta^{s_a}\varphi(t)}{\theta t} \le \frac{s_a}{i_a}\theta^{s_a-1}\varphi'(t).$$

Thus, we finish the proof of this lemma. □

In the subsequent analysis, we proceed to verify that the weak solution u of equation (1.1) can be approximated by that of a reference equation with constant coefficients, which exhibits favorable analytical properties. Before proceeding, we first define the ball $B_r(x_0)$ as the open ball with center x_0 and radius r, and specify B_r as $B_r := B_r(0)$.

Lemma 2.2. *Assume that the conditions (1.2)–(1.5) hold and let $u \in W^{1,\Phi}_{loc}(\Omega)$ be a local weak solution of (1.1) in $\Omega \supset B_1$ with $\|u\|_{L^\infty(B_1)} \le 1$ and $u(0) = 0$. For any $\epsilon > 0$, there exists a positive constant δ, depending on $n, q, i_a, s_a, \sigma, \sigma_0$ and ϵ, such that if*

$$\|f\|_{L^q(B_1)} \le \delta, \qquad [\boldsymbol{F}]_{C^{0,\sigma_0}(B_1)} \le \delta$$

and

$$\sup_{B_1} \left|a(x,\xi) - a(0,\xi)\right| \le \varphi(|\xi|)\delta,$$

then there exists a function h weak solution of

$$-\operatorname{div} \bar{a}(Dh) = 0 \quad \text{in } B_{3/4} \text{ with } h(0) = 0 \tag{2.3}$$

for a constant coefficient field $\bar{a}$ satisfying (1.2)–(1.5) and $w \equiv 0$, such that

$$\sup_{B_{1/2}} |u - h| + |Du(0) - Dh(0)| \le \epsilon.$$

Proof. We prove this by contradiction. Suppose, for the sake of contradiction, that the result is false. Then there exist $\epsilon_0 > 0$, $\{f_j\}_{j=1}^\infty$, $\{\mathbf{F}_j\}_{j=1}^\infty$, $\{a_j(x,\xi)\}_{j=1}^\infty$ and $\{u_j\}_{j=1}^\infty$ satisfying

$$\int_\Omega \left[a_j(x, Du_j)\cdot D\phi - \mathbf{F}_j \cdot D\phi - f_j\phi\right]dx = 0 \quad \text{for any } \phi \in C_0^\infty(\Omega), \tag{2.4}$$

$$\begin{aligned}
\|u_j\|_{L^\infty(B_1)} &\le 1,\\
u_j(0) &= 0,\\
\|f_j\|_{L^q(B_1)} &\le \frac{1}{j},\\
[\mathbf{F}_j]_{C^{0,\sigma_0}(B_1)} &\le \frac{1}{j},\\
\left|a_j(x,\xi) - a_j(0,\xi)\right| &\le \frac{1}{j}\varphi(|\xi|),
\end{aligned}$$

so that for any weak solution h of the homogeneous constant-coefficient equation (2.3) in $B_{3/4}$ satisfying $h(0) = 0$, we have

$$\sup_{B_{1/2}} |u_j - h| + |Du_j(0) - Dh(0)| \ge \epsilon_0. \tag{2.5}$$

In light of this, a standard regularity estimate for weak solutions of (2.4) guarantees that the sequence $\{u_j\}_{j=1}^{\infty}$ satisfies $|Du_j| \le L/2$ for some $L > 0$ and all $x \in B_{3/4}$, and forms a pre-compact sequence in the C^1-topology (see [7, Corollary 1.3]). This further implies the existence of a function $u_\infty \in C^1$ with $u_\infty(0) = 0$ and

$$\sup_{B_{1/2}} |u_j - u_\infty| + |Du_j(0) - Du_\infty(0)| \to 0 \quad \text{as } j \to +\infty. \tag{2.6}$$

Define

$$b_j(x,\xi) := a_j(x,\xi)\chi_{\{|\xi|\le L\}} + L\,\chi_{\{|\xi|\ge L\}}.$$

Since $\{b_j(0,\cdot)\}$ is equicontinuous and uniformly bounded, by the Ascoli–Arzelà theorem, we can find $b_\infty(0,\cdot)$ such that

$$b_j(0,\cdot) \to b_\infty(0,\cdot) \quad \text{uniformly in } B_L := \{|\xi| \le L\} \text{ as } j \to \infty,$$

which implies that

$$\big|a_j(x,\xi) - b_\infty(0,\xi)\big| \le \varphi(|\xi|)\frac{1}{j} + \big|a_j(0,\xi) - b_\infty(0,\xi)\big| \to 0 \quad \text{as } j \to +\infty \tag{2.7}$$

uniformly in $B_{3/4} \times B_L$. Now, applying (2.4), (2.6)–(2.7) and standard arguments, we find that u_∞ is a weak solution of the constant-coefficient equation

$$\int_{B_{3/4}} b_\infty(0, Du_\infty) \cdot D\phi \, dx = 0 \quad \text{for any } \phi \in C_0^\infty(B_{3/4}) \tag{2.8}$$

with $u_\infty(0) = 0$. However, this contradicts (2.5) by (2.6) because u_∞ can serve as the function h described in (2.5). Thus, the proof is complete. □

In addition, by making full use of the above lemma we are able to prove the following crucial results which play an essential role in the subsequent discussion.

Lemma 2.3. *Assume that the conditions (1.2)–(1.5) hold and let $u \in W^{1,\Phi}_{loc}(\Omega)$ be a local weak solution of (1.1) in $\Omega \supset B_1$ with $\|u\|_{L^\infty(B_1)} \le 1$ and $u(0) = 0$.*

1. *There exist two positive constants δ_0 and $\rho_0 \in (0,1)$, depending on $n, q, i_a, s_a, \sigma, \sigma_0$ and α, such that if*

$$\|f\|_{L^q(B_1)} \le \delta_0, \quad [\boldsymbol{F}]_{C^{0,\sigma_0}(B_1)} \le \delta_0, \quad \sup_{B_1} \big|a(x,\xi) - a(0,\xi)\big| \le \varphi(|\xi|)\delta_0 \tag{2.9}$$

and

$$|Du(0)| \le \frac{1}{4}\rho_0^\alpha,$$

then we have

$$\sup_{B_{\rho_0}} |u(x)| \le \rho_0^{1+\alpha}.$$

2. *If*

$$|Du(0)| \le \frac{1}{4}\rho_0^{i\alpha}$$

for some positive integer $i \in \mathbb{N}$ and (2.9) hold, then we have

$$\sup_{B_{\rho_0^i}} |u(x)| \le C\rho_0^{i(1+\alpha)},$$

where C depends on $n, q, i_a, s_a, \sigma, \sigma_0$ and α.

3. *If*

$$|Du(0)| \le \frac{1}{4}\rho^{\alpha}$$

for any $0 < \rho \le \rho_0 < 1$ and (2.9) hold, then we have

$$\sup_{B_\rho} |u(x)| \le C\rho^{1+\alpha},$$

where C depends on $n, q, i_a, s_a, \sigma, \sigma_0$ and α.

Proof. (1) In accordance with Lemma 2.2, for any $\epsilon > 0$, there exists a weak solution h to the constant-coefficient equation (2.3) satisfying

$$|Du(0) - Dh(0)| \le \epsilon$$

and

$$\sup_{B_\rho} |u| \le \epsilon + \sup_{B_\rho} |h|$$

for any $0 < \rho \le 1/2$. Meanwhile, from the interior C^{1,α_m}-regularity estimates for the constant coefficient equation (2.3) together with the fact that $h(0) = 0$, we conclude that

$$\sup_{B_\rho} |h| \le C\rho^{1+\alpha_m} + |Dh(0)|\rho,$$

where the positive constant $C > 1$ depends on n, i_a and s_a, which implies that

$$\begin{aligned}\sup_{B_{\rho_0}} |u| &\le \epsilon + C\rho_0^{1+\alpha_m} + (\epsilon + |Du(0)|)\,\rho_0 \\ &\le \epsilon + C\rho_0^{1+\alpha_m} + \left(\epsilon + \frac{1}{4}\rho_0^{\alpha}\right)\rho_0 \\ &\le \rho_0^{1+\alpha}\end{aligned}$$

by choosing $\rho_0 = (4C)^{\frac{1}{\alpha-\alpha_m}}$ and $\epsilon = \frac{1}{4}\rho_0^{1+\alpha}$.

(2) We prove it by induction. From (1) we know that the result is true for $i = 1$. Let us assume the conclusion is true for $1, 2, \dots i$. Suppose u satisfies

$$|Du(0)| \le \frac{1}{4}\rho_0^{(i+1)\alpha}. \tag{2.10}$$

We denote $u_i(x)$ by

$$u_i(x) := \frac{u\left(\rho_0^i x\right)}{\rho_0^{i(\alpha+1)}}.$$

Then $u_i(x)$ solves

$$-\operatorname{div} a_i(x, Du_i) = f_i \quad \text{in } B_1,$$

where

$$\begin{aligned}a_i(x,\xi) &:= \frac{a(\rho_0^i x, \rho_0^{i\alpha}\xi)}{\varphi(\rho_0^{i\alpha})}, \\ f_i &:= \frac{\rho_0^i f(\rho_0^i x)}{\varphi(\rho_0^{i\alpha})}, \\ \mathbf{F}_i &:= \frac{\mathbf{F}(\rho_0^i x)}{\varphi(\rho_0^{i\alpha})}.\end{aligned}$$

We set

$$\varphi_i(t) := \frac{\varphi(\rho_0^{i\alpha} t)}{\varphi(\rho_0^{i\alpha})}.$$

It is easy to check that $a_i(x,\xi)$ and φ_i still satisfy the assumptions (1.2)–(1.5), and $f_i(x)$ and $\mathbf{F}_i(x)$ satisfy

$$\|f_i\|_{L^q(B_1)} \le \frac{\rho_0^{i(1-\frac{n}{q})}}{\varphi(\rho_0^{i\alpha})}\|f\|_{L^q(B_1)} \le \rho_0^{i(1-\frac{n}{q}-\alpha s_a)}\|f\|_{L^q(B_1)} \le \delta_0$$

and

$$\begin{aligned}
[\mathbf{F}_i]_{C^{0,\sigma_0}(B_1)} &:= \sup_{x,y\in B_1} \frac{|\mathbf{F}_i(x)-\mathbf{F}_i(y)|}{|x-y|^{\sigma_0}} \\
&= \frac{1}{\varphi(\rho_0^{i\alpha})} \sup_{x,y\in B_1} \frac{|\mathbf{F}(\rho_0^i x)-\mathbf{F}(\rho_0^i y)|}{|x-y|^{\sigma_0}} \\
&\le \frac{\rho_0^{i\sigma_0}}{\varphi(\rho_0^{i\alpha})}[\mathbf{F}]_{C^{0,\sigma_0}(B_1)} \\
&\le \rho_0^{i(\sigma_0-\alpha s_a)}[\mathbf{F}]_{C^{0,\sigma_0}(B_1)} \\
&\le \delta_0
\end{aligned}$$

in view of (1.12), (1.13), (2.1) and the facts that

$$1-\frac{n}{q}-\alpha s_a \ge 0 \quad \text{and} \quad \sigma_0 - \alpha s_a \ge 0.$$

Moreover, using the inductive result for the case i, one can deduce that

$$|Du_i(0)| \le \frac{1}{4}\rho_0^{\alpha}$$

by the assumed condition (2.10). Then it follows from (1) that

$$\sup_{B_{\rho_0}} |u_i(x)| \le \rho_0^{1+\alpha}.$$

Finally, the definition of u_i implies that

$$\sup_{B_{\rho_0^{i+1}}} |u(x)| \le \rho_0^{(i+1)(1+\alpha)},$$

which completes the proof of (2).

(3) For $0 < \rho \le \rho_0 < 1$, there exists a positive integer $k \in \mathbb{N}$ such that $\rho_0^{k+1} < \rho \le \rho_0^k$. By the given conditions, we derive

$$|Du(0)| \le \frac{1}{4}\rho^{\alpha} \le \frac{1}{4}\rho_0^{k\alpha}$$

and then by (2),

$$\sup_{B_\rho} |u(x)| \le \sup_{B_{\rho_0^k}} |u(x)| \le \rho_0^{k(1+\alpha)} = \rho_0^{-(1+\alpha)}\rho_0^{(k+1)(1+\alpha)} \le \rho_0^{-(1+\alpha)}\rho^{1+\alpha}.$$

This completes our proof. □

Our approach is based on the following two oscillation estimates, which are similarly to the classical Taylor expansion, themselves interesting and can reveal some essential qualities or characteristics of the solutions to the problem (1.1). More precisely, they can give the precise control on the oscillation of weak solutions to the problem (1.1) in term of the magnitude of the gradients

$$\sup_{B_r} \left|u(x) - u(0)\right| \lesssim r^{1+\alpha} + |Du(0)|\, r.$$

It is noteworthy that we shall need to solve some difficulties cased by the differences of balls B_r with large radii: $|Du(0)| \lesssim r$ and with small radii: $r \lesssim |Du(0)|$. Next, we shall first derive the following sharp regularity estimates for the large radii. Moreover, we would like to remark that the positive constants C are called universal if they only depend on $n, i_a, s_a, \sigma, \sigma_0, \alpha$, $\|u\|_{W^{1,\Phi}_{loc}(\Omega)}$, $\|w\|_{C^{0,\sigma}_{loc}(\Omega)}$, $[\mathbf{F}]_{C^{0,\sigma_0}_{loc}(\Omega)}$, $\|f\|_{L^q_{loc}(\Omega)}$ and $\operatorname{dist}(\Omega', \partial\Omega)$.

Proposition 2.4. *Assume that the conditions (1.2)–(1.5) hold and let $u \in W^{1,\Phi}_{loc}(\Omega)$ be a local weak solution of (1.1). Let $\Omega' \subset\subset \Omega$ and let $x_0 \in \Omega'$, there exist universal positive constants κ, C and $\bar{\rho}$ such that if*

$$|Du(x_0)| \le \kappa \rho^{\alpha} \tag{2.11}$$

for some $0 < \rho \le \rho_0$ with $B_{\rho_0}(x_0) \subset \Omega' \subset\subset \Omega$, then we have

$$\sup_{B_\rho(x_0)} \left|u(x) - u(x_0)\right| \le C\rho^{1+\alpha} \tag{2.12}$$

and

$$\sup_{B_\rho(x_0)} \left|u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)\right| \le C\rho^{1+\alpha} \tag{2.13}$$

for any $0 < \rho \le \bar{\rho} < \rho_0 < 1$.

Proof. We denote $v(x)$ by

$$v(x) := \frac{u(x_0 + A_0 x) - u(x_0)}{B_0}$$

and then $v(x)$ solves

$$-\operatorname{div} a_0(x, Dv) = -\operatorname{div} \mathbf{F}_0 + f_0 \quad \text{in } B_1,$$

where

$$\begin{aligned}
A_0 &:= \min\left\{1, \frac{d_0}{2}, \frac{w^{-1}(\delta_0)}{d_0}\right\} \quad \text{with } d_0 = \operatorname{dist}(\Omega', \partial\Omega),\\
B_0 &:= \max\left\{1, 2\|u\|_{L^\infty(\Omega')}, \left(\|f\|_{L^q(\Omega')}\delta_0^{-1}\right)^{\frac{1}{i_a}}, \left([\mathbf{F}]_{C^{0,\sigma_0}(\Omega')}\delta_0^{-1}\right)^{\frac{1}{i_a}}\right\},\\
a_0(x,\xi) &:= \frac{a(x_0 + A_0 x, \frac{B_0}{A_0}\xi)}{\varphi\left(\frac{B_0}{A_0}\right)},\\
f_0 &:= \frac{A_0 f(x_0 + A_0 x)}{\varphi\left(\frac{B_0}{A_0}\right)},\\
\mathbf{F}_0 &:= \frac{\mathbf{F}_0(x_0 + A_0 x)}{\varphi\left(\frac{B_0}{A_0}\right)}.
\end{aligned}$$

We set

$$\varphi_0(t) := \frac{\varphi(\frac{B_0}{A_0}t)}{\varphi\left(\frac{B_0}{A_0}\right)}.$$

It is easy to check that $a_0(x,\xi)$ and φ_0 still satisfy the assumptions (1.2)–(1.5), $v(0) = 0$, $\|v\|_{L^\infty(B_1)} \le 1$,

$$\begin{aligned}
|a_0(x,\xi) - a_0(0,\xi)| &= \left| \frac{a(x_0 + A_0 x, \frac{B_0}{A_0}\xi)}{\varphi\left(\frac{B_0}{A_0}\right)} - \frac{a(x_0, \frac{B_0}{A_0}\xi)}{\varphi\left(\frac{B_0}{A_0}\right)} \right| \\
&\le w\left(A_0|x|\right)\varphi_0(|\xi|) \\
&\le \delta_0 \varphi_0(|\xi|),
\end{aligned}$$

$$\begin{aligned}
\|f_0\|_{L^q(B_1)} &\le \frac{A_0^{1-\frac{n}{q}}}{\varphi\left(\frac{B_0}{A_0}\right)} \|f\|_{L^q(\Omega')} \\
&\le A_0^{1-\frac{n}{q}+i_a} B_0^{-i_a} \|f\|_{L^q(\Omega')} \\
&\le B_0^{-i_a} \|f\|_{L^q(\Omega')} \le \delta_0,
\end{aligned}$$

$$\begin{aligned}
[\mathbf{F}_0]_{C^{0,\sigma_0}(B_1)} &\le \frac{A_0^{\sigma_0}}{\varphi\left(\frac{B_0}{A_0}\right)} [\mathbf{F}]_{C^{0,\sigma_0}(\Omega')} \\
&\le A_0^{\sigma_0+i_a} B_0^{-i_a} [\mathbf{F}]_{C^{0,\sigma_0}(\Omega')} \\
&\le \delta_0
\end{aligned}$$

in view of (1.5) and (2.1), and

$$|Dv(0)| \le C\rho^\alpha$$

for $\rho \le \rho_0$, by the assumed condition (2.11). Then by Lemma 2.3, we obtain

$$\sup_{B_\rho} |v(x)| \le C\rho^{1+\alpha}$$

for some $0 < \rho \le \rho_0$, which implies that

$$\sup_{B_{A_0\rho}(x_0)} |u(x) - u(x_0)| \le C\rho^{1+\alpha} \le C\left(A_0\rho\right)^{1+\alpha}.$$

Thus, we can finish the proof of (2.12)–(2.13) by choosing $\bar{\rho} = A_0\rho_0 \le \rho_0$. □

Here we are going to prove another regularity estimates in the balls B_r with small radii $r \lesssim |Du|$ which enable the vector field $a(x,\xi)$ can be viewed as essentially a function with linear growth in the variable ξ.

Proposition 2.5. *Assume that the conditions (1.2)–(1.5) hold and let $u \in W^{1,\Phi}_{loc}(\Omega)$ be a local weak solution of (1.1). Let $\Omega' \subset\subset \Omega$ and let $x_0 \in \Omega'$, there exist universal positive constants κ, C and $\tilde{\rho}$ such that if*

$$|Du(x_0)| > \kappa\rho^\alpha \tag{2.14}$$

for $0 < \rho \le \tilde{\rho}$ with $B_{\tilde{\rho}}(x_0) \subset \Omega' \subset\subset \Omega$, then for $0 < \rho \le \tilde{\rho}$ we have

$$\sup_{B_\rho(x_0)} \big|u(x) - u(x_0)\big| \le C\rho^\alpha \tag{2.15}$$

and

$$\sup_{B_\rho(x_0)} \big|u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)\big| \le C\rho^{1+\alpha}. \tag{2.16}$$

Proof. We define $v(x)$ by

$$v(x) := \frac{u(x_0 + \rho_* x) - u(x_0)}{\rho_*^{1+\alpha}}$$

and then $v(x)$ solves

$$-\operatorname{div} a_*(x, Dv) = -\operatorname{div}\mathbf{F}_*(x) + f_*(x) \quad \text{in } B_1, \tag{2.17}$$

where

$$\begin{aligned}
\rho_* &:= \Big[\kappa^{-1}|Du(x_0)|\Big]^{\frac{1}{\alpha}},\\
a_*(x,\xi) &:= \frac{a(x_0 + \rho_* x, \rho_*^\alpha \xi)}{\varphi(\rho_*^\alpha)},\\
f_* &:= \frac{\rho_* f(x_0 + \rho_* x)}{\varphi(\rho_*^\alpha)},\\
\mathbf{F}_* &:= \frac{\mathbf{F}(x_0 + \rho_* x)}{\varphi(\rho_*^\alpha)}.
\end{aligned}$$

We set

$$\varphi_*(t) := \frac{\varphi(\rho_*^\alpha t)}{\varphi(\rho_*^\alpha)}.$$

It is easy to check that $a_*(x,\xi)$ and φ_* still satisfy the assumptions (1.2)–(1.5). Now we divide into two cases.

Case 1: $\rho_* \le \bar{\rho} < 1$, where $\bar{\rho}$ is defined in Proposition 2.4. Then we find that

$$|Du(x_0)| = \kappa\rho_*^\alpha \le \kappa\bar{\rho}^\alpha.$$

From Proposition 2.4, we know that

$$\sup_{B_{\rho_*}(x_0)} \big|u(x) - u(x_0)\big| \le C\rho_*^{1+\alpha} \tag{2.18}$$

and

$$\sup_{B_{\rho_*}(x_0)} \big|u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)\big| \le C\rho_*^{1+\alpha}, \tag{2.19}$$

which implies that

$$\sup_{B_1} |v(x)| \le C \sup_{B_{\rho_*}(x_0)} \frac{\big|u(x) - u(x_0)\big|}{\rho_*^{1+\alpha}} \le C.$$

Consequently, by applying the C^0-estimates to Dv, there exists $\tau_* > 0$ such that

$$\operatorname{osc}_{B_{\tau_*}} |Dv| < \frac{\kappa}{2}.$$

Since $Dv(0) = \kappa$, it follows that $|Dv(x)| > \kappa/2$ in B_{τ_*}. Thus, there is a universal constant $c_0 > 1$ satisfying

$$c_0^{-1} \le |Dv(x)| \le c_0 \quad \text{in } B_{\tau_*}.$$

At this stage, the nonlinear PDE (2.17) can be treated as essentially linear because

$$|a_*(x,\xi)| + |D_\xi a_*(x,\xi)||\xi| \le C\varphi'(c_0)|\xi|,$$
$$D_\xi a_*(x,\xi)\eta \cdot \eta \ge C\varphi'\left(\frac{1}{c_0}\right)|\eta|^2,$$
$$|a_*(x_1,\xi) - a_*(x_2,\xi)| \le Cw(|x_1 - x_2|)\varphi'(c_0)|\xi|$$

in view of (1.5) and Lemma 2.1. Hence, by the $C^{1,\beta}$ estimates for linear equations (see Theorem 3.1 in [4]), we obtain

$$\sup_{B_r} |v(x) - v(0)| \le Cr^\beta$$

and

$$\sup_{B_r} |v(x) - v(0) - Dv(0)\cdot x| \le Cr^{1+\beta}$$

for any $0 < r \le \tau_*/2$ and

$$\beta := \begin{cases} \min\left\{\sigma, \sigma_0, 1 - \frac{n}{q}\right\} & \text{if } n < q < \infty, \\ \min\{\sigma, \sigma_0\} & \text{if } q = \infty. \end{cases}$$

Consequently, we deduce that

$$\sup_{B_{\rho_* r}(x_0)} |u(x) - u(x_0)| \le C\rho_*^{1+\alpha} r^\beta \le C(\rho_* r)^\alpha$$

and

$$\sup_{B_{\rho_* r}(x_0)} |u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)| \le C\rho_*^{1+\alpha} r^{1+\beta} \le C(\rho_* r)^{1+\alpha}$$

for any $0 < r \le \tau_*/2$, which implies that

$$\sup_{B_\rho(x_0)} |u(x) - u(x_0)| \le C\rho^\alpha$$

and

$$\sup_{B_\rho(x_0)} |u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)| \le C\rho^{1+\alpha}$$

for any $0 < \rho \le \tau_*\rho_*/2$. On the one hand, if $\tau_*\rho_*/2 < \rho \le \rho_* \le \bar{\rho} < 1$, (2.18) implies that

$$\sup_{B_\rho(x_0)} |u(x) - u(x_0)| \le C\rho_*^{1+\alpha} \le C\rho_*^\alpha \le C\left(\frac{2}{\tau_*}\right)^\alpha \rho^\alpha \le C\rho^\alpha$$

and then

$$\sup_{B_\rho(x_0)} |u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)| \le C\rho_*^{1+\alpha} \le C\left(\frac{2}{\tau_*}\right)^{1+\alpha} \rho^{1+\alpha} \le C\rho^{1+\alpha},$$

which completes the proof of Case 1.

Case 2: $\rho_* > \bar{\rho}$. Then the definition of ρ_* implies that

$$|Du(x_0)| = \kappa\rho_*^{\alpha} > \kappa\bar{\rho}^{\alpha}.$$

Since the argument applied previously in Case 1 for the function v can also be directly used to the function u for the universal constant $\kappa\bar{\rho}^{\alpha} > 0$, we can directly get the desired results (2.15)–(2.16) for any $0 < \rho < \rho'$ with some positive constant ρ' and then finish the final proof of this proposition by choosing $\tilde{\rho} := \min\{\rho', \bar{\rho}\}$. □

3 Final proof

Finally, we shall combine the previous Proposition 2.4 and Proposition 2.5 for the large radii and small radii cases respectively to finish the proof of the main result in this paper.

Proof of Theorem 1.3. From Proposition 2.4 and Proposition 2.5 we can find that for any compact subset Ω' of Ω there exist positive constants κ, C and $\tilde{\rho}$, depending on $n, i_a, s_a, \alpha, \sigma, \sigma_0$, $\|u\|_{W^{1,\Phi}_{loc}(\Omega)}$, $\|w\|_{C^{0,\sigma}_{loc}(\Omega)}$, $[\mathbf{F}]_{C^{0,\sigma_0}_{loc}(\Omega)}$, $\|f\|_{L^{q}_{loc}(\Omega)}$ and $\operatorname{dist}(\Omega', \partial\Omega)$, such that for $0 < \rho \le \tilde{\rho} < 1$ with $B_{\tilde{\rho}}(x_0) \subset \Omega' \subset\subset \Omega$ we have

$$\sup_{B_\rho(x_0)} \big|u(x) - u(x_0)\big| \le C\rho^{\alpha} \tag{3.1}$$

and

$$\sup_{B_\rho(x_0)} \big|u(x) - u(x_0) - Du(x_0)\cdot(x - x_0)\big| \le C\rho^{1+\alpha}, \tag{3.2}$$

where α is defined in (1.13). Let $x, y \in \Omega'$ and $R = |x - y| \le \tilde{\rho} < 1$. Then from (3.1) we deduce that

$$\big|u(x) - u(y)\big| \le CR^{\alpha}.$$

And then we can conclude that

$$\sup_{\substack{x,y\in\Omega'\\ x\neq y}} \frac{|u(x) - u(y)|}{|x - y|^{\alpha}} \le C$$

holds true by a standard finite covering argument, which implies that (1.14) is true. Furthermore, without loss of generality we may as well assume that $x = (x_1, x') \in \Omega'$ and $y = (x_2, x') \in \Omega'$ with $x' \in \mathbb{R}^{n-1}$. At this time we can obtain that $R = |x - y| = |x_1 - x_2| \le \tilde{\rho} < 1$,

$$u(y) = u(x) + \frac{\partial u(x)}{\partial x_1}(x_2 - x_1) + O\left(|x_1 - x_2|^{\alpha+1}\right)$$

and

$$u(x) = u(y) - \frac{\partial u(y)}{\partial x_1}(x_2 - x_1) + O\left(|x_1 - x_2|^{\alpha+1}\right),$$

which implies that

$$\left|\frac{\partial u(x)}{\partial x_1} - \frac{\partial u(y)}{\partial x_1}\right| |x_2 - x_1| = O\left(|x_1 - x_2|^{\alpha+1}\right).$$

Therefore, we can reach the conclusion that

$$\sup_{\substack{x,y\in\Omega'\\ x\neq y}} \frac{\left|\frac{\partial u(x)}{\partial x_1} - \frac{\partial u(y)}{\partial x_1}\right|}{|x - y|^{\alpha}} \le C$$

by a standard finite covering argument. Similarly, we also can prove that

$$\sup_{\substack{x,y\in\Omega'\\ x\neq y}} \frac{\left|\frac{\partial u(x)}{\partial x_i}-\frac{\partial u(y)}{\partial x_i}\right|}{|x-y|^{\alpha}} \leq C \quad \text{for } 2\leq i\leq n.$$

Thus, we can finish the final proof of the conclusion (1.15). □

Acknowledgments

The authors wish to thank the editor and anonymous reviewer for their many valuable comments and suggestions that have helped improve the clarity of the manuscript.

Abstract. This article proposes a non-autonomous mathematical model of confrontation between two countries and examines the influence of the factor of hostility between countries on the stability of the equilibrium state. Namely, conditions for stability (asymptotic stability) at zero hostility have been established; an estimate was found for the total level of armament of the two countries, provided that the zero equilibrium state is stable in the linear approximation of the model; conditions for stability under parametric disturbances in the linear approximation of the model are established. For a non-autonomous quasi-linear model of confrontation between two countries, a new estimate of the deviation of the weapons vector from the equilibrium ray is obtained and stability conditions are indicated.

Keywords: non-autonomous mathematical models, arms race, hostility, stability, equilibrium.

2020 Mathematics Subject Classification: 70K20, 93D30, 91F10.

1 Introduction

Mathematical modeling of the arms race process goes back to the original work of Richardson [20] published in 1960. Over the past period of time, many researchers have developed the Richardson model or proposed alternative models. See, for example, [1, 3, 5, 18, 21–25, 29, 31] and the references therein.

These works are of theoretical importance, since they contain general conditions for which arms race can be controlled (stable) or can lead to real conflict between opposing countries. It is not by chance that the authors in [6] discussed the "responsibility of mathematicians and mathematics educators for achieving peace and dignity for mankind via mathematics (research and development) and mathematics education".

The question of reinterpreting and improving the mathematical models of the arms race has become very relevant recently against the background of the increasing number of conflicts between two countries. In fact, the relevance of research in the field of stability of the

✉Corresponding author. Email: ivanka.stamova@utsa.edu

equilibrium of opposing countries and their alliances increases significantly, including analysis of the strategy of countries that own atomic weapons. This motivate numerous researchers to extend the existing models and advance the theory. For example, in [4] mathematical models of confrontation between two and n countries, including countries with nuclear weapons, have been proposed and analyzed. As a result of the analysis, stability conditions of the equilibrium state of the warring countries are established, and also the influence of hostility on the decrease (increase) in the norm of the vector of weapons n countries participating in alliances is considered. The edited by Gleditsch book [8] presents a very good overview of the recent research directed on the development of the Richardson arms race models. The paper [19] applied the fractional-order approach to extend the classical arms race model.

Most of the above papers investigated the stability behavior of the corresponding models. In fact, stability analysis is a fundamental approach in a wide range of fields in control theory and the qualitative theory of differential equations [11, 13, 26, 28]. This analysis is of a significant importance in the study of the patterns of many real world phenomena and opens the possibilities of additional knowledge about their behavior [7, 9, 10, 27].

One of the more strong and effective approaches applied in the stability analysis of systems is the second method of Lyapunov or the method of Lyapunov-like functions [2, 12, 30]. This interesting and fruitful technique is gaining more and more importance and gives a decisive impetus for the modern development of the stability theory of differential equations and their applications.

The Lyapunov-like function method has been applied in the recent paper [4] to establish conditions for the stability of the zero equilibrium state of a quasi-linear mathematical model of the confrontation between two countries.

The aim of this paper is to analyze the influence of the level of hostility between two opposing countries on the stability of the equilibrium state based on a non-autonomous quasi-linear model that generalizes the Richardson arms race model. In the article [4], such an analysis was started based on a quasi-linear model with an autonomous linear approximation.

In this case, the factor of hostility between opposing countries is filled with expanded content. In addition, it is noted that hostility between countries is formed by the media in order to control public opinion about the arms race of opposing countries. Thus, the dynamic properties of the model proposed in the article are rich and meaningful, which can motivate its future analysis, as well as the application of the obtained results in the study of arms race processes.

The analysis of the proposed mathematical model of confrontation is carried out using the Lyapunov function method and nonlinear integral inequalities [14–17].

The paper is arranged using the following agenda. Section 1 provides a generalized non-autonomous mathematical model of confrontation between two countries. Section 2 discusses the stability of the equilibrium state under zero hostility and under parametric perturbations of the weapon matrix. Section 3 discusses the mathematical model of confrontation with neutral stability of the linear approximation of the original Richardson's model of confrontation between countries. Section 4 examines the general problem of stability in a generalized Richardson's arms race model. In Section 5, for the non-autonomous quasi-linear model of confrontation between two countries conditions for the stability of weapon vector evasion from the beam balance of arms are established. The final Section 6 provides comments on the results obtained. Some future directions for research are also discussed.

2 Generalized Richardson model of arms race

The classical Richardson's model of a two country arms race is given by a system of differential equations:

$$\frac{dx}{dt} = ky - ax + g, \qquad \frac{dy}{dt} = lx - by + h, \tag{2.1}$$

where $x(t)$ and $y(t)$ represents the armament expenditures (or armament levels) of two countries (nations) at time t, $\frac{dx}{dt}$ or $\dot{x}$ is the rate of change in expenditures over time for the country N_1, and $\frac{dy}{dt}$ or $\dot{y}$ is the rate of change in expenditures over time for the country N_2, k, l, a, b are positive constants and g, h are real constants. The constants k and l describe mutual fear; the constants a and b measure proportionality factors for the "internal brakes" to further arms increases (economic burden parameters, called "fatigue and expense" initially by Richardson). Positive values for g and h correspond to underlying factors of ill will or distrust that would persist even if arms expenditures dropped to zero. Negative values for g and h represent a contribution based on good will [20].

The model (2.1) has been generalized and modified in different directions. In [4], the following generalization is studied:

$$\frac{dx}{dt} = ky - ax + g(t,x,y), \qquad \frac{dy}{dt} = lx - by + h(t,x,y), \tag{2.2}$$

where $t \in \mathbb{R}_\tau$, τ is a finite number or the symbol $+\infty$, $x, y \in \mathbb{R}_+$ represent measures of the levels of the countries' N_1 and N_2 armament, correspondingly, the parameters $k > 0$ and $l > 0$ describe the "threat" between the countries, parameters $a > 0$, $b > 0$ characterize the "expenses" of each from countries to maintain the level of their armament. The functions $g(t,x,y)$ and $h(t,x,y)$ characterize the factor of "hostility" between the countries N_1 and N_2, which depends on the level of public opinion about the confrontation between countries and their armament.

In this paper, we will extend the model (2.2) considering the non-autonomous quasi-linear system of differential equations:

$$\begin{aligned} \frac{dx}{dt} &= k(t)y - a(t)x + g(t,x,y), \qquad x(t_0) = x_0, \\ \frac{dy}{dt} &= l(t)x - b(t)y + h(t,x,y), \qquad y(t_0) = y_0, \end{aligned} \tag{2.3}$$

where $t_0 \in \mathbb{R}_\tau$, all the parameters $k(t) > 0$, $l(t) > 0$, $a(t) > 0$ and $b(t) > 0$ are supposed to be bounded for all $t \in \mathbb{R}_\tau$, and the rest of the parameters are as in [4].

Remark 2.1. The proposed model (2.3) extends and improve the classical Richardson's model [20] and numerous related models [1, 3, 5, 8, 25, 31] in which all the parameters $k(t)$, $l(t)$, $a(t)$ and $b(t)$ are positive constants and the hostility functions $g(t,x,y)$ and $h(t,x,y)$ are real constants, too. The model (2.3) extends also the recent model proposed in [4] in which the parameters $k(t)$, $l(t)$, $a(t)$ and $b(t)$ are positive constants.

Remark 2.2. If the countries N_1 and N_2 possess nuclear weapons, then the parameters $k(t)$ and $l(t)$ can take arbitrarily large values for any $t \in \mathbb{R}_\tau$ while remaining bounded.

From a practical point of view, we will also assume that hostility between countries N_1 and N_2 does not exceed some threshold level $\bar{b} = (\bar{b}_1, \bar{b}_2)^T$ on any finite time interval at any

level of armament of the opposing countries. Thus, for the components of the hostility vector function $(g(t,x,y),h(t,x,y))^T$ there exist constants $\bar{b}_1 > 0$ and $\bar{b}_2 > 0$ such that

$$|g(t,x,y)| \leq \bar{b}_1, \qquad |h(t,x,y)| \leq \bar{b}_2 \tag{2.4}$$

for all $t \in \mathbb{R}_\tau$ and $x, y \in \mathbb{R}_+$.

Remark 2.3. As noted in [4], limit values of permissible hostility $\bar{b}_1$ and $\bar{b}_2$ between the countries N_1 and N_2 should be under the control of the civil society of these countries and/or international organizations, given that modern means of influence on the human psyche have reached the level of criminality.

3 Stability conditions for time-zero hostility

In this section, together with system (2.3) we will consider the following system

$$\frac{dx}{dt} = k(t)y - a(t)x, \qquad \frac{dy}{dt} = l(t)x - b(t)y, \tag{3.1}$$

with zero hostility $g(t,x,y) = 0$ and $h(t,x,y) = 0$ for all $t \in \mathbb{R}_\tau$ and $x, y \in \mathbb{R}_+$.

It is clear that $(x,y)^T = (0,0)^T$ is an equilibrium for the model (3.1).

Proposition 3.1. *If the model's parameters $k(t), a(t), l(t), b(t)$ in (3.1) are such that:*

(H_1) $$-a(t) \leq 0 \quad \text{for all } t \in \mathbb{R}_\tau,$$

(H_2) $$a(t)b(t) - (k(t) + l(t))^2 \geq 0 \quad \text{for all } \ t \in \mathbb{R}_\tau,$$

then its zero equilibrium $(x,y)^T = (0,0)^T$ is stable.

Proof. Consider a Lyapunov-like function

$$V(x,y) = \frac{1}{2}\left(x^2 + y^2\right).$$

For the derivative of the above function with respect to the system (3.1), we have

$$\frac{d}{dt}V(x,y) = \frac{dx}{dt}x + \frac{dy}{dt}y = x\left(k(t)y - a(t)x\right) + y\left(l(t)x - b(t)y\right). \tag{3.2}$$

Conditions (H_1) and (H_2) of Proposition 3.1 imply that $\frac{d}{dt}V(x,y)$ is non-negative, i.e., the zero equilibrium $(x,y)^T = (0,0)^T$ is stable by Lyapunov [12,30]. □

Proposition 3.2. *If for the model's parameters $k(t), a(t), l(t), b(t)$ in (3.1) there exist positive constants α, β such that:*

(H_3) $$-a(t) \leq -\alpha \quad \text{for all } t \in \mathbb{R}_\tau,$$

(H_4) $$a(t)b(t) - (k(t) + l(t))^2 \geq \beta \quad \text{for all } t \in \mathbb{R}_\tau,$$

then its zero equilibrium $(x,y)^T = (0,0)^T$ is asymptotically stable.

Proof. If we apply again the Lyapunov-like function

$$V(x,y) = \frac{1}{2}\left(x^2 + y^2\right),$$

its derivative with respect to the system (3.1) will be strictly negative under the conditions (H_3) and (H_4) of Proposition 3.2, which guarantees the asymptotic stability (by Lyapunov) of the zero equilibrium $(x,y)^T = (0,0)^T$ [12,30]. □

Next, we will rewrite system (3.1) in the matrix form $\frac{dw}{dt} = A(t)w$ and consider the initial value problem (IVP)

$$\frac{dw}{dt} = A(t)w, \quad w(t_0) = w_0, \tag{3.3}$$

where the initial time $t_0 \in \mathbb{R}_\tau$, $w = (x,y)^T$ and $A(t)$ is a (2×2) bounded weapon matrix. We will study the stability of the equilibrium state $(x,y)^T = (0,0)^T$ of (3.3) for parametric perturbations of the weapons matrix. The initial value $w(t_0)$ denotes the levels of the two countries' armament at time $t = t_0$, the beginning of the interaction between the two actors.

Let at the moment $t = t^* \in \mathbb{R}_\tau$ the matrix $A(t^*)$ has an eigenvalue λ, that satisfies $Re\lambda \leq -\alpha$, i.e., the equilibrium state $(x,y)^T = (0,0)^T$ of (3.3) with the weapon matrix $A(t^*)$ is asymptotically stable.

System (3.3) can be represented in the form

$$\frac{dw}{dt} = A(t^*)w + \Delta A(t)w, \quad w(t^*) = w^*, \tag{3.4}$$

where we denote $\Delta A(t) = A(t) - A(t^*)$.

For system (3.4) we will consider a Lyapunov-like function $V(w) = w^T w$ and the following conditions:

(H_5) $$w^T\left(A^T(t^*) + A(t^*)\right)w \leq -\lambda_M w^T w \quad \text{for all } t \in \mathbb{R}_\tau;$$

(H_6) $$w^T\left(\Delta A^T(t) + \Delta A(t)\right)w \leq \mu_M(t) w^T w \quad \text{for all } t \in \mathbb{R}_\tau,$$

where λ_M is the greatest eigenvalue of the matrix $A^T(t^*) + A(t^*)$ and $\mu_M(t)$ is the greatest eigenvalue of the matrix $\Delta A^T(t) + \Delta A(t)$ for all $t \in \mathbb{R}_\tau$.

Proposition 3.3. *If conditions (H_5) and (H_6) are satisfied for the model's parameters in (3.4), and for any $\varepsilon > 0$ there exists a $\delta = \delta(t^*, \varepsilon) > 0$ such that:*

$$\exp\left(-\lambda_M(t - t^*) + \int_{t^*}^{t} \mu_M(s)ds\right) < \frac{\varepsilon}{\delta} \text{ for all } t \in \mathbb{R}_\tau,$$

then the zero equilibrium $w = 0$ of (3.4) is stable.

Proof. For the total derivative of the positive definite Lyapunov function $V(w) = w^T w$ with respect to system (3.4) under the hypotheses (H_5) and (H_6), we have

$$\frac{d}{dt}V(w(t)) \leq (-\lambda_M + \mu_M(t))V(w(t)) \text{ for all } t \in \mathbb{R}_\tau. \tag{3.5}$$

From estimate (3.5) it follows that

$$V(w(t)) \leq V(w((t^*)) \exp\left(\int_{t^*}^{t}(-\lambda_M + \mu_M(s))ds\right) \text{ for all } t \in \mathbb{R}_\tau.$$

Hence, if the conditions of Proposition 3.3 are met, then the equilibrium state $w = 0$ of system (3.4) is stable under parametric perturbations of the weapons matrix $A(t^*)$. □

4 Stability conditions for a neutral linear approximation of the model

In this section, we will consider the case where at time $t_r \in \mathbb{R}_\tau$ the linear approximation of system (2.3) is neutral stable. In this case,

$$k(t_r)y - a(t_r)x = 0, \qquad l(t_r)x - b(t_r)y = 0, \tag{4.1}$$

and, the mathematical model of confrontation between two countries (2.3) takes the form

$$\frac{dx}{dt} = g(t,x,y), \quad x(t_r) = x_0^r; \qquad \frac{dy}{dt} = h(t,x,y), \quad y(t_r) = y_0^r \tag{4.2}$$

where $t \geq t_r$.

Let us assume that the hostility functions $g(t,x,y)$, $h(t,x,y)$ are essentially nonlinear (do not contain linear approximations). Denote by

$$(x(t),y(t))^T = (x(t;t_r,x_0^r),y(t;t_r,y_0^r))^T$$

the solution of the model (4.2).

System (4.2) will be unstable if its solutions $(x(t),y(t))^T$ increase for all $t > t_r$ and for arbitrarily small initial conditions $(x_0^r,y_0^r)^T$ at $t = t_r$.

We associate the positive and bounded Lyapunov function $V(x,y) = xy$, $x > 0$, $y > 0$ to the system of equations (4.2) and prove that the following statement is true.

Proposition 4.1. *Let the hostility functions in the mathematical model of confrontation* (4.2) *are such that* $g(t,x,y) \neq 0$ *and* $h(t,x,y) \neq 0$ *for all* $t \geq t_r$. *If there exists a positive function* $\theta_0 = \theta_0(t)$, *with* $\int_0^\infty \theta(s)ds = \infty$ *for which the inequality*

$$g(t,x,y)y + h(t,x,y)x \geq \theta_0(t)xy, \tag{4.3}$$

holds for any $t \geq t_r$, $x,y > 0$, *then the system* (4.2) *is unstable.*

Proof. When inequality (4.3) is satisfied, the total derivative of the Lyapunov function $V(x,y) = xy$ on the solutions of system (4.2) is an increasing function

$$V(x(t),y(t)) \geq V(x(t_r),y(t_r)) \exp\left(\int_{t_r}^t \theta_0(s)ds\right)$$

for any $t \geq t_r$.

It follows that for a given $\varepsilon > 0$, for any $\delta > 0$ such that $x(t_r)y(t_r) < \delta$, there exists a value $t^* > t_r$ such that $x(t^*)y(t^*) > \varepsilon$. Consequently, the system (4.2) is unstable according to the first theorem on Lyapunov instability (see [12]). □

Remark 4.2. If the condition $g(t,x,y)y + h(t,x,y)x > 0$ hold, then the system (4.2) may be stable.

Next, we consider the dynamics in model (4.2) for $(t,x,y) \in \mathbb{R}_\tau \times \mathbb{R}_+ \times \mathbb{R}_+$ under the following assumption:

(H_7) There exist non-negative integrable functions $\psi_1(t)$, $\psi_2(t)$ such that for $(t,x,y) \in \mathbb{R} \times \mathbb{R}_+ \times \mathbb{R}_+$ we have

(a) $$|g(t,x,y)y| \le \psi_1(t)(xy)^p,$$

(b) $$|h(t,x,y)x| \le \psi_2(t)(xy)^q,$$

(c) $$g(t,x_0^r,y_0^r) \neq 0,\ h(t,x_0^r,y_0^r) \neq 0,$$

where $1 < p,\ 1 \le q < \infty$.

Let us introduce the following definition (cf. [30]).

Definition 4.3. The arms race between two countries, described by the system of equations (4.2) is:

(a) β-bounded, if there exists a constant $\beta > 0$ such that

$$x(t;t_r,x_0^r)y(t;t_r,y_0^r) < \beta$$

for all $t \ge t_r$, where β may depend on each solution;

(b) equi-β-bounded, if for any $\alpha > 0$ and $t_r \in \mathbb{R}$ there exists a constant $\bar{\beta}(t_r,\alpha) > 0$ such that $x_0^r y_0^r < \alpha$ implies $x(t;t_r,x_0^r)y(t;t_r,y_0^r) < \bar{\beta}(t_r,\alpha)$ for all $t \ge t_r$;

(c) uniformly β-bounded, if $\bar{\beta}(t_r,\alpha)$ in Definition 4.3 (b) is independent on t_r.

For the Lyapunov function $V(x,y) = xy$ the following result holds.

Lemma 4.4. *Assume that for the model (4.2) the hypothesis (H_7) holds and the inequality*

$$N(t,t_r) = (p+q-2)\left[(V(x_0^r,y_0^r))^{p-1}\int_{t_r}^{t}\psi_1(s)ds + (V(x_0^r,y_0^r))^{q-1}\int_{t_r}^{t}\psi_2(s)ds\right] < 1 \tag{4.4}$$

is satisfied for $t \ge t_r$.

Then, for the Lyapunov function $V(x,y)$ with respect to the solutions of (4.2), the following estimate

$$V(x(t),y(t))) \le V(x_0^r,y_0^r)\,(1-N(t,t_r))^{-\frac{1}{p+q-2}} \tag{4.5}$$

holds for all $t \in \mathbb{R}_\tau$.

Proof. If conditions (a)–(c) of the hypothesis (H_7) are satisfied for the function $V(x,y)$, it is not difficult to obtain the integral inequality

$$V(x(t),y(t)) \le V(x_0^r,y_0^r) + \int_{t_r}^{t}(\psi_1(s)V^p(x(s),\ y(s))ds + \psi_2(s)V^q(x(s),\ y(s)))ds, \quad t \ge t_r. \tag{4.6}$$

Next, we represent the resulting inequality in the pseudo-linear form

$$\begin{aligned} &V(x(t),y(t)) \\ &\quad \le V(x_0^r,y_0^r) + \int_{t_r}^{t}\left(\psi_1(s)V(x(s),y(s))^{p-1} + \psi_2(s)V(x(s),y(s))^{q-1}\right)V(x(s),y(s))\ ds \end{aligned} \tag{4.7}$$

for $t \ge t_r$.

Applying the Gronwall–Bellman lemma [16,17] to inequality (4.7), we obtain the estimate

$$V(x(t),y(t)) \leq V(x_0^r,y_0^r)\exp\left[\int_{t_r}^{t}(\psi_1(s)V(x(s),y(s))^{p-1}+\psi_2(s)V(x(s),y(s))^{q-1})ds\right] \tag{4.8}$$

for all $t \geq t_r$.

From inequality (4.8), we have

$$\begin{aligned}(V(x(t),y(t)))^{p-1} &\leq (V(x_0^r,y_0^r))^{p-1}\exp\left[(p-1)\int_{t_0}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}\right.\\ &\qquad\left.+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right],\\ (V(x(t),y(t)))^{q-1} &\leq (V(x_0^r,y_0^r))^{q-1}\exp\left[(q-1)\int_{t_0}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}\right.\\ &\qquad\left.+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right]\end{aligned} \tag{4.9}$$

for all $t \geq t_r$.

For $p > 1$ and $q \geq 1$, we have from (4.9) that

$$\begin{aligned}(V(x(t),y(t)))^{p-1} &\leq (V(x_0^r,y_0^r))^{p-1}\exp\left[(p+q-2)\int_{t_0}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}\right.\\ &\qquad\left.+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right],\\ (V(x(t),y(t)))^{q-1} &\leq (V(x_0^r,y_0^r))^{q-1}\exp\left[(p+q-2)\int_{t_0}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}\right.\\ &\qquad\left.+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right]\end{aligned} \tag{4.10}$$

for $t \geq t_r$.

Multiplying both sides of the first inequality from system (4.10) by $(p+q-2)\psi_1(t)$ and the second by $(p+q-2)\psi_2(t)$, we obtain

$$\begin{aligned}&-(V(x(t),y(t)))^{p-1}\psi_1(t)(p+q-2)\exp\left[-(p+q-2)\int_{t_r}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}\right.\\ &\qquad\left.+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right] \geq -(V(x_0^r,y_0^r))^{p-1}(p+q-2)\psi_1(t),\\ &-(V(x(t),y(t)))^{q-1}\psi_2(t)(p+q-2)\exp\left[-(p+q-2)\int_{t_r}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}\right.\\ &\qquad\left.+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right] \geq -(V(x_0^r,y_0^r))^{q-1}(p+q-2)\psi_2(t)\end{aligned} \tag{4.11}$$

for all $t \geq t_r$.

Hence,

$$\begin{aligned}&\frac{d}{dt}\exp\left[-(p+q-2)\int_{t_r}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right]\\ &\qquad\geq -(V(x_0^r,y_0^r))^{p-1}(p+q-2)\psi_1(t)-(V(x_0^r,y_0^r))^{q-1}(p+q-2)\psi_2(s)\end{aligned} \tag{4.12}$$

for all $t \geq t_r$.

Integrating both sides of inequality (4.12) from t_r to t, we obtain the estimate

$$\exp\left[(p+q-2)\int_{t_r}^{t}(\psi_1(s)(V(x(s),y(s)))^{p-1}+\psi_2(s)(V(x(s),y(s)))^{q-1})ds\right] \leq (1-N(t,t_r))^{-1} \tag{4.13}$$

for all $t \in \mathbb{R}_\tau$ such that $N(t,t_r) < 1$.

Taking into account the estimate (4.13), the estimate (4.8) implies

$$(V(x(t),y(t)))^{p+q-2}\,(V(x_0^r,y_0^r))^{-(p+q-2)} \leq (1-N(t,t_r))^{-1}$$

or, finally,

$$V(x(t),y(t)) \leq V(x_0^r,y_0^r)(1-N(t,t_r))^{-\frac{1}{p+q-2}} \tag{4.14}$$

for all $t \in \mathbb{R}_\tau$ for which $N(t,t_r) < 1$. □

Remark 4.5. The proof of Lemma 4.4 takes into account the estimation technique for nonlinear integral inequalities established in [16,17]. The technique is applied to the nonlinear integral inequality (4.6).

Lemma 4.4 allows us to establish new boundedness conditions for the arms race of two opposite countries.

Proposition 4.6. *Assume that conditions of Lemma 4.4 for the model (4.2) are met. In addition, assume that for initial weapon levels x_0^r, y_0^r for any $\alpha > 0$, $x_0^r y_0^r < \alpha$ we have:*

(1) $\bar{N}(t,t_r) < 1$ for all $t \geq t_r$;

(2) for a given $\bar{\beta} = \bar{\beta}(\alpha) > 0$ we have

$$\left(1-\bar{N}(t,t_r)\right)^{-\frac{1}{p+q-2}} < \frac{\bar{\beta}(\alpha)}{\alpha}$$

for all $t \geq t_r$, where

$$\bar{N}(t,t_r) = (p+q-2)\left[(\alpha)^{p-1}\int_{t_r}^{t}\psi_1(s)ds + (\alpha)^{q-1}\int_{t_r}^{t}\psi_2(s)ds\right] \tag{4.15}$$

Then the arms race of the two opposing countries is uniformly β-bounded.

Proof. Proposition 4.6 follows directly from estimate (4.5). □

5 Stability analysis of the generalized Richardson model

The unlimited growth of hostility between the countries N_1 and N_2 (lack of restrictions (2.4)) can lead to a real conflict with unpredictable consequences. Here, we will consider some cases of stability (instability) of the equilibrium state in model (2.3) with time-varying hostility.

We will consider the system of equations (2.3) in which the functions $g(t,x,y)$ and $h(t,x,y)$ are defined in the region $t > 0$ and $x \leq H$, $y \leq H$, where H is a positive constant, are continuous and satisfy the condition under which equations (2.3) have a unique solution under given initial conditions. The functions $g(t,x,y)$ and $h(t,x,y)$, in contrast to the linear approximation of system (2.3), always remain unknown. We will assume that they are small and satisfy the next condition:

(H_8) In the region $t > 0$ and $x \leq H$, $y \leq H$, the hostility functions $g(t,x,y)$, $h(t,x,y)$ are such that

$$g(t,x,y) \neq 0, \qquad h(t,x,y) \neq 0, \qquad t \in \mathbb{R}_\tau.$$

The linear approximation of system (2.3)

$$\frac{dx}{dt} = k(t)y - a(t)x, \quad x(t_0) = x_0, \qquad \frac{dy}{dt} = l(t)x - b(t)y, \quad y(t_0) = y_0, \tag{5.1}$$

has a zero solution, the stability (instability) of which we will study further under the influence of hostility functions.

Definition 5.1. The state $x = y = 0$ of the system (5.1) will be stable under the influence of hostility $g(t,x,y)$, $h(t,x,y)$ if for any $\varepsilon > 0$ and $t_0 \geq 0$ one can specify three numbers $\eta_1(t_0,\varepsilon)$, $\eta_2(t_0,\varepsilon)$, and $\eta_3(t_0,\varepsilon)$ such that any solution $(x(t,t_0,x_0),y(t,t_0,y_0))^T$ satisfying the initial condition $|x_0 + y_0| < \eta_1(t_0,\varepsilon)$ with hostility $g(t,x,y)$, $h(t,x,y)$, satisfying in the region $t > t_0$ and $|x+y| < H$ the condition $|g(t,x,y)| < \eta_2(t_0,\varepsilon)$, $|h(t,x,y)| < \eta_3(t_0,\varepsilon)$, satisfies the inequality $(x(t,t_0,x_0) + y(t,t_0,y_0)) < \varepsilon$ for all $t > t_0$.

We will show that the following statement holds.

Proposition 5.2. *Assume that for the model* (2.3) *hypothesis* (H_8) *holds and there exist positive function* $\theta_1(t)$ *such that for* $t \in \mathbb{R}_\tau$, $x, y > 0$ *the next inequality*

$$g(t,x,y)x + h(t,x,y)y + (k(t)+l(t))xy - a(t)x^2 - b(t)y^2 \leq \theta_1(t)(x^2+y^2), \quad \text{holds for } \int_{t_0}^{\infty} \theta_1(s)ds = L_1 < \infty \tag{5.2}$$

then the state equilibrium $(x,y)^T$=$(0,0)^T$ *of the system* (5.1) *is stable under the influence of hostility.*

Proof. The stability of the system (2.3) will be analyzed by the use of the Lyapunov function $2V(x,y) = (x^2+y^2)$.

The total derivative of the function $V(x,y)$ with respect to system (2.3) has the form

$$\frac{d}{dt}V(x,y) = x\frac{dx}{dt} + y\frac{dy}{dt} = g(t,x,y)x + h(t,x,y)y + (k(t)+l(t))xy - a(t)x^2 - b(t)y^2. \tag{5.3}$$

From this equality and condition (5.2) follows the estimate

$$\begin{aligned} V(x(t),y(t)) &\leq V(x(t_0),y(t_0)) \exp\left(\int_{t_0}^{t} 2\theta_1(s)ds\right) \\ &\leq V(x(t_0),y(t_0)) \exp^{2L_1}, \qquad t \geq t_0. \end{aligned}$$

The stability of the equilibrium state $(x,y)^T = (0,0)^T$ of the system (5.1) follows from the fact that the function $V(x(t),y(t))$ does not increase on the solutions of system (2.3) for any $t \geq t_0$. □

Corollary 5.3. *If the equilibrium state* $(x,y)^T = (0,0)^T$ *of the linear approximation* (5.1) *of system* (2.3) *is asymptotically stable, then it is stable under the influence of hostility* $g(t,x,y)$, $h(t,x,y)$.

Example 5.4. Let us consider the system of equations (2.3) with the linear approximation (5.1) which has the following parameters: $a(t) = b(t) = k(t) = l(t) = 1 + t$ for $t \geq t_\tau > 0$ and hostility functions $g(t,x,y)$ and $h(t,x,y)$ satisfying the conditions (2.4).

We introduce the notation $R(t,x,y) = g(t,x,y)x + h(t,x,y)y \leq \eta_2(t_0,\varepsilon)x + \eta_3(t_0,\varepsilon)y$ for $t \geq t_\tau > 0$ in the region $t > t_0$ and $|x+y| < H$.

The total derivative of the function $2V(x,y) = \left(x^2+y^2\right)$ with respect to system (2.3) has the form

$$\begin{aligned}\frac{d}{dt}V(x(t),y(t))|_{(2.3)} &= x\frac{dx}{dt} + y\frac{dy}{dt} = \frac{d}{dt}V(x(t),y(t))|_{(5.1)} + R(t,x,y)\\ &= -(1+t)(x-y)^2 + R(t,x,y).\end{aligned} \tag{5.4}$$

We assume that the hypothesis (H_8) holds for the hostility functions $g(t,x,y)$ and $h(t,x,y)$ and calculate $\bar{\eta} = \max\{\eta_2(t_0,\varepsilon), \eta_3(t_0,\varepsilon)\}$. Then if $\bar{\eta} < \frac{(1+t)(x-y)^2}{x+y}$, then

$$\frac{d}{dt}V(x(t),y(t))|_{(2.3)} \leq -(1+t)(x-y)^2 + \bar{\eta}(x+y) < 0. \tag{5.5}$$

Hence, by Lyapunov's first theorem on stability it follows that the zero equilibrium of (5.1) is stable under the influence of hostility.

Next, we establish the conditions for the instability of the equilibrium state $(x,y)^T = (0,0)^T$ of the system of equations (5.1) under the assumption (H_8)

Proposition 5.5. *Assume that for the model (2.3) hypothesis (H_8) holds and there exist positive function $\theta_2 = \theta_2(t)$ such that for $t \in \mathbb{R}_\tau,\ x,y > 0$ the next inequality*

$$\begin{aligned}g(t,x,y)y + h(t,x,y)x - (a(t)+b(t))xy + l(t)x^2 + k(t)y^2 \geq \theta_2(t)xy,\\ \text{holds for } \int_{t_0}^{\infty}\theta_2(s)ds = \infty,\end{aligned} \tag{5.6}$$

then the state equilibrium $(x,y)^T$=$(0,0)^T$ of the system (2.3) is unstable under the influence of hostility.

Proof. The instability of the system (2.3) will be analyzed by the use of the Lyapunov function $V(x,y) = xy$.

The total derivative of the function $V(x,y)$ with respect to system (2.3) has the form

$$\begin{aligned}\frac{d}{dt}V(x,y) &= \frac{dx}{dt}y + x\frac{dy}{dt}\\ &= g(t,x,y)y + h(t,x,y)x - (a(t)+b(t))xy + l(t)x^2 + k(t)y^2.\end{aligned} \tag{5.7}$$

If condition (5.6) is satisfied, then the equilibrium state $(x,y)^T = (0,0)^T$ of the system (5.1) is unstable under the influence of hostility due to the increase of the function $V(x,y) = xy$ on the solutions of system (2.3):

$$V(x(t),y(t)) \geq V(x(t_0),y(t_0))\exp\left(\int_{t_0}^{t}\theta_2(s)ds\right),$$

for $t \to \infty$ (see [12] and Proposition 4.1). □

Example 5.6. Let us consider the system of equations (2.3) with the linear approximation (5.1) which has the following parameters: $a(t) = b(t) = 1/2$, $k(t) = l(t) = 1$ for $t \geq 0$.

Consider hostility functions $g(t,x,y)$ and $h(t,x,y)$ that satisfy hypothesis (H_8), and introduce the notation $Q(t,x,y) = g(t,x,y)y + h(t,x,y)x \leq \eta_2(t_0,\varepsilon)x + \eta_3(t_0,\varepsilon)y$ for $t \geq t_\tau > 0$ in the region $t > t_0$ and $|x+y| < H$.

For the total derivative of the function $V(x,y) = xy$ with respect to system (2.3) we have

$$\begin{aligned}\frac{d}{dt}V(x(t),y(t))|_{(2.3)} = y\frac{dx}{dt} + x\frac{dy}{dt} &= \frac{d}{dt}V(x(t),y(t))|_{(5.1)} + Q(t,x,y)\\ &= x^2 + y^2 - xy + Q(t,x,y) \geq Q(t,x,y) + xy.\end{aligned} \tag{5.8}$$

If there exists a positive function $\theta_2 = \theta_2(t)$, such that $Q(t,x,y) \geq (\theta_2 - 1)xy$, then

$$\frac{d}{dt}V(x(t),y(t))|_{(2.3)} \geq \theta_2(t)xy \quad \text{for all } t \in \mathbb{R}_+,\ x,y > 0.$$

Hence, by Proposition 5.5 it follows that the zero equilibrium of (5.1) is unstable.

Next, we will consider the case, where at time $t_c \in \mathbb{R}_\tau$ the hostility functions $g(t,x,y)$, $h(t,x,y)$ are equivalent in influence to the level of threats, i.e. the following condition holds.

(H_9) The hostility functions $g(t,x,y)$, $h(t,x,y)$ are such that

$$g(t,x,y) - k(t)y \equiv 0, \quad h(t,x,y) - l(t)x \equiv 0, \quad t \in \mathbb{R}_\tau,\ x,y \in \mathbb{R}_+.$$

Proposition 5.7. *Assume that for the model (2.3) hypotheses (H_8) and (H_9) are satisfied.*
Then, the levels of armament of opposing countries are decreasing exponentially.

Proof. If the assumption (H_9) is satisfied, then the mathematical model (2.3) degenerates into the model

$$\frac{dx}{dt} = -a(t)x, \quad x(t_c) = x_{0c}; \qquad \frac{dy}{dt} = -b(t)y, \quad y(t_c) = y_{0c}. \tag{5.9}$$

Using a Lyapunov function of the form $V(x,y) = xy$ it is not difficult to show that

$$x(t;t_c,x_{0c})y(t;t_c,y_{0c}) = x_{0c}y_{0c}\exp\left(-(a(t)+b(t))(t-t_c)\right) \tag{5.10}$$

or

$$x(t;t_c,x_{0c}) = x_{0c}\exp\left(-a(t-t_c)\right), \qquad y(t;t_c,y_{0c}) = y_{0c}\exp\left(-b(t-t_c)\right) \tag{5.11}$$

for all $t \geq t_c \in \mathbb{R}_\tau$.

The statement of Proposition 5.7 follows from (5.7) and representations (5.8). □

Remark 5.8. The case considered in Proposition 5.7 may indicate some kind of emergency situation, since in the normal mode of coexistence of opposing countries such a phenomenon is not observed.

Finally, in this section we will consider the case where at time $t_c \in \mathbb{R}_\tau$ the hostility functions $g(t,x,y)$, $h(t,x,y)$ are equivalent in terms of the impact of the level of expenditures of each country on maintaining its armament, i.e., the following condition holds.

(H_{10}) The hostility functions $g(t,x,y)$, $h(t,x,y)$ are negative and

$$-g(t,x,y) + a(t)x \equiv 0, \qquad -h(t,x,y) + b(t)y \equiv 0, \qquad t \in \mathbb{R}_\tau,\ x,y \in \mathbb{R}_+.$$

Proposition 5.9. *Assume that for the model (2.3) hypotheses (H_8) and (H_{10}) are satisfied, and for all $t \geq t_c \in \mathbb{R}_\tau$ each country determines its level of armament based on the level of armament of the opposite side without taking into account their own economic expenses.*

Then, the zero equilibrium $(x, y)^T = (0, 0)^T$ of (2.3) is unstable.

Proof. If the assumption (H_{10}) is satisfied, then the mathematical model (2.3) degenerates into the model

$$\frac{dx}{dt} = k(t)y, \quad x(t^c) = x_0^c; \qquad \frac{dy}{dt} = l(t)x, \quad y(t^c) = y_0^c.$$

For the Lyapunov function $V(x, y) = \frac{1}{2}(x^2 + y^2)$ with respect to the system (5.9), we have

$$V(x(t), y(t)) = V(x_0^c, y_0^c) \exp(k(t) + l(t))(t - t_c)$$

for all $t \geq t_c \in \mathbb{R}_\tau$, which implies the statement of Proposition 5.9. □

Remark 5.10. The case considered in Proposition 5.9 may correspond to a global militarization of countries involved in the confrontation.

6 Stability of weapon vector evasion from the equilibrium vector

We rewrite the system of equations (2.3) in the form

$$\frac{dw}{dt} = A(t)w + B(t, w), \qquad w(t_0) = w_0, \tag{6.1}$$

where $w \in \mathbb{R}^2_+$ is the vector of weapons of the two countries, $A(t) = [a_{ij}(t)]$, is a (2×2) matrix with entries $a_{11}(t) = -a(t), a_{12}(t) = k(t), a_{21}(t) = l(t), a_{22}(t) = -b(t)$, which characterizes the armaments of the two countries changing at time t, $B(t, w) = (g(t, w), h(t, w))^T$ denotes a vector function, nonlinear in w, which characterizes the public opinion about the race weapons and hostility between the two countries.

Suppose that for the two opposing countries there is only one weapon balance beam (ray) (which is equilibrium vector of (6.1)) on the form $L = \{w_e \in K : w_e = \lambda e\}$, where $e = (1, 1) \in \mathbb{R}^2_+$, λ is a positive constant, K is a cone in $\mathbb{R}^2_+$.

Also, let us assume that the vector functions $A(t)w$ and $B(t, w)$ in the system of equations (6.1) meet the conditions.

(H_{11}) There exist nonnegative functions $f_1(t)$, $f_2(t)$ such that

- (a) $d[A(t)w, L] \leq f_1(t)d[w, L]$ for all $t \in \mathbb{R}_\tau$, and $w \in \mathbb{R}^2_+$;
- (b) $d[B(t, w), L] \leq f_2(t)d^\alpha[w, L]$ for all $t \in \mathbb{R}_\tau$ $\alpha > 1$ and $w \in \mathbb{R}^2_+$,

where $d[\cdot, \cdot]$ is the distance in $\mathbb{R}^2_+$.

(H_{12}) For $t \in \mathbb{R}_\tau$, we have

$$N(t, t_0) = (\alpha - 1)d^{\alpha-1}[w_0, L] \int_{t_0}^{t} f_2(s) \exp\left((\alpha - 1)\int_{t_0}^{s} f_1(\tau)d\tau\right) ds < 1. \tag{6.2}$$

In this section, using a nonlinear integral inequality, we will establish an estimate of the deviation of the weapon vector $w(t)$ from the equilibrium ray weapons L of system (6.1).

Lemma 6.1. *Assume that for the system (6.1) hypotheses (H_{11}) and (H_{12}) hold.*
Then, the deviation of the arms vector from the equilibrium ray is estimated by the inequality

$$d[w(t;t_0,w_0),L] \leq d[w_0,L]\exp\int_{t_0}^{t} f_1(s)ds\,(1-N(t,t_0))^{-\frac{1}{\alpha-1}} \tag{6.3}$$

for $t \in \mathbb{R}_\tau$.

Proof. From (6.1), we have

$$w(t;t_0,w_0) = w_0 + \int_{t_0}^{t} (A(s)w(s) + B(s,w(s))ds. \tag{6.4}$$

Hence, using the estimates in (H_{11}), we obtain

$$\begin{aligned} d[w(t;t_0,w_0),L] &= d[w_0,L] + \int_{t_0}^{t} d[(A(s)w(s) + B(s,w(s)),L]ds \\ &\leq d[w_0,L] + \int_{t_0}^{t} (f_1(s)d[w(s,t_0,w_0),L] + f_2(s)d^{\alpha}[w(s,t_0,w_0),L])ds. \end{aligned} \tag{6.5}$$

From inequality (6.5) it follows

$$d[w(t;t_0,w_0),L] \leq d[w_0,L] + \int_{t_0}^{t} (f_1(s)d[w(s),L] + f_2(s)d^{\alpha}[w(s),L]))\,ds \tag{6.6}$$

for all $t \in \mathbb{R}_\tau$.

We will represent inequality (6.6) in the pseudo-linear form

$$d[w(t;t_0,w_0),L] \leq d[w_0,L] + \int_{t_0}^{t} \left(f_1(s) + f_2(s)d^{\alpha-1}[w(s),L]\right) d[w(s;t_0,w_0),L]ds \tag{6.7}$$

for all $t \in \mathbb{R}_\tau$.

Applying the Gronwall–Bellman lemma to inequality (6.7), we obtain an estimate in the form

$$d[w(t;t_0,w_0),L] \leq d[w_0,L]\exp\left(\int_{t_0}^{t} \left(f_1(s) + f_2(s)d^{\alpha-1}[w(s),L]\right) ds\right) \tag{6.8}$$

for all $t \in \mathbb{R}_\tau$.

Next, we will apply integral inequalities from [14,15] to evaluate

$$\exp\left(\int_{t_0}^{t} \left(f_1(s) + f_2(s)d^{\alpha-1}[w(s),L]\right) ds\right). \tag{6.9}$$

in (6.8).

Namely, we represent inequality (6.8) in the form

$$\begin{aligned} &d^{\alpha-1}[w(t;t_0,w_0),L] \\ &\quad\leq d^{\alpha-1}[w_0,L]\exp\left((\alpha-1)\int_{t_0}^{t} \left(f_1(s) + f_2(s)d^{\alpha-1}[w(s;t_0,w_0),L]\right) ds\right). \end{aligned} \tag{6.10}$$

Multiplying both parts of inequality (6.10) by the negative factor

$$-(\alpha-1)f_2(t)\exp\left(-(\alpha-1)\int_{t_0}^{t} f_2(s)d^{\alpha-1}[w(s;t_0,w_0),L])ds\right),$$

we obtain

$$-d^{\alpha-1}[w(t;t_0,w_0),L](\alpha-1)f_2(t)\exp\left(-(\alpha-1)\int_{t_0}^{t}f_2(s)d^{\alpha-1}[w(s;t_0,w_0),L]ds\right)$$
$$\geq -(\alpha-1)d^{\alpha-1}[w_0,L]f_2(t)\exp\left((\alpha-1)\int_{t_0}^{t}f_1(s)ds\right). \tag{6.11}$$

The inequality (6.11) implies

$$\frac{d}{dt}\left\{\exp\left[-(\alpha-1)\int_{t_0}^{t}f_2(s)d^{\alpha-1}[w(s;t_0,w_0),L]ds\right]\right\}$$
$$\geq -(\alpha-1)d^{\alpha-1}[w_0,L]f_2(t)\exp\Big((\alpha-1)\int_{t_0}^{t}f_1(s)ds\Big). \tag{6.12}$$

Integrating the above inequality from t_0 to $t\in\mathbb{R}_\tau$, we have

$$\exp\left(-(\alpha-1)\int_{t_0}^{t}f_2(s)d^{\alpha-1}[w(s;t_0,w_0),L]ds\right)$$
$$\geq 1-(\alpha-1)d^{\alpha-1}[w_0,L]\int_{t_0}^{t}f_2(s)\exp\left(-(\alpha-1)\int_{t_0}^{t}f_1(s)d^{\alpha-1}[w(s;t_0,w_0),L]ds\right), \tag{6.13}$$

where $\exp\{t_0\}=1$.

Hence,

$$\exp\left[(\alpha-1)\int_{t_0}^{t}f_2(s)d^{\alpha-1}[w(s;t_0,w_0),L]ds\right]$$
$$\leq\left\{1-(\alpha-1)d^{\alpha-1}[w_0,L]\int_{t_0}^{t}f_2(s)\exp\left[(\alpha-1)\int_{t_0}^{s}f_1(\tau)d\tau\right]ds\right\}^{-1} \tag{6.14}$$

for all $t\in\mathbb{R}_\tau$.

Combining (6.10) and (6.14), we get

$$d^{\alpha-1}[w(t;t_0,w_0),L]\leq\frac{d^{\alpha-1}[w_0,L]\exp\left[(\alpha-1)\int_{t_0}^{t}f_1(s)ds\right]}{1-N(t,t_0)},$$

from which, taking into account (H_{12}), the deviation of the weapon vector $w(t)$ from the ray of equilibrium L is estimated by the inequality (6.3). □

Proposition 6.2. *Assume that for the system (6.1) hypotheses (H_{11}) and (H_{12}) hold. If for any $\varepsilon>0$ there exists a $\delta=\delta(t_0,\varepsilon)>0$ such that:*

(1) $d[w_0,L]<\delta$,

(2) $\overline{N}(t,t_0)=(\alpha-1)\delta^{\alpha-1}\int_{t_0}^{t}f_2(s)\exp\left((\alpha-1)\int_{t_0}^{s}f_1(\tau)d\tau\right)ds<1$ *for all* $t\in\mathbb{R}_\tau$,

(3) $\exp\left(\int_{t_0}^{t}f_1(s)ds\right)\left(1-\overline{N}(t,t_0)\right)^{-\frac{1}{\alpha-1}}<\frac{\varepsilon}{\delta}$, $t\in\mathbb{R}_\tau$,

then

$$d[w(t;t_0,w_0),L]<\varepsilon,\qquad t\in\mathbb{R}_\tau. \tag{6.15}$$

Proof. Under the conditions of Proposition 6.2 the deviation of the weapon vector from the equilibrium beam is estimated by inequality (6.3), from which the statement of Proposition 6.2 follows. □

Remark 6.3. Conditions (1)–(3) of Proposition 6.2 are sufficient for the stability of the deviation of the weapon vector of two countries in model (6.1) from the weapon equilibrium ray L.

7 Concluding remarks

In this paper, the influence of the hostility factor between countries on the stability of the equilibrium state is studied in detail for the non-autonomous model (2.3) of confrontation between two countries. Namely:

- the criteria for stability (asymptotic stability) are established under zero hostility;
- the criteria for stability (instability) of the arms race between two countries are established under the condition of neutral stability of the zero equilibrium state in the linear approximation of the proposed model (2.3);
- the criteria for stability of parametric disturbances of the armament matrix are established in the linear approximation of system (2.3);
- under various assumptions about the hostility between the two countries changing over time, the criteria for stability (instability) of the zero equilibrium state are derived;
- for the non-autonomous quasi-linear model of confrontation between two countries, a new estimate of the deviation of the armament vector from the equilibrium ray is obtained and the conditions for the stability of the equilibrium state are indicated.

The approaches to the analysis of the influence of hostility on the stability of the equilibrium state of the extended model (2.3) proposed in this paper are new and contribute to the development of the theory. It is also expected that this contribution will stimulate further improvement and analysis of arms race models.

Directions for expanding and increasing the flexibility of models include taking into account delay factors in the linear approximation of model (2.3), assessing the influence of control in functions describing hostility, including impulse disturbance. It is of interest to use fractional analysis or sequential modeling. An interesting direction for future research is also to consider an arms race model with more than two countries and with periodic coefficients in the linear approximation. Studying discrete versions of model (2.3) is also important for numerical modeling.

Acknowledgements

The authors would like to thank Professor D. D. Šiljak (Canada) for his careful reading of one of the versions of the manuscript [4] and his suggestions that stimulated further research on this topic, as well as Professor Bo Zhang (USA) for interesting and important comments on Propositions 4.1 and 5.2.

Positive solutions for a degenerate p-Kirchhoff problem with singular and sublinear nonlinearities

Rezak Souilah and **Hocine Ayadi**✉

Laboratory of Mathematics and its Applications, Faculty of Sciences,
University of Medea, Medea, Algeria

Received 28 May 2025, appeared 20 October 2025
Communicated by Gabriela Bonanno

Abstract. In this paper, we study the following p-Kirchhoff-type elliptic problem:

$$\begin{cases} -M\left(\int_\Omega |\nabla u|^p\right) \operatorname{div}\left(|\nabla u|^{p-2}\nabla u\right) = \dfrac{f(x)}{u^\gamma} + g(x)\,u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded smooth domain, $1 < p < N$, $0 < \gamma \leq 1$, $0 < q < p-1$ and $M : \mathbb{R}^+ \to \mathbb{R}^+$ is a continuous function satisfying additional hypotheses. The data f and g belonging to suitable Lebesgue space. Our approaches are based on an approximation scheme and the pseudomonotone operators theory.

Keywords: nonlocal elliptic equations, singular nonlinearity, pseudomonotone operators theory, weighted eigenvalue problems.

2020 Mathematics Subject Classification: 35A15, 35J75, 47H05, 35P30.

1 Introduction

Let Ω be a bounded open subset in $\mathbb{R}^N$ with $1 < p < N$. We consider the following non local elliptic problem

$$\begin{cases} -M\left(\|u\|^p\right)\Delta_p u = \frac{f(x)}{u^\gamma} + g(x)\,u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\|u\|^p = \int_\Omega |\nabla u|^p\,dx$, $0 < \gamma \leq 1$ and $M : \mathbb{R}^+ = [0, +\infty[\to \mathbb{R}^+$ is a continuous nondecreasing function satisfying the following structural assumption:

$$\exists\, m_0 > 0,\ \mu > 1 :\ M(t) \geq m_0\, t^{\mu-1},\ \forall t \in [0,1]. \tag{1.2}$$

✉Corresponding author. Email: ayadi.hocine@univ-medea.dz

Observe that condition (1.2) is trivially satisfied in the non-degenerate case, i.e., when $M(0) > 0$. A prototypical example of a Kirchhoff-type function satisfying (1.2) is:

$$M(t) = a + brt^{r-1}, \qquad a, b \geq 0,\ a + b > 0,\ r \geq 1,\ t \geq 0.$$

Such a condition has been previously utilized by Pucci et al. in [30].

We assume the source terms f and g satisfy the following conditions:

$$f, g \geq 0, \quad \underline{h} := \inf(f, g) \not\equiv 0, \tag{1.3}$$

$$f \in L^m(\Omega), \quad \text{with } m = \frac{pN}{N(p-1) + p + \gamma(N-p)} = \begin{cases} \left(\frac{p^*}{1-\gamma}\right)' & \text{if } 0 < \gamma < 1, \\ 1 & \text{if } \gamma = 1. \end{cases}, \tag{1.4}$$

$$g \in L^{\left(\frac{p*}{1+q}\right)'}(\Omega). \tag{1.5}$$

Due to the nonlocal term $M\left(\|u\|^p\right)$, the first equation in (1.1) is no longer a pointwise identity. This introduces significant mathematical challenges, making the study of such problems particularly interesting.

For $p = 2$, the operator $M\left(\|u\|^p\right)\Delta_p$ arises naturally in the Kirchhoff equation:

$$\rho \frac{\partial^2 u}{\partial t^2} - \left(\frac{P_0}{h} + \frac{E}{2L}\int_0^L \left|\frac{\partial u}{\partial x}\right|^2 dx\right)\frac{\partial^2 u}{\partial x^2} = 0,$$

which generalizes the classical D'Alembert wave equation for vibrating strings:

$$\frac{\partial^2 u}{\partial t^2} - c^2 \frac{\partial^2 u}{\partial x^2} = 0, \qquad x \in (0, L),\ t > 0.$$

For more on this physical background, see [11,23–25,27] and the references therein.

Before presenting the details of our results, we briefly review existing results for singular and nonlocal problems.

In the local case, i.e., $M \equiv 1$, the problem (1.1) is closely related to the foundational work in [10], where the authors showed the existence of a solution for the following nonlinear singular elliptic equation

$$\begin{cases} -\Delta u = \frac{\lambda}{u^\gamma} + u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^N$ $(N \geq 3)$ is a bounded domain with smooth boundary $\partial\Omega$, $\lambda > 0$, and the exponent q of the sublinear term satisfies $0 < q < 1$.

Giacomoni, Schindler, and Takáč in [18] extended this analysis to the quasilinear setting:

$$\begin{cases} -\Delta_p u = \frac{\lambda}{u^\gamma} + u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $0 < \gamma < 1$, $1 < p < N$ and $p - 1 < q < p^* - 1$, with $p^* = \frac{Np}{N-p}$ denotes the critical Sobolev exponent for the embedding $W_0^{1,p}(\Omega)$ in to $L^t(\Omega)$ for every $t \in [1, p^*]$.

In [15], the author considered:

$$\begin{cases} -\Delta_p u = \frac{f(x)}{u^\gamma} + g(x)u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.6}$$

where $0 \leq q \leq p-1$, f and g are nonnegative functions belonging to suitable Lebesgue spaces. The author proved that

- If $q < p-1$, $0 < \gamma < 1$, $f \in \left(\frac{p^*}{1-\gamma}\right)'$, and $g \in L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)$, then the solution u belongs to $W_0^{1,p}(\Omega)$.
- if $\gamma = 1$, $f \in L^1(\Omega)$, and $g \in L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)$, then $u \in W_0^{1,p}(\Omega)$.

In the nonlocal setting, Corrêa et al. [12] studied:

$$\begin{cases} -M\left(\|u\|^p\right)\Delta_p u = \frac{f(x)}{u^\gamma} + u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.7}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded smooth domain, $2 \leq p \leq N$, $0 < \gamma, q < 1$, $f : \bar{\Omega} \to \mathbb{R}$ is continuous function with $f > 0$ on $\bar{\Omega}$, and $M : \mathbb{R}^+ \to \mathbb{R}^+$ is a continuous function satisfying

- there are $m_0 > 0$ and $\theta_1 > 0$ such that $M(t) \geq m_0$ $\forall t \geq \theta_1$;
- $\theta_2 = \sup\{t > 0;\ M(t) = 0\} > 0$.

The authors consider an approximation of problem (1.7) by a regularized problem. They then prove that there is at least one solution in $W_0^{1,p}(\Omega)$ by employing the Galerkin method along with a variant of Brouwer's fixed point theorem [22, Lemme 4.3]. Subsequently, they pass to the limit to obtain a solution of (1.7).

Motivated by the above works, in this paper we investigate the existence and regularity of solutions to problem (1.1), extending some results from [15] to the degenerate nonlocal case. To the best of our knowledge, this work provides the first treatment of a degenerate Kirchhoff-type problem involving both singular and sublinear nonlinearities, under optimal integrability assumptions on the source terms f and g.

Before presenting our main results, we first define what we mean by a weak solution to (1.1). Following Giacomoni et al. [18], the solutions of (1.1) are understood in the following sense

Definition 1.1. A weak solution to problem (1.1) is a function $u \in W_0^{1,p}(\Omega)$ such that

$$\forall \omega \subset\subset \Omega,\ \exists c_\omega > 0 :\ u \geq c_\omega > 0 \text{ in } \omega, \tag{1.8}$$

and

$$M\left(\|u\|^p\right)\int_\Omega |\nabla u|^{p-2}\nabla u \nabla \varphi = \int_\Omega \left(\frac{f(x)}{u^\gamma} + g(x)\,u^q\right)\varphi, \qquad \forall \varphi \in C_0^\infty(\Omega). \tag{1.9}$$

Remark 1.2. If u is a weak solution to problem (1.1) in the sense of Definition 1.1, then for every test function $\varphi \in C_0^\infty(\Omega)$, the right-hand side of the weak formulation (1.9) is finite. Indeed, the local positivity condition (1.8) implies

$$\int_\Omega \frac{f\varphi}{u^\gamma} \leq \frac{\|\varphi\|_{L^\infty(\Omega)}}{c_w^\gamma} \int_\Omega f < +\infty.$$

Hence, $\frac{f(x)}{u^\gamma} \in L^1_{loc}(\Omega)$, and consequently,

$$\frac{f(x)}{u^\gamma} + g(x)\, u^q \in L^1_{loc}(\Omega).$$

Therefore, the weak formulation (1.9) is well-defined.

2 Statements of the main result

Here is the main result of this paper.

Theorem 2.1. *Let us assume that* (1.2)–(1.3) *hold true,* $g \in L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)$, *and* $f \in L^m(\Omega)$, *with*

$$m = \frac{pN}{N(p-1) + p + \gamma(N-p)}. \tag{2.1}$$

Then there exists at least one weak solution to problem (1.1).

Remark 2.2. Note that

$$\frac{pN}{N(p-1) + p + \gamma(N-p)} = \begin{cases} \left(\frac{p^*}{1-\gamma}\right)' & \text{if } 0 < \gamma < 1, \\ 1 & \text{if } \gamma = 1. \end{cases}$$

The structure of the rest of this paper is as follows. Section 3 introduces the necessary notations and preliminary results that will be used throughout our analysis. Section 4 establishes the existence of a solution to the approximated problem by employing pseudomonotone operator theory. Section 5 derives essential a priori estimates for the approximate solution, which play a crucial role in proving the main result. Section 6 proves the main result by taking the limit of the sequence of approximated problems. Finally, Section 7 examines additional regularity properties of the obtained solution.

3 Notations and mathematical background

We begin by establishing the necessary framework for our analysis. Let Ω be a bounded smooth domain in $\mathbb{R}^N$ with $1 < p < N$. The truncation function $T_k : \mathbb{R} \to \mathbb{R}$ at level $k > 0$ is defined as

$$T_k(s) = \max\{-k, \min\{s, k\}\}.$$

We now present fundamental results concerning the spectrum of the p-Laplacian operator with weights. For further details on this topic, the reader is referred to [3,17,21,28].

3.1 Weighted eigenvalue problems

Let $V(x) \geq 0$ be a measurable function, not identically zero, $V(x) \in L^\infty(\Omega)$. Let us consider the problem:

$$\begin{cases} u \in W_0^{1,p}(\Omega),\ u \not\equiv 0, \\ -\text{div}\left(|\nabla u|^{p-2}\nabla u\right) = \lambda V(x)|u|^{p-2}u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{P_λ}$$

We define the functionals $\mathcal{A}$ and $\mathcal{B}$ as follows:

$$\begin{cases} \mathcal{A}(w) = \dfrac{1}{p}\|w\|_{W_0^{1,p}(\Omega)}, \\ \mathcal{B}(w) = \dfrac{1}{p}\displaystyle\int_\Omega V(x)|w(x)|^p\,dx, \end{cases}$$

for all $w \in W_0^{1,p}(\Omega)$.

Definition 3.1 ([3]). A real number $\lambda \in \mathbb{R}$ is called an eigenvalue if there exists a function u such that the pair (u, λ) is a solution to problem (P_λ). Such a function (non-trivial by definition) is called an eigenfunction associated with λ. The first eigenvalue λ_1 is defined by:

$$\lambda_1 = \inf\left\{\mathcal{A}(w) :\ w \in W_0^{1,p}(\Omega),\ \text{and } \mathcal{B}(w) = 1\right\}.$$

Lemma 3.2 ([14, 19, 33]). *Let $u \in W_0^{1,p}(\Omega)\setminus\{0\}$ be an eigenfunction associated to λ. Then $u \in L^\infty(\Omega)$.*

Lemma 3.3 ([3, Lemma 3.1]). *If u is an eigenfunction of (P_λ), then $u \in \mathcal{C}^{1,\alpha}(\overline{\Omega})$ for some $\alpha \in (0,1)$. Moreover, if $u \geq 0$, then $u > 0$ in Ω and $\frac{\partial u}{\partial \nu} < 0$ on $\partial\Omega$, where ν denotes the unit exterior normal vector to $\partial\Omega$.*

Lemma 3.4 ([3, Lemma 3.3]). *Every eigenfunction u associated with λ_1 has constant sign, i.e., either $u > 0$ or $u < 0$ in Ω.*

Lemma 3.5 ([3, Theorem 3.1]). *The first eigenvalue λ_1 is simple, i.e., if u and v are two eigenfunctions associated with λ_1, then $u = \alpha v$ for some $\alpha \in \mathbb{R}$.*

3.2 Weak comparison principle

The following weak comparison principle will be essential for our subsequent analysis. For the proof, we refer to [28, Lemma A.0.7] or the more general version in [26, Lemma 3].

Lemma 3.6. *Let $u_1, u_2 \in W^{1,p}(\Omega)$ satisfying*

$$\begin{cases} -\Delta_p u_1 \leq -\Delta_p u_2, & \text{in } \Omega,\ (\text{in the weak sense}) \\ u_1 \leq u_2, & \text{on } \partial\Omega. \end{cases}$$

Then, $u_1 \leq u_2$ a.e. in Ω.

3.3 Pseudomonotone operator theory

The following operator classes are fundamental to our nonlinear analysis framework. We recall these standard definitions from [37, Definition 26.1].

Definition 3.7. Let $A : X \to X'$ be an operator on the real reflexive Banach space X.

1. A is said to be hemicontinuous iff the real function
$$t \mapsto \langle A(u + tv), w \rangle,$$
is continuous on $[0, 1]$ for all u, v, $w \in X$.
2. A is said to be strongly continuous iff $u_n \rightharpoonup u$ implies $A(u_n) \to A(u)$.
3. A is called to be bounded iff A maps bounded sets into bounded sets.
4. A is said to be monotone iff
$$\langle A(u) - A(v), u - v \rangle \geq 0 \quad \text{for all } u, v \in X.$$
5. A is called coercive if
$$\lim_{\|u\| \to \infty} \frac{\langle A(u), u \rangle}{\|u\|} = +\infty.$$

The following properties of the p-Laplacian operator are well-known, see [32, Theorem 17.11].

Lemma 3.8. *The p-Laplacian operator $-\Delta_p : W_0^{1,p}(\Omega) \to W^{-1,p'}(\Omega)$ is monotone, coercif and continuous.*

The following definition, originally introduced by Brézis [8], plays a fundamental role in our existence proof.

Definition 3.9. [37, Definition 27.5] Let $A : X \to X'$ be an operator on the real reflexive Banach space X. The operator A is called pseudomonotone iff $u_n \rightharpoonup u$ as $n \to \infty$ and
$$\limsup_{n \to \infty} \langle A(u_n), u_n - u \rangle \leq 0,$$
implies that
$$\langle A(u), u - w \rangle \leq \liminf_{n \to \infty} \langle A(u_n), u_n - w \rangle.$$

The following result relates pseudomonotonicity to the sum of a monotone hemicontinuous operator and a strongly continuous operator, see [37, Proposition 27.6].

Lemma 3.10. *Let $A : X \to X'$ be an operator on the real reflexive Banach space X. If A is monotone and hemicontinuous and B is strongly continuous, then $A + B$ is pseudomonotone.*

For our existence proof, we rely on the following surjectivity result due to Brézis [8]. The proof can be found in [31, Theorem 2.6].

Lemma 3.11. *Let X be real, separable, and reflexive Banach space with $\dim X = \infty$. If $A : X \to X'$ is pseudomonotone, bounded, and coercive then A is surjective; this means, for any $f \in X'$, there is at least one solution to the equation*
$$A(u) = f.$$

3.4 Nemytskii's operators

We begin by recalling the definition of Nemytskii's operator.

Definition 3.12 ([1, 2]). Let $F : \Omega \times \mathbb{R} \to \mathbb{R}$. The Nemytskii operator associated to F is the map $\mathcal{N}_F$ defined on $\mathcal{M}(\Omega)$ (the set of all measurable real valued functions defined on Ω) by setting

$$\mathcal{N}_F(u(x)) = F(x, u(x)).$$

We recall the following fundamental result about Nemytskii operators [1, Theorem 2.2], with a more general version can be found in [2, Theorem 1.7].

Lemma 3.13. *Let $\alpha, \beta \geq 1$, and $F : \Omega \times \mathbb{R} \to \mathbb{R}$ be a Carathéodory function. Assume that there exist a positive function $a_1 \in L^{\beta}(\Omega)$ and a constant $a_2 > 0$ such that*

$$|F(x,t)| \leq a_1(x) + a_2|t|^{\frac{\alpha}{\beta}}, \quad a.e\ x \in \Omega,\ \forall t \in \mathbb{R}.$$

Then the Nemystskii's operator $\mathcal{N}_F$ associated to the function F is continuous from $L^{\alpha}(\Omega)$ to $L^{\beta}(\Omega)$.

4 The approximated problem

We approximate the problem (1.1) by the following non-singular and non-degenerate problem

$$\begin{cases} -M_n\left(\|u_n\|^p\right)\Delta_p u_n = \dfrac{f_n}{\left(u_n + \frac{1}{n}\right)^{\gamma}} + g_n\, u_n^q & \text{in } \Omega, \\ u_n = 0 & \text{on } \partial\Omega, \end{cases} \tag{4.1}$$

where $f_n = T_n(f)$, $g_n = T_n(g)$ and

$$M_n(t) = M(t) + \frac{1}{n}, \qquad \forall t \in \mathbb{R}^+. \tag{4.2}$$

Lemma 4.1. *Assume that (1.2)–(1.5) hold. Then, problem (4.1) has at least one nonnegative weak solution $u_n \in W_0^{1,p}(\Omega) \cap L^{\infty}(\Omega)$.*

Proof. Our proof relies on pseudomonotone operator theory. We define the operators $\mathcal{A}_n$, $\mathcal{F}_n : W_0^{1,p}(\Omega) \to W^{-1,p'}(\Omega)$ by

$$\langle \mathcal{A}_n(u), v\rangle = M_n\left(\|u\|^p\right) \int_{\Omega} |\nabla u|^{p-2}\nabla u \cdot \nabla v, \tag{4.3}$$

and

$$\langle \mathcal{F}_n(u), v\rangle = \int_{\Omega} \mathcal{N}_F(u) v\, dx, \tag{4.4}$$

where $\mathcal{N}_F$ is the Nemyskii operator associated to the function F defined by

$$F(x,t) := -\frac{f_n(x)}{\left(t^+ + \frac{1}{n}\right)^{\gamma}} - g_n(x)(t^+)^q \quad \text{a.e. } x \in \Omega,\ \forall t \in \mathbb{R},$$

where $t^+ := \max(t, 0)$. Next, we set

$$\mathcal{B}_n(u) = \mathcal{A}_n(u) + \mathcal{F}_n(u), \tag{4.5}$$

We now verify that $\mathcal{B}_n$ satisfies the hypotheses of Lemma 3.11. The proof proceeds in several steps.

Step 1: Hemicontinuity of $\mathcal{A}_n$. This follows directly from the continuity of the p-Laplacian operator (see Lemma 3.8) and the continuity of the function M_n.

Step 2: Monotonicity of $\mathcal{A}_n$. Let $u, v \in W_0^{1,p}(\Omega)$. Then,

$$\begin{aligned}\langle \mathcal{A}_n(u) - \mathcal{A}_n(v), u - v \rangle &= \langle M_n(\|u\|^p)\Delta_p u + M_n(\|v\|^p)\Delta_p v, u - v \rangle \\ &= M_n(\|u\|^p)\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla(u - v) \\ &\quad - M_n(\|v\|^p)\int_\Omega |\nabla v|^{p-2}\nabla v \cdot \nabla(u - v) \\ &= M_n(\|u\|^p)\|u\|^p - M_n(\|u\|^p)\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla v \\ &\quad + M_n(\|v\|^p)\|v\|^p - M_n(\|v\|^p)\int_\Omega |\nabla v|^{p-2}\nabla v \cdot \nabla u.\end{aligned} \tag{4.6}$$

Applying Young's inequality:

$$\int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla v \le \frac{1}{p'}\|u\|^p + \frac{1}{p}\|v\|^p, \tag{4.7}$$

and

$$\int_\Omega |\nabla v|^{p-2}\nabla v \cdot \nabla u \le \frac{1}{p'}\|v\|^p + \frac{1}{p}\|u\|^p. \tag{4.8}$$

Combining (4.6), (4.7) and (4.8) yields:

$$\begin{aligned}\langle \mathcal{A}_n(u) - \mathcal{A}_n(v), u - v \rangle &\ge M_n(\|u\|^p)\|u\|^p\left(1 - \frac{1}{p'}\right) - \frac{1}{p}M_n(\|u\|^p)\|v\|^p \\ &\quad + M_n(\|v\|^p)\|v\|^p\left(1 - \frac{1}{p'}\right) - \frac{1}{p}M_n(\|v\|^p)\|u\|^p \\ &= \frac{1}{p}\left(M_n(\|u\|^p) - M_n(\|v\|^p)\right)\left(\|u\|^p - \|v\|^p\right) \\ &= \frac{1}{p}\left(M(\|u\|^p) - M(\|v\|^p)\right)\left(\|u\|^p - \|v\|^p\right) \\ &\ge 0,\end{aligned} \tag{4.9}$$

where the last inequality holds because M is nondecreasing function.

Step 3: Strong continuity of $\mathcal{F}_n$. Note that F satisfies the growth condition

$$|F(x,t)| \le C(n)\left(1 + (t^+)^{(q+1)-1}\right), \tag{4.10}$$

where $C(n) > 0$ is a constant depending on n.

Let $(u_k)_{k\in\mathbb{N}} \subset W_0^{1,p}(\Omega)$ be a sequence converging weakly to $u \in W_0^{1,p}(\Omega)$. By the Sobolev compact embedding theorem, we have

$$u_k \to u \quad \text{strongly in } L^r(\Omega), \text{ for all } 1 \le r < p^*. \tag{4.11}$$

Since $q + 1 < p < p^*$, it follows that

$$u_k \to u \quad \text{strongly in } L^{q+1}(\Omega).$$

By Lemma 3.13, the Nemytskii operator $\mathcal{N}_F$ associated with the function F is continuous from $L^{q+1}(\Omega)$ into $L^{(q+1)'}(\Omega)$. Hence,

$$\mathcal{N}_F(u_k) \to \mathcal{N}_F(u) \quad \text{strongly in } L^{(q+1)'}(\Omega).$$

Moreover, since $(q+1)' > (p^*)'$ (due to $q+1 < p^*$), we further deduce

$$\mathcal{N}_F(u_k) \to \mathcal{N}_F(u) \quad \text{strongly in } L^{(p^*)'}(\Omega). \tag{4.12}$$

Now, let $\varphi \in W_0^{1,p}(\Omega)$. Applying Hölder's inequality and the Sobolev embedding theorem, we obtain

$$\begin{aligned}\left|\langle \mathcal{F}_n(u_k) - \mathcal{F}_n(u), \varphi \rangle\right| &\leq \int_\Omega |\mathcal{N}_F(u_k) - \mathcal{N}_F(u)||\varphi|\, dx \\ &\leq \|\mathcal{N}_F(u_k) - \mathcal{N}_F(u)\|_{L^{(p^*)'}(\Omega)} \|\varphi\|_{L^{p^*}(\Omega)} \\ &\leq \mathcal{S}_p \|\mathcal{N}_F(u_k) - \mathcal{N}_F(u)\|_{L^{(p^*)'}(\Omega)} \|\varphi\|_{W_0^{1,p}(\Omega)},\end{aligned}$$

where $\mathcal{S}_p$ is the optimal Sobolev constant for the embedding $W_0^{1,p}(\Omega)$ into $L^{p^*}(\Omega)$.

Consequently,

$$\|\mathcal{F}_n(u_k) - \mathcal{F}_n(u)\|_{W^{-1,p'}(\Omega)} \leq \mathcal{S}_p \|\mathcal{N}_F(u_k) - \mathcal{N}_F(u)\|_{L^{(p^*)'}(\Omega)}. \tag{4.13}$$

Combining (4.12) and (4.13), we conclude that

$$\mathcal{F}_n(u_k) \to \mathcal{F}_n(u) \quad \text{strongly in } W^{-1,p'}(\Omega).$$

Step 4: Pseudomonotonicity of $\mathcal{B}_n$. Since the operator $\mathcal{A}_n$ is monotone, hemicontinuous, and the operator $\mathcal{F}_n$ is strongly continuous, by Lemma 3.10, we deduce that $\mathcal{B}_n$ is pseudomonotone operator.

Step 5: Boundedness of $\mathcal{B}_n$. It suffices to prove that both $\mathcal{A}_n$ and $\mathcal{F}_n$ are bounded operators.

1. **Boundedness of $\mathcal{A}_n$.** Let $R > 0$ and consider $u \in W_0^{1,p}(\Omega)$ with $\|u\| \leq R$. For any test function $v \in W_0^{1,p}(\Omega)$, we apply assumptions (1.2), (4.2) and Hölder's inequality to obtain:

$$\begin{aligned}\left|\langle \mathcal{A}_n(u), v \rangle\right| &\leq (M(\|u\|^p) + 1) \int_\Omega |\nabla u|^{p-1} |\nabla v|\, dx \\ &\leq (M(R^p) + 1)\, R^{p-1} \|v\|_{W_0^{1,p}(\Omega)}.\end{aligned}$$

   Hence,

$$\|\mathcal{A}_n(u)\|_{W^{-1,p'}(\Omega)} \leq (M(R^p) + 1)\, R^{p-1}.$$

   This establishes that $\mathcal{A}_n$ maps bounded subsets of $W_0^{1,p}(\Omega)$ to bounded subsets of $W^{-1,p'}(\Omega)$.

2. **Boundedness of $\mathcal{F}_n$.** For any $u, v \in W_0^{1,p}(\Omega)$, we use the growth condition (4.10) and the fact that $p' < \frac{p}{q}$ (since $q < p-1$), we have

$$\begin{aligned}\left|\langle \mathcal{F}_n(u), v \rangle\right| &\leq C \int_\Omega (1 + |u|^q)\, v\, dx \\ &\leq C_1 \|v\|_{L^p(\Omega)} + \left(\int_\Omega u^{p'q}\right)^{\frac{1}{p'}} \|v\|_{L^p(\Omega)} \\ &\leq C_1 \|v\|_{L^p(\Omega)} + C_2 \|u\|^q_{L^p(\Omega)} \|v\|_{L^p(\Omega)} \\ &\leq C_3 \left(1 + \|u\|^q_{W_0^{1,p}(\Omega)}\right) \|v\|_{W_0^{1,p}(\Omega)}\end{aligned}$$

Consequently,

$$\|\mathcal{F}_n(u)\|_{W^{-1,p'}(\Omega)} \leq C_3 \left(1 + \|u\|^q_{W_0^{1,p}(\Omega)}\right).$$

Therefore, $\mathcal{F}_n$ maps bounded subsets of $W_0^{1,p}(\Omega)$ into bounded subsets of $W^{-1,p'}(\Omega)$.

Step 6: Coercivity of $\mathcal{B}_n$. Let $u \in W_0^{1,p}(\Omega)$. Using the growth condition (4.10), we obtain

$$\begin{aligned}
\langle \mathcal{B}_n(u), u \rangle &= \langle \mathcal{A}_n(u), u \rangle + \langle \mathcal{F}_n(u), u \rangle \\
&= M_n\left(\|u\|^p\right)\|u\|^p - \int_\Omega F(x,u)u \\
&\geq \frac{1}{n}\|u\|^p - C_1\|u\| - C_2\|u\|^{q+1} \\
&\geq \|u\|^p \left(\frac{1}{n} - C_1\|u\|^{1-p} - C_2\|u\|^{q+1-p}\right).
\end{aligned}$$

Since $q < p-1$, it follows that

$$\lim_{\|u\|\to\infty} \frac{\langle \mathcal{B}_n(u), u \rangle}{\|u\|} = +\infty.$$

The operator $\mathcal{B}$ satisfies all assumptions of Lemma 3.11. Consequently, there exists $u_n \in W_0^{1,p}(\Omega)$ such that $\mathcal{B}_n(u) = 0$, meaning u_n weakly solves:

$$\begin{cases} -M_n\left(\|u_n\|^p\right)\Delta_p u_n = \dfrac{f_n}{\left(u_n^+ + \frac{1}{n}\right)^\gamma} + g_n\left(u_n^+\right)^q & \text{in } \Omega, \\ u_n = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.14}$$

Non-negativity and regularity Choosing u_n^- as a test function in the weak formulation of (4.14) yields:

$$-\int_\Omega |\nabla u_n^-|^p = \frac{1}{M_n\left(\|u_n\|^p\right)} \int_\Omega \left(\frac{f_n}{\left(u_n^+ + \frac{1}{n}\right)^\gamma} + g_n\left(u_n^+\right)^q\right) u_n^- \geq 0, \tag{4.15}$$

which implies $u_n^- = 0$ a.e. in Ω, and thus $u_n \geq 0$.

Furthermore, by [19, Proposition 1.2], we have u_n belongs to $L^t(\Omega)$ for any $t \in [1, +\infty)$. Since the right-hand side of (4.1) belongs to $L^\beta(\Omega)$ with $\beta > \frac{N}{p}$, the L^∞-regularity result of [34, Théorème 4.2] implies that $u_n \in L^\infty(\Omega)$. This completes the proof of Lemma 4.1. □

5 A priori estimates

Lemma 5.1. *Let $(u_n)_n$ be a sequence of nonnegative solutions to problem (4.1). Assume that*

$$g \in L^{\left(\frac{p*}{1+q}\right)'}(\Omega) \quad \text{and} \quad f \in L^m(\Omega),$$

where

$$m = \frac{pN}{N(p-1) + p + \gamma(N-p)}.$$

Then there exists a constant $L > 0$, independent of n, such that

$$\|u_n\|_{W_0^{1,p}(\Omega)} \leq L \quad \text{for all } n \in \mathbb{N}^*. \tag{5.1}$$

Proof. We argue by contradiction. Suppose that (5.1) does not hold. Then, there exists a subsequence, still denoted by (u_n), such that

$$\|u_n\|^p_{W_0^{1,p}(\Omega)} \to +\infty \quad \text{as } n \to +\infty. \tag{5.2}$$

Consequently, for n sufficiently large, we have

$$\|u_n\|^p_{W_0^{1,p}(\Omega)} \geq 1. \tag{5.3}$$

Since the function M is nondecreasing and satisfies assumption (1.2), it follows from (5.3) that

$$\|u_n\|^p_{W_0^{1,p}(\Omega)} \geq M(1) \geq m_0. \tag{5.4}$$

Testing (4.1) with u_n, and using (5.4), we obtain

$$m_0\|u_n\|^p_{W_0^{1,p}(\Omega)} \leq \int_\Omega \frac{f_n\, u_n}{\left(u_n + \frac{1}{n}\right)^\gamma} + \int_\Omega g_n\, u_n^{1+q}. \tag{5.5}$$

We now distinguish two cases depending on the value of γ.

Case 1: $0 < \gamma < 1$. In this case, the exponent m satisfies $1 < m < \frac{N}{p}$.

Since $f_n \leq f$ and $g_n \leq g$, we apply Hölder inequality to both terms on the right-hand side of (5.5):

$$m_0\|u_n\|^p_{W_0^{1,p}(\Omega)} \leq \|f\|_{L^{\left(\frac{p^*}{1-\gamma}\right)'}(\Omega)} \|u_n\|^{1-\gamma}_{L^{p^*}(\Omega)} + \|g\|_{L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)} \|u_n\|^{q+1}_{L^{p^*}(\Omega)}. \tag{5.6}$$

Applying Sobolev's inequality on the left-hand side, we derive:

$$Sm_0\|u_n\|^p_{L^{p^*}(\Omega)} \leq \|f\|_{L^{\left(\frac{p^*}{1-\gamma}\right)'}(\Omega)} \|u_n\|^{1-\gamma}_{L^{p^*}(\Omega)} + \|g\|_{L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)} \|u_n\|^{q+1}_{L^{p^*}(\Omega)}. \tag{5.7}$$

Since $0 < 1-\gamma < q+1 < p$, it follows from inequality (5.7) that the sequence (u_n) is uniformly bounded in $L^{p^*}(\Omega)$.

Letting n tends to infinity in (5.6), we arrive at a contradiction: the right-hand side remains bounded, while the left-hand side diverges to infinity as a consequence of assumption (5.2).

Case 2: $\gamma = 1$. In this case $m = 1$. From (5.5) and $f_n \leq f$, we have:

$$m_0\|u_n\|^p_{W_0^{1,p}(\Omega)} \leq \|f\|_{L^1(\Omega)} + \int_\Omega g_n\, u_n^{1+q}. \tag{5.8}$$

Using the fact that $g_n \leq g$, and Hölder inequality on the right hand side of (5.8), we obtain

$$m_0\|u_n\|^p_{W_0^{1,p}(\Omega)} \leq \|f\|_{L^1(\Omega)} + \|g\|_{L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)} \|u_n\|^{q+1}_{L^{p^*}(\Omega)}. \tag{5.9}$$

Again, applying Sobolev's inequality on the right-hand side of (5.9), we get

$$m_0\|u_n\|^p_{W_0^{1,p}(\Omega)} \leq \|f\|_{L^1(\Omega)} + \mathcal{S}^{q+1}\|g\|_{L^{\left(\frac{p^*}{1+q}\right)'}(\Omega)} \|u\|^{q+1}_{W_0^{1,p}(\Omega)}. \tag{5.10}$$

Since $q+1 < p$, inequality (5.10) implies that the sequence (u_n) is uniformly bounded in $W_0^{1,p}(\Omega)$, contradicting (5.2).

In both cases, we reach a contradiction, which completes the proof of Lemma 5.1. □

Lemma 5.2. *Let u_n be a nonnegative solution of problem (4.1). Then, for any $\omega \subset\subset \Omega$, there exists a constant $c_\omega > 0$ such that*

$$u_n \geq c_\omega \quad \text{in } \omega, \text{ for all } n \in \mathbb{N}^*. \tag{5.11}$$

Proof. Using (5.1) and the fact that M is a nondecreasing function, we obtain

$$M_n(\|u_n\|^p) \leq M(L) = M_\infty, \quad \forall n \in \mathbb{N}^*. \tag{5.12}$$

Thus, in the sense of distributions, we have

$$\begin{aligned} -\Delta_p u_n &\geq \frac{T_1(f) + T_1(g)}{M_\infty} \left(\frac{1}{(u_n+1)^\gamma} + u_n^q \right) \\ &\geq \frac{\min\left(T_1(f) + T_1(g)\right)}{M_\infty} \left(\frac{1}{(u_n+1)^\gamma} + u_n^q \right) \\ &\geq \frac{c_0}{M_\infty} T_1(\underline{h}) = V(x), \end{aligned} \tag{5.13}$$

where we have used the fact the function $\frac{1}{t^\gamma+1} + t^q$, attains a positive minimum on $[0, +\infty[$.

Now consider the problem:

$$\begin{cases} -\Delta_p v = V(x) & \text{in } \Omega, \\ v = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.14}$$

and the weighted eigenvalue problem:

$$\begin{cases} -\Delta_p \phi_1 = \lambda_1 V(x) |\phi_1|^{p-2} \phi_1 & \text{in } \Omega, \\ \phi_1 = 0 & \text{on } \partial\Omega, \end{cases} \tag{5.15}$$

where λ_1 is the first eigenvalue of $-\Delta_p$ with weight V, and $\phi_1 \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ is its associated eigenfunction. By Lemma 3.3, $\phi_1 \in C^{1,\alpha}(\overline{\Omega})$ for some $\alpha \in (0,1)$ and $\phi_1(x) > 0$ for all $x \in \Omega$. Choose $\eta > 0$ sufficiently small so that

$$\lambda_1 \eta^{p-1} \|\phi_1\|_{L^\infty(\Omega)}^{p-1} \leq 1. \tag{5.16}$$

Then, $\underline{v} = \eta\phi_1$ is a subsolution for problem (5.14), since

$$-\Delta_p \underline{v} = -\Delta_p(\eta\phi_1) = \eta^{p-1}\lambda_1 V(x) \phi_1^{p-1} \leq V(x) \quad \text{in } \Omega.$$

By the weak comparison principle, we obtain

$$u_n(x) \geq v(x) \geq \eta\phi_1(x) \quad \text{a.e. in } \Omega. \tag{5.17}$$

Since $\phi_1 > 0$ in Ω and $\omega \subset\subset \Omega$, there exists $c_\omega = \min_\omega \phi_1 > 0$ such that

$$u_n(x) \geq c_\omega > 0 \quad \text{for a.e. } x \in \omega \text{ for all } n \in \mathbb{N}^*. \tag{5.18}$$

This completes the proof of Lemma 5.2. □

Lemma 5.3. *Let u_n be a nonnegative solution of (4.1). Then there exists a constant $\Lambda > 0$, independent of n, such that*

$$M\left(\|u_n\|^p\right) \geq \Lambda > 0 \quad \text{for all } n \in \mathbb{N}^*. \tag{5.19}$$

Proof. Let ϕ_1 be as in the proof of Lemma 5.2. By normalizing ϕ_1, we may assume that

$$\|\phi_1\|^p_{L^p(\Omega)} = \int_\Omega \phi_1^p \, dx = 1. \tag{5.20}$$

Using the normalization (5.20), the uniform positivity (5.17), and Poincaré's inequality, we obtain

$$\eta^p = \eta^p \int_\Omega \phi_1^p dx \leq \int_\Omega u_n^p dx \leq C_\Omega \|u_n\|^p_{W_0^{1,p}(\Omega)}.$$

This yields

$$\|u_n\|^p_{W_0^{1,p}(\Omega)} \geq \frac{\eta^p}{C_\Omega}. \tag{5.21}$$

Since M is nondecreasing, it follows from (5.21) that

$$M\left(\|u_n\|^p\right) \geq M\left(\frac{\eta^p}{C_\Omega}\right). \tag{5.22}$$

Next, we choose $\eta > 0$ sufficiently small so that it satisfies both (5.16) and

$$0 < \frac{\eta^p}{C_\Omega} \leq 1.$$

Applying the growth condition (1.2) on M, we get

$$M\left(\frac{\eta^p}{C_\Omega}\right) \geq m_0 \left(\frac{\eta^p}{C_\Omega}\right)^{\mu-1}. \tag{5.23}$$

Combining (5.22) and (5.23), we conclude that

$$M\left(\|u_n\|^p\right) \geq m_0 \left(\frac{\eta^p}{C_\Omega}\right)^{\mu-1} = \Lambda.$$

This completes the proof. □

6 Proof of the main results

By Lemma 5.1, the sequence (u_n) is bounded in $W_0^{1,p}(\Omega)$. Consequently, there exists a function $u \in W_0^{1,p}(\Omega)$ such that, up to subsequence,

$$u_n \to u \quad \text{weakly in} \quad W_0^{1,p}(\Omega),$$

and

$$u_n \to u \quad \text{almost everywhere in } \Omega.$$

Moreover, using (5.11), we deduce that u satisfies (1.8).

Furthermore, by (5.19) and (5.11), the sequence

$$\frac{1}{M_n\left(\|u_n\|^p\right)} \left(\frac{f_n}{\left(u_n + \frac{1}{n}\right)^\gamma} + g_n \, u_n^q \right),$$

is bounded in $L^1_{\text{loc}}(\Omega)$. By Theorem 2.1 of [5], it follows that

$$\nabla u_n \to \nabla u \quad \text{almost everywhere in } \Omega.$$

We now prove that u satisfies (1.9). Let $\varphi \in C_0^\infty(\Omega)$. The inequality (5.11) implies

$$0 \leq \left| \frac{f_n \varphi}{\left(u_n + \frac{1}{n}\right)^\gamma} \right| \leq \left| \frac{f_n \varphi}{u_n^\gamma} \right| \leq \frac{\|\varphi\|_{L^\infty(\Omega)}}{c_\omega^\gamma} f,$$

where ω is the compact support of the function φ. By the Lebesgue dominated convergence theorem,

$$\lim_{n\to+\infty} \int_\Omega \frac{f_n \varphi}{\left(u_n + \frac{1}{n}\right)^\gamma} = \int_\Omega \frac{f\varphi}{u^\gamma}. \tag{6.1}$$

Since $g \in L^{\frac{p^*}{p^*-q-1}}(\Omega)$ and (u_n) is bounded in $L^{p^*}(\Omega)$, Vitali's theorem (see [36, p. 333]) ensures

$$\int_\Omega g_n \, u_n^q \varphi \to \int_\Omega g u^q \varphi. \tag{6.2}$$

Indeed, for any measurable subset $E \subset \Omega$, we have

$$\begin{aligned}
\int_E g_n \, u_n^q \varphi \, dx &\leq \|\varphi\|_{L^\infty(\Omega)} \int_E |g(x)| \, |u_n|^q \, dx \\
&\leq \|\varphi\|_{L^\infty(\Omega)} \|g\|_{L^{\frac{p^*}{p^*-q-1}}(\Omega)} \left(\int_E |u_n|^{\frac{qp^*}{q+1}} \, dx \right)^{\frac{q+1}{p^*}} \\
&\leq \|\varphi\|_{L^\infty(\Omega)} \|g\|_{L^{\frac{p^*}{p^*-q-1}}(\Omega)} \|u_n\|_{L^{p^*}(\Omega)} |E|^{\frac{1}{p^*}} \to 0 \quad \text{as } |E| \to 0.
\end{aligned}$$

Thus, $\left(g_n \, u_n^q \varphi\right)_n$ is equi-integrable, and since it converges a.e. to $g \, u^q \varphi$, (6.2) holds by Vitali's theorem.

Combining (6.1) and (6.2), we obtain

$$\lim_{n\to+\infty} \int_\Omega \left(\frac{f_n}{\left(u_n + \frac{1}{n}\right)^\gamma} + g_n \, u_n^q \right) \varphi = \int_\Omega \left(\frac{f}{u^\gamma} + g \, u^q \right) \varphi. \tag{6.3}$$

Recalling that u_n satisfies the identity

$$\int_\Omega |\nabla u_n|^{p-2} \nabla u_n \cdot \nabla \varphi = \frac{1}{M_n\left(\|u_n\|^p\right)} \int_\Omega \left(\frac{f_n}{\left(u_n + \frac{1}{n}\right)^\gamma} + g_n \, u_n^q \right) \varphi, \tag{6.4}$$

for every $\varphi \in C_0^\infty(\Omega)$. By Lemma 5.3, the sequence (u_n) is bounded in $W_0^{1,p}(\Omega)$, so up to a subsequence,

$$\|u_n\| \longrightarrow \theta_0. \tag{6.5}$$

Passing to the limit in (6.4) using (6.3) and (6.5), we conclude

$$M(\theta_0^p) \int_\Omega |\nabla u|^{p-2} \nabla u \cdot \nabla \varphi = \int_\Omega \left(\frac{f}{u^\gamma} + g u^q \right) \varphi, \ \forall \varphi \in C_0^\infty(\Omega). \tag{6.6}$$

To complete the proof of (1.9), it remains to show that

$$M(\theta_0^p) = M\left(\|u\|^p\right).$$

Let $\varphi_\varepsilon \in C_0^\infty(\Omega)$ such that $\varphi_\varepsilon \to u$ strongly in $W_0^{1,p}(\Omega)$. Testing (6.6) with φ_ε and taking liminf (using Fatou's Lemma) yields

$$M(\theta_0^p)\|u\|^p \geq \int_\Omega f u^{1-\gamma} + \int_\Omega g u^{q+1}. \tag{6.7}$$

On the other hand, testing the weak formulation (4.1) with u_n gives

$$M_n\left(\|u_n\|^p\right)\|u_n\|^p = \int_\Omega \frac{f_n\, u_n}{\left(u_n+\frac{1}{n}\right)^\gamma} + \int_\Omega g_n\, u_n^{q+1}. \tag{6.8}$$

To pass to the limit in the right side of (6.8), we distinguish two cases based on the value of γ.

Case 1: $0<\gamma<1$. Since $f \in L^{\frac{p^*}{p^*+\gamma-1}}(\Omega)$ and $g \in L^{\frac{p^*}{p^*-q-1}}(\Omega)$, it follows from [6, Theorem 2.5.7] that for every for every $\varepsilon>0$, there exists $\delta>0$ such that for every measurable set $E\subset\Omega$ with $|E|\le\delta$, we have

$$\int_E |f(x)|^{\frac{p^*}{p^*+\gamma-1}}\,dx \le \varepsilon^{\frac{p^*}{p^*+\gamma-1}}, \quad \int_E |g(x)|^{\frac{p^*}{p^*-q-1}}\,dx \le \varepsilon^{\frac{p^*}{p^*-q-1}},$$

Applying Hölder's inequality, we obtain

$$\begin{aligned}\int_E \left(\frac{f_n\, u_n}{\left(u_n+\frac{1}{n}\right)^\gamma} + g_n\, u_n^{q+1}\right)dx &\le \|u_n\|^{1-\gamma}_{L^{p*}(\Omega)}\left(\int_E |f(x)|^{\frac{p^*}{p^*+\gamma-1}}\,dx\right)^{\frac{p^*+\gamma-1}{p^*}} \\ &\quad + \|u_n\|^{q+1}_{L^{p*}(\Omega)}\left(\int_E |g(x)|^{\frac{p^*}{p^*-q-1}}\,dx\right)^{\frac{p^*-q-1}{p^*}} \\ &\le C\varepsilon,\end{aligned} \tag{6.9}$$

where the constant $C>0$ is independent of n, thanks to the uniform boundedness of (u_n) in $W_0^{1,p}(\Omega)$ and the continuous Sobolev embedding.

From (6.9), we deduce that the sequences

$$\left(\frac{f_n\, u_n}{\left(u_n+\frac{1}{n}\right)^\gamma}\right)_n \quad \text{and} \quad \left(g_n\, u_n^{q+1}\right)_n$$

are equi-integrable. Therefore, by Vitali's convergence theorem, we obtain

$$\int_\Omega \frac{f_n\, u_n}{\left(u_n+\frac{1}{n}\right)^\gamma}\,dx \to \int_\Omega f u^{1-\gamma}, \tag{6.10}$$

and

$$\int_\Omega g_n\, u_n^{q+1}\,dx \to \int_\Omega g u^{q+1}\,dx. \tag{6.11}$$

Combining (6.10) and (6.11), it follows that

$$\int_\Omega \frac{f_n\, u_n}{\left(u_n+\frac{1}{n}\right)^\gamma}\,dx + \int_\Omega g_n\, u_n^{q+1}\,dx \to \int_\Omega f u^{1-\gamma} + \int_\Omega g u^{q+1}\,dx. \tag{6.12}$$

Case 2: $\gamma=1$. In this case, observe that

$$\frac{f_n\, u_n}{u_n+\frac{1}{n}} \le f,$$

and

$$\frac{f_n\, u_n}{u_n+\frac{1}{n}} \to f \quad \text{almost everywhere in } \Omega.$$

Hence, by the Lebesgue dominated convergence theorem, we deduce

$$\int_\Omega \frac{f_n\, u_n}{u_n + \frac{1}{n}}\, dx \to \int_\Omega f\, dx. \tag{6.13}$$

Combining (6.13) with the already established convergence (6.11), we obtain

$$\int_\Omega \frac{f_n\, u_n}{u_n + \frac{1}{n}}\, dx + \int_\Omega g_n\, u_n^{q+1}\, dx \to \int_\Omega f\, dx + \int_\Omega g u^{q+1}\, dx. \tag{6.14}$$

Using (6.5) in conjunction with either (6.12) or (6.14) (depending on the value of γ), we can pass to the limit in (6.8). This leads to the following identity:

$$M\left(\theta_0^p\right)\theta_0^p = \int_\Omega f u^{1-\gamma} + \int_\Omega g\, u^{q+1}. \tag{6.15}$$

Comparing (6.7) and (6.15), we obtain $M(\theta_0^p)\|u\|^p \geq M\left(\theta_0^p\right)\theta_0^p$, which implies $\|u\| \geq \theta_0$, since $M(\theta_0) \geq \Lambda > 0$.

On the other hand, since u_n converges weakly to u in $W_0^{1,p}(\Omega)$, and given that $\|u_n\|$ converges to θ_0, we have

$$\theta_0 = \liminf_{n\to+\infty} \|u_n\| \geq \|u\|.$$

Thus, $\|u\| = \theta_0$, and the proof of Theorem 2.1 is complete.

7 Regularity results

In this section, we investigate how the regularity of a solution u to problem (1.1) depends on the summability of f and g.

We begin with a key lemma that extends the class of admissible test functions in the weak formulation (1.9) from $\mathcal{C}_0^\infty(\Omega)$ to $W_0^{1,p}(\Omega)$.

Lemma 7.1. *Let $u \in W_0^{1,p}(\Omega)$ be a weak solution of the problem (1.1). Then, the formulation (1.9) holds for all test functions $W_0^{1,p}(\Omega)$, i.e.,*

$$M\left(\|u\|^p\right)\int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla\varphi = \int_\Omega \left(\frac{f(x)}{u^\gamma} + g(x)u^q\right)\varphi, \tag{7.1}$$

for every $\varphi \in W_0^{1,p}(\Omega)$.

Proof. The proof follows the approach of [18, Lemma A.5] and also [16, Lemma 5.1]. Let $u \in W_0^{1,p}(\Omega)$ be a weak solution of the problem (1.1). Given $\varphi \in W_0^{1,p}(\Omega)$, there exists a sequence $(\varphi_\varepsilon)_{\varepsilon>0} \subset \mathcal{C}_0^\infty(\Omega)$ such that

$$\varphi_\varepsilon \to \varphi \quad \text{strongly in } W_0^{1,p}(\Omega). \tag{7.2}$$

Define $\psi_\varepsilon = |\varphi_\varepsilon - \varphi|$. By density, for each fixed $\varepsilon > 0$, there exists a sequence of nonnegative functions $\left(\psi_{\varepsilon\eta}\right)_{\eta>0} \subset \mathcal{C}_0^\infty(\Omega)$ such that

$$\psi_{\varepsilon\eta} \to \psi_\varepsilon \quad \text{in } W_0^{1,p}(\Omega) \text{ and a.e. in } \Omega.$$

Testing (1.9) with $\psi_{\varepsilon\eta}$ yields

$$M\left(\|u\|^p\right)\int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla\psi_{\varepsilon\eta}=\int_\Omega\left(\frac{f(x)}{u^\gamma}+g(x)u^q\right)\psi_{\varepsilon\eta}.$$

Taking the lim inf as $\eta\to 0$ and applying Fatou's lemma to the right-hand side, we obtain

$$\int_\Omega\left(\frac{f(x)}{u^\gamma}+g(x)u^q\right)\psi_\varepsilon\le M\left(\|u\|^p\right)\int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla\psi_\varepsilon \tag{7.3}$$

Using Hölder's inequality on the right-hand side of (7.3), we deduce

$$\int_\Omega\left(\frac{f(x)}{u^\gamma}+g(x)u^q\right)|\varphi_\varepsilon-\varphi|\le M\left(\|u\|^p\right)\|u\|^{p-1}\|\psi_\varepsilon\|.$$

Passing to the limit as $\varepsilon\to 0$, we conclude that

$$\int_\Omega\left(\frac{f(x)}{u^\gamma}+g(x)u^q\right)\varphi_\varepsilon\to\int_\Omega\left(\frac{f(x)}{u^\gamma}+g(x)u^q\right)\varphi. \tag{7.4}$$

From (7.2), it follows that

$$M\left(\|u\|^p\right)\int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla\varphi_\varepsilon\to M\left(\|u\|^p\right)\int_\Omega |\nabla u|^{p-2}\nabla u\cdot\nabla\varphi. \tag{7.5}$$

Combining (7.4) and (7.5), we obtain the desired result. □

Theorem 7.2. *Assume that $f\in L^m(\Omega)$, with $m>\frac{N}{p}$, and $g\in L^\infty(\Omega)$. Let u be a positive solution of (1.1). Then, $u\in L^\infty(\Omega)$.*

Proof. The proof follows the approach in [14,29,35]. For $k\ge 1$, define the truncation function

$$G_k(t)=t-T_k(t)=\begin{cases}k & \text{if } t>k,\\ t & \text{if } -k\le t\le k,\\ -k & \text{if } t<-k.\end{cases}$$

For $s>0$ and $h>0$, define the test function

$$w=G_k(u)\min\left\{G_k(u)^{ps},h^p\right\}.$$

Testing the weak formulation (7.1) with w, and using the uniform lower bound $M\left(\|u\|^p\right)\ge\Lambda$ from Lemma 5.3 (see (5.19)), we obtain

$$\begin{aligned}\Lambda\int_\Omega |\nabla G_k(u)|^p\min\left\{G_k(u)^{ps},h^p\right\}+ps\int_{\{0\le G_k(u)^s\le h\}}G_k(u)^{ps}|\nabla G_k(u)|^p\\ \le\int_\Omega\left(\frac{f}{u^\gamma}+g\,u^q\right)G_k(u)\min\left\{G_k(u)^{ps},h^p\right\}.\end{aligned}$$

Since $u\ge 1$ on the set $\{u\ge k\}$, we deduce that

$$\begin{aligned}\Lambda\int_\Omega\left|\nabla\left(G_k(u)\min\left\{G_k(u)^s,h\right\}\right)\right|^p\le\int_\Omega fG_k(u)\min\left\{G_k(u)^{ps},h^p\right\}\\ +\|g\|_{L^\infty(\Omega)}\int_\Omega G_k(u)^p\min\left\{G_k(u)^{ps},h^p\right\}.\end{aligned}$$

Since $f \in L^{\frac{N}{p}}(\Omega)$, the absolute continuity of the integral (see [6, Theorem 2.5.7]) implies that for every $\varepsilon > 0$, there exists $\delta > 0$ such that for any measurable set $E \subset \Omega$ with $|E| \leq \delta$, we have

$$\int_E |f(x)|^{\frac{N}{p}} dx \leq \varepsilon^{\frac{N}{p}}. \tag{7.6}$$

Now, by the Chebyshev inequality (see [7, Lemma 20.1])), for any $c > 0$,

$$|\{f(x) > c\}| \leq \frac{1}{c^{\frac{N}{p}}} \int_\Omega |f(x)|^{\frac{N}{p}} dx.$$

Then choosing c sufficiently large, we conclude that

$$|\{f > c\}| \leq \delta. \tag{7.7}$$

Combining (7.6) and (7.7), it follows that

$$\left(\int_{\{f \geq c\}} |f|^{\frac{N}{p}} \right)^{\frac{p}{N}} < \varepsilon.$$

Assume $G_k(u) \in L^{p(s+1)}(\Omega)$. Applying the Sobolev inequality on the left-hand side and the Hölder inequality on the right hand-side, we obtain

$$\begin{aligned} &S\Lambda \left(\int_\Omega \left| G_k(u) \min\{G_k(u)^s, h\} \right|^{p^*} \right)^{\frac{p}{p^*}} \\ &\leq h^p |\Omega|^{\frac{p-1}{p^*}} \left(\int_{\{f \geq c\}} |f|^{\frac{N}{p}} \right)^{\frac{p}{N}} \|G_k(u)\|_{L^{p^*}(\Omega)} + \left(c + \|g\|_{L^\infty(\Omega)} \right) \int_\Omega G_k(u)^{p(s+1)} \\ &\leq \varepsilon h^p |\Omega|^{\frac{p-1}{p^*}} \|G_k(u)\|_{L^{p^*}(\Omega)} + \left(c + \|g\|_{L^\infty(\Omega)} \right) \int_\Omega G_k(u)^{p(s+1)}. \end{aligned}$$

Choosing $\varepsilon < \frac{1}{h^p |\Omega|^{\frac{p-1}{p^*}}}$, we derive

$$\left(\int_\Omega \left| G_k(u) \min\{G_k(u)^s, h\} \right|^{p^*} \right)^{\frac{p}{p^*}} \leq \frac{1}{S\Lambda} \|G_k(u)\|_{L^{p^*}(\Omega)} + \frac{c + \|g\|_{L^\infty(\Omega)}}{S\Lambda} \|G_k(u)\|^{p(s+1)}_{L^{p(s+1)}(\Omega)}.$$

Taking $h \to \infty$, we obtain

$$\left(\int_\Omega |G_k(u)|^{p^*(s+1)} \right)^{\frac{p}{p^*}} \leq \frac{1}{S\Lambda} \|G_k(u)\|_{L^{p^*}(\Omega)} + \frac{c + \|g\|_{L^\infty(\Omega)}}{S\Lambda} \|G_k(u)\|^{p(s+1)}_{L^{p(s+1)}(\Omega)}. \tag{7.8}$$

Since $u \in W_0^{1,p}(\Omega)$, it follows from Sobolev's embedding theorem that $G_k(u) \in L^{p^*}(\Omega)$. Therefore, the bootstrap inequality (7.8) holds for $s = s_0 = 0$.

Now, set $s = s_1$ in (7.8) such that

$$p(s_1 + 1) = p^* = \frac{pN}{N - p},$$

which gives

$$s_1 + 1 = (s_0 + 1)N/(N - p).$$

This implies $G_k(u) \in L^{p^*(s_1+1)}(\Omega)$.

We now iterate this argument. Suppose $G_k(u) \in L^{p^*(s_{i-1}+1)}(\Omega)$; then, applying the same reasoning, we obtain

$$G_k(u) \in L^{p^*(s_i+1)}(\Omega), \quad \text{where } s_i + 1 = N(s_{i-1}+1)/(N-p).$$

The sequence $(s_i)_{i\in\mathbb{N}}$ is positive (since $s_1 > 0$) and increasing because $s_i + 1 = N(s_{i-1} + 1)/(N-p) > s_{i-1}+1$. Thus, $(s_i)_{i\in\mathbb{N}}$ approaches a limit l as $i \to \infty$. Suppose, for contradiction, that l is finite. Then, passing to the limit in the recurrence relation gives

$$l + 1 = N(l+1)/(N-p),$$

which is impossible since $\frac{N}{N-p} > 1$. Hence $l = +\infty$, and we conclude that

$$G_k(u) \in L^\rho(\Omega) \quad \text{for all } \rho \in (1, \infty).$$

Next, we take $G_k(u)$ as a test function in the weak formulation (7.1). Using the uniform positivity estimate $M(\|u\|^p) \geq \Lambda$ from Lemma 5.3 (see (5.19)), we obtain

$$\Lambda \int_\Omega |\nabla G_k(u)|^p \leq \int_\Omega \left(\frac{f}{u^\gamma} + g u^q \right) G_k(u).$$

Since $u \geq k \geq 1$ on the set $\{u \geq k\}$, it follows that

$$\int_\Omega |\nabla G_k(u)|^p \leq \frac{1}{\Lambda} \int_\Omega (f + g G_k(u)^q)\, G_k(u).$$

Because $f + g G_k(u)^q \in L^\alpha(\Omega)$ for some $\alpha > \frac{N}{p}$, we can apply Stampacchia's L^∞-regularity result (see [34]) to conclude that $u \in L^\infty(\Omega)$. □

Abstract. Denote by **QS** the class of all non-degenerate planar quadratic differential systems and by **QSP** the subclass of **QS** of all systems possessing at least one invariant parabola. In this paper we consider the subfamily of **QSP** defined by the condition $\eta \neq 0$, which means the presence of three distinct infinite singularities real or complex. We denote this subfamily by $\mathbf{QSP}_{(\eta\neq 0)}$. We investigate all possible configurations of invariant parabolas and invariant straight lines which systems in $\mathbf{QSP}_{(\eta\neq 0)}$ could possess and their geometric properties encoded in such configurations. The classification presented here is taken modulo the action of the group of real affine transformations and time rescaling and it is given in terms of affine invariant polynomials. It yields a total of 144 distinct configurations. The obtained classification is an algorithm which makes it possible for any given real quadratic differential system in $\mathbf{QSP}_{(\eta\neq 0)}$ to specify its configuration of invariant parabolas and straight lines. This work will prove helpful in studying the integrability of the systems in $\mathbf{QSP}_{(\eta\neq 0)}$.

Keywords: quadratic differential systems, algebraic solution, configuration of algebraic solutions, invariant parabolas, affine invariant polynomials, group action.

1 Introduction and statement of main results

For every planar differential system of the form

$$\frac{dx}{dt} = P(x,y), \qquad \frac{dy}{dt} = Q(x,y), \tag{1.1}$$

✉Corresponding author. Email: alexcr@ufscar.br

where $P, Q \in \mathbb{R}[x, y]$, that is, P and Q are polynomials in x and y with real coefficients, we associate the vector field

$$X = P(x, y)\frac{\partial}{\partial x} + Q(x, y)\frac{\partial}{\partial y}.$$

The *degree* of such a system is defined as the integer $m = \max(\deg P, \deg Q)$. In particular, system (1.1) is called a *quadratic differential system* when $m = 2$; here, **QS** denotes the entire class of real quadratic differential systems. From now on, we assume that P and Q are coprime polynomials. Otherwise, by an appropriate rescaling of time, system (1.1) can be reduced to a linear or constant system. Quadratic differential systems satisfying this coprimality condition are referred to as *non-degenerate quadratic systems*.

Quadratic systems appear in various research fields including models of population dynamics [6], fluid dynamics [9], control systems [11] and even quantum dynamics [2]. They are also of theoretical interest because we have open problems on these systems stated more than a century ago; see for example [1] for a bibliographical survey.

Given $f \in \mathbb{C}[x, y]$, we say that the algebraic curve $f(x, y) = 0$ is an *invariant algebraic curve* of systems (1.1) if there exists $K \in \mathbb{C}[x, y]$ (it is called cofactor of the invariant curve $f = 0$) such that

$$P\frac{\partial f}{\partial x} + Q\frac{\partial f}{\partial y} = Kf.$$

Quadratic systems with invariant algebraic curves have been studied extensively by many authors. For example, Druzhkova [10] (1968) presented necessary and sufficient conditions on the coefficients of a quadratic system, as well as on the coefficients of a conic, for the conic to be an invariant curve of the system. Christopher [7] (1989) provided a normal form for quadratic systems possessing invariant parabolas. Qin Yuan-xum [18] (1996) investigated quadratic systems having an ellipse as a limit cycle. Cairó and Llibre [5] (2002) studied quadratic systems with invariant algebraic conics in the context of Darboux integrability. Schlomiuk and Vulpe [19, 21] (2004, 2008) classified quadratic systems with invariant straight lines of total multiplicity at least four, according to their geometric configurations. Many other works have also contributed to this topic.

The primary objective of this research is to study non-degenerate quadratic systems that possess invariant conics. Irreducible affine conics over the real field $\mathbb{R}$ include hyperbolas, ellipses, and parabolas. These conics can be distinguished by analyzing their behavior at infinity. Specifically, a hyperbola is a real irreducible affine conic with two distinct real points at infinity. A parabola, in contrast, has a single real point at infinity, where the conic meets the line at infinity with multiplicity two. An ellipse, on the other hand, has two complex conjugate points at infinity.

The classifications of **QS** with invariant hyperbolas [14, 15] and with invariant ellipses [13, 16] were obtained in previous works. In this study, we focus on the class **QSP** of non-degenerate quadratic differential systems that possess an invariant parabola. The novel contribution of this work lies in adopting a global approach, employing global tools such as the theory of invariant polynomials for differential systems.

The group of real affine transformations combined with time rescaling acts on the class **QS**. Consequently, modulo this group action, quadratic systems in this class depend on five essential parameters. The same group also acts on the subclass **QSP**, and, modulo the group action, systems in **QSP** depend on at most three parameters. To ensure our study is intrinsic and independent of any particular normal form representation, we employ invariant polynomials and geometric invariants to carry out the desired classification.

In the paper [24], the necessary and sufficient conditions for a non-degenerate quadratic system in **QS** to have invariant parabolas are established. Moreover, [24] presents invariant criteria that determine the number, position, and multiplicity of such parabolas.

The present paper is a continuation of [24]. More precisely, using the conditions from that work, we classify all possible configurations of invariant parabolas and invariant lines that a system in $\mathbf{QSP}_{(\eta\neq 0)}$ may possess. The investigation of configurations within the family $\mathbf{QSP}_{(\eta=0)}$ is currently in progress.

A key concept in this study is the notion of a *configuration of algebraic invariant curves* for a polynomial differential system. This concept was first introduced in [22], with an earlier version focusing solely on invariant lines presented in [19]. Following Darboux's definition, an *algebraic solution* of a polynomial differential system is an algebraic invariant curve defined by an irreducible polynomial over $\mathbb{C}$.

Definition 1.1. A *configuration of invariant algebraic curves* of a real polynomial differential system is defined as a finite set of algebraic invariant curves of the system, each endowed with its multiplicity, together with the real singularities, whether finite or infinite, located on these curves, each also endowed with its multiplicity.

It is worth noting that [8] introduces various notions of multiplicity for an algebraic invariant curve, including infinitesimal, integrable, algebraic, geometric, and holonomic multiplicities. In this work, we adopt the concept of *geometric multiplicity*, defined via perturbations within the family **QS** as follows.

Definition 1.2. An invariant conic

$$\Phi(x,y) = p + qx + ry + sx^2 + 2vxy + uy^2 = 0,$$

with $(s,v,u) \neq (0,0,0)$ and parameters $(p,q,r,s,v,u) \in \mathbb{C}^6$, for a quadratic vector field X, is said to have *multiplicity* m if there exists a sequence of real quadratic vector fields $\{X_k\}$ converging to X (under the topology induced by their coefficients on the sphere S^{11}) such that each X_k admits m distinct (complex) invariant conics

$$\Phi_k^1 = 0, \ \ldots, \ \Phi_k^m = 0,$$

all converging to $\Phi = 0$ as $k \to \infty$ (under the topology induced by their coefficients on the sphere S^5). Moreover, this property does not hold for $m+1$. When an invariant conic $\Phi(x,y) = 0$ has multiplicity one, it is called *simple*.

We note that two non-equivalent systems, modulo the group action, may have the "same configuration" of invariant parabolas and straight lines. Therefore, it is necessary to define when two configurations are considered "the same" or equivalent.

Definition 1.3. Suppose we have two systems (S_1) and (S_2) in **QSP**, each with a finite number of singularities (finite or infinite), a finite set of invariant parabolas

$$\mathcal{P}_i : g_i(x,y) = 0, \quad i = 1,\ldots,k,$$

of (S_1) (respectively

$$\mathcal{P}'_i : g'_i(x,y) = 0, \quad i = 1,\ldots,k,$$

of (S_2)), and a finite set (possibly empty) of invariant straight lines

$$\mathcal{L}_j : f_j(x,y) = 0, \quad j = 1,\ldots,k',$$

of (S_1) (respectively

$$\mathcal{L}'_j : f'_j(x,y) = 0, \quad j = 1, \ldots, k',$$

of (S_2)). We say that the configurations $\mathcal{C}_1$ and $\mathcal{C}_2$ of parabolas and lines of these systems are *equivalent* if there exist one-to-one correspondences

$$\phi_p : \{\mathcal{P}_i\} \to \{\mathcal{P}'_i\} \quad \text{and} \quad \phi_l : \{\mathcal{L}_j\} \to \{\mathcal{L}'_j\}$$

such that:

(i) ϕ_p and ϕ_l preserve multiplicities of parabolas and lines, and map real invariant curves to real invariant curves, and complex invariant curves to complex invariant curves;

(ii) for each parabola $\mathcal{P} : g(x,y) = 0$ in $\mathcal{C}_1$ (respectively each line $\mathcal{L} : f(x,y) = 0$), there is a one-to-one correspondence between the real singularities on $\mathcal{P}$ (respectively on $\mathcal{L}$) and the real singularities on $\phi_p(\mathcal{P})$ (respectively on $\phi_l(\mathcal{L})$), preserving both their multiplicities and locations;

(iii) furthermore, consider the total curves

$$\mathcal{F} : \prod_i G_i(X,Y,Z) \cdot \prod_j F_j(X,Y,Z) \cdot Z = 0,$$

and

$$\mathcal{F}' : \prod_i G'_i(X,Y,Z) \cdot \prod_j F'_j(X,Y,Z) \cdot Z = 0,$$

where $G_i(X,Y,Z) = 0$ and $F_j(X,Y,Z) = 0$ (respectively $G'_i(X,Y,Z) = 0$ and $F'_j(X,Y,Z) = 0$) are the projective completions of $\mathcal{P}_i$ and $\mathcal{L}_j$ (respectively $\mathcal{P}'_i$ and $\mathcal{L}'_j$). Then there is a correspondence ψ between the singularities of $\mathcal{F}$ and $\mathcal{F}'$, preserving their multiplicities as singularities of the total curves.

Our main results are summarized in the following theorem.

Main Theorem. *Consider the class $\mathbf{QSP}_{(\eta\neq 0)}$ of all non-degenerate quadratic differential systems (1.1) possessing an invariant parabola and three distinct infinite singularities (real or complex).*

(A) *This family is classified according to the configurations of invariant parabolas and invariant straight lines, resulting in 144 distinct configurations. Among these, 112 configurations belong to the subclass $\mathbf{QSP}_{(\eta>0)}$ and 32 to the subclass $\mathbf{QSP}_{(\eta<0)}$. This geometric classification is illustrated in Figures 1.1 and 1.2, and is characterized by necessary and sufficient invariant conditions presented in Diagrams 1.1, 1.2, and 1.3.*

(B) *Using 70 invariant polynomials, we derive the bifurcation diagram in the space $\mathbb{R}^{12}$ of the coefficients of systems in $\mathbf{QSP}_{(\eta\neq 0)}$. These diagrams, shown in Diagrams 1.1, 1.2, and 1.3, classify the systems according to their configurations of invariant parabolas and straight lines. Furthermore, the diagrams provide an algorithmic procedure to compute the configuration of any quadratic differential system with an invariant parabola, irrespective of its chosen normal form.*

(C) *Figures 1.1 and 1.2 present all possible configurations for systems in the subclasses $\mathbf{QSP}_{(\eta>0)}$ and $\mathbf{QSP}_{(\eta<0)}$, respectively. We prove that all 144 configurations are realizable within $\mathbf{QSP}_{(\eta\neq 0)}$, and that these configurations are topologically distinct. This proof, based on geometric invariants, is provided in Subsection 3.4 and is illustrated in Diagrams 3.1 and 3.2.*

Remark 1.4. Every branch of the graphs in Diagrams 1.1, 1.2, and 1.3 terminates at a unique configuration *Config.* $\mathcal{P}.1$ through *Config.* $\mathcal{P}.144$, with a single exception. Specifically, in Diagram 1.1 (page 11), there is a branch that leads to an indeterminacy between two configurations: either *Config.* $\mathcal{P}.32$ or *Config.* $\mathcal{P}.33$. We are convinced that there exists an invariant polynomial capable of distinguishing between these two configurations, although we have not yet identified it. The determination of such an invariant remains an open problem.

2 Preliminaries

Consider real quadratic systems of the form:

$$\begin{aligned} \frac{dx}{dt} &= p_0 + p_1(x,y) + p_2(x,y) \equiv P(x,y), \\ \frac{dy}{dt} &= q_0 + q_1(x,y) + q_2(x,y) \equiv Q(x,y), \end{aligned} \tag{2.1}$$

where p_i and q_i $(i = 0,1,2)$ are homogeneous polynomials of degree i in x and y:

$$\begin{aligned} &p_0 = a_{00}, \quad && p_1(x,y) = a_{10}x + a_{01}y, \quad && p_2(x,y) = a_{20}x^2 + 2a_{11}xy + a_{02}y^2, \\ &q_0 = b_{00}, \quad && q_1(x,y) = b_{10}x + b_{01}y, \quad && q_2(x,y) = b_{20}x^2 + 2b_{11}xy + b_{02}y^2. \end{aligned}$$

Such a system (2.1) can be identified with a point in $\mathbb{R}^{12}$. Let

$$\tilde{a} = (a_{00}, a_{10}, a_{01}, a_{20}, a_{11}, a_{02}, b_{00}, b_{10}, b_{01}, b_{20}, b_{11}, b_{02}),$$

and consider the polynomial ring $\mathbb{R}[a_{00}, \ldots, a_{02}, b_{00}, \ldots, b_{02}, x, y]$, which we denote by $\mathbb{R}[\tilde{a}, x, y]$.

It is known that the group $Aff(2,\mathbb{R})$ of affine transformations of the plane acts on the set **QS** of all quadratic differential systems (2.1) (cf. [20]). For every subgroup $G \subseteq Aff(2,\mathbb{R})$, there is an induced action of G on **QS**.

We can identify the set **QS** with a subset of $\mathbb{R}^{12}$ via the map **QS** $\to \mathbb{R}^{12}$, which associates to each system (2.1) the 12-tuple $\tilde{a} = (a_{00}, \ldots, b_{02})$ of its coefficients.

To study this group action, we associate to the systems certain polynomials in x, y and the system parameters that transform in a controlled way under the action. These are known as GL-comitants, T-comitants, and CT-comitants. For detailed definitions and constructions of these comitants, we refer the reader to [20] (see also [1]).

2.1 The main invariant polynomials associated to invariant parabolas

We single out the following five polynomials, which serve as basic ingredients in constructing invariant polynomials for systems (2.1):

$$\begin{aligned} C_i(\tilde{a}, x, y) &= y p_i(x,y) - x q_i(x,y), \quad (i = 0,1,2), \\ D_i(\tilde{a}, x, y) &= \frac{\partial p_i}{\partial x} + \frac{\partial q_i}{\partial y}, \quad (i = 1,2). \end{aligned} \tag{2.2}$$

As shown in [23], these polynomials, which are linear in the coefficients of systems (2.1), are GL-comitants of these systems.

For $f, g \in \mathbb{R}[\tilde{a}, x, y]$, we define the *transvectant of index* k of (f,g) by

$$(f,g)^{(k)} = \sum_{h=0}^{k} (-1)^h \binom{k}{h} \frac{\partial^k f}{\partial x^{k-h} \partial y^h} \cdot \frac{\partial^k g}{\partial x^h \partial y^{k-h}}.$$

The resulting polynomial $(f,g)^{(k)}$ belongs to $\mathbb{R}[\tilde{a}, x, y]$ (cf. [12, 17]).

Proposition 2.1 (see [25]). *Any GL-comitant of systems (2.1) can be constructed from the elements (2.2) by using the operations $+$, $-$, $\times$, and by applying the differential operation $(*,*)^{(k)}$.*

Remark 2.2. We point out that the elements (2.2) generate the entire set of GL-comitants, and consequently also the full set of affine comitants and T-comitants, since any affine comitant and any T-comitant can be constructed from GL-comitants using the same operations: $+$, $-$, $\times$, and $(*,*)^{(k)}$.

We construct the following GL-comitants of second degree with respect to the coefficients of the initial systems:

$$\begin{aligned} &T_1 = (C_0, C_1)^{(1)}, \quad && T_2 = (C_0, C_2)^{(1)}, \quad && T_3 = (C_0, D_2)^{(1)}, \\ &T_4 = (C_1, C_1)^{(2)}, \quad && T_5 = (C_1, C_2)^{(1)}, \quad && T_6 = (C_1, C_2)^{(2)}, \\ &T_7 = (C_1, D_2)^{(1)}, \quad && T_8 = (C_2, C_2)^{(2)}, \quad && T_9 = (C_2, D_2)^{(1)}. \end{aligned} \tag{2.3}$$

Using these GL-comitants, together with the polynomials defined in (2.2), we construct additional invariant polynomials. To enable the direct computation of the required invariant polynomials for each canonical system, we now define a family of T-comitants expressed in terms of the polynomials C_i $(i = 0, 1, 2)$ and D_j $(j = 1, 2)$:

$$\begin{aligned}
\hat{A} &= \left(C_1, T_8 - 2T_9 + D_2^2\right)^{(2)}/144, \\
\widehat{D} &= \left[2C_0(T_8 - 8T_9 - 2D_2^2) + C_1(6T_7 - T_6 - (C_1, T_5)^{(1)} + 6D_1(C_1D_2 - T_5) - 9D_1^2C_2\right]/36, \\
\widehat{E} &= \left[D_1(2T_9 - T_8) - 3\,(C_1, T_9)^{(1)} - D_2(3T_7 + D_1D_2)\right]/72, \\
\widehat{F} &= \left[6D_1^2(D_2^2 - 4T_9) + 4D_1D_2(T_6 + 6T_7) + 48C_0\,(D_2, T_9)^{(1)} - 9D_2^2T_4 + 288D_1\widehat{E}\right. \\
&\quad \left. - 24\left(C_2, \widehat{D}\right)^{(2)} + 120\left(D_2, \widehat{D}\right)^{(1)} - 36C_1\,(D_2, T_7)^{(1)} + 8D_1\,(D_2, T_5)^{(1)}\right]/144, \\
\widehat{K} &= (T_8 + 4T_9 + 4D_2^2)/72, \\
\widehat{H} &= (8T_9 - T_8 + 2D_2^2)/72, \\
\widehat{B} &= \Big\{16D_1\,(D_2, T_8)^{(1)}\,(3C_1D_1 - 2C_0D_2 + 4T_2) + 32C_0\,(D_2, T_9)^{(1)}\,(3D_1D_2 - 5T_6 + 9T_7) \\
&\quad + 2\,(D_2, T_9)^{(1)}\,\left(27C_1T_4 - 18C_1D_1^2 - 32D_1T_2 + 32\,(C_0, T_5)^{(1)}\right) \\
&\quad + 6\,(D_2, T_7)^{(1)}\,[8C_0(T_8 - 12T_9) - 12C_1(D_1D_2 + T_7) \\
&\quad + D_1(26C_2D_1 + 32T_5) + C_2(9T_4 + 96T_3)] \\
&\quad + 6\,(D_2, T_6)^{(1)}\,[32C_0T_9 - C_1(12T_7 + 52D_1D_2) - 32C_2D_1^2] + 48D_2\,(D_2, T_1)^{(1)}\,\left(2D_2^2 - T_8\right) \\
&\quad - 32D_1T_8\,(D_2, T_2)^{(1)} + 9D_2^2T_4\,(T_6 - 2T_7) - 16D_1\,(C_2, T_8)^{(1)}\,\left(D_1^2 + 4T_3\right) \\
&\quad + 12D_1\,(C_1, T_8)^{(2)}\,(C_1D_2 - 2C_2D_1) + 6D_1D_2T_4\,\left(T_8 - 7D_2^2 - 42T_9\right) \\
&\quad + 12D_1\,(C_1, T_8)^{(1)}\,(T_7 + 2D_1D_2) + 96D_2^2\left[D_1\,(C_1, T_6)^{(1)} + D_2\,(C_0, T_6)^{(1)}\right] - \\
&\quad - 16D_1D_2T_3\,\left(2D_2^2 + 3T_8\right) - 4D_1^3D_2\,\left(D_2^2 + 3T_8 + 6T_9\right) + 6D_1^2D_2^2\,(7T_6 + 2T_7) \\
&\quad - 252D_1D_2T_4T_9\Big\}/(2^8 3^3),
\end{aligned}$$

These polynomials, together with those defined in (2.2) and (2.3), will serve as fundamental building blocks for constructing affine invariant polynomials for systems (2.1).

The following 42 affine invariants, labeled $A_1, \ldots, A_{42}$, constitute a minimal polynomial basis of affine invariants up to degree 12. This result was established in [4], where the invariants $A_1, \ldots, A_{42}$ were explicitly constructed using the aforementioned building blocks:

$$
\begin{aligned}
A_1 &= \hat{A},\\
A_2 &= (C_2, \widehat{D})^{(3)}/12,\\
A_3 &= \left[C_2, D_2)^{(1)}, D_2\right)^{(1)}, D_2\right)^{(1)}/48,\\
A_4 &= (\widehat{H}, \widehat{H})^{(2)},\\
A_5 &= (\widehat{H}, \widehat{K})^{(2)}/2,\\
A_6 &= (\widehat{E}, \widehat{H})^{(2)}/2,\\
A_7 &= \left[C_2, \widehat{E})^{(2)}, D_2\right)^{(1)}/8,\\
A_8 &= \left[\widehat{D}, \widehat{H})^{(2)}, D_2\right)^{(1)}/8,\\
A_9 &= \left[\widehat{D}, D_2)^{(1)}, D_2\right)^{(1)}, D_2\right)^{(1)}/48,\\
A_{10} &= \left[\widehat{D}, \widehat{K})^{(2)}, D_2\right)^{(1)}/8,\\
A_{11} &= (\widehat{F}, \widehat{K})^{(2)}/4,\\
A_{12} &= (\widehat{F}, \widehat{H})^{(2)}/4,\\
A_{13} &= \left[C_2, \widehat{H})^{(1)}, \widehat{H}\right)^{(2)}, D_2\right)^{(1)}/24,\\
A_{14} &= (\widehat{B}, C_2)^{(3)}/36,\\
A_{15} &= (\widehat{E}, \widehat{F})^{(2)}/4,\\
A_{16} &= \left[\widehat{E}, D_2)^{(1)}, C_2\right)^{(1)}, \widehat{K}\right)^{(2)}/16,\\
A_{17} &= \left[\widehat{D}, \widehat{D})^{(2)}, D_2\right)^{(1)}, D_2\right)^{(1)}/64,\\
A_{18} &= \left[\widehat{D}, \widehat{F})^{(2)}, D_2\right)^{(1)}/16,\\
A_{19} &= \left[\widehat{D}, \widehat{D})^{(2)}, \widehat{H}\right)^{(2)}/16,\\
A_{20} &= \left[C_2, \widehat{D})^{(2)}, \widehat{F}\right)^{(2)}/16,\\
A_{21} &= \left[\widehat{D}, \widehat{D})^{(2)}, \widehat{K}\right)^{(2)}/16,\\
A_{22} &= \left[C_2, \widehat{D})^{(1)}, D_2\right)^{(1)}, D_2\right)^{(1)}, D_2\right)^{(1)} D_2\right)^{(1)}/1152,\\
A_{23} &= \left[\widehat{F}, \widehat{H})^{(1)}, \widehat{K}\right)^{(2)}/8,\\
A_{24} &= \left[C_2, \widehat{D})^{(2)}, \widehat{K}\right)^{(1)}, \widehat{H}\right)^{(2)}/32,\\
A_{25} &= \left[\widehat{D}, \widehat{D})^{(2)}, \widehat{E}\right)^{(2)}/16,\\
A_{26} &= (\widehat{B}, \widehat{D})^{(3)}/36,\\
A_{27} &= \left[\widehat{B}, D_2)^{(1)}, \widehat{H}\right)^{(2)}/24,\\
A_{28} &= \left[C_2, \widehat{K})^{(2)}, \widehat{D}\right)^{(1)}, \widehat{E}\right)^{(2)}/16,\\
A_{29} &= \left[\widehat{D}, \widehat{F})^{(1)}, \widehat{D}\right)^{(3)}/96,\\
A_{30} &= \left[C_2, \widehat{D})^{(2)}, \widehat{D}\right)^{(1)}, \widehat{D}\right)^{(3)}/288,\\
A_{31} &= \left[\widehat{D}, \widehat{D})^{(2)}, \widehat{K}\right)^{(1)}, \widehat{H}\right)^{(2)}/64,
\end{aligned}
$$

$$
\begin{aligned}
A_{32} &= \big[\widehat{D},\widehat{D})^{(2)},D_2\big)^{(1)},\widehat{H}\big)^{(1)},D_2\big)^{(1)}/64,\\
A_{33} &= \big[\widehat{D},D_2)^{(1)},\widehat{F}\big)^{(1)},D_2\big)^{(1)},D_2\big)^{(1)}/128,\\
A_{34} &= \big[\widehat{D},\widehat{D})^{(2)},D_2\big)^{(1)},\widehat{K}\big)^{(1)},D_2\big)^{(1)}/64,\\
A_{35} &= \big[\widehat{D},\widehat{D})^{(2)},\widehat{E}\big)^{(1)},D_2\big)^{(1)},D_2\big)^{(1)}/128,\\
A_{36} &= \big[\widehat{D},\widehat{E})^{(2)},\widehat{D}\big)^{(1)},\widehat{H}\big)^{(2)}/16,\\
A_{37} &= \big[\widehat{D},\widehat{D})^{(2)},\widehat{D}\big)^{(1)},\widehat{D}\big)^{(3)}/576,\\
A_{38} &= \big[C_2,\widehat{D})^{(2)},\widehat{D}\big)^{(2)},\widehat{D}\big)^{(1)},\widehat{H}\big)^{(2)}/64,\\
A_{39} &= \big[\widehat{D},\widehat{D})^{(2)},\widehat{F}\big)^{(1)},\widehat{H}\big)^{(2)}/64,\\
A_{40} &= \big[\widehat{D},\widehat{D})^{(2)},\widehat{F}\big)^{(1)},\widehat{K}\big)^{(2)}/64,\\
A_{41} &= \big[C_2,\widehat{D})^{(2)},\widehat{D}\big)^{(2)},\widehat{F}\big)^{(1)},D_2\big)^{(1)}/64,\\
A_{42} &= \big[\widehat{D},\widehat{F})^{(2)},\widehat{F}\big)^{(1)},D_2\big)^{(1)}/16.
\end{aligned}
$$

In the above list, the bracket "[" is used as a typographical device to avoid writing up to five consecutive parentheses "(" in some of the expressions.

Using the elements of the minimal polynomial basis listed above, we construct two groups of affine invariant polynomials. The first group contains invariant polynomials associated with the existence of an invariant parabola for a quadratic system, and they are:

$$
\begin{aligned}
\chi_1 &= 32A_3 + 45A_4 - 160A_5;\\
\chi_2 &= 32A_8(14A_8 - 48A_9 + 37A_{10} + 24A_{11}) + 16A_5(76A_{17} + 74A_{18} + 313A_{19} - 80A_{20}\\
&\quad - 167A_{21}) + A_4(160A_2^2 + 368A_{18} - 3363A_{19} + 736A_{20} + 2109A_{21}) + 32(17A_{10}^2\\
&\quad + 27A_{10}A_{11} + 24A_{11}^2 - 48A_9A_{12} + 51A_{10}A_{12} + 24A_{11}A_{12} + 288A_6A_{14} - 96A_7A_{14});\\
\chi_3 &= 6520480A_{20}(407A_{18} - 2253A_{21}) + 24A_{18}(1057715458A_{19} + 5944853225A_{21})\\
&\quad + 28800A_{14}(1872476A_{25} - 122259A_{26}) + 144A_{12}(3620283092A_{29} - 1554910481A_{30})\\
&\quad + 1440A_{15}(107225339A_{25} - 19561440A_{26}) - 72A_{11}(8198511476A_{29} - 2965514443A_{30})\\
&\quad + 652048(4544A_{18}^2 + 125A_{20}^2 - 8955A_2A_{42}) - 9(264364688A_{19}^2 + 39417454842A_{19}A_{21}\\
&\quad - 54474141921A_{21}^2) + 3448898760A_{19}A_{20};\\
\chi_4 &= 62713A_{10}^2 + 45787A_{10}A_{11} - 157928A_{11}^2 + 81202A_{10}A_{12} + A_{19}353474A_{11}A_{12} - 145848A_{12}^2\\
&\quad + 64320A_7A_{15} + 28600A_5A_{17};\\
\zeta_1 &= 13A_4 - 24A_5;\\
\zeta_2 &= -A_4;\\
\zeta_3 &= 16A_5 - 17A_4;\\
\zeta_4 &= 9A_1A_4 - 7A_1A_5 - 2A_{16};\\
\zeta_5 &= 166A_8 + 384A_9 - 1120A_{10} - 512A_{11} - 62A_{12};\\
\zeta_6 &= A_6;\\
\zeta_7 &= 40(71436A_7A_{20} - 640883A_7A_{21} + 1008622A_1A_{32}) + 12A_{12}(3585035A_{14} + 14919259A_{15})\\
&\quad - 5(8092193A_{10} + 15970731A_{11})A_{14} - (129780821A_{10} + 269944167A_{11})A_{15};\\
\zeta_8 &= A_2;
\end{aligned}
$$

$$\begin{aligned}
\zeta_9 &= 1040(2256A_7A_{15}+143A_3A_{21})-264(162941A_{10}+315202A_{11})A_{12}\\
&\quad +3A_{11}(25887132A_{10}+24385177A_{11})+20603609A_{10}^2+24896016A_{12}^2;\\
\zeta_{10} &= 250A_1^2+34A_{11}-41A_{12};\\
\mathcal{R}_1 &= 531A_2A_4-1472A_2A_5-8352A_1A_6+320A_{22}-3216A_{23}+1488A_{24};\\
\mathcal{R}_2 &= 15A_{10}-10A_8-6A_9;\\
\mathcal{R}_3 &= 4800(6650951968A_{14}A_{15}-2382132830A_{14}^2-9860550485A_{15}^2)+1600(4765089473A_{11}\\
&\quad -7838161089A_{12})A_{20}+640(15664652914A_{11}-50944340271A_{12})A_{18}\\
&\quad -6(20392663986679A_{10}+34357804389813A_{11}-739275727012A_{12})A_{21}\\
&\quad +3(46944212550227A_{10}+83455057317969A_{11}-22899810934956A_{12})A_{19};\\
\mathcal{R}_4 &= 251A_1^2+25A_{12};\\
\mathcal{R}_7 &= 62250A_1^2+8956A_9-46223A_{10}-50129A_{11}+14766A_{12}.
\end{aligned}$$

The invariant polynomials from the second group are responsible for the classification of the configurations of invariant parabolas and lines. They are:

$$\begin{aligned}
\xi_1 &= 342A_1^2A_2+A_2(35A_{10}-15A_8-16A_9+97A_{11}-83A_{12})-48A_1(4A_{14}+3A_{15})\\
&\quad +16(2A_{32}+A_{33}-3A_{34})+90A_{31};\\
\xi_2 &= -A_{19};\\
\xi_3 &= 12(49836514A_8^2-40804544A_8A_9-63384469A_8A_{10}-4515985A_{10}^2+93824435A_8A_{11}\\

2.2 Results involving the use of polynomial invariants

A few more definitions and results, which play an important role in the proof of part (A) of the Main Theorem, are needed. We do not prove these results here but indicate where they can be found.

Consider the differential operator $\mathcal{L} = x \cdot L_2 - y \cdot L_1$, introduced in [3], acting on $\mathbb{R}[\tilde{a}, x, y]$, where the operators L_1 and L_2 are given by

$$
\begin{aligned}
L_1 &= 2a_{00}\frac{\partial}{\partial a_{10}} + a_{10}\frac{\partial}{\partial a_{20}} + \frac{1}{2}a_{01}\frac{\partial}{\partial a_{11}} + 2b_{00}\frac{\partial}{\partial b_{10}} + b_{10}\frac{\partial}{\partial b_{20}} + \frac{1}{2}b_{01}\frac{\partial}{\partial b_{11}},\\
L_2 &= 2a_{00}\frac{\partial}{\partial a_{01}} + a_{01}\frac{\partial}{\partial a_{02}} + \frac{1}{2}a_{10}\frac{\partial}{\partial a_{11}} + 2b_{00}\frac{\partial}{\partial b_{01}} + b_{01}\frac{\partial}{\partial b_{02}} + \frac{1}{2}b_{10}\frac{\partial}{\partial b_{11}}.
\end{aligned}
$$

Using the differential operator $\mathcal{L}$ introduced above and the affine invariant

$$
\mu_0 = \frac{\operatorname{Res}_x\left(p_2(\tilde{a}, x, y), q_2(\tilde{a}, x, y)\right)}{y^4},
$$

we construct the following family of polynomials:

$$
\mu_i(\tilde{a}, x, y) = \frac{1}{i!}\mathcal{L}^{(i)}(\mu_0), \quad i = 1, \ldots, 4,
$$

where the iterated operator $\mathcal{L}^{(i)}$ is defined recursively by

$$
\mathcal{L}^{(i)}(\mu_0) = \mathcal{L}\big(\mathcal{L}^{(i-1)}(\mu_0)\big), \quad \text{with } \mathcal{L}^{(0)}(\mu_0) = \mu_0.
$$

These polynomials μ_i are $GL(2,\mathbb{R})$-comitants of the quadratic systems (2.1), as established in [3]. Their geometric interpretation is detailed in Lemma 5.2 of [1].

From these invariant polynomials, one constructs the affine invariant polynomials **D** and **R**, which characterize the existence of multiple finite singularities in quadratic differential systems:

$$\mathbf{D} = \frac{1}{48}\left[3\big((\mu_3,\mu_3)^{(2)},\mu_2\big)^{(2)} - \big(6\mu_0\mu_4 - 3\mu_1\mu_3 + \mu_2^2,\mu_4\big)^{(4)}\right], \quad \mathbf{R} = 3\mu_1^2 - 8\mu_0\mu_2,$$

where $(*,*)^{(k)}$ denotes the bilinear operation transvectant.

Next, we construct the following T-comitants (for the definition of T-comitants, see [20]), which play a fundamental role in characterizing the existence of invariant straight lines for systems (2.1):

$$B_3(\tilde{a},x,y) = (C_2,\widehat{D})^{(1)} = \text{Jacob}(C_2,\widehat{D}),$$
$$B_2(\tilde{a},x,y) = (B_3,B_3)^{(2)} - 6B_3(C_2,\widehat{D})^{(3)},$$
$$B_1(\tilde{a}) = \frac{\text{Res}_x(C_2,\widehat{D})}{y^9} = -2^{-9}3^{-8}\,(B_2,B_3)^{(4)}.$$

The following result, whose proof can be found in [19], provides a necessary condition for the existence of invariant straight lines in quadratic differential systems.

Lemma 2.3 (see [19]). *For system (2.1) to possess invariant straight lines in one, two, or three distinct directions in the affine plane, it is necessary that the following conditions hold, respectively:*

$$B_1 = 0, \quad B_2 = 0, \quad B_3 = 0.$$

In order to detect the presence of parallel invariant straight lines, we require the following invariant polynomials:

$$N(\tilde{a},x,y) = D_2^2 + T_8 - 2T_9 = 9\widehat{N},$$
$$\theta(\tilde{a}) = 2A_5 - A_4 \quad \big(\equiv \text{Discriminant}\left(N(\tilde{a},x,y)\right)/1296\big).$$

With these definitions, the following necessary condition holds.

Lemma 2.4 (see [19]). *A necessary condition for the existence of one couple (respectively two couples) of parallel invariant straight lines in system (2.1), corresponding to a parameter vector $\tilde{a} \in \mathbb{R}^{12}$, is that $\theta(\tilde{a}) = 0$ (respectively $N(\tilde{a},x,y) = 0$).*

Next, we introduce some important GL-comitants relevant to the study of invariant conics. Let us consider

$$C_2(\tilde{a},x,y) = y\,p_2(\tilde{a},x,y) - x\,q_2(\tilde{a},x,y),$$

which defines a cubic binary form in x and y. Using this form, we define the following polynomials:

$$\eta = \text{Discrim}[C_2], \qquad M = \text{Hessian}[C_2].$$

It is worth noting (see [23]) that the invariant polynomials C_2, η, and M are responsible for controlling the number of infinite singularities (real or complex) of system (2.1).

Remark 2.5. In order to describe the various kinds of multiplicities for infinite singularities, we use the concepts and notations introduced in [19]. Thus, we denote by (a,b) the maximum number a (respectively, b) of infinite (respectively, finite) singularities that can be obtained by perturbation of a multiple infinite singularity. In this case, we say that an infinite singular point *has multiplicity* (a,b).

In this paper, we consider only the case $\eta \neq 0$, that is, $\eta > 0$ or $\eta < 0$. In the first case, according to [23], a quadratic system possesses at infinity three real distinct singularities, whereas in the second case, it possesses one real and two complex singularities.

In [24], necessary and sufficient conditions for a system to belong to the family **QSP** of quadratic systems possessing at least one invariant parabola, in terms of invariant polynomials, are determined.

We extract from [24] only the information related to the case $\eta \neq 0$, and for this, we need some notations.

Definition 2.6. By the *direction of an invariant parabola* of a quadratic system (S), we mean the direction of its axis of symmetry, which intersects the invariant line $Z = 0$ at an infinite singular point of (S).

In order to distinguish the invariant parabolas that a quadratic system could have, we use the following notations:

- $\cup$ for a simple invariant parabola;
- $\Cup$ for two simple invariant parabolas in the same direction (they could intersect);
- $\cup\!\subset$ for two simple invariant parabolas in different directions;
- $\cup^2$ for one double invariant parabola;
- $\Cup\subset$ for three simple invariant parabolas: two in one direction and one in another direction.

The proof of the next proposition can be found in [24].

Proposition 2.7. *Assume that for a non-degenerate arbitrary quadratic system, the conditions $\eta > 0$ and $\zeta_1 \neq 0$ are satisfied. Then, this system could possess invariant parabolas only in one direction. More exactly, it could only possess one of the following sets of invariant parabolas: $\cup$, $\Cup$ and $\cup^2$. Moreover, this system has one of the above sets of parabolas if and only if $\chi_1 = \chi_2 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$$
\begin{array}{lll}
(\mathcal{A}_1) & \zeta_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_4 \neq 0,\ \mathcal{R}_1 \neq 0 & \Rightarrow \cup; \\
(\mathcal{A}_2) & \zeta_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_4 = 0,\ \mathcal{R}_2 \neq 0,\ \zeta_5 \neq 0 & \Rightarrow \Cup; \\
(\mathcal{A}_3) & \zeta_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_4 = 0,\ \mathcal{R}_2 \neq 0,\ \zeta_5 = 0 & \Rightarrow \cup^2; \\
(\mathcal{A}_4) & \zeta_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_4 = 0,\ \mathcal{R}_2 = 0,\ \zeta_5 \neq 0 & \Rightarrow \cup; \\
(\mathcal{A}_5) & \zeta_2 \neq 0,\ \zeta_3 = 0,\ \zeta_4 \neq 0,\ \mathcal{R}_1 \neq 0 & \Rightarrow \cup; \\
(\mathcal{A}_6) & \zeta_2 \neq 0,\ \zeta_3 = 0,\ \zeta_4 = 0,\ \mathcal{R}_2 \neq 0\ \zeta_5 \neq 0 & \Rightarrow \Cup; \\
(\mathcal{A}_7) & \zeta_2 \neq 0,\ \zeta_3 = 0,\ \zeta_4 = 0,\ \mathcal{R}_2 \neq 0,\ \zeta_5 = 0 & \Rightarrow \cup^2; \\
(\mathcal{A}_8) & \zeta_2 \neq 0,\ \zeta_3 = 0,\ \zeta_4 = 0,\ \mathcal{R}_2 = 0,\ \zeta_5 \neq 0 & \Rightarrow \cup; \\
(\mathcal{A}_9) & \zeta_2 = 0,\ \zeta_6 \neq 0,\ \mathcal{R}_1 = 0,\ \mathcal{R}_2 \neq 0 & \Rightarrow \cup.
\end{array}
$$

Furthermore, in the case of the existence of an invariant parabola, a system with $\eta > 0$ and $\zeta_1 \neq 0$ could be brought via an affine transformation and time rescaling to the following canonical form:

$$
\dot{x} = m + nx - \frac{1}{2}(1+g)y + gx^2 + xy, \quad \dot{y} = 2mx + 2ny + (g-1)xy + 2y^2 \tag{2.4}
$$

possessing the invariant parabola $\Phi(x, y) = x^2 - y = 0$.

However, examining the conditions $(\mathcal{A}_1)$–$(\mathcal{A}_9)$, we detect that some of the sets of these conditions could be joined. More exactly, we observe that $(\mathcal{A}_1)$ and $(\mathcal{A}_5)$ contain the same conditions except for the condition involving ζ_3. Therefore, by eliminating the conditions involving only ζ_3, we obtain a new set of conditions which we denote by $(\mathcal{A}_1^*)$: $\zeta_2 \neq 0, \quad \zeta_4 \neq 0, \quad \mathcal{R}_1 \neq 0$.

We perform the analogous operation on $(\mathcal{A}_2)$ and $(\mathcal{A}_6)$ (respectively $(\mathcal{A}_3)$ and $(\mathcal{A}_7)$; $(\mathcal{A}_4)$ and $(\mathcal{A}_8)$), resulting in the new conditions $(\mathcal{A}_2^*)$ (respectively $(\mathcal{A}_3^*)$; $(\mathcal{A}_4^*)$).

Thus, we can replace the first part of Proposition 2.7 obtaining the following one:

Proposition 2.7*. *Assume that for a non-degenerate arbitrary quadratic system, the conditions $\eta > 0$ and $\zeta_1 \neq 0$ are satisfied. Then, this system could possess invariant parabolas only in one direction. More exactly, it could only possess one of the following sets of invariant parabolas: $\bigcup$, $\Cup$ and $\bigcup^2$. Moreover, this system has one of the above sets of parabolas if and only if $\chi_1 = \chi_2 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$$
\begin{array}{lll}
(\mathcal{A}_1^*) & \zeta_2 \neq 0, \zeta_4 \neq 0, \mathcal{R}_1 \neq 0 & \Rightarrow \bigcup; \\
(\mathcal{A}_2^*) & \zeta_2 \neq 0, \zeta_4 = 0, \mathcal{R}_2 \neq 0, \zeta_5 \neq 0 & \Rightarrow \Cup; \\
(\mathcal{A}_3^*) & \zeta_2 \neq 0, \zeta_4 = 0, \mathcal{R}_2 \neq 0, \zeta_5 = 0 & \Rightarrow \bigcup^2; \\
(\mathcal{A}_4^*) & \zeta_2 \neq 0, \zeta_4 = 0, \mathcal{R}_2 = 0, \zeta_5 \neq 0 & \Rightarrow \bigcup; \\
(\mathcal{A}_5^*) & \zeta_2 = 0, \ \zeta_6 \neq 0, \mathcal{R}_1 = 0, \mathcal{R}_2 \neq 0 & \Rightarrow \bigcup.
\end{array}
$$

The proof of the next two propositions could also be found in [24].

Proposition 2.8. *Assume that for a non-degenerate arbitrary quadratic system, the conditions $\eta > 0$ and $\zeta_1 = 0$ are satisfied. Then, this system could possess invariant parabolas in one or two directions. More exactly, it could only possess one of the following sets of invariant parabolas: $\bigcup$, $\Cup$, $\bigcup^2$, $\bigcup\subset$ and $\Cup\subset$. Moreover, this system has one of the above sets of invariant parabolas if and only if $\chi_1 = \chi_3 = 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$$
\begin{array}{lll}
(\mathcal{B}_1) & \chi_4 \neq 0, \zeta_7 \neq 0, \mathcal{R}_3 \neq 0 & \Rightarrow \bigcup; \\
(\mathcal{B}_2) & \chi_4 \neq 0, \zeta_7 = 0, \mathcal{R}_4 \neq 0, \zeta_8 \neq 0 & \Rightarrow \Cup; \\
(\mathcal{B}_3) & \chi_4 \neq 0, \zeta_7 = 0, \mathcal{R}_4 \neq 0, \zeta_8 = 0 & \Rightarrow \bigcup^2; \\
(\mathcal{B}_4) & \chi_4 \neq 0, \zeta_7 = 0, \mathcal{R}_4 = 0 & \Rightarrow \bigcup; \\
(\mathcal{B}_5) & \chi_4 = 0, \zeta_5 \neq 0, \zeta_9 \neq 0 & \Rightarrow \bigcup\subset; \\
(\mathcal{B}_6) & \chi_4 = 0, \zeta_5 \neq 0, \zeta_9 = 0, \zeta_{10} \neq 0 & \Rightarrow \bigcup; \\
(\mathcal{B}_7) & \chi_4 = 0, \zeta_5 = 0, \zeta_6 \neq 0 & \Rightarrow \Cup\subset.
\end{array}
$$

Furthermore, in the case of the existence of an invariant parabola, a system with $\eta > 0$ and $\zeta_1 = 0$ could be brought via an affine transformation and time rescaling to the systems (2.4) with $g = 2$.

Proposition 2.9. *Assume that for a non-degenerate arbitrary quadratic system, the conditions $\eta < 0$ is satisfied. Then, this system could only possess one of the following sets of invariant parabolas: $\bigcup$, $\Cup$ and $\bigcup^2$. Moreover, this system has one of the above sets of invariant parabolas if and only if $\chi_1 = \chi_2 = 0$ and $\zeta_1 \neq 0$ and one of the following sets of conditions are satisfied, correspondingly:*

$$
\begin{array}{lll}
(\mathcal{E}_1) & \zeta_4 \neq 0, \mathcal{R}_1 \neq 0 & \Rightarrow \bigcup; \\
(\mathcal{E}_2) & \zeta_4 = 0, \mathcal{R}_7 \neq 0, \zeta_5 \neq 0 & \Rightarrow \Cup; \\
(\mathcal{E}_3) & \zeta_4 = 0, \mathcal{R}_7 \neq 0, \zeta_5 = 0 & \Rightarrow \bigcup^2; \\
(\mathcal{E}_4) & \zeta_4 = 0, \mathcal{R}_7 = 0, \zeta_5 \neq 0 & \Rightarrow \bigcup.
\end{array}
$$

Furthermore, in the case of the existence of an invariant parabola, a system with $\eta < 0$ could be brought via an affine transformation and time rescaling to the following canonical form:

$$\dot{x} = m + (2n-1)x/2 + gx^2 - gy/2 - xy, \quad \dot{y} = 2mx - x^2 + 2ny + gxy - 2y^2, \tag{2.5}$$

with $C_2 = x(x^2+y^2)$, *possessing the invariant parabola* $\Phi(x,y) = x^2 - y = 0$.

3 The proof of the Main Theorem

The statement $(\boldsymbol{B})$ follows directly from the form of the conditions given in Diagrams 1.1, 1.2, and 1.3. These conditions can be evaluated for any point $a \in \mathbb{R}^{12}$ corresponding to a quadratic system satisfying $\eta \neq 0$.

In order to prove the statement $(\boldsymbol{A})$ of the Main Theorem, we must examine the sets of conditions provided by each one of Propositions 2.7*, 2.8, and 2.9.

3.1 Systems in $\mathbf{QSP}_{(\eta>0)}$ with the condition $\zeta_1 \neq 0$

In what follows, we examine the configurations of the systems in $\mathbf{QSP}_{(\eta>0)}$ in each one of the cases provided by Proposition 2.7*. According to Proposition 2.7, we consider the canonical form (2.4), i.e., the systems:

$$\dot{x} = m + nx - \frac{1}{2}(1+g)y + gx^2 + xy, \quad \dot{y} = 2mx + 2ny + (g-1)xy + 2y^2, \tag{3.1}$$

possessing the invariant parabola $\Phi(x,y) = x^2 - y = 0$.

3.1.1 The statement $(\mathcal{A}_1^*)$

For systems (3.1), we calculate:

$$\begin{aligned}
\zeta_1 &= 2(g-2)(3+g), \quad \zeta_2 = 4g(1+g),\\
\zeta_4 &= (g-2)(3+g)(1+7g+15g^2+9g^3-4m+2n+6gn)/16,\\
\mathcal{R}_1 &= -15g(1+g)(g-2)(3+g)(1+7g+15g^2+9g^3-4m+2n+6gn)/2,\\
B_1 &= m(g+8m+4n)(gn-2m-n)(1+2g+g^2-4m+2n+2gn)\\
&\quad \times (g+2g^2+g^3+4m+2n+2gn)/4.
\end{aligned} \tag{3.2}$$

We consider two cases: $B_1 \neq 0$ and $B_1 = 0$.

The case $B_1 \neq 0$**.** Then, according to Lemma 2.3, systems (3.1) could not possess any invariant line.

We examine the finite singularities of these systems. Following [1, Proposition 5.1], we calculate the invariant polynomial $\mathbf{D} = 48F_1^2F_2$, where

$$\begin{aligned}
F_1 &= -4m^2 + 2(g+1)m(g^2-2n) - (g+1)^2n^2,\\
F_2 &= 108m^2 + 2(g-1)m\big(1-2g+g^2-18n\big) + n^2\big(16n-1+2g-g^2\big).
\end{aligned} \tag{3.3}$$

Thus, we discuss two subcases: $\mathbf{D} \neq 0$ and $\mathbf{D} = 0$.

The subcase $\mathbf{D} \neq 0$. We determine that systems (3.1) possess four finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with the coordinates

$$
\begin{aligned}
x_1 &= -\frac{2m+n+gn}{g(1+g)},\ y_1 = \frac{2m}{1+g};\ \ x_2 = \frac{1}{6\mathcal{Z}^{1/3}}\big[\mathcal{Y} + (1-g)\mathcal{Z}^{1/3} + \mathcal{Z}^{2/3}\big],\\
y_2 &= \frac{1}{36\mathcal{Z}}\big[3(\mathcal{Y}+4n)\mathcal{Z} + \mathcal{Y}^2\mathcal{Z}^{1/3} - 2(g-1)\mathcal{Y}\mathcal{Z}^{2/3} - 2(g-1)\mathcal{Z}^{4/3} + \mathcal{Z}^{5/3};\\
x_3 &= \frac{1}{12\mathcal{Z}^{1/3}}\big[-(1+i\sqrt{3})\mathcal{Y} + 2(1-g)\mathcal{Z}^{1/3} - (1-i\sqrt{3})\mathcal{Z}^{2/3}\big],\\
y_3 &= -\frac{1}{72\mathcal{Z}}\big[-6(\mathcal{Y}+4n)\mathcal{Z} + (1-i\sqrt{3})\mathcal{Y}^2\mathcal{Z}^{1/3} - 2(1+i\sqrt{3})(g-1)\mathcal{Y}\mathcal{Z}^{2/3}\\
&\quad - 2(1-i\sqrt{3})(g-1)\mathcal{Z}^{4/3} + (1+i\sqrt{3})\mathcal{Z}^{5/3}\big];\\
x_4 &= \frac{1}{12\mathcal{Z}^{1/3}}\big[(-1+i\sqrt{3})\mathcal{Y} + 2(1-g)\mathcal{Z}^{1/3} - (1+i\sqrt{3})\mathcal{Z}^{2/3}\big],\\
y_4 &= -\frac{1}{72\mathcal{Z}}\big[-6(\mathcal{Y}+4n)\mathcal{Z} + (1+i\sqrt{3})\mathcal{Y}^2\mathcal{Z}^{1/3} - 2(1-i\sqrt{3})(g-1)\mathcal{Y}\mathcal{Z}^{2/3}\\
&\quad - 2(1+i\sqrt{3})(g-1)\mathcal{Z}^{4/3} + (1-i\sqrt{3})\mathcal{Z}^{5/3}\big],
\end{aligned}
\tag{3.4}
$$

where

$$
\mathcal{Z} = 1 - 3g + 3g^2 - g^3 - 108m - 18n + 18gn + 6\sqrt{3}\sqrt{F_2}, \quad \mathcal{Y} = (1-g)^2 - 12n.
$$

Calculations yield:

$$
\Phi(x_2, y_2) = \Phi(x_3, y_3) = \Phi(x_4, y_4) = 0, \quad \Phi(x_1, y_1) = -\frac{F_1}{g^2(1+g)^2},
$$

and therefore we deduce that three singularities M_2, M_3 and M_4 of systems (3.1) are located on the invariant parabola. Moreover, M_1 is located outside the parabola and could belong to it if and only if the condition $F_1 = 0$ holds, where F_1 is given in (3.3). However, we have $\mathbf{D} = 48F_1^2F_2 \neq 0$, and hence on the parabola we always have exactly three distinct singularities.

On the other hand, according to [1, Proposition 5.1], if $\mathbf{D} > 0$, systems (3.1) possess two real and two complex finite singularities. For $\mathbf{D} < 0$, we could either have four real or four complex finite singularities. However, since M_1 is a real singular point for these systems, we conclude that in the case $\mathbf{D} < 0$ we have four real finite distinct singularities.

Thus, since the real singularity M_1 is outside the invariant parabola and all other three finite singularities on the parabola (real or complex) are distinct and furthermore we could not have any invariant line, we arrive at the configuration *Config.* $\mathcal{P}$.1 if $\mathbf{D} < 0$ and *Config.* $\mathcal{P}$.2 if $\mathbf{D} > 0$.

The subcase $\mathbf{D} = 0$. This implies $F_1F_2 = 0$, and for systems (3.1), we calculate:

$$
\xi_1 = -6\zeta_4 F_1 \ \Rightarrow\ F_1 = 0 \ \Leftrightarrow\ \xi_1 = 0.
$$

So we examine two possibilities: $\xi_1 \neq 0$ and $\xi_1 = 0$.

1: The possibility $\xi_1 \neq 0$. Then $F_1 \neq 0$, and therefore the condition $\mathbf{D} = 0$ implies $F_2 = 0$.

We observe that the polynomial F_2 is quadratic with respect to the parameter m, and we calculate

$$
\text{Discrim}\,[F_2, m] = 4(1 - 2g + g^2 - 12n)^3.
$$

Therefore, since the parameters m, n, and g of systems (3.1) must be real, we conclude that the condition $1-2g+g^2-12n\geq 0$ has to be fulfilled. Setting a new parameter v by $1-2g+g^2-12n=v^2\geq 0$, we get $n=\left[(g-1)^2-v^2\right]/12$, and then we calculate

$$F_2=\frac{1}{432}\left[216m-(1-g+v)^2(g-1+2v)\right]\left[216m-(1-g-v)^2(g-1-2v)\right]=0$$

and due to the change $v\mapsto -v$, we may force the first factor to vanish. Then we obtain

$$m=\frac{(1-g+v)^2(g-1+2v)}{216},$$

and considering the expressions for the parameters m and n, we arrive at the two-parameter family of systems

$$\begin{aligned}\dot{x}&=\frac{(1-g+v)^2(g-1+2v)}{216}+\frac{(g-1)^2-v^2}{12}\,x-\frac{1}{2}(1+g)y+gx^2+xy,\\ \dot{y}&=\frac{(1-g+v)^2(g-1+2v)}{108}\,x+\frac{(g-1)^2-v^2}{6}\,y+(g-1)xy+2y^2,\end{aligned}\tag{3.5}$$

possessing the invariant parabola $\Phi(x,y)=x^2-y=0$. We observe that for the above systems, we have the following conditions on the parameters g and v:

$$\begin{aligned}&\zeta_1\zeta_2\zeta_4\mathcal{R}_1\neq 0\ \Leftrightarrow\ g(g-2)(1+g)(3+g)(2+4g-v)(4+8g+v)\neq 0;\\ &\xi_1\neq 0\ \Leftrightarrow\ (g-2)(3+g)(g-1-v)(2+g-v)(2+4g-v)(4+8g+v)^2\\ &\qquad\times(4-2g-2g^2-4v-8gv+v^2)\neq 0;\\ &B_1\neq 0\ \Leftrightarrow\ (g-1-v)(2+g-v)(2+4g-v)(2g-2+v)(1+2g+v)(4+2g+v)\\ &\qquad\times(g-1+2v)(2+g+2v)\neq 0.\end{aligned}\tag{3.6}$$

We determine that systems (3.5) possess three finite singularities $M_i(x_i,y_i)$ $(i=1,2,3)$ with the coordinates

$$\begin{aligned}&x_1=\frac{1-g+v}{6},\ y_1=\frac{(1-g+v)^2}{36};\ \ x_2=\frac{1-g-2v}{6},\ y_2=\frac{(1-g-2v)^2}{36};\\ &x_3=\frac{(1-g+v)(5g^2-4-g+4v+5gv-v^2)}{54g(1+g)},\ y_3=\frac{(1-g+v)^2(g-1+2v)}{108(1+g)}.\end{aligned}\tag{3.7}$$

We calculate

$$\begin{aligned}&\Phi(x_1,y_1)=\Phi(x_2,y_2)=0,\\ &\Phi(x_3,y_3)=\frac{(g-1-v)^2(2+g-v)^2(4-2g-2g^2-4v-8gv+v^2)}{2916g^2(1+g)^2},\end{aligned}$$

and we conclude that the singular points M_1 and M_2 are located on the invariant parabola.

On the other hand, considering the conditions (3.6), we obtain that M_3 will be located on $\Phi(x,y)=0$ if and only if

$$\alpha=4-2g(1+g)-4v-8gv+v^2=0.$$

However, considering (3.6), we conclude that $\alpha\neq 0$ (due to $\xi_1\neq 0$), and hence the singularity M_3 is not located on the invariant parabola in the considered case.

We claim that M_1 is a multiple singularity of systems (3.5). Indeed, applying the corresponding translation, we could place M_1 at the origin of coordinates and arrive at the systems

$$\begin{aligned}\dot{x} &= -\frac{(g-v-1)(4g-v+2)}{18}x - \frac{4g-v+2}{6}y + gx^2 + xy,\\ \dot{y} &= \frac{(g-v-1)^2(2g+v-2)}{54}x + \frac{(g-v-1)(2g+v-2)}{18}y + (g-1)xy + 2y^2,\end{aligned}$$

where $M_0(0,0)$ is a singularity of the above systems corresponding to the singularity M_2.

Considering [1, Lemma 5.2], we calculate the following invariant polynomials: $\mu_4 = \mu_3 = 0$, and

$$\mu_2 = -\frac{1}{324}v(g-v-1)(g-v+2)\big[(2g+v-2)x+6y\big]\big[g(g-v-1)x+(2+4g-v)y\big].$$

Therefore, by [1, Lemma 5.2, statement (ii)], the point M_0 is of multiplicity at least 2. We observe that due to the condition $\xi_1 \neq 0$, we have $\mu_2 = 0$ if and only if $v = 0$. In this case, we calculate

$$\mu_2 = 0, \quad \mu_1 = \frac{1}{27}(g-1)(g+2)\big[g(g-1)x+2(2g+1)y\big] \neq 0,$$

due to $\xi_1 \neq 0$. According to [1, Lemma 5.2, statement (ii)], $M_0(0,0)$ is a double point if $v \neq 0$, and it is a triple one if $v = 0$.

On the other hand, for systems (3.5), we have

$$\xi_2 = \frac{1}{209952}(g-1-v)^2(2+g-v)^2v^2\alpha^2,$$

and due to the conditions (3.6), we conclude that the condition $v = 0$ is equivalent to $\xi_2 = 0$.

Thus, for systems (3.5), we have the configuration *Config.* $\mathcal{P}$.3 if $\xi_2 \neq 0$ and *Config.* $\mathcal{P}$.4 if $\xi_2 = 0$.

2: The possibility $\xi_1 = 0$. This implies $F_1 = 0$, and since the polynomial F_1 is quadratic with respect to the parameter m, we calculate

$$\text{Discrim}\,[F_1, m] = 4g^2(1+g)^2(g^2-4n).$$

Since $g(g+1) \neq 0$ (due to $\zeta_2 \neq 0$), we must have $g^2 - 4n \geq 0$. So we set a new parameter u as follows: $g^2 - 4n = u^2 \geq 0$, and we get $n = (g^2-u^2)/4$. Then, calculation yields

$$F_1 = -\frac{1}{16}\big[8m-(1+g)(g+u)^2\big]\big[8m-(1+g)(g-u)^2\big] = 0,$$

and due to the change $u \mapsto -u$, we may force the second factor to vanish. In this case, we obtain

$$m = \frac{(1+g)(g-u)^2}{8},$$

and considering the expression for the parameters m and n, we arrive at the two-parameter family of systems

$$\begin{aligned}\dot{x} &= \frac{(1+g)(g-u)^2}{8} + \frac{g^2-u^2}{4}x - \frac{1}{2}(1+g)y + gx^2 + xy,\\ \dot{y} &= \frac{(1+g)(g-u)^2}{4}x + \frac{g^2-u^2}{2}y + (g-1)xy + 2y^2,\end{aligned} \tag{3.8}$$

possessing the invariant parabola $\Phi(x,y) = x^2 - y = 0$. We observe that for the above systems, we have the following condition on the parameters g and u:

$$\begin{gathered}\zeta_1\zeta_2\zeta_4\mathcal{R}_1 \neq 0 \;\Leftrightarrow\; (g-2)g(1+g)(3+g)(1+2g+u)(1+5g+5g^2-u-2gu) \neq 0;\\ B_1 \neq 0 \;\Leftrightarrow\; g(1+g)(g-u)(1+g-u)(1+2g-u)(-1+u)(1+u) \neq 0.\end{gathered} \tag{3.9}$$

We determine that systems (3.8) possess three finite singularities $M_i(x_i,y_i)$ $(i=1,2,3)$ with the coordinates

$$\begin{gathered}x_1 = \frac{u-g}{2},\; y_1 = \frac{(u-g)^2}{4};\;\; x_{2,3} = \frac{1}{4}\big(1-u \pm \sqrt{Z_1}\,\big),\\ y_{2,3} = \frac{1}{8}\big[1-2g-2g^2+2gu+u^2 \mp (u-1)\sqrt{Z_1}\,\big],\;\; Z_1 = -4g^2+4g(-1+u)+(1+u)^2.\end{gathered} \tag{3.10}$$

We calculate

$$\Phi(x_1,y_1) = \Phi(x_2,y_2) = \Phi(x_3,y_3) = 0,$$

and therefore all three singularities are located on the invariant parabola.

We point out that M_1 is a multiple singularity of systems (3.8). Indeed, applying the corresponding translation, we could place M_1 at the origin of coordinates and arrive at the systems

$$\begin{aligned}\dot{x} &= -\frac{1}{2}g(g-u)x + \frac{1}{2}(u-2g-1)y + gx^2 + xy,\\ \dot{y} &= \frac{1}{2}g(g-u)^2x + \frac{1}{2}(2g-u+1)(g-u)y + (g-1)xy + 2y^2,\end{aligned}$$

where $M_0(0,0)$ is a singularity of the above systems corresponding to the singularity M_1.

Considering [1], we calculate the invariant polynomials μ_4, μ_3, μ_2, and we obtain $\mu_4 = \mu_3 = 0$, and

$$\mu_2 = \frac{1}{2}g(g+1)(g-u)(g-u+1)\big[g(g-u)x^2 + (2g-1-u)xy + 2y^2\big] \neq 0,$$

due to the conditions (3.9). By [1, Lemma 5.2, statement (ii)], the point M_0 is of multiplicity exactly 2.

On the other hand, it is clear that the singularities M_2 and M_3 could be complex (respectively real; coinciding) if $Z_1 < 0$ (respectively $Z_1 > 0$; $Z_1 = 0$). We observe that for systems (3.8), we have:

$$\xi_2 = g^2(1+g)^2(g-u)^2(1+g-u)^2Z_1,$$

and due to the conditions (3.9), we conclude that the sign of Z_1 is governed by the invariant polynomial ξ_2. So we discuss three cases: $\xi_2 < 0$, $\xi_2 > 0$, and $\xi_2 = 0$.

2.1: *The case* $\xi_2 < 0$. This implies $Z_1 < 0$, and then systems (3.5) possess only one real singular point M_1 (which is double), and evidently we get the configuration *Config.* $\mathcal{P}$.5.

2.2: *The case* $\xi_2 > 0$. Then $Z_1 > 0$, and this implies the existence of three real singularities, and we have to determine the position of the double point with respect to the simple ones. So we calculate

$$(x_3-x_1)(x_2-x_1) = \frac{(g-u)(1+g-u)}{2} \equiv \frac{\alpha_1}{2},\;\; \operatorname{sign}\big((x_3-x_1)(x_2-x_1)\big) = \operatorname{sign}(\alpha_1), \tag{3.11}$$

where $\alpha_1 \neq 0$ due to $B_1 \neq 0$. This means that the singularity M_1 could not coalesce with one of the singularities M_2 or M_3.

On the other hand, for systems (3.5), calculations yield:

$$\xi_3 = \frac{27249129}{2} g^2(1+g)^2\alpha_1^3 Z_1.$$

So, due to the conditions (3.9), we deduce that sign $(\xi_3) =$ sign $(\alpha_1 Z_1)$.

Therefore, in the case $\xi_3 < 0$, the double singular point M_1 is located on the parabola between M_2 and M_3, and we arrive at the configuration *Config.* $\mathcal{P}$.6. If $\xi_3 > 0$, we evidently get the configuration *Config.* $\mathcal{P}$.7.

2.3: *The case* $\xi_2 = 0$. Then $Z_1 = 0$, which implies the coalescence of the singularities M_2 and M_3. Therefore, systems (3.5) possess two double singularities located on the invariant parabola. So we obtain the configuration *Config.* $\mathcal{P}$.8.

It remains to mention that the case $u = 0$ (i.e., when the discriminant of F_1 vanishes) is included in the previous examination because the condition $u \neq 0$ was not necessary. So, in this case, we obtain the same configurations for the corresponding conditions, respectively.

The case $B_1 = 0$**.** Considering (3.2), we observe that the condition $B_1 = 0$ splits into five conditions at the coefficient level. However, due to an affine transformation, we can reduce this number. More precisely, we have the following lemma.

Lemma 3.1. *The condition* $(g+8m+4n)(1+2g+g^2-4m+2n+2gn) = 0$ *for systems* (3.1) *can be transformed into the condition* $m(gn-2m-n) = 0$ *via an affine transformation.*

Proof. Applying to systems (3.1) the transformation

$$x_1 = -x + \frac{1}{2}, \quad y_1 = -x + y + \frac{1}{4},$$

we obtain the systems

$$\begin{aligned}
\dot{x}_1 &= -\frac{1}{8}(g+8m+4n) + \frac{1}{4}(1+2g+4n)x_1 + \frac{g}{2}y_1 - (1+g)x_1^2 + x_1y_1,\\
\dot{y}_1 &= -\frac{1}{4}(g+8m+4n)x_1 + \frac{1}{2}(1+2g+4n)y_1 - (g+2)x_1y_1 + 2y_1^2.
\end{aligned}$$

So, setting the new parameters

$$\begin{aligned}
m_1 &= -\frac{1}{8}(g+8m+4n), \qquad n_1 = \frac{1}{4}(1+2g+4n), \qquad g_1 = -(1+g) \;\Rightarrow\\
m &= -\frac{1}{8}(g_1+8m_1+4n_1), \qquad n = \frac{1}{4}(1+2g_1+4n_1), \qquad g = -(1+g_1),
\end{aligned} \tag{3.12}$$

we obtain the family of systems

$$\dot{x}_1 = m_1 + n_1x_1 - \frac{1+g_1}{2}y_1 + g_1x_1^2 + x_1y_1, \quad \dot{y}_1 = 2m_1x_1 + 2n_1y_1 + (g_1-1)x_1y_1 + 2y_1^2.$$

which has the same form as (3.1).

Then, considering (3.12), calculations yield:

$$g+8m+4n = -8m_1, \quad 1+2g+g^2-4m+2n+2gn = 2(2m_1+n_1-g_1n_1),$$

and this completes the proof of the lemma. □

Thus, by Lemma 3.1, in order to examine the condition $B_1 = 0$, it is sufficient to consider the condition

$$m(gn - 2m - n)(g + 2g^2 + g^3 + 4m + 2n + 2gn) = 0.$$

In order to determine the invariant conditions that distinguish the three possibilities provided by the above equality, for systems (3.1) we calculate:

$$\begin{aligned} \xi_4 &= 21 \cdot 2^6 5^4 m(g + 8m + 4n)\zeta_4, \\ \xi_5 &= -14 \cdot 5^5 (gn - 2m - n)(1 + 2g + g^2 - 4m + 2n + 2gn)\zeta_4. \end{aligned} \tag{3.13}$$

Hence, due to $\zeta_4 \neq 0$, the condition $\xi_4 = 0$ is equivalent to $m(g + 8m + 4n) = 0$ (which implies $B_1 = 0$), whereas the condition $\xi_5 = 0$ is equivalent to $(gn - 2m - n)(1 + 2g + g^2 - 4m + 2n + 2gn) = 0$ (which also implies $B_1 = 0$).

The subcase $\xi_4 \neq 0$. Then $m(g + 8m + 4n) \neq 0$, and we consider two possibilities: $\xi_5 \neq 0$ and $\xi_5 = 0$.

1: The possibility $\xi_5 \neq 0$. In this case, we have $(gn - 2m - n)(1 + 2g + g^2 - 4m + 2n + 2gn) \neq 0$, and therefore the condition $B_1 = 0$ implies $g + 2g^2 + g^3 + 4m + 2n + 2gn = 0$. This yields $m = -(1 + g)(g + g^2 + 2n)/4$, and we get the family of systems

$$\begin{aligned} \dot{x} &= -\frac{1}{4}(1 + g - 2x)(g + g^2 + 2n + 2gx + 2y), \\ \dot{y} &= -\frac{(1 + g)(g + g^2 + 2n)}{2}\, x + 2ny + (g - 1)xy + 2y^2 \end{aligned} \tag{3.14}$$

possessing the invariant line $x = (g + 1)/2$. For these systems, we calculate

$$\begin{aligned} B_2 &= -81g^2(1 + g)^2(g + g^2 + 2n)(1 + 4g + 2g^2 + 4n)(1 + 2g + g^2 + 4n)^2 x^4, \\ \xi_4 &= 13125g(1 + g)(g - 2)(3 + g)(1 + 2g)(g + g^2 + 2n)(1 + 4g + 2g^2 + 4n)(1 + 6g + 5g^2 + 4n), \\ \xi_5 &= -21875(g - 2)g(1 + g)(3 + g)(1 + 2g)(1 + 2g + g^2 + 4n)^2(1 + 6g + 5g^2 + 4n)/16, \end{aligned}$$

and we observe that the condition $\xi_4\xi_5 \neq 0$ implies $B_2 \neq 0$.

Then, by Lemma 2.3, besides the invariant line $x = (g + 1)/2$, systems (3.14) could not possess invariant lines in other directions. However, they could have a parallel invariant line, and by Lemma 2.4, for this to occur it is necessary that $\theta = 0$. This condition implies $(g - 1)(g + 2) = 0$. A straightforward calculation shows that neither of the conditions $g = 1$ nor $g = -2$ could imply the appearance of an additional parallel invariant line.

Next, we determine that systems (3.14) possess four finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with the coordinates

$$\begin{gathered} x_1 = \frac{1 + g}{2},\ y_1 = \frac{(1 + g)^2}{4};\quad x_2 = \frac{1 + g}{2},\ y_2 = -\frac{g + g^2 + 2n}{2};\quad x_{3,4} = \frac{1}{2}\big(-g \pm \sqrt{Z_2}\big), \\ y_{3,4} = \frac{1}{2}\big(-g - 2n \mp g\sqrt{Z_2}\big),\quad Z_2 = -(2g + g^2 + 4n). \end{gathered} \tag{3.15}$$

We determine that the singularities M_1, M_3, and M_4 are located on the invariant parabola. At the same time, M_1 and M_2 are located on the invariant line $x = (g + 1)/2$, and M_1 is the point of intersection of this invariant line with the parabola.

In order to determine the relative position of the singularities M_1 and M_2 on the vertical invariant line, we calculate

$$y_2 - y_1 = -\frac{1+4g+3g^2+4n}{4} \equiv -\frac{\alpha_2}{4} \;\Rightarrow\; \text{sign}\,(y_2-y_1) = -\text{sign}\,(\alpha_2). \tag{3.16}$$

Since the singularities M_3 and M_4 are either complex, real, or coinciding depending on the value of Z_2, we need to distinguish these conditions using affine invariant polynomials. For systems (3.14), we calculate:

$$\begin{aligned} \zeta_4 &= \frac{1}{16}(g-2)(3+g)(1+2g)(1+6g+5g^2+4n) \equiv \frac{1}{16}(g-2)(3+g)(1+2g)\beta_2, \\ \mathbf{D} &= -\frac{3}{4}g^4(1+g)^4\beta_2^2\alpha_2^2 Z_2, \quad \zeta_2 = 4g(1+g), \end{aligned} \tag{3.17}$$

and due to $\zeta_2\zeta_4 \neq 0$, we conclude that $\mathbf{D} = 0$ is equivalent to $\alpha_2 Z_2 = 0$. Moreover, if $\mathbf{D} \neq 0$, then $\text{sign}\,(\mathbf{D}) = -\text{sign}\,(Z_2)$. Thus, we discuss three cases: $\mathbf{D} < 0$, $\mathbf{D} > 0$, and $\mathbf{D} = 0$.

1.1: *The case* $\mathbf{D} < 0$. This implies $Z_2 > 0$, and systems (3.14) possess four real singularities. Clearly, it is necessary to know the position of the real singularities $M_{3,4}$ with respect to M_1, all located on the invariant parabola. We calculate:

$$\begin{gathered} (x_3-x_1)(x_4-x_1) = \frac{\beta_2}{4}, \quad (x_3-x_1)+(x_4-x_1) = -(1+2g), \\ \text{sign}\,\big((x_3-x_1)(x_4-x_1)\big) = \text{sign}\,(\beta_2), \quad \text{sign}\,\big((x_1-x_3)+(x_1-x_4)\big) = -\text{sign}\,(1+2g). \end{gathered}$$

We observe that $\beta_2 \neq 0$ due to the condition $\zeta_4 \neq 0$, and moreover $\alpha_2 \neq 0$ due to $\mathbf{D} \neq 0$.

On the other hand, we need the invariant polynomials that govern the signs of β_2 and α_2. Thus, for systems (3.14), we calculate:

$$\xi_7 = 1174627500\, g^2(1+g)^2(1+2g)^2\alpha_2^2\beta_2 Z_2, \quad \xi_8 = 61822500 g^2(1+g)^2(1+2g)^2\alpha_2\beta_2^2 Z_2.$$

Due to the conditions $\zeta_4 \neq 0$ and $\mathbf{D} < 0$, which imply $g(1+g)(1+2g)\alpha_2\beta_2 \neq 0$ and $Z_2 > 0$ (also ensuring $\xi_7\xi_8 \neq 0$), we have the following relations:

$$\text{sign}\,(\beta_2) = \text{sign}\,(\xi_7), \quad \text{sign}\,(\alpha_2) = \text{sign}\,(\xi_8).$$

Thus, considering the above relations, in the case $\mathbf{D} < 0$ we detect the following configurations:

$$\begin{array}{lll} \xi_7 < 0, \xi_8 < 0 & \Rightarrow & (x_3-x_1)(x_4-x_1) < 0, y_2 > y_1 \;\Rightarrow\; \textit{Config.}\,\mathcal{P}.9; \\ \xi_7 < 0, \xi_8 > 0 & \Rightarrow & (x_3-x_1)(x_4-x_1) < 0, y_2 < y_1 \;\Rightarrow\; \textit{Config.}\,\mathcal{P}.10; \\ \xi_7 > 0, \xi_8 < 0 & \Rightarrow & (x_3-x_1)(x_4-x_1) > 0, y_2 > y_1 \;\Rightarrow\; \textit{Config.}\,\mathcal{P}.11; \\ \xi_7 > 0, \xi_8 > 0 & \Rightarrow & (x_3-x_1)(x_4-x_1) > 0, y_2 < y_1 \;\Rightarrow\; \textit{Config.}\,\mathcal{P}.12. \end{array}$$

1.2: *The case* $\mathbf{D} > 0$. Then $Z_2 < 0$, and we claim that this condition implies $\alpha_2 > 0$. Indeed, supposing the contrary (i.e., $\alpha_2 < 0$), we must have $Z_2 + \alpha_2 < 0$. However, calculations yield:

$$Z_2 + \alpha_2 = -(2g+g^2+4n) + (1+4g+3g^2+4n) = (1+g)^2 + g^2 > 0. \tag{3.18}$$

The contradiction obtained proves our claim.

Therefore, since M_3 and M_4 are complex, we arrive at the configuration *Config.* $\mathcal{P}.13$.

1.3: *The case* $\mathbf{D} = 0$. Considering (3.17), we deduce that, due to $\zeta_2\zeta_4 \neq 0$, the condition $\mathbf{D} = 0$ implies $\alpha_2 Z_2 = 0$.

On the other hand, for systems (3.14), we calculate:

$$\xi_1 = \frac{3}{32} g^2 (1+g)^2 (g-2)(3+g)(1+2g)\alpha_2\beta_2.$$

Thus, due to $\zeta_2\zeta_4 \neq 0$ (i.e., $g(1+g)(g-2)(3+g)(1+2g)\beta_2 \neq 0$), we obtain that the condition $\alpha_2 = 0$ is equivalent to $\xi_1 = 0$. Therefore, we discuss two subcases: $\xi_1 \neq 0$ and $\xi_1 = 0$.

1.3.1: *The subcase* $\xi_1 \neq 0$. In this case, we have $\alpha_2 \neq 0$, and the condition $\mathbf{D} = 0$ implies $Z_2 = 0$. Then M_3 and M_4 coalesce, producing a double point located on the invariant parabola. Considering (3.18), we deduce that the condition $Z_2 = 0$ implies $\alpha_2 > 0$.

Thus, it is not difficult to determine that, in this case, we arrive at the configuration *Config.* $\mathcal{P}.14$.

1.3.2: *The subcase* $\xi_1 = 0$. This implies $\alpha_2 = 0$, and, as we have mentioned earlier (see formulas (3.16)), in this case, we get $y_2 = y_1$, and hence the intersection point M_1 of the invariant line $x = (g+1)/2$ with the parabola becomes a double singularity of systems (3.14). Moreover, the position of the real singularities M_3 and M_4 with respect to M_1 depends on the sign of β_2.

Thus, the condition $\alpha_2 = 0$ implies $n = -(1+g)(1+3g)/4$, and then we obtain

$$\beta_2 = 2g(1+g), \quad \zeta_2 = 4g(1+g) \;\Rightarrow\; \operatorname{sign}(\beta_2) = \operatorname{sign}(\zeta_2).$$

Therefore, in the case $\alpha_2 = 0$ (i.e., $\xi_1 = 0$), we obtain the following two configurations:

$$\begin{array}{lll} \zeta_2 < 0 & \Rightarrow & (x_3 - x_1)(x_4 - x_1) < 0,\ y_2 = y_1 \quad \Rightarrow \textit{ Config. } \mathcal{P}.15; \\ \zeta_2 > 0 & \Rightarrow & (x_3 - x_1)(x_4 - x_1) > 0,\ y_2 = y_1 \quad \Rightarrow \textit{ Config. } \mathcal{P}.16. \end{array}$$

2: The possibility $\xi_5 = 0$. Considering (3.13) and the condition $\zeta_4 \neq 0$, we obtain that the condition $\xi_5 = 0$ implies

$$(gn - 2m - n)(1 + 2g + g^2 - 4m + 2n + 2gn) = 0.$$

On the other hand, according to Lemma 3.1, it is sufficient to examine the condition given by the first factor, because the condition defined by the second factor can be brought to the first one via an affine transformation.

Thus, in what follows, we assume that for systems (3.1), the condition $gn - 2m - n = 0$ holds. Then $m = n(g-1)/2$, and we arrive at the family of systems

$$\dot{x} = \frac{n(g-1)}{2} + nx - \frac{1}{2}(1+g)y + gx^2 + xy, \quad \dot{y} = (n+y)(gx - x + 2y), \tag{3.19}$$

which possess the invariant line $y = -n$ and the invariant parabola $\Phi(x,y) = x^2 - y = 0$. For these systems, we calculate

$$\begin{aligned} B_2 &= -81g^2(1+4n)\left[(1+g)^2 + 4n\right]^2 y^4/2, \\ \xi_4 &= 26250(g-1)g(1+g)(g-2)(3+g)n(1+4n)(1+6g+9g^2+4n), \end{aligned} \tag{3.20}$$

and we consider two cases: $B_2 \neq 0$ and $B_2 = 0$.

2.1: *The case* $B_2 \neq 0$. In this case, by Lemma 2.3, systems (3.19) cannot possess invariant lines in other directions than the invariant line $y = -n$. However, by Lemma 2.4, these systems could possess an invariant line parallel to the existing one if $\theta = -8(g-1)(2+g) = 0$. Thus,

due to $\xi_4 \neq 0$, this condition implies $g = -2$. However, in this case, systems (3.19) do not have any invariant line parallel to $y = -n$.

Next, we determine that systems (3.19) possess the finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with coordinates

$$\begin{gathered} x_1 = \sqrt{-n},\ y_1 = -n;\ \ x_2 = -\sqrt{-n},\ y_2 = -n;\ \ x_3 = \frac{1-g}{2},\ y_3 = \frac{(1-g)^2}{4}; \\ x_4 = -\frac{2n}{1+g},\ y_4 = \frac{n(g-1)}{1+g}. \end{gathered} \tag{3.21}$$

We observe that the singular points M_1, M_2, and M_3 lie on the invariant parabola $\Phi(x, y) = x^2 - y = 0$. Moreover, M_1 and M_2 are the points of intersection between the parabola and the invariant line $y = -n$, and since $n \neq 0$ (due to $\xi_4 \neq 0$), they are either complex (for $n > 0$) or real (for $n < 0$).

On the other hand, for systems (3.19), calculations yield:

$$\mathbf{D} = 48g^4n^3(1 - g^2 + 4n)^2(1 - 2g + g^2 + 4n)^2 \equiv 48g^4n^3\,\alpha_3^2\,\beta_3^2,$$

and it is clear that, in the case $\mathbf{D} \neq 0$, we have $\operatorname{sign}(\mathbf{D}) = \operatorname{sign}(n)$.

To determine the position of the singular point M_4, we calculate

$$\Phi(x_4, y_4) = \frac{n\alpha_3}{(1+g)^2},$$

and since $n \neq 0$ (due to $\xi_4 \neq 0$), we deduce that the singular point M_4 lies on the invariant parabola if and only if $\alpha_3 = 0$.

To examine the configurations of the systems, we consider three subcases: $\mathbf{D} < 0$, $\mathbf{D} > 0$, and $\mathbf{D} = 0$.

2.1.1: *The subcase* $\mathbf{D} < 0$. Then $n < 0$, and the singular points M_1 and M_2 are real. In order to determine the position of the singularity M_3 with respect to the real singularities M_1 and M_2, we calculate

$$\begin{gathered} (x_3 - x_1)(x_3 - x_2) = \frac{1}{4}\left[(1-g)^2 + 4n\right] \equiv \beta_3, \quad (x_3 - x_1) + (x_3 - x_2) = 1 - g; \\ \operatorname{sign}\left((x_3 - x_1)(x_3 - x_2)\right) = \operatorname{sign}(\beta_3), \quad \operatorname{sign}\left((x_3 - x_1) + (x_3 - x_2)\right) = \operatorname{sign}(1 - g). \end{gathered}$$

We observe that $\alpha_3\beta_3 \neq 0$ due to $\mathbf{D} \neq 0$, and we need to determine the invariant polynomials responsible for the signs of β_3 and $g - 1$. Calculations yield:

$$\begin{aligned} \xi_9 &= 22359252960\,g^6(1+g)^2(1+2g+g^2+4n)^2\beta_3, \\ \xi_{10} &= 24814861965\,(g-1)g^2(1+g)^2(1+2g+g^2+4n)^2(1+6g+9g^2+4n)^2/2. \end{aligned} \tag{3.22}$$

Taking into account the condition $\xi_4 B_2 \neq 0$ and from (3.20), we deduce that $\operatorname{sign}(\beta_3) = \operatorname{sign}(\xi_9)$ and $\operatorname{sign}(g - 1) = \operatorname{sign}(\xi_{10})$.

Thus, considering the above relations, in the case $\mathbf{D} < 0$, we arrive at the following configurations:

$$\begin{aligned} \xi_9 < 0 &\ \Rightarrow\ (x_3 - x_1)(x_3 - x_2) < 0 &&\ \Rightarrow\ \textit{Config. } \mathcal{P}.17; \\ \xi_9 > 0,\ \xi_{10} < 0 &\ \Rightarrow\ (x_3 - x_1) > 0,\ (x_3 - x_2) > 0 &&\ \Rightarrow\ \textit{Config. } \mathcal{P}.18; \\ \xi_9 > 0,\ \xi_{10} > 0 &\ \Rightarrow\ (x_3 - x_1) < 0,\ (x_3 - x_2) < 0 &&\ \Rightarrow\ \textit{Config. } \mathcal{P}.19. \end{aligned}$$

2.1.2: *The subcase* $\mathbf{D} > 0$. Then $n > 0$, and the singular points M_1 and M_2 are complex. Therefore, due to the condition $\alpha_3 \neq 0$, we arrive at the configuration *Config.* $\mathcal{P}.20$.

2.1.3: *The subcase* $\mathbf{D} = 0$. Since $n \neq 0$ (due to $\xi_4 \neq 0$), this implies $\alpha_3\,\beta_3 = 0$, and we have to distinguish two cases: $\beta_3 \neq 0$ and $\beta_3 = 0$. From (3.22) we observe that, due to $\xi_4 B_2 \neq 0$, the condition $\xi_9 = 0$ is equivalent to $\beta_3 = 0$.

2.1.3.1: *The possibility* $\xi_9 \neq 0$. Then $\beta_3 \neq 0$, and the condition $\mathbf{D} = 0$ implies $\alpha_3 = 0$, yielding $n = (g^2-1)/4$. Considering (3.21), we observe that in this case the singular point M_4 coalesces with M_3, producing a double singular point on the invariant parabola. Thus, the finite singularities of systems (3.19) have the following coordinates:

$$x_1 = \frac{\sqrt{1-g^2}}{2}, \quad y_1 = \frac{1-g^2}{4}; \quad x_2 = -\frac{\sqrt{1-g^2}}{2}, \quad y_2 = \frac{1-g^2}{4};$$
$$x_3 = x_4 = \frac{1-g}{2}, \quad y_3 = y_4 = \frac{(1-g)^2}{4}.$$

We note that in this case $\beta_3 = 2g(g-1)$, and it is necessary to determine, in an invariant way, the signs of the expressions $1-g^2$ and $g(g-1)$. For systems (3.19) with $n = (g^2-1)/4$, we calculate:

$$\xi_2 = \frac{1}{2}(1-g^2)^3 g^4, \quad \xi_9 = 44718505920(g-1)g^9(1+g)^4.$$

We observe that $\operatorname{sign}(\xi_2) = \operatorname{sign}(1-g^2)$ and $\operatorname{sign}(\xi_9) = \operatorname{sign}(g(g-1))$.

Thus, in the case $\alpha_3 = 0$ which implies $\mathbf{D} = 0$ (and the existence of a double real singularity on the invariant parabola), we obtain the following configurations:

$$\begin{array}{lll} \xi_2 < 0 & \Rightarrow\ M_1 \text{ and } M_2 \text{ are complex} & \Rightarrow\ \textit{Config. } \mathcal{P}.21; \\ \xi_2 > 0,\ \xi_9 < 0 & \Rightarrow\ (x_3-x_1)(x_3-x_2) < 0 & \Rightarrow\ \textit{Config. } \mathcal{P}.22; \\ \xi_2 > 0,\ \xi_9 > 0 & \Rightarrow\ (x_3-x_1) > 0,\ (x_3-x_2) > 0 & \Rightarrow\ \textit{Config. } \mathcal{P}.23. \end{array}$$

2.1.3.2: *The possibility* $\xi_9 = 0$. This implies $\beta_3 = 0$, and hence we get $n = -(g-1)^2/4$. We observe that in this case, considering (3.21), we obtain:

$$x_1 = \frac{1}{2}\sqrt{(g-1)^2}, \quad y_1 = \frac{(g-1)^2}{4}; \quad x_2 = -\frac{1}{2}\sqrt{(g-1)^2}, \quad y_2 = \frac{(g-1)^2}{4};$$
$$x_3 = \frac{1-g}{2}, \quad y_3 = \frac{(g-1)^2}{4}; \quad x_4 = \frac{(g-1)^2}{2(1+g)}, \quad y_4 = \frac{(g-1)^3}{4(1+g)}.$$

We observe that the singular point M_3 either coincides with M_1 or with M_2. Since x_1 is positive and x_2 is negative, we conclude that M_3 coalesces with M_1 if $1-g > 0$, and with M_2 if $1-g < 0$.

On the other hand, for systems (3.19) with $n = -(g-1)^2/4$, we have:

$$\xi_{10} = 12705209326080(g-1)g^6(1+g)^4,$$

and hence we obtain $\operatorname{sign}(\xi_{10}) = \operatorname{sign}(g-1)$. Therefore, it is not difficult to determine that we obtain the configuration *Config.* $\mathcal{P}.24$ if $\xi_{10} < 0$, and *Config.* $\mathcal{P}.25$ if $\xi_{10} > 0$.

2.2: *The case* $B_2 = 0$. Since $\xi_4 \neq 0$ (i.e., $g(1+4n) \neq 0$), considering (3.20), this condition implies $(1+g)^2 + 4n = 0$.

Then we get $n = -(1+g)^2/4$, which leads to the family of systems:

$$\dot{x} = -\frac{1}{8}(1+g-2x)(-1+g^2+4gx+4y), \quad \dot{y} = -\frac{1}{4}(1+2g+g^2-4y)(-x+gx+2y), \tag{3.23}$$

which possess the following three invariant affine lines:

$$1+g-2x = 0, \quad 1+2g+g^2-4y = 0, \quad 1-g^2-4x+4y = 0.$$

For these systems, we have $B_2 = B_3 = 0$, and we see that they possess invariant lines in three distinct directions. However, parallel invariant lines may appear, and by Lemma 2.4, for this to occur, it is necessary that $\theta = 0$. Thus, we discuss two subcases: $\theta \neq 0$ and $\theta = 0$.

2.2.1: *The subcase* $\theta \neq 0$. For the above systems, we calculate the coordinates of the finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$:

$$x_1 = \frac{1+g}{2}, \quad y_1 = \frac{(1+g)^2}{4}; \quad x_2 = -\frac{1+g}{2}, \quad y_2 = \frac{(1+g)^2}{4};$$
$$x_3 = \frac{1-g}{2}, \quad y_3 = \frac{(1-g)^2}{4}; \quad x_4 = \frac{1+g}{2}, \quad y_4 = \frac{1-g^2}{4}.$$

We observe that the singular point M_1 is the intersection point of all three invariant lines, as well as lying on the invariant parabola. Since this point, together with M_4, lies on the vertical invariant line $1 + g - 2x = 0$, the relative positions of these two points are crucial for determining the configurations of systems (3.23). Thus, we calculate:

$$y_4 - y_1 = -\frac{g(g+1)}{2} \quad \Rightarrow \quad \text{sign}\,(y_4 - y_1) = -\text{sign}\,\big(g(g+1)\big).$$

We also point out that the position of the vertical invariant line $x = (g+1)/2$ is important, and we must consider sign $(g+1)$.

On the other hand, for systems (3.23), we calculate: $\zeta_2 = 4g(1+g)$, and then we determine the following configurations:

$$\begin{array}{lll} \zeta_2 < 0 \text{ (i.e., } -1 < g < 0) & \Rightarrow \ x_1 > 0,\ y_4 > y_1 & \Rightarrow \ \textit{Config. } \mathcal{P}.26; \\ \zeta_2 > 0 \text{ and } g < -1 & \Rightarrow \ x_1 < 0,\ y_4 < y_1 & \Rightarrow \ \textit{Config. } \mathcal{P}.27; \\ \zeta_2 > 0 \text{ and } g > 0 & \Rightarrow \ x_1 > 0,\ y_4 < y_1 & \Rightarrow \ \simeq \textit{Config. } \mathcal{P}.27. \end{array}$$

2.2.2: *The subcase* $\theta = 0$. This condition implies $(g-1)(g+2) = 0$.

If $g = 1$, we arrive at the system:

$$\dot{x} = (x-1)(x+y), \quad \dot{y} = 2(y-1)y, \tag{3.24}$$

which possesses four invariant affine lines: $x = 1$, $y = 0$, $y = 1$, and $y = x$. Therefore, it is easy to determine that this system corresponds to the configuration *Config.* $\mathcal{P}.28$.

Assuming $g = -2$, we arrive at the system:

$$\dot{x} = \frac{1}{8}(1+2x)(3-8x+4y), \quad \dot{y} = -\frac{1}{4}(4y-1)(3x-2y),$$

which, via the transformation $x_1 = -x + 1/2$, $y_1 = -x + y + 1/4$, can be brought to the system (3.24), thus also corresponding to configuration *Config.* $\mathcal{P}.28$.

The subcase $\xi_4 = 0$**.** Considering (3.13) and the condition $\zeta_4 \neq 0$, we obtain that the condition $\xi_4 = 0$ implies:

$$m(g + 8m + 4n) = 0.$$

On the other hand, according to Lemma 3.1, it is sufficient to examine the condition $m = 0$ because the condition $g + 8m + 4n = 0$ can be brought to $m = 0$ via an affine transformation.

Thus, setting $m = 0$, we arrive at the family of systems:

$$\dot{x} = nx - \frac{1}{2}(1+g)y + gx^2 + xy, \quad \dot{y} = y(2n - x + gx + 2y), \tag{3.25}$$

which possess the invariant line $y = 0$ and the invariant parabola $\Phi(x, y) = x^2 - y = 0$. It is clear that the invariant line $y = 0$ is tangent to the invariant parabola at the origin.

We determine that for the above systems, the condition $\zeta_1\zeta_2\zeta_4\mathcal{R}_1 \neq 0$ implies:

$$g(1+g)(g-2)(3+g)(1+3g)(1+4g+3g^2+2n) \neq 0. \tag{3.26}$$

For systems (3.25), we calculate:

$$\begin{gathered} B_2 = -\frac{81}{2}(1+g)^2(1+g+2n)(g+g^2+2n)(g+4n)y^4, \\ \theta = -8(g-1)(2+g). \end{gathered} \tag{3.27}$$

We now consider two possibilities: $B_2 \neq 0$ and $B_2 = 0$.

1: *The possibility* $B_2 \neq 0$. Then, besides the invariant line $y = 0$, systems (3.25) cannot possess invariant lines in other directions. However, there could exist an invariant line parallel to $y = 0$, and by Lemma 2.4, a necessary condition for this is $\theta = 0$. Therefore, we discuss two cases: $\theta \neq 0$ and $\theta = 0$.

1.1: *The case* $\theta \neq 0$. The systems (3.25) possess four finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with coordinates:

$$\begin{gathered} x_1 = 0, \quad y_1 = 0; \\ x_2 = -\frac{n}{g}, \quad y_2 = 0; \\ x_{3,4} = \frac{1}{4}\big(1 - g \pm \sqrt{Z_3}\,\big), \quad y_{3,4} = \frac{1}{8}\big[(1-g)^2 - 8n \pm (1-g)\sqrt{Z_3}\,\big], \\ Z_3 = (1-g)^2 - 16n. \end{gathered} \tag{3.28}$$

We observe that $\Phi(x_3, y_3) = \Phi(x_4, y_4) = 0$, meaning that the singular points M_3 and M_4 lie on the invariant parabola. Moreover, the singularity M_2 lies on the invariant line $y = 0$ and coalesces with M_1 if and only if $n = 0$.

The singularities M_3 and M_4 are complex (respectively, real) if $Z_3 < 0$ (respectively, $Z_3 > 0$), and they coincide (producing a multiple singular point) when $Z_3 = 0$.

On the other hand, for systems (3.25), we have:

$$\mathbf{D} = 48(1+g)^4n^6(-1+2g-g^2+16n) = -48(1+g)^4n^6Z_3,$$

and we proceed to discuss three subcases: $\mathbf{D} < 0$, $\mathbf{D} > 0$, and $\mathbf{D} = 0$.

1.1.1: *The subcase* $\mathbf{D} < 0$. Then $Z_3 > 0$, and therefore the finite singularities M_3 and M_4 are real and distinct [1, Proposition 5.1]. To determine their positions on the parabola with respect to the singularity M_1, we calculate:

$$\begin{gathered} (x_3 - x_1)(x_4 - x_1) = n, \quad (x_3 - x_1) + (x_4 - x_1) = (1-g)/2; \\ \operatorname{sign}\big((x_3 - x_1)(x_4 - x_1)\big) = \operatorname{sign}(n), \quad \operatorname{sign}\big((x_3 - x_1) + (x_4 - x_1)\big) = \operatorname{sign}(1-g). \end{gathered} \tag{3.29}$$

We point out that $g - 1 \neq 0$ (due to $\theta \neq 0$), and the sign of $1 - g$ is only relevant when $n > 0$ (i.e., when $(x_3 - x_1)(x_4 - x_1) > 0$).

Furthermore:

$$x_2 - x_1 = -n/g \quad \Rightarrow \quad \operatorname{sign}(x_2 - x_1) = -\operatorname{sign}(gn).$$

For systems (3.25), calculations yield:

$$\xi_{11} = -95982880gn(g-2)^2(1+g)^2(3+g)^2(1+3g)^2(1+4g+3g^2+2n)^2,$$
$$\xi_{28} = 3244620(1+g)^2(3+g)^2(1+3g)^2(1+4g+3g^2+2n)^2(g+4n),$$
$$\xi_{29} = 1700495253(g-1)g(1+g)^2(3+g)(1+3g)(1+4g+3g^2+2n)^2(g+4n)/16.$$

Remark 3.2. We observe that due to the condition (3.26), we have $\xi_{11} \neq 0$, with $\text{sign}\,(\xi_{11}) = -\text{sign}\,(gn)$. If $\xi_{11} < 0$ (i.e., $gn > 0$), then $\text{sign}\,(\xi_{28}) = \text{sign}\,(g+4n)$. Moreover, in the case $g > 0$ and $n > 0$, we also have $\text{sign}\,(\xi_{29}) = \text{sign}\,(g-1)$.

Thus, considering the above relations in the case $\mathbf{D} < 0$, we obtain the following configurations:

$\xi_{11} < 0$, $n < 0$ (then $g < 0$) $\Rightarrow$ $(x_3 - x_1)(x_4 - x_1) < 0$, $x_2 < x_1$ $\Rightarrow$ *Config.* $\mathcal{P}$.29;
$\xi_{11} < 0$, $n > 0$ (then $g > 0$), $g < 1$ $\Rightarrow$ $x_3 > x_1$, $x_4 > x_1$, $x_2 < x_1$ $\Rightarrow$ *Config.* $\mathcal{P}$.30;
$\xi_{11} < 0$, $n > 0$ (then $g > 0$), $g > 1$ $\Rightarrow$ $x_3 < x_1$, $x_4 < x_1$, $x_2 < x_1$ $\Rightarrow$ *Config.* $\mathcal{P}$.31;
$\xi_{11} > 0$, $n < 0$ (then $g > 0$) $\Rightarrow$ $(x_3 - x_1)(x_4 - x_1) < 0$, $x_2 > x_1$ $\Rightarrow$ *Config.* $\mathcal{P}$.32;
$\xi_{11} > 0$, $n > 0$ (then $g < 0$) $\Rightarrow$ $x_3 > x_1$, $x_4 > x_1$, $x_2 > x_1$ $\Rightarrow$ *Config.* $\mathcal{P}$.33.

Taking into account Remark 3.2, we obtain the following invariant conditions:

$\xi_{11} < 0$, $\xi_{28} < 0$ $\Rightarrow$ *Config.* $\mathcal{P}$.29;
$\xi_{11} < 0$, $\xi_{28} > 0$, $\xi_{29} < 0$ $\Rightarrow$ *Config.* $\mathcal{P}$.30;
$\xi_{11} < 0$, $\xi_{28} > 0$, $\xi_{29} > 0$ $\Rightarrow$ *Config.* $\mathcal{P}$.31;
$\xi_{11} > 0$ $\Rightarrow$ *Config.* $\mathcal{P}$.32, or *Config.* $\mathcal{P}$.33.

1.1.2: *The subcase* $\mathbf{D} > 0$. Then $Z_3 < 0$, and hence the finite singularities M_3 and M_4 are complex. This condition also implies $n > 0$, meaning that the singular point $M_2(-n/g, 0)$ cannot coalesce with $M_1(0,0)$. Moreover, its position relative to M_1 depends on the sign of the parameter g.

Since $n > 0$, we have:

$$\text{sign}\,(\xi_{11}) = -\text{sign}\,(gn) = -\text{sign}\,(g).$$

Therefore, we obtain *Config.* $\mathcal{P}$.34 if $\xi_{11} < 0$, and *Config.* $\mathcal{P}$.35 if $\xi_{11} > 0$.

1.1.3: *The subcase* $\mathbf{D} = 0$. Considering (3.26), we deduce that $\mathbf{D} = 0$ implies $nZ_3 = 0$. For systems (3.25), we calculate:

$$\xi_1 = 3(g-2)(1+g)^2(3+g)(1+3g)n^2(1+4g+3g^2+2n)/8.$$

By (3.26), the condition $n = 0$ is equivalent to $\xi_1 = 0$. Thus, we examine two possibilities: $\xi_1 \neq 0$ and $\xi_1 = 0$.

1.1.3.1: *The possibility* $\xi_1 \neq 0$. Then $\mathbf{D} = 0$ implies $Z_3 = 0$. From (3.28), we get $n = (1-g)^2/16 \neq 0$, and thus:

$$x_1 = 0, \quad y_1 = 0; \quad x_2 = -\frac{(1-g)^2}{16g}, \quad y_2 = 0;$$
$$x_3 = x_4 = \frac{1-g}{4}, \quad y_3 = y_4 = \frac{(1-g)^2}{16};$$
$$\text{sign}\,(x_2 - x_1) = -\text{sign}\,(g), \quad \text{sign}\,(x_3 - x_1) = \text{sign}\,(1-g).$$

Therefore, there is a double singular point on the invariant parabola. For the parameter g, the bifurcation values are $g \in \{0, 1\}$.

For systems (3.25) with $n = (1-g)^2/16$ (i.e., $Z_3 = 0$), we compute:

$$\xi_{11} = -\frac{2999465}{32}(g-2)^2(g-1)^2g(1+g)^2(3+g)^2(1+3g)^2(3+5g)^4, \quad \theta = -8(g-1)(2+g),$$
$$\zeta_2 = 4g(1+g), \quad \zeta_4 = (g-2)(3+g)(1+3g)(3+5g)^2/128, \quad \xi_{12} = g(g-1)^3\psi_1(g)/256,$$

where $\psi_1(g) = 1105 + 1774g + 961g^2$. Observing that Discrim $[\psi_1(g), g] = -1100544 < 0$, we note that $\psi_1(g)$ does not vanish for real g.

Considering the condition $\zeta_4\theta \neq 0$, we conclude:

$$\text{sign}\,(\xi_{11}) = -\text{sign}\,(g), \quad \text{sign}\,(\xi_{12}) = \text{sign}\,(g(g-1)).$$

Thus, we determine the following configurations:

$$\begin{array}{lcll} \xi_{12} < 0 & \Rightarrow & x_2 < x_1,\, x_3 > x_1 & \Rightarrow \textit{ Config. } \mathcal{P}.36; \\ \xi_{12} > 0,\, \xi_{11} < 0 & \Rightarrow & x_2 < x_1,\, x_3 > x_1 & \Rightarrow \textit{ Config. } \mathcal{P}.37; \\ \xi_{12} > 0,\, \xi_{11} > 0 & \Rightarrow & x_2 > x_1,\, x_3 > x_1 & \Rightarrow \textit{ Config. } \mathcal{P}.38. \end{array}$$

1.1.3.2: *The possibility* $\xi_1 = 0$. In this case, $n = 0$, and the singular point $M_2(-n/g, 0)$ coalesces with $M_1(0,0)$. Moreover, one of the singularities M_3 or M_4 also coalesces with M_1, resulting in a triple finite singularity at $M_1(0,0)$. There could still remain a distinct simple singularity (M_3 or M_4), whose position depends on sign $(1-g)$ (see (3.29)).

For $n = 0$, systems (3.25) satisfy:

$$\xi_{10} = 24814861965(g-1)g^2(1+g)^6(1+3g)^4/2,$$

so that: sign (ξ_{10}) = sign $(g-1)$. Therefore:

$\xi_{10} < 0 \;\Rightarrow$ *Config.* $\mathcal{P}.39$;
$\xi_{10} > 0 \;\Rightarrow$ *Config.* $\mathcal{P}.40$.

1.2: *The case* $\theta = 0$. This condition implies $(g-1)(g+2) = 0$. For systems (3.25), we calculate:

$$\begin{array}{c} \xi_1 = 3(g-2)(1+g)^2(3+g)(1+3g)n^2(1+4g+3g^2+2n)/8, \\ \xi_5 = -21875(g-1)(1+g)(g-2)(3+g)(1+3g)n(1+g+2n)(1+4g+3g^2+2n)/8. \end{array} \tag{3.30}$$

We now discuss two subcases: $\xi_1 \neq 0$ and $\xi_1 = 0$.

1.2.1: *The subcase* $\xi_1 \neq 0$. This implies $n \neq 0$, and considering (3.26) and $B_2 \neq 0$ (i.e., $1+g+2n \neq 0$), we conclude that the condition $g = 1$ is equivalent to $\xi_5 = 0$. Thus, we analyze two possibilities: $\xi_5 \neq 0$ and $\xi_5 = 0$.

1.2.1.1: *The possibility* $\xi_5 \neq 0$. Then $g - 1 \neq 0$, and the condition $\theta = 0$ implies $g = -2$. Straightforward calculations show that for $g = -2$, the systems (3.25) do not possess any invariant line parallel to $y = 0$.

For $g = -2$, the systems (3.25) yield:

$$\begin{array}{c} \mathbf{D} = 48n^6(16n-9), \\ \xi_{11} = 76786304000n(5+2n)^2, \\ \zeta_4 = 5(5+2n)/4. \end{array}$$

Thus, sign $(\xi_{11}) = \text{sign}\,(n)$, and sign $(\mathbf{D}) = \text{sign}\,(16n-9)$. Moreover, since $n \neq 0$, we conclude that $\mathbf{D} = 0$ corresponds to $16n - 9 = 0$.

Therefore, considering that $g = -2 < 0$ and applying the previous analysis for systems (3.25), we determine the following configurations:

$$\begin{array}{lll} \mathbf{D} < 0, \xi_{11} < 0 & \Rightarrow & \textit{Config.}\ \mathcal{P}.29; \\ \mathbf{D} < 0, \xi_{11} > 0 & \Rightarrow & \textit{Config.}\ \mathcal{P}.33; \\ \mathbf{D} > 0 & \Rightarrow & \textit{Config.}\ \mathcal{P}.35; \\ \mathbf{D} = 0 & \Rightarrow & \textit{Config.}\ \mathcal{P}.38. \end{array}$$

1.2.1.2: *The possibility* $\xi_5 = 0$. Then $g = 1$, leading to the family of systems:

$$\dot{x} = nx - y + x^2 + xy, \quad \dot{y} = 2y(n + y), \tag{3.31}$$

which possess the additional invariant line $y + n = 0$.

From (3.28), we find:

$$\begin{array}{c} x_1 = 0, \quad y_1 = 0; \\ x_2 = -n, \quad y_2 = 0; \\ x_{3,4} = \pm\sqrt{-n}, \quad y_3 = y_4 = -n. \end{array}$$

We observe that the invariant line $y = -n$ intersects the invariant parabola $\Phi(x, y) = x^2 - y = 0$ at two points $M_{3,4}(\pm\sqrt{-n}, -n)$, which are distinct due to $\xi_1 \neq 0$ (i.e., $n \neq 0$). These points are real if $n < 0$ and complex if $n > 0$.

Calculating the invariant $\mathbf{D} = 12288n^7$, we get sign $(\mathbf{D}) = \text{sign}\,(n)$. Therefore:

$\mathbf{D} < 0 \Rightarrow$ *Config.* $\mathcal{P}.41$;
$\mathbf{D} > 0 \Rightarrow$ *Config.* $\mathcal{P}.42$.

1.2.2: *The subcase* $\xi_1 = 0$. This implies $n = 0$, and for systems (3.25) we obtain:

$$B_2 = -81g^2(1+g)^4y^4/2, \quad \xi_9 = 5589813240(g-1)^2g^6(1+g)^6.$$

Therefore, since $B_2 \neq 0$, we conclude that the condition $\xi_9 = 0$ is equivalent to $g - 1 = 0$. Thus, we discuss two cases: $\xi_9 \neq 0$ and $\xi_9 = 0$.

1.2.2.1: *The case* $\xi_9 \neq 0$. Then, $\theta = 0$ implies $g = -2$, and we obtain the system:

$$\dot{x} = \frac{y}{2} - 2x^2 + xy, \quad \dot{y} = -y(3y - 2x).$$

This system belongs to the family (3.25) with $n = 0$ (i.e., $\xi_1 = 0$) and $g = -2$. As previously shown (see point ***1.1.3.2*** on page 41), in the case $n = 0$, the singular point $M_2(-n/g, 0)$ coalesces with $M_1(0,0)$. Moreover, one of the singular points M_3 or M_4 also coalesces with $M_1(0,0)$, yielding a triple finite singularity at $M_1(0,0)$.

On the other hand, since sign $(\xi_{10}) = \text{sign}\,(g-1)$, for $g = -2$ we get $\xi_{10} < 0$. Therefore, the system has the configuration *Config.* $\mathcal{P}.39$.

1.2.2.2: *The case* $\xi_9 = 0$. Then $g = 1$, and we obtain the systems (3.31). For $n = 0$, the invariant line $y = -n$ coalesces with $y = 0$, producing a double invariant line. Moreover, all finite singular points coalesce, generating a quadruple singularity at $M_1(0,0)$. As a result, the system has the configuration *Config.* $\mathcal{P}.43$.

2: *The possibility* $B_2 = 0$. We first make a remark.

Remark 3.3. The condition $B_2 = 0$ implies $n \neq 0$ for systems (3.25). Indeed, in the case $n = 0$, for systems (3.25), we obtain:

$$B_2 = -81g^2(1+g)^4y^4/2 \neq 0$$

due to the condition $\zeta_2 \neq 0$ (i.e., $g(g+1) \neq 0$).

Thus, $n \neq 0$, and since $g+1 \neq 0$, considering (3.27), we get the condition:

$$(1+g+2n)(g+g^2+2n)(g+4n) = 0.$$

Considering (3.30), we examine two cases: $\xi_5 \neq 0$ and $\xi_5 = 0$.

2.1: *The case* $\xi_5 \neq 0$. Then, by (3.30), we get $1+g+2n \neq 0$, and hence the condition $B_2 = 0$ implies: $(g+g^2+2n)(g+4n) = 0$.

On the other hand, for systems (3.25), we calculate:

$$\xi_{13} = 27(1+g)^2(3+g)(1+3g)n^2(g+4n)/4,$$

and considering Remark 3.3 and the condition (3.26), we conclude that $\xi_{13} = 0$ is equivalent to $g+4n = 0$.

2.1.1: *The subcase* $\xi_{13} \neq 0$. Then $g+4n \neq 0$, and therefore $B_2 = 0$ implies $g+g^2+2n = 0$. In this case, we get $n = -g(g+1)/2$, and we arrive at the following family of systems:

$$\dot{x} = (2x-1-g)(gx+y)/2, \quad \dot{y} = -y(g+g^2+x-gx-2y), \tag{3.32}$$

which possess the invariant lines $y = 0$ and $x = (g+1)/2$.

Considering Lemma 2.3, for these systems we calculate:

$$B_3 = -3(g-1)g(1+g)^2(1+2g)x^2y^2/4, \quad \theta = -8(g-1)(g+2),$$
$$\xi_5 = -21875(g-2)(g-1)^2g(1+g)^4(3+g)(1+2g)(1+3g)/16.$$

We observe that $B_3 \neq 0$ due to $\xi_5 \neq 0$, and hence by Lemma 2.3, the above systems cannot have any invariant line in the third direction.

However, according to Lemma 2.4, we could have parallel invariant lines if $\theta = 0$. Due to $B_3 \neq 0$ (i.e., $g-1 \neq 0$), the condition $\theta = 0$ is equivalent to $g+2 = 0$. It is straightforward to check that for $g = -2$, systems (3.32) do not have any invariant line parallel to $y = 0$ or to $x = (g+1)/2$.

The systems (3.32) possess the following finite singularities $M_i(x_i, y_i)$, $(i = 1,2,3,4)$, with coordinates:

$$x_1 = 0, \quad y_1 = 0;\ x_2 = \frac{1+g}{2}, \quad y_2 = 0;\ x_3 = -g, \quad y_3 = g^2;\ x_4 = \frac{1+g}{2}, \quad y_4 = \frac{(1+g)^2}{4}.$$

We observe that the invariant line $x = (g+1)/2$ intersects the invariant parabola at point M_4 and the invariant line $y = 0$ at singularity M_2. Furthermore, the invariant line $y = 0$ is tangent to the parabola at M_1.

To determine the relative positions of the line $x = (g+1)/2$ and the singularities, we calculate:

$$x_2 - x_1 = \frac{1+g}{2},\ x_3 - x_1 = -g,\ x_3 - x_4 = -\frac{1+3g}{2},$$
$$\operatorname{sign}(x_2 - x_1) = \operatorname{sign}(1+g),\ \operatorname{sign}(x_3 - x_1) = -\operatorname{sign}(g),\ \operatorname{sign}(x_3 - x_4) = -\operatorname{sign}(1+3g).$$

Thus, for the parameter g, we have the following possible bifurcation values: $g \in \{-1, -1/3, 0\}$.

On the other hand, for systems (3.32), we calculate:

$$\zeta_2 = 4g(g+1), \quad \xi_7 = 1174627500g^4(1+g)^7(1+2g)^2(1+3g),$$
$$\xi_{11} = 47991440(g-2)^2g^2(1+g)^5(3+g)^2(1+2g)^2(1+3g)^2$$

and we observe that:

$$\text{sign}\,(\zeta_2) = \text{sign}\,(g(g+1)), \quad \text{sign}\,(\xi_7) = \text{sign}\,((g+1)(1+3g)), \quad \text{sign}\,(\xi_{11}) = \text{sign}\,(g+1).$$

Moreover, in the case $\zeta_2 < 0$, we have $-1 < g < 0$ (i.e., $g+1 > 0$), and then:

$$\text{sign}\,(\xi_7) = \text{sign}\,(1+3g).$$

Thus, considering the above relations, we obtain the following configurations:

$\zeta_2 < 0, \xi_7 < 0$ (i.e., $-1 < g < -1/3$) $\Rightarrow$ $x_2 > x_1, x_3 > x_1, x_3 > x_4 \Rightarrow$ *Config.* $\mathcal{P}.44$;
$\zeta_2 < 0, \xi_7 > 0$ (i.e., $-1/3 < g < 0$) $\Rightarrow$ $x_2 > x_1, x_1 < x_3 < x_4 \Rightarrow$ *Config.* $\mathcal{P}.45$;
$\zeta_2 > 0, \xi_{11} < 0$ (i.e., $g < -1$) $\Rightarrow$ $x_2 < x_1, x_3 > x_1 \Rightarrow$ *Config.* $\mathcal{P}.46$;
$\zeta_2 > 0, \xi_{11} > 0$ (i.e., $g > 0$) $\Rightarrow$ $x_2 > x_1, x_3 < x_1 \Rightarrow$ *Config.* $\mathcal{P}.47$.

2.1.2: *The subcase* $\xi_{13} = 0$. This implies $g + 4n = 0$ (i.e., $n = -g/4$) and we arrive at the family of systems

$$\dot{x} = -g(1+g)x/2 - (1+g)y/2 + gx^2 + xy, \quad \dot{y} = -y(g + g^2 + x - gx - 2y), \tag{3.33}$$

possessing the invariant lines $y = 0$ and $y = x - 1/4$. For these systems we have

$$\xi_5 = 21875(g-2)g(1+g)(g-1)(2+g)(3+g)(1+2g)(1+3g)(2+3g)/128,$$
$$B_3 = 3g(1+g)(1+2g)(x-y)^2y^2/8, \quad \theta = -8(g-1)(2+g),$$

and since $\xi_5 \neq 0$, we obtain $B_3\theta \neq 0$. So, by Lemmas 2.3 and 2.4, we conclude that the above systems could not have a third invariant line.

The systems (3.33) possess the finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with coordinates

$$x_1 = 0,\ y_1 = 0; \quad x_2 = 1/4,\ y_2 = 0; \quad x_3 = 1/2,\ y_3 = 1/4; \quad x_4 = -g/2,\ y_4 = g^2/4;$$
$$\text{sign}\,(x_4 - x_1) = -\text{sign}\,(g), \quad x_4 - x_3 = -(g+1)/2 \ \Rightarrow\ \text{sign}\,(x_4 - x_3) = -\text{sign}\,(g+1).$$

It could be checked directly that the invariant line $y = x - 1/4$ is tangent to the invariant parabola at the singular point $M_3(1/2, 1/4)$. Therefore, considering the above relations, we obtain the following configurations:

$\zeta_2 < 0$ (i.e., $-1 < g < 0$) $\Rightarrow$ $x_4 > x_1, x_4 < x_3$ $\Rightarrow$ *Config.* $\mathcal{P}.48$;
$\zeta_2 > 0$ and $g < -1$ $\Rightarrow$ $x_4 > x_1, x_4 > x_3$ $\Rightarrow$ *Config.* $\mathcal{P}.49$;
$\zeta_2 > 0$ and $g > 0$ $\Rightarrow$ $x_4 < x_1, x_4 < x_3$ $\Rightarrow$ $\simeq$ *Config.* $\mathcal{P}.49$.

2.2: *The case* $\xi_5 = 0$. Considering (3.30), the conditions (3.26) and Remark 3.3 imply $(g-1)(1+g+2n) = 0$, and we examine two subcases: $\theta \neq 0$ and $\theta = 0$.

2.2.1: *The subcase* $\theta \neq 0$. Then $g - 1 \neq 0$, and we get $1 + g + 2n = 0$. Therefore, $n = -(1+g)/2 \neq 0$, and we arrive at the family of systems

$$\dot{x} = -(1+g)(x+y)/2 + gx^2 + xy, \quad \dot{y} = -y(1 + g + x - gx - 2y), \tag{3.34}$$

possessing the invariant lines $y = 0$ and $y = x$, and the finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with the coordinates:

$$x_1 = 0, \quad y_1 = 0; \quad x_2 = \frac{1+g}{2g}, \quad y_2 = 0; \quad x_3 = 1, \quad y_3 = 1; \quad x_4 = -\frac{1+g}{2}, \quad y_4 = \frac{(1+g)^2}{4}.$$

On the other hand, considering Lemma 2.3, we calculate B_3 and we have:

$$B_3 = 3(g-1)(1+g)^2(x-y)^2y^2/4 \neq 0,$$

due to the conditions (3.26) and $\theta \neq 0$. Then, by Lemma 2.3, we could not have any invariant line in the third direction. Moreover, by Lemma 2.4, we could not have parallel invariant lines due to $\theta \neq 0$.

Next, considering the coordinates of the finite singularities of these systems, it follows immediately:

$$\begin{gathered}\operatorname{sign}(x_4 - x_1) = -\operatorname{sign}(1+g), \quad \operatorname{sign}(x_2 - x_1) = \operatorname{sign}\big(g(1+g)\big), \\ x_4 - x_3 = -(g+3)/2 \;\Rightarrow\; \operatorname{sign}(x_4 - x_3) = -\operatorname{sign}(g+3).\end{gathered}$$

We remark that $g(g+1)(g+3) \neq 0$ due to the condition (3.26), and hence for the parameter g we have the following possible bifurcation values: $g \in \{-3, -1, 0\}$.

On the other hand, for systems (3.34), we calculate:

$$\begin{gathered}\zeta_2 = 4g(1+g), \quad \xi_9 = 5589813240(g-1)^2g^2(1+g)^9(3+g), \\ \xi_{10} = -223333757685(g-1)^2g^2(1+g)^6(2+g)(1+3g)^2/2,\end{gathered}$$

and hence we have

$$\operatorname{sign}(\zeta_2) = \operatorname{sign}\big(g(1+g)\big), \quad \operatorname{sign}(\xi_9) = \operatorname{sign}\big((1+g)(3+g)\big), \quad \operatorname{sign}(\xi_{10}) = -\operatorname{sign}(2+g).$$

Remark 3.4. We observe that the conditions $\zeta_2 > 0$ and $\xi_9 > 0$ imply either $g > 0$ or $g < -3$. In order to distinguish these two possibilities, we use the invariant ξ_{10} even though this invariant does not vanish in the bifurcation values of g.

Considering the above remark, we arrive at the following configurations:

$\zeta_2 < 0$ (i.e., $-1 < g < 0$)	$\Rightarrow$ $x_2 < x_1$, $x_4 < x_1$	$\Rightarrow$ *Config.* $\mathcal{P}.50$;
$\zeta_2 > 0$, $\xi_9 < 0$ (i.e., $-3 < g < -1$)	$\Rightarrow$ $x_2 > x_1$, $x_1 < x_4 < x_3$	$\Rightarrow$ *Config.* $\mathcal{P}.51$;
$\zeta_2 > 0$, $\xi_9 > 0$, $\xi_{10} < 0$ (i.e., $g > 0$)	$\Rightarrow$ $x_2 > x_1$, $x_3 < x_1$	$\Rightarrow$ *Config.* $\mathcal{P}.52$;
$\zeta_2 > 0$, $\xi_9 > 0$, $\xi_{10} > 0$ (i.e., $g < -3$)	$\Rightarrow$ $x_2 > x_1$, $x_4 > x_3$	$\Rightarrow$ *Config.* $\mathcal{P}.53$.

2.2.2: *The subcase* $\theta = 0$. This implies $(g-1)(g+2) = 0$, and we discuss two possibilities: $B_3 \neq 0$ and $B_3 = 0$.

2.2.2.1: *The possibility* $B_3 \neq 0$. We claim that in this case we get the same configuration either if $g = 1$ or if $g = -2$.

Indeed, assume first $g = -2$. Then, calculations yield

$$\begin{gathered}\xi_5 = -328125\,n(2n-1)(5+2n)/2, \quad B_2 = -162(1+n)(2n-1)^2y^4, \\ B_3 = 3y^2\left[n(4n-5)x^2 + 2(1+n)xy - (1+n)y^2\right]/2,\end{gathered} \tag{3.35}$$

and the condition $\xi_5 = B_2 = 0$ gives us $n = 1/2$. This leads to the system

$$\dot{x} = (x+y)/2 - 2x^2 + xy, \quad \dot{y} = y(1 - 3x + 2y), \tag{3.36}$$

possessing three invariant affine lines: $y = 0$, $y = x$ and $y = x - 1/4$. Then, this system has the configuration equivalent to *Config.* $\mathcal{P}.54$.

Suppose now $g = 1$. Then, we have

$$\xi_5 = 0, \quad B_2 = -648(1+n)^2(1+4n)y^4, \quad B_3 = -3(1+n)y^2\left(4nx^2+2xy-y^2\right),$$

and due to $B_3 \neq 0$, the condition $B_2 = 0$ implies $n = -1/4$. In this case, we arrive at the system

$$\dot{x} = -x/4 - y + x^2 + xy, \quad \dot{y} = y(4y-1)/2,$$

which via the affine transformation $x_1 = -x + 1/2, \quad y_1 = -x + y + 1/4$ could be brought to system (3.36). Thus, our claim is proved and we get the configuration *Config.* $\mathcal{P}.54$.

2.2.2.2: *The possibility* $B_3 = 0$. Considering (3.35), we conclude that the condition $g = -2$ implies $B_3 \neq 0$, and hence the condition $\theta = 0$ gives us $g = 1$. In this case, we arrive at the system

$$\dot{x} = (x-1)(x+y), \quad \dot{y} = 2(y-1)y,$$

possessing four invariant affine lines: $x = 1$, $y = 0$, $y = 1$ and $y = x$. Therefore, it is easy to determine that this system possesses the configuration equivalent to *Config.* $\mathcal{P}.28$.

3.1.2 The statement $(\mathcal{A}_2^*)$

According to the statement $(\mathcal{A}_2^*)$ of Proposition 2.7*, for systems (3.1) the condition $\zeta_4 = 0$ must hold. Considering (3.2), we obtain

$$(g-2)(3+g)(1+7g+15g^2+9g^3-4m+2n+6gn) = 0,$$

and since $(g-2)(3+g) \neq 0$ (due to $\zeta_1 \neq 0$), we get

$$m = \frac{1}{4}(1+3g)(1+4g+3g^2+2n).$$

Then, we arrive at the two-parameter family of systems

$$\begin{aligned} \dot{x} &= \frac{1}{4}(1+3g)(1+4g+3g^2+2n) + nx - \frac{1}{2}(1+g)y + gx^2 + xy, \\ \dot{y} &= \frac{1}{2}(1+3g)(1+4g+3g^2+2n)x + 2ny + (g-1)xy + 2y^2 \end{aligned} \tag{3.37}$$

possessing the following two invariant parabolas: $\Phi_1(x,y) = x^2 - y = 0$ and

$$\begin{aligned} \Phi_2(x,y) = &-(1+4g+3g^2+2n)(1+4g+3g^2+4n) + 2(1+g)(1+4g+3g^2+4n)x \\ &+ 4g(1+g)x^2 - 2(1+6g+5g^2+4n)y = 0. \end{aligned} \tag{3.38}$$

Following the statement $(\mathcal{A}_2^*)$, for the above systems we calculate

$$\begin{aligned} \zeta_1 &= 2(g-2)(3+g), \quad \zeta_2 = 4g(1+g), \quad \zeta_4 = 0, \\ \zeta_5 &= 19(g-2)(3+g)(1+4g+3g^2+4n)^2/4, \\ \mathcal{R}_2 &= -(g-2)(3+g)(8+27g+27g^2)(1+6g+5g^2+4n)/16, \\ B_1 &= g(1+g)(1+2g)(1+3g)(2+3g)(1+4g+3g^2+2n)(1+6g+5g^2+4n) \\ &\quad \times (1+6g+6g^2+4n)(1+6g+9g^2+4n)(5+14g+9g^2+4n)/32. \end{aligned} \tag{3.39}$$

According to Lemma 2.3, for the existence of an invariant line of systems (3.37), the condition $B_1 = 0$ is necessary.

The case $B_1 \neq 0$**.** Then we could not have any invariant line. The systems (3.37) possess four finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with the coordinates

$$\begin{aligned} x_1 &= -\frac{1+3g}{2},\ y_1 = \frac{(1+3g)^2}{4}; \quad x_2 = -\frac{(1+g)\,(1+3g)^2 + 4(1+2g)\,n}{2g(1+g)}, \\ y_2 &= \frac{(1+3g)\,(1+4g+3g^2+2n)}{2(1+g)}; \quad x_{3,4} = \frac{1}{2}\big(1+g \pm \sqrt{Z_4}\,\big), \\ y_{3,4} &= -\frac{1}{2}\big(2g+2g^2+2n \mp (g+1)\sqrt{Z_4}\,\big), \quad Z_4 = -(1+6g+5g^2+4n). \end{aligned} \tag{3.40}$$

In order to determine the position of the finite singularities with respect to the parabolas $\Phi_1(x, y) = 0$ and $\Phi_2(x, y) = 0$, we calculate

$$\Phi_1(x_1, y_1) = \Phi_1(x_3, y_3) = \Phi_1(x_4, y_4) = 0; \quad \Phi_2(x_2, y_2) = \Phi_2(x_3, y_3) = \Phi_2(x_4, y_4) = 0. \tag{3.41}$$

Therefore, the singularities M_3 and M_4 are the finite intersection points of these two invariant parabolas. We observe that the points of intersection of the invariant parabolas are complex if $Z_4 < 0$ and they are real if $Z_4 > 0$.

On the other hand, for systems (3.37) we calculate:

$$\mathbf{D} = -3Z_4(1+4g+3g^2+4n)^2\,\alpha_4^2\,\beta_4^2/4, \tag{3.42}$$

where

$$\alpha_4 = 5+22g+21g^2+4n, \quad \beta_4 = (1+g)(1+3g)(1+6g+7g^2) + 4(1+2g)^2 n. \tag{3.43}$$

So if $\mathbf{D} \neq 0$, then $\operatorname{sign}(\mathbf{D}) = -\operatorname{sign}(Z_4)$ and we discuss three possibilities: $\mathbf{D} < 0$, $\mathbf{D} > 0$ and $\mathbf{D} = 0$.

1: *The possibility* $\mathbf{D} < 0$. Then $Z_4 > 0$ and systems (3.37) possess four real singularities and it is necessary to know the positions of the singularities $M_{3,4}$ with respect to M_1 and M_2. We calculate

$$\begin{aligned} (x_1-x_3)(x_1-x_4) &= \frac{\alpha_4}{4}, \quad (x_1-x_3)+(x_1-x_4) = -2(1+2g), \\ (x_2-x_3)(x_2-x_4) &= -\frac{Z_4\,\beta_4}{4g^2(1+g)^2}, \quad (x_2-x_3)+(x_2-x_4) = -\frac{(1+2g)\,Z_4}{g(1+g)}. \end{aligned}$$

Therefore, considering the condition $Z_4 > 0$, we obtain

$$\begin{gathered} \operatorname{sign}\big((x_1-x_3)(x_1-x_4)\big) = \operatorname{sign}(\alpha_4), \quad \operatorname{sign}\big((x_1-x_3)+(x_1-x_4)\big) = -\operatorname{sign}(1+2g) \quad \text{if } \alpha_4 > 0; \\ \operatorname{sign}\big((x_2-x_3)(x_2-x_4)\big) = -\operatorname{sign}(\beta_4), \\ \operatorname{sign}\big((x_2-x_3)+(x_2-x_4)\big) = -\operatorname{sign}\big(g(1+g)(1+2g)\big) \quad \text{if } \beta_4 < 0, \end{gathered}$$

where $1+2g \neq 0$ due to $B_1 \neq 0$.

We need invariant polynomials governing the signs of α_4 and β_4. For systems (3.37), we calculate:

$$\xi_{14} = 1235\alpha_4\beta_4/2, \quad \xi_{30} = 1235\big[Z_4\,\beta_4 - g^2(1+g)^2\,\alpha_4\big]/4, \quad \zeta_2 = 4g(1+g),$$

and we have

$$\operatorname{sign}(\xi_{14}) = \operatorname{sign}(\alpha_4\beta_4), \quad \operatorname{sign}(\zeta_2) = \operatorname{sign}\big(g(1+g)\big).$$

Moreover, in the case $\xi_{14} < 0$ (i.e. $\alpha_4\beta_4 < 0$) and $\mathbf{D} < 0$ (i.e. $Z_4 > 0$), we obtain

$$\operatorname{sign}(\xi_{30}) = \operatorname{sign}\left(Z_4\beta_4 - g^2(1+g)^2\alpha_4\right) = \operatorname{sign}(\beta_4).$$

On the other hand, considering the form of the invariant parabola $\Phi_2(x,y) = 0$, we have

$$\begin{aligned} y = & -\frac{1}{Z_4}\left[(1+g)(1+4g+3g^2+4n)x - \frac{1}{2}(1+4g+3g^2+2n)(1+4g+3g^2+4n)\right] \\ & -\frac{2g(1+g)}{Z_4}x^2. \end{aligned} \tag{3.44}$$

Therefore, since $Z_4 > 0$, we deduce that the invariant parabolas $\Phi_1(x,y) = 0$ and $\Phi_2(x,y) = 0$ have the same point at infinity on the Poincaré disk if $\zeta_2 < 0$, and opposite points at infinity if $\zeta_2 > 0$. So we consider these two cases separately.

1.1: *The case* $\zeta_2 < 0$. Then $g(g+1) < 0$ and considering the above relations, in this case we obtain the following configurations:

$\xi_{14} < 0$, $\beta_4 < 0$, $2g+1 < 0$ (i.e. $\beta_4 < 0$, $\alpha_4 > 0$, $-1 < g < -1/2$) $\Rightarrow$
$x_2 - x_3 > 0$, $x_2 - x_4 > 0$, $x_1 - x_3 > 0$, $x_1 - x_4 > 0$ $\Rightarrow$ *Config.* $\mathcal{P}$*.55*;
$\xi_{14} < 0$, $\beta_4 < 0$, $2g+1 > 0$ (i.e. $\beta_4 < 0$, $\alpha_4 > 0$, $-1/2 < g < 0$) $\Rightarrow$
$x_2 - x_3 < 0$, $x_2 - x_4 < 0$, $x_1 - x_3 < 0$, $x_1 - x_4 < 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.55*;
$\xi_{14} < 0$, $\beta_4 > 0$ (i.e. $\beta_4 > 0$, $\alpha_4 < 0$, $-1 < g < 0$) $\Rightarrow$
$(x_2 - x_3)(x_2 - x_4) < 0$, $(x_1 - x_3)(x_1 - x_4) < 0$ $\Rightarrow$ *Config.* $\mathcal{P}$*.56*;
$\xi_{14} > 0$, $\beta_4 < 0$, $2g+1 < 0$ (i.e. $\beta_4 < 0$, $\alpha_4 < 0$, $-1 < g < -1/2$) $\Rightarrow$
$x_2 - x_3 > 0$, $x_2 - x_4 > 0$, $(x_1 - x_3)(x_1 - x_4) < 0$ $\Rightarrow$ *Config.* $\mathcal{P}$*.57*;
$\xi_{14} > 0$, $\beta_4 < 0$, $2g+1 > 0$ (i.e. $\beta_4 < 0$, $\alpha_4 < 0$, $-1/2 < g < 0$) $\Rightarrow$
$x_2 - x_3 < 0$, $x_2 - x_4 < 0$, $(x_1 - x_3)(x_1 - x_4) < 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.57*;
$\xi_{14} > 0$, $\beta_4 > 0$, $2g+1 < 0$ (i.e. $\beta_4 > 0$, $\alpha_4 > 0$, $-1 < g < -1/2$) $\Rightarrow$
$(x_2 - x_3)(x_2 - x_4) < 0$, $x_1 - x_3 > 0$, $x_1 - x_4 > 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.57*;
$\xi_{14} > 0$, $\beta_4 > 0$, $2g+1 > 0$ (i.e. $\beta_4 > 0$, $\alpha_4 > 0$, $-1/2 < g < 0$) $\Rightarrow$
$(x_2 - x_3)(x_2 - x_4) < 0$, $x_1 - x_3 < 0$, $x_1 - x_4 < 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.57*.

1.2: *The case* $\zeta_2 > 0$. Then $g(g+1) > 0$ and we obtain the following configurations:

$\xi_{14} < 0$, $\beta_4 < 0$, $2g+1 < 0$ (i.e. $\beta_4 < 0$, $\alpha_4 > 0$, $g < -1$) $\Rightarrow$
$x_2 - x_3 < 0$, $x_2 - x_4 < 0$, $x_1 - x_3 > 0$, $x_1 - x_4 > 0$ $\Rightarrow$ *Config.* $\mathcal{P}$*.58*;
$\xi_{14} < 0$, $\beta_4 < 0$, $2g+1 > 0$ (i.e. $\beta_4 < 0$, $\alpha_4 > 0$, $g > 0$) $\Rightarrow$
$x_2 - x_3 > 0$, $x_2 - x_4 > 0$,$x_1 - x_3 < 0$, $x_1 - x_4 < 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.58*;
$\xi_{14} > 0$, $\beta_4 < 0$, $2g+1 < 0$ (i.e. $\beta_4 < 0$, $\alpha_4 < 0$, $g < -1$) $\Rightarrow$
$x_2 - x_3 < 0$, $x_2 - x_4 < 0$, $(x_1 - x_3)(x_1 - x_4) < 0$ $\Rightarrow$ *Config.* $\mathcal{P}$*.59*;
$\xi_{14} > 0$, $\beta_4 < 0$, $2g+1 > 0$ (i.e. $\beta_4 < 0$, $\alpha_4 < 0$, $g > 0$) $\Rightarrow$
$x_2 - x_3 > 0$, $x_2 - x_4 > 0$, $(x_1 - x_3)(x_1 - x_4) < 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.59*;
$\xi_{14} > 0$, $\beta_4 > 0$, $2g+1 < 0$ (i.e. $\beta_4 > 0$, $\alpha_4 > 0$, $g < -1$) $\Rightarrow$
$(x_2 - x_3)(x_2 - x_4) < 0$, $x_1 - x_3 > 0$, $x_1 - x_4 > 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.59*;
$\xi_{14} > 0$, $\beta_4 > 0$, $2g+1 > 0$ (i.e. $\beta_4 > 0$, $\alpha_4 > 0$, $g < -1$) $\Rightarrow$
$(x_2 - x_3)(x_2 - x_4) < 0$, $x_1 - x_3 < 0$, $x_1 - x_4 < 0$ $\Rightarrow \simeq$ *Config.* $\mathcal{P}$*.59*.

Applying the Mathematica function "FindInstance" (or "Reduce") we detect that the conditions $\mathbf{D} < 0$, $\zeta_2 > 0$, $\xi_{14} < 0$, and $\beta_4 > 0$ (i.e. $Z_4 > 0$, $g(g+1) > 0$, $\alpha_4 < 0$, and $\beta_4 > 0$) are incompatible.

We observe that in both cases (i.e. $\zeta_2 < 0$ and $\zeta_2 > 0$) the configurations do not depend on the sign $(1+2g)$. As a result we obtain the following lemma.

Lemma 3.5. *Assume that for the systems* (3.37) *the condition* $\mathbf{D} < 0$ *holds. Then, these systems exhibit the following configurations if and only if the respective conditions are satisfied:*

$$\begin{array}{ll} \zeta_2 < 0,\ \xi_{14} < 0,\ \xi_{30} < 0 & \Leftrightarrow \textit{ Config. } \mathcal{P}.55; \\ \zeta_2 < 0,\ \xi_{14} < 0,\ \xi_{30} > 0 & \Leftrightarrow \textit{ Config. } \mathcal{P}.56; \\ \zeta_2 < 0,\ \xi_{14} > 0 & \Leftrightarrow \textit{ Config. } \mathcal{P}.57; \\ \zeta_2 > 0,\ \xi_{14} < 0 & \Leftrightarrow \textit{ Config. } \mathcal{P}.58; \\ \zeta_2 > 0,\ \xi_{14} > 0 & \Leftrightarrow \textit{ Config. } \mathcal{P}.59. \end{array}$$

2: *The possibility* $\mathbf{D} > 0$. Then $Z_4 < 0$ and the systems (3.37) possess only two real singularities: M_1 (located on the parabola $\Phi_1(x,y) = 0$) and M_2 (located on the parabola $\Phi_2(x,y) = 0$). As mentioned earlier, the direction of the second invariant parabola depends on the sign of $g(1+g)$ (see (3.44)).

Thus, considering the condition $\mathbf{D} > 0$ (i.e., $Z_4 < 0$), we have the configuration *Config.* $\mathcal{P}.60$ if $\zeta_2 < 0$ (i.e., $g(g+1) < 0$) and *Config.* $\mathcal{P}.61$ if $\zeta_2 > 0$ (i.e., $g(g+1) > 0$).

3: *The possibility* $\mathbf{D} = 0$. From (3.42), (3.39), and the condition $\zeta_5\mathcal{R}_2 \neq 0$ (i.e., $Z_4(1+4g+3g^2+4n) \neq 0$), it follows that $\mathbf{D} = 0$ implies $\alpha_4\beta_4 = 0$. This yields the next lemma.

Lemma 3.6. *For systems* (3.37)*, the condition* $\beta_4 = 0$ *can be transformed by an affine change of variables into the condition* $\alpha_4 = 0$.

Proof. Apply to the systems (3.37) the transformation

$$x_1 = \delta x - \frac{(1+g)(1+4g+3g^2+4n)}{2Z_4}, \quad y_1 = \delta y - \frac{(1+g)(1+3g)(1+4g+3g^2+4n)}{4Z_4}, \\ t_1 = \frac{1}{\delta}, \quad \delta = -\frac{2g(1+g)}{Z_4}. \tag{3.45}$$

Define

$$n_1 = -\frac{(1+g)(1+11g+31g^2+21g^3+4n+20gn)}{4(1+6g+5g^2+4n)} \quad \Rightarrow \\ n = -\frac{(1+g)(1+11g+31g^2+21g^3+4n_1+20gn_1)}{4(1+6g+5g^2+4n_1)}. \tag{3.46}$$

Then we arrive at the family

$$\begin{aligned} \dot{x}_1 &= \frac{1}{4}(1+3g)(1+4g+3g^2+2n_1) + n_1x_1 - \frac{1}{2}(1+g)y_1 + gx_1^2 + x_1y_1, \\ \dot{y}_1 &= \frac{1}{2}(1+3g)(1+4g+3g^2+2n_1)x_1 + 2n_1y_1 + (g-1)x_1y_1 + 2y_1^2. \end{aligned} \tag{3.47}$$

Observe that this family coincides with (3.37) up to notation of variables and parameters. Calculating for the above system, we get:

$$\begin{aligned} \beta_4(g,n_1) &= (1+g)(1+3g)(1+6g+7g^2) + 4(1+2g)^2n_1 \\ &= \frac{g^2(1+g)^2(5+22g+21g^2+4n)}{1+6g+5g^2+4n} = -\frac{g^2(1+g)^2\alpha_4(g,n)}{Z_4}, \\ \alpha_4(g,n_1) &= 5+22g+21g^2+4n_1 \\ &= \frac{4(1+10g+34g^2+46g^3+21g^4+4n+16gn+16g^2n)}{1+6g+5g^2+4n} = -\frac{4\beta_4(g,n)}{Z_4}. \end{aligned}$$

Since $g(g+1)Z_4 \neq 0$, the condition $\beta_4(g,n_1)=0$ (respectively $\alpha_4(g,n_1)=0$) for systems (3.47) implies $\alpha_4(g,n)=0$ (respectively $\beta_4(g,n)=0$) for the original systems (3.37). This completes the proof. □

Thus, in what follows, we assume that the condition

$$\alpha_4 = 5+22g+21g^2+4n=0$$

holds, which implies

$$n=-\frac{(1+3g)(5+7g)}{4}.$$

We then obtain the following family of systems:

$$\begin{aligned}\dot{x} =& -\frac{1}{8}(1+3g)^2(3+5g)-\frac{1}{4}(1+3g)(5+7g)x-\frac{1}{2}(1+g)y+gx^2+xy,\\ \dot{y} =& -\frac{1}{4}(1+3g)^2(3+5g)x-\frac{1}{2}(1+3g)(5+7g)y+(g-1)xy+2y^2,\end{aligned} \tag{3.48}$$

possessing the two invariant parabolas $\Phi_1(x,y)=x^2-y=0$ and

$$\begin{aligned}\Phi_2(x,y) =& -(1+3g)^2(2+3g)(3+5g)-4(1+g)(1+3g)(2+3g)x\\ &+4g(1+g)x^2+8(1+2g)^2y=0.\end{aligned}$$

Considering the coordinates of the finite singularities (3.40), we observe that for $\alpha_4=0$, the singular point M_4 coalesces with M_1, producing a double finite singularity. Thus, systems (3.48) possess three finite singularities $M_i(x_i,y_i)$, $i=1,2,3$ (with M_1 being double), with coordinates

$$\begin{aligned}&x_1=-\frac{1+3g}{2}, && y_1=\frac{(1+3g)^2}{4}; && x_2=\frac{(1+3g)(4+13g+11g^2)}{2g(1+g)},\\ &y_2=-\frac{(1+3g)^2(3+5g)}{4(1+g)}; && x_3=\frac{3+5g}{2}, && y_3=\frac{(3+5g)^2}{4}.\end{aligned}$$

Using (3.41), we see that the singular points $M_1(\equiv M_4)$ and M_3 are the intersection points of the invariant parabolas, while M_2 lies on the parabola $\Phi_2(x,y)=0$. We calculate

$$\begin{aligned}(x_2-x_1)(x_2-x_3) &= \frac{(1+2g)^2(1+3g)(2+3g)(2+7g+7g^2)}{g^2(1+g)^2},\\ (x_2-x_1)+(x_2-x_3) &= \frac{4(1+2g)^3}{g(1+g)}\neq 0 \quad \text{if } (x_2-x_1)(x_2-x_3)>0.\end{aligned}$$

Since the discriminant $\mathrm{Discrim}\,[2+7g+7g^2,g]=-7<0$, it follows that

$$\begin{aligned}\operatorname{sign}\big((x_2-x_1)(x_2-x_3)\big) &= \operatorname{sign}\big((1+3g)(2+3g)\big),\\ \operatorname{sign}\big((x_2-x_1)+(x_2-x_3)\big) &= \operatorname{sign}\big(g(1+g)(1+2g)\big).\end{aligned}$$

Note that $\operatorname{sign}(1+2g)$ is only relevant if $(1+3g)(2+3g)>0$.

On the other hand, for systems (3.48) we have

$$\begin{aligned}&\zeta_2=4g(1+g), \quad \zeta_5=19(g-2)(3+g)(1+3g)^2(2+3g)^2,\\ &\xi_3=217993032\,g(1+g)(1+3g)^3(2+3g)^3(2+7g+7g^2)^2,\end{aligned}$$

and since $\zeta_2\zeta_5 \neq 0$, it follows that

$$\operatorname{sign}(\xi_3) = \operatorname{sign}\big(g(1+g)(1+3g)(2+3g)\big), \quad \operatorname{sign}(\zeta_2) = \operatorname{sign}(g(1+g)).$$

We claim that $\zeta_2 > 0$ implies $\xi_3 > 0$. Indeed, suppose $\zeta_2 > 0$ but $\xi_3 < 0$. This implies $(1+3g)(2+3g) < 0$, i.e., $-2/3 < g < -1/3$. Hence, $-1 < g < 0$, which contradicts $\zeta_2 > 0$. This proves the claim.

Therefore, considering the above relations, for systems (3.48) we obtain the following configurations:

$$\begin{array}{ll}
\zeta_2 < 0, \xi_3 < 0, 2g+1 < 0 \text{ (i.e. } -1 < g < -2/3) & \Rightarrow x_2 - x_1 > 0,\ x_2 - x_3 > 0 \Rightarrow \textit{Config. } \mathcal{P}.62;\\
\zeta_2 < 0, \xi_3 < 0, 2g+1 > 0 \text{ (i.e. } -1/3 < g < 0) & \Rightarrow x_2 - x_1 < 0,\ x_2 - x_3 < 0 \Rightarrow \simeq \textit{Config. } \mathcal{P}.62;\\
\zeta_2 < 0, \xi_3 > 0 \text{ (i.e. } -2/3 < g < -1/3) & \Rightarrow (x_2 - x_1)(x_2 - x_3) < 0 \quad \Rightarrow \textit{Config. } \mathcal{P}.63.\\
\zeta_2 > 0, 2g+1 < 0 \text{ (i.e. } g < -1) & \Rightarrow x_2 - x_1 < 0,\ x_2 - x_3 < 0 \Rightarrow \textit{Config. } \mathcal{P}.64;\\
\zeta_2 > 0, 2g+1 > 0 \text{ (i.e. } g > 0) & \Rightarrow x_2 - x_1 > 0,\ x_2 - x_3 > 0 \Rightarrow \simeq \textit{Config. } \mathcal{P}.64.
\end{array}$$

We observe that these configurations do not depend on the sign of $2g+1$. Hence, we arrive at the following lemma.

Lemma 3.7. *Assume that for systems* (3.37) *the condition* $\mathbf{D} = 0$ *holds. Then these systems possess the following configurations if and only if the corresponding conditions are satisfied:*

$$\begin{array}{ll}
\zeta_2 < 0, \xi_3 < 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.62;\\
\zeta_2 < 0, \xi_3 > 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.63;\\
\zeta_2 > 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.64.
\end{array}$$

The case $B_1 = 0$. Considering (3.39) and the condition $\zeta_2\mathcal{R}_2 \neq 0$ (i.e., $g(g+1)(1+6g+5g^2+4n) \neq 0$), we conclude that the condition $B_1 = 0$ is equivalent to

$$\begin{aligned}
&(1+2g)(1+3g)(2+3g)(1+4g+3g^2+2n)(1+6g+6g^2+4n)\\
&\times(1+6g+9g^2+4n)(5+14g+9g^2+4n) = 0.
\end{aligned} \tag{3.49}$$

However, through suitable transformations, we can reduce the number of cases arising from the condition $B_1 = 0$. This is stated in the following lemma.

Lemma 3.8. *The condition* (3.49) *can be transformed, via affine transformations and time rescaling, into the simpler condition*

$$(1+2g)(1+3g)(1+4g+3g^2+2n) = 0. \tag{3.50}$$

Proof. We prove this lemma in two steps: *(i)* by applying a transformation that replaces the line $y = 0$ with $y = x$ while preserving the invariant parabola $\Phi_1(x,y) = x^2 - y = 0$; and *(ii)* by applying a transformation that maps the invariant parabola $\Phi_2(x,y) = 0$ (see (3.38)) to the parabola $\Phi_1(x,y) = x^2 - y = 0$.

Step (i): Applying to systems (3.37) the change of variables

$$x_1 = -x + 1/2, \quad y_1 = -x + y + 1/4,$$

we obtain the transformed system

$$\begin{aligned}
\dot{x}_1 &= -\frac{1}{8}(2+3g)(1+6g+6g^2+4n) + \frac{1}{4}(1+2g+4n)x_1 + \frac{g}{2}y_1 - (1+g)x_1^2 + x_1y_1,\\
\dot{y}_1 &= -\frac{1}{4}(2+3g)(1+6g+6g^2+4n)x_1 + \frac{1}{2}(1+2g+4n)y_1 - (g+2)x_1y_1 + 2y_1^2.
\end{aligned}$$

Setting new parameters

$$\begin{aligned} n_1 &= \frac{1}{4}(1+2g+4n), \quad g_1 = -(1+g), \quad \Rightarrow \\ n &= \frac{1}{4}(1+2g_1+4n_1), \quad g = -(1+g_1), \end{aligned} \tag{3.51}$$

the system becomes

$$\begin{aligned} \dot{x}_1 &= \frac{1}{4}(1+3g_1)(1+4g_1+3g_1^2+2n_1) + n_1x_1 - \frac{1+g_1}{2}y_1 + g_1x_1^2 + x_1y_1, \\ \dot{y}_1 &= \frac{1}{2}(1+3g_1)(1+4g_1+3g_1^2+2n_1)x_1 + 2n_1y_1 + (g_1-1)x_1y_1 + 2y_1^2, \end{aligned}$$

which has the same form as (3.37).

Moreover, calculations show that

$$\begin{gathered} 2+3g = -(1+3g_1), \quad 1+6g+6g^2+4n = 2(1+4g_1+3g_1^2+2n_1), \\ 5+14g+9g^2+4n = 1+6g_1+9g_1^2+4n_1, \end{gathered}$$

thus reducing the condition (3.49) to

$$(1+2g)(1+3g)(1+4g+3g^2+2n)(1+6g+9g^2+4n) = 0.$$

Step (ii): As shown in the proof of Lemma 3.6, via the transformation (3.45), systems (3.37) can be brought to the canonical form (3.47) but with a new parameter n_1 given by (3.46). Calculations give

$$1+6g+9g^2+4n_1 = \frac{8g^2(1+4g+3g^2+2n)}{4(1+6g+5g^2+4n)}.$$

Since $g \neq 0$, the condition $1+6g+9g^2+4n = 0$ can be transformed into $1+4g+3g^2+2n = 0$. Consequently, we arrive at the condition (3.50), completing the proof of Lemma 3.8. □

For systems (3.37), we compute

$$\zeta_3 = 8(1+2g)^2, \quad \xi_{15} = 2(1+3g)(2+3g),$$

and distinguish two subcases: $\zeta_3 \neq 0$ and $\zeta_3 = 0$.

1: *The subcase* $\zeta_3 \neq 0$. Then $1+2g \neq 0$, and considering (3.50) together with Lemma 3.8, to satisfy the condition $B_1 = 0$ it is sufficient to consider $(1+3g)(1+4g+3g^2+2n) = 0$. Clearly, we must distinguish two possibilities: $\xi_{15} \neq 0$ and $\xi_{15} = 0$.

1.1: *The possibility* $\xi_{15} \neq 0$. Then $1+3g \neq 0$, and in this case we obtain $1+4g+3g^2+2n = 0$, i.e., $n = -(1+g)(1+3g)/2$. This leads to the following one-parameter family of systems:

$$\begin{aligned} \dot{x} &= -\frac{1}{2}(1+g)(1+3g)\,x - \frac{1}{2}(1+g)\,y + gx^2 + xy, \\ \dot{y} &= -\,y\left(1+4g+3g^2+x-gx-2y\right), \end{aligned} \tag{3.52}$$

which, besides the invariant parabolas

$$\Phi_1(x,y) = x^2 - y = 0, \quad \Phi_2(x,y) = (1+g)(1+3g)\,x - 2gx^2 - (1+g)\,y = 0,$$

also possess the invariant line $y = 0$.

Using Lemmas 2.3 and 2.4, we compute:

$$\theta = -8(g-1)(2+g), \quad B_2 = \frac{243}{2} g(1+g)^4(1+2g)^2(2+3g)\, y^4. \tag{3.53}$$

Thus, we need to consider the cases $B_2 \neq 0$ and $B_2 = 0$.

1.1.1: *The case* $B_2 \neq 0$. Then, by Lemma 2.3, the system cannot have invariant lines in directions other than $y = 0$. However, by Lemma 2.4, parallel invariant lines could exist if $\theta = 0$.

1.1.1.1: *The subcase* $\theta \neq 0$. The systems (3.52) possess four finite singularities $M_i(x_i, y_i)$ for $i = 1, 2, 3, 4$, with coordinates:

$$\begin{aligned} &x_1 = 0, \quad y_1 = 0; \quad x_2 = \frac{(1+g)(1+3g)}{2g}, \quad y_2 = 0; \\ &x_3 = 1+g, \quad y_3 = (1+g)^2; \quad x_4 = -\frac{1+3g}{2}, \quad y_4 = \frac{(1+3g)^2}{4}. \end{aligned}$$

From the conditions stated in the statement $(\mathcal{A}_2^*)$, for systems (3.52) we have:

$$\zeta_1\zeta_2\zeta_5\mathcal{R}_2 \neq 0 \quad \Leftrightarrow \quad g(1+g)(g-2)(3+g)(1+3g)(8+27g+27g^2) \neq 0. \tag{3.54}$$

We observe that the invariant parabolas intersect at two points: M_1 and M_3. Moreover, the invariant line $y = 0$ has a contact point at M_1 with the parabola $\Phi_1(x, y) = 0$ and two intersection points, M_1 and M_2, with the parabola $\Phi_2(x, y) = 0$.

Thus, three finite singularities are fixed by the intersections of the invariant curves, with their positions determined by the value of the parameter g.

On the other hand, the singular point M_4 lies on the invariant parabola $\Phi_1(x, y) = 0$ and is a floating singularity. Therefore, we must determine its position relative to the other two singularities on the same invariant curve. To this end, we calculate:

$$(x_4 - x_1)(x_4 - x_3) = \frac{1}{4}(1+3g)(3+5g), \quad (x_4 - x_1) + (x_4 - x_3) = -2(1+2g).$$

Therefore, we obtain:

$$\begin{aligned} \operatorname{sign}\big((x_4 - x_1)(x_4 - x_3)\big) &= \operatorname{sign}\big((1+3g)(3+5g)\big), \\ \operatorname{sign}\big((x_4 - x_1) + (x_4 - x_3)\big) &= -\operatorname{sign}(1+2g). \end{aligned}$$

We observe that the direction of the second invariant parabola depends on $\operatorname{sign}(g(g+1))$.

Furthermore, for systems (3.52), calculations yield:

$$\begin{aligned} \zeta_2 = 4g(g+1), \quad \xi_{16} &= \frac{3705}{2} g^2(1+g)^2(1+3g)(3+5g), \\ \xi_{17} &= \frac{3705}{4}(1+g)^2(1+2g)(1+3g)(3+5g). \end{aligned}$$

Thus, we have:

$$\begin{aligned} \operatorname{sign}(\zeta_2) = \operatorname{sign}\big(g(g+1)\big), \quad \operatorname{sign}(\xi_{16}) &= \operatorname{sign}\big((1+3g)(3+5g)\big), \\ \operatorname{sign}(\xi_{17}) &= \operatorname{sign}\big((1+2g)(1+3g)(3+5g)\big). \end{aligned}$$

Therefore, we establish the following configurations:

$\zeta_2 < 0, \xi_{16} < 0$ (i.e. $-3/5 < g < -1/3$) $\Rightarrow (x_4 - x_1)(x_4 - x_3) < 0 \Rightarrow$ *Config.* $\mathcal{P}.65$;
$\zeta_2 < 0, \xi_{16} > 0, \xi_{17} < 0$ (i.e. $-1 < g < -3/5$) $\Rightarrow x_4 > x_1, x_4 > x_3 \Rightarrow$ *Config.* $\mathcal{P}.66$;
$\zeta_2 < 0, \xi_{16} > 0, \xi_{17} > 0$ (i.e. $-1/3 < g < 0$) $\Rightarrow x_4 < x_1, x_4 < x_3 \Rightarrow$ *Config.* $\mathcal{P}.67$;
$\zeta_2 > 0, \xi_{17} < 0$ (i.e. $g < -1$) $\Rightarrow x_4 > x_1, x_4 > x_3 \Rightarrow$ *Config.* $\mathcal{P}.68$;
$\zeta_2 > 0, \xi_{17} > 0$ (i.e. $g > 0$) $\Rightarrow x_4 < x_1, x_4 < x_3 \Rightarrow$ *Config.* $\mathcal{P}.69$.

1.1.1.2: *The subcase* $\theta = 0$. This condition implies $(g-1)(g+2) = 0$, and since for systems (3.52) we have

$$\zeta_6 = \frac{(g-1)(1+g)(2+5g+5g^2)}{8},$$

we consider two possibilities: $\zeta_6 \neq 0$ and $\zeta_6 = 0$.

1.1.1.2.1: *The possibility* $\zeta_6 \neq 0$. In this case, the condition $\theta = 0$ implies $g = -2$. We then obtain the system:

$$\dot{x} = -\frac{5x}{2} + \frac{y}{2} - 2x^2 + xy, \quad \dot{y} = -y\,(5 + 3x - 2y)\,,$$

which, besides the invariant parabolas:

$$\Phi_1(x,y) = x^2 - y = 0, \quad \Phi_2(x,y) = 5x + 4x^2 + y = 0,$$

possesses only one invariant line: $y = 0$. This means that the condition $g = -2$ does not imply the appearance of any additional parallel invariant line.

Since $g = -2 < -1$, we conclude that this case corresponds to configuration *Config.* $\mathcal{P}.68$ (as detected earlier).

1.1.1.2.2: *The possibility* $\zeta_6 = 0$. Then $\theta = 0$ implies $g = 1$, and we arrive at the system:

$$\dot{x} = -4x - y + x^2 + xy, \quad \dot{y} = 2y(y-4),$$

which possesses the invariant lines $y = 0$ and $y = 4$, as well as the invariant parabolas:

$$\Phi_1(x,y) = x^2 - y = 0, \quad \Phi_2(x,y) = -4x + x^2 + y = 0.$$

In this case, we obtain configuration *Config.* $\mathcal{P}.70$.

1.1.2: *The case* $B_2 = 0$. Considering (3.53) and (3.54), the condition $B_2 = 0$ implies $g = -2/3$, and we arrive at the system:

$$\dot{x} = \frac{x}{6} - \frac{y}{6} - \frac{2x^2}{3} + xy, \quad \dot{y} = \frac{1}{3}y(1 - 5x + 6y), \tag{3.55}$$

which possesses the invariant lines $y = 0$ and $y = x - 1/4$, as well as the invariant parabolas:

$$\Phi_1(x,y) = x^2 - y = 0, \quad \Phi_2(x,y) = x - 4x^2 + y = 0.$$

We observe that the invariant line $y = x - 1/4$ is tangent to the invariant parabola $\Phi_1(x,y) = 0$ at the point $M_4(1/2, 1/4)$ and also tangent to the parabola $\Phi_2(x,y) = 0$ at the point $M_2(1/4, 0)$. Therefore, in this case, we obtain configuration *Config.* $\mathcal{P}.71$.

Thus, we have proved the following lemma.

Lemma 3.9. *Assume that for systems (3.37) the conditions $B_1 = 0$ and $\zeta_3\xi_{15} \neq 0$ hold. Then these systems possess the following configurations, provided the corresponding conditions are satisfied:*

$$\begin{array}{ll}
B_2 \neq 0,\ \theta \neq 0,\ \zeta_2 < 0,\ \xi_{16} < 0 & \Rightarrow \textit{Config. } \mathcal{P}.65; \\
B_2 \neq 0,\ \theta \neq 0,\ \zeta_2 < 0,\ \xi_{16} > 0,\ \xi_{17} < 0 & \Rightarrow \textit{Config. } \mathcal{P}.66; \\
B_2 \neq 0,\ \theta \neq 0,\ \zeta_2 < 0,\ \xi_{16} > 0,\ \xi_{17} > 0 & \Rightarrow \textit{Config. } \mathcal{P}.67; \\
B_2 \neq 0,\ \theta \neq 0,\ \zeta_2 > 0,\ \xi_{17} < 0 & \Rightarrow \textit{Config. } \mathcal{P}.68; \\
B_2 \neq 0,\ \theta \neq 0,\ \zeta_2 > 0,\ \xi_{17} > 0 & \Rightarrow \textit{Config. } \mathcal{P}.69; \\
B_2 \neq 0,\ \theta = 0,\ \zeta_6 \neq 0 & \Rightarrow \textit{Config. } \mathcal{P}.68; \\
B_2 \neq 0,\ \theta = 0,\ \zeta_6 = 0 & \Rightarrow \textit{Config. } \mathcal{P}.70; \\
B_2 = 0 & \Rightarrow \textit{Config. } \mathcal{P}.71.
\end{array}$$

1.2: *The possibility $\xi_{15} = 0$.* Then, considering the proof of Lemma 3.8, we may assume $1 + 3g = 0$. This yields $g = -1/3$, leading to the following one-parameter family of systems:

$$\dot{x} = nx - \frac{y}{3} - \frac{x^2}{3} + xy, \quad \dot{y} = \frac{2}{3}y\,(3n - 2x + 3y)\,, \tag{3.56}$$

which, besides the invariant parabolas:

$$\Phi_1(x,y) = x^2 - y = 0, \quad \Phi_2(x,y) = 9n^2 - 6nx + x^2 + (9n-1)y = 0,$$

also possesses the invariant line $y = 0$.

Considering Lemmas 2.3 and 2.4, we compute:

$$B_2 = -8(1+3n)(9n-1)(12n-1)y^4/9, \quad \mathbf{D} = 4096n^6(9n-1)/243,$$
$$\theta = 160/9 \neq 0, \quad \zeta_5 = -4256n^2/9, \quad \mathcal{R}_2 = 28(9n-1)/81.$$

Thus, we discuss the cases $B_2 \neq 0$ and $B_2 = 0$.

1.2.1: *The case $B_2 \neq 0$.* By Lemmas 2.3 and 2.4, no additional invariant line can exist.

Moreover, considering (3.40), the systems (3.56) possess four finite singularities $M_i(x_i, y_i)$ for $i = 1, 2, 3, 4$, with coordinates:

$$x_1 = 0,\ y_1 = 0; \quad x_2 = 3n,\ y_2 = 0;\ x_{3,4} = \frac{1}{3}\left(1 \pm \sqrt{1-9n}\right), \quad y_{3,4} = \frac{1}{9}\left(2 - 9n \pm 2\sqrt{1-9n}\right).$$

We observe that in this case $n(1-9n) \neq 0$ due to $\zeta_5\mathcal{R}_2 \neq 0$, ensuring all finite singularities are distinct. Moreover, the invariant line $y = 0$ is tangent to the parabola $\Phi_1(x,y) = 0$ at the singular point $M_1(0,0)$ and tangent to $\Phi_2(x,y) = 0$ at $M_2(3n,0)$.

Since $\mathbf{D} \neq 0$ and $\operatorname{sign}(1-9n) = -\operatorname{sign}(\mathbf{D})$, we examine two subcases: $\mathbf{D} < 0$ and $\mathbf{D} > 0$.

1.2.1.1: *The subcase $\mathbf{D} < 0$.* Then $1 - 9n > 0$ (i.e., $n < 1/9$), and we arrive at configuration *Config. $\mathcal{P}.72$*, independent of the relative position of the singularity $M_2(3n,0)$ with respect to $M_1(0,0)$.

1.2.1.2: *The subcase $\mathbf{D} > 0$.* This implies $1 - 9n < 0$, so the singularities M_3 and M_4 become complex. In this case, we arrive at configuration *Config. $\mathcal{P}.73$*.

1.2.2: *The case $B_2 = 0$.* Since $9n - 1 \neq 0$ due to $\mathcal{R}_2 \neq 0$, the condition $B_2 = 0$ implies:

$$(1+3n)(12n-1) = 0.$$

1.2.2.1: *The subcase* $1+3n=0$. Then $n=-1/3$, leading to the system:

$$\dot{x}=-\frac{1}{3}x-\frac{1}{3}y-\frac{1}{3}x^2+xy,\quad \dot{y}=\frac{2}{3}y(-1-2x+3y).$$

Applying the transformation $x_1=(1-x)/4$, $y_1=(y-x)/4$, and $t_1=4t$, we recover system (3.55), corresponding to configuration *Config.* $\mathcal{P}.71$.

1.2.2.2: *The subcase* $12n-1=0$. This implies $n=1/12$, and we arrive at the system:

$$\dot{x}=\frac{1}{12}x-\frac{1}{3}y-\frac{1}{3}x^2+xy,\quad \dot{y}=\frac{1}{6}y(1-8x+12y).$$

Applying the affine transformation $x_1=-x+1/2$, $y_1=y-x+1/4$, the system is brought to the form (3.55), again corresponding to configuration *Config.* $\mathcal{P}.71$.

2: *The subcase* $\zeta_3=0$. Then $g=-1/2$, which implies $B_1=0$. This leads to the following one-parameter family of systems:

$$\dot{x}=(4x-1)\,(8n-1-4x+8y)\,/32,\quad \dot{y}=(x-8nx+32ny-24xy+32y^2)/16, \tag{3.57}$$

which possess the following two invariant parabolas: $\Phi_1(x,y)=x^2-y=0$, and

$$\Phi_2(x,y)=(8n-1)(16n-1)-4(16n-1)x+16x^2+8(16n-3)y=0,$$

as well as the invariant line $x=1/4$.

For the above systems, we calculate:

$$\zeta_5=-475(16n-1)^2/256,\quad \mathcal{R}_2=125(16n-3)/1024,$$

and according to the conditions given by statement $(\mathcal{A}_2^*)$, we require $\zeta_5\mathcal{R}_2\neq 0$. This implies $(16n-1)(16n-3)\neq 0$, and by Proposition 2.7*, the invariant parabolas $\Phi_1(x,y)=0$ and $\Phi_2(x,y)=0$ are distinct.

For these systems, we compute:

$$B_1=0,\quad B_2=-\frac{81}{2048}(8n-1)^2(1+16n)^2x^4,\quad \theta=18\neq 0, \tag{3.58}$$

and since $\theta\neq 0$, by Lemma 2.4, these systems cannot possess an invariant line parallel to $x=1/4$.

On the other hand, according to Lemma 2.3, the existence of an invariant line in another direction would require $B_2=0$. Thus, we consider the possibilities $B_2\neq 0$ and $B_2=0$.

2.1: The possibility $B_2\neq 0$. The systems (3.57) possess four finite singularities $M_i(x_i,y_i)$ $(i=1,2,3,4)$ with coordinates:

$$\begin{gathered} x_1=\frac{1}{4},\ y_1=\frac{1}{16};\quad x_2=\frac{1}{4},\ y_2=\frac{1-8n}{8};\\ x_{3,4}=\frac{1}{4}\left(1\pm\sqrt{3-16n}\right),\quad y_{3,4}=\frac{1}{8}\left(2-8n\pm\sqrt{3-16n}\right). \end{gathered} \tag{3.59}$$

We observe that the invariant parabolas intersect at two points: M_3 and M_4. The invariant line $x=1/4$ intersects the parabola $\Phi_1(x,y)=0$ at M_1 and the parabola $\Phi_2(x,y)=0$ at M_2.

Thus, all four finite singularities are located at the intersections of invariant curves, and their positions are determined by the parameter n. Furthermore, the singularities M_3 and M_4 are real if $3-16n>0$, and complex if $3-16n<0$.

For systems (3.57), we compute:

$$\mathbf{D} = 3(16n-3)^3(16n-1)^2/1048576 \neq 0,$$

due to $\zeta_5\mathcal{R}_2 \neq 0$. Therefore, sign $(\mathbf{D})$ = sign $(16n-3)$.

Thus, for $B_2 \neq 0$, we conclude: if $\mathbf{D} < 0$, the system corresponds to configuration *Config.* $\mathcal{P}.74$, and if $\mathbf{D} > 0$, it corresponds to configuration *Config.* $\mathcal{P}.75$.

2.2: The possibility $B_2 = 0$. From (3.58), this condition implies $(8n-1)(1+16n) = 0$. We analyze two cases: $(1+16n) \neq 0$ and $(1+16n) = 0$.

If $8n-1=0$, i.e., $n = 1/8$, we obtain the system:

$$\dot{x} = -(4x-1)(x-2y)/8, \quad \dot{y} = y(1-6x+8y)/4, \tag{3.60}$$

which possesses the following five invariant curves (two parabolas and three invariant lines):

$$\Phi_1(x,y) = x^2 - y, \quad \Phi_2(x,y) = -x + 4x^2 - 2y, \quad x = 1/4, \quad y = 0, \quad y = x - 1/4.$$

For this system, we obtain configuration *Config.* $\mathcal{P}.76$.

In the case $1+16n=0$, we get $n = -1/16$, leading to the system:

$$\dot{x} = -(4x-1)(3+8x-16y)/64, \quad \dot{y} = -(16y-1)(3x-4y)/32,$$

which can be brought to system (3.60) via the affine transformation and time rescaling:

$$x_1 = x/2 + 1/8, \quad y_1 = y/2 - 1/32, \quad t_1 = 2t.$$

Thus, in this case, we again obtain configuration *Config.* $\mathcal{P}.76$.

3.1.3 The statement $(\mathcal{A}_3^*)$

In this case, the conditions $\zeta_4 = \zeta_5 = 0$, together with (3.39) and the assumption $\zeta_1 \neq 0$ (i.e., $(g-2)(g+3) \neq 0$), yield the condition $1 + 4g + 3g^2 + 4n = 0$, which implies:

$$n = -\frac{1}{4}(1+g)(1+3g).$$

This leads to the following family of systems:

$$\begin{aligned} \dot{x} &= \frac{1}{8}(1+g)(1+3g)^2 - \frac{1}{4}(1+g)(1+3g)x - \frac{1}{2}(1+g)y + gx^2 + xy, \\ \dot{y} &= \frac{1}{4}(1+g)(1+3g)^2x - \frac{1}{2}(1+g)(1+3g)y + (g-1)xy + 2y^2, \end{aligned} \tag{3.61}$$

which possess the invariant parabola $\Phi(x,y) = x^2 - y = 0$ with multiplicity 2.

Following statement $(\mathcal{A}_3^*)$, for the above systems we calculate:

$$\begin{aligned} \zeta_1 &= 2(g-2)(g+3), \quad \zeta_2 = 4g(1+g), \quad \zeta_4 = \zeta_5 = 0, \\ \mathcal{R}_2 &= -\frac{g(1+g)(g-2)(g+3)\left(8+27g+27g^2\right)}{8}, \\ B_1 &= \frac{g^4(1+g)^4(1+2g)(1+3g)^3(2+3g)^3}{8}. \end{aligned} \tag{3.62}$$

Since the quadratic polynomial $8 + 27g + 27g^2$ has a negative discriminant, for systems (3.61) we have:

$$\zeta_1\zeta_2\mathcal{R}_2 \neq 0 \quad \Rightarrow \quad g(1+g)(g-2)(g+3) \neq 0. \tag{3.63}$$

According to Lemma 2.3, the existence of an invariant line for systems (3.61) requires the condition $B_1 = 0$. Thus, we analyze two cases: $B_1 \neq 0$ and $B_1 = 0$.

The case $B_1 \neq 0$**.** Then, no invariant line can exist. The systems (3.61) possess three finite singularities $M_i(x_i, y_i)$, for $i = 1, 2, 3$, with coordinates:

$$\begin{aligned} x_1 = -\frac{1+3g}{2}, \quad y_1 = \frac{(1+3g)^2}{4}; \\ x_{2,3} = \frac{1}{2}\big(1+g \pm \sqrt{-2g(1+g)}\,\big), \quad y_{2,3} = \frac{g+1}{4}\big(1-g \pm 2\sqrt{-2g(1+g)}\,\big). \end{aligned} \tag{3.64}$$

We point out that M_1 is a multiple singularity of systems (3.61). Indeed, by applying the corresponding translation, M_1 can be placed at the origin, yielding the transformed system:

$$\begin{aligned} \dot{x} &= -\frac{1}{2}g(3g+1)x - (2g+1)y + gx^2 + xy, \\ \dot{y} &= \frac{1}{2}g(3g+1)^2x + (2g+1)(3g+1)y + (g-1)xy + 2y^2, \end{aligned}$$

where $M_0(0,0)$ is the singularity corresponding to M_1.

Following [1], we compute the corresponding invariant polynomials at M_0: $\mu_4 = \mu_3 = 0$, and

$$\mu_2 = \frac{1}{2}g(g+1)(3g+1)(3g+2)\left[g(1+3g)x^2 + 4gxy + 2y^2\right] \neq 0,$$

due to $B_1 \neq 0$. By [1, Lemma 5.2, statement (ii)], the point M_0 has multiplicity exactly 2.

We also observe that:

$$\Phi(x_1, y_1) = \Phi(x_2, y_2) = \Phi(x_3, y_3) = 0,$$

meaning that all three singularities lie on the invariant parabola.

The nature (real or complex) of M_2 and M_3 depends on the sign of $g(g+1) \neq 0$ (since $\zeta_2 \neq 0$). Given that $\zeta_2 = 4g(g+1)$, we analyze two subcases: $\zeta_2 < 0$ and $\zeta_2 > 0$.

1: *The subcase* $\zeta_2 < 0$. This implies $g(g+1) < 0$, i.e., $-1 < g < 0$. In this case, all three singularities on the invariant parabola are real. We need to determine the relative position of the double singularity M_1 with respect to the simple singularities M_2 and M_3.

From (3.64), we calculate:

$$(x_2 - x_1)(x_3 - x_1) = (1+3g)(2+3g)/2 \;\Rightarrow\; \operatorname{sign}\big((x_2 - x_1)(x_3 - x_1)\big) = \operatorname{sign}\big((1+3g)(2+3g)\big).$$

On the other hand, for systems (3.61) we obtain:

$$\xi_{15} = 2(1+3g)(2+3g) \neq 0,$$

due to $B_1 \neq 0$.

Therefore, if $\xi_{15} < 0$, the double point M_1 lies between the singularities M_2 and M_3, yielding configuration *Config.* $\mathcal{P}.77$, and if $\xi_{15} > 0$, the double point M_1 lies outside the curvilinear interval (M_2, M_3), yielding configuration *Config.* $\mathcal{P}.78$.

2: *The subcase* $\zeta_2 > 0$. Then $g(g+1) > 0$, so the singularities M_2 and M_3 are complex. In this case, we get only configuration *Config.* $\mathcal{P}.79$.

The case $B_1 = 0$. Considering (3.62) together with the condition (3.63), we conclude that $B_1 = 0$ is equivalent to the condition $(1+2g)(1+3g)(2+3g) = 0$. For systems (3.61), we also have $\zeta_3 = 8(1+2g)^2$, so we consider two subcases: $\zeta_3 \neq 0$ and $\zeta_3 = 0$.

1: *The subcase $\zeta_3 \neq 0$.* Then $1+2g \neq 0$, and the condition $B_1 = 0$ implies $(1+3g)(2+3g) = 0$.

If $g = -1/3$, we arrive at the system:

$$\dot{x} = -(y + x^2 - 3xy)/3, \quad \dot{y} = -2y(2x - 3y)/3, \tag{3.65}$$

which possesses the invariant line $y = 0$, tangent to the double invariant parabola at the singular point $M_1(0,0)$. In this case, the singular point M_3 has coalesced with M_1, producing a triple singularity. Therefore, we obtain configuration *Config.* $\mathcal{P}$*.80*.

Now, consider $g = -2/3$. Then, the system becomes:

$$\dot{x} = (1 + 2x - 4y - 16x^2 + 24xy)/24, \quad \dot{y} = (x + 2y - 20xy + 24y^2)/12,$$

which, via the affine transformation $x_1 = -x + 1/2$, $y_1 = y - x + 1/4$, can be brought to system (3.65), also possessing configuration *Config.* $\mathcal{P}$*.80*.

2: *The subcase $\zeta_3 = 0$.* Then $g = -1/2$, and we arrive at the system:

$$\dot{x} = -(4x-1)(1+8x-16y)/64, \quad \dot{y} = (x + 4y - 48xy + 64y^2)/32,$$

which possesses the invariant line $x = 1/4$ and the double invariant parabola $\Phi_1(x,y) = x^2 - y = 0$. In this case, the singular points M_1 and M_2 have coalesced, and it is straightforward to verify that this yields configuration *Config.* $\mathcal{P}$*.81*.

Thus, we have proved the following lemma.

Lemma 3.10. *Assume that for a quadratic system the conditions $(\mathcal{A}_3^*)$ are satisfied. Then, the system possesses one of the following configurations, if and only if the corresponding conditions below hold:*

$$\begin{array}{lll}
B_1 \neq 0,\ \zeta_2 < 0,\ \xi_{15} < 0 & \Rightarrow & \textit{Config. } \mathcal{P}\textit{.77;} \\
B_1 \neq 0,\ \zeta_2 < 0,\ \xi_{15} > 0 & \Rightarrow & \textit{Config. } \mathcal{P}\textit{.78;} \\
B_1 \neq 0,\ \zeta_2 > 0 & \Rightarrow & \textit{Config. } \mathcal{P}\textit{.79;} \\
B_1 = 0,\ \zeta_3 \neq 0 & \Rightarrow & \textit{Config. } \mathcal{P}\textit{.80;} \\
B_1 = 0,\ \zeta_3 = 0 & \Rightarrow & \textit{Config. } \mathcal{P}\textit{.81.}
\end{array}$$

3.1.4 The statement $(\mathcal{A}_4^*)$

In this case, the conditions $\zeta_4 = \mathcal{R}_2 = 0$ hold. Considering (3.39) and the condition $\zeta_1 \neq 0$ (i.e., $(g-2)(g+3) \neq 0$), we get:

$$(8 + 27g + 27g^2)(1 + 6g + 5g^2 + 4n) = 0.$$

However, the discriminant of the quadratic polynomial $8 + 27g + 27g^2$ equals $-135 < 0$, so this factor cannot vanish. Thus, we obtain:

$$1 + 6g + 5g^2 + 4n = 0 \ \Rightarrow\ n = -\frac{1}{4}(1+g)(1+5g).$$

This leads to the following family of systems:

$$\begin{aligned}
\dot{x} &= \frac{1}{8}(1 + g - 2x)(1 + 4g + 3g^2 - 4gx - 4y), \\
\dot{y} &= \frac{1}{4}(1+g)^2(1+3g)\,x - \frac{1}{2}(1+g)(1+5g)y + (g-1)xy + 2y^2,
\end{aligned} \tag{3.66}$$

which possess the invariant parabola $\Phi(x,y) = x^2 - y = 0$ and the invariant line $x = (g+1)/2$.

For the above systems, following the statement $(\mathcal{A}_4^*)$, we calculate:

$$\begin{aligned} &\zeta_1 = 2(g-2)(3+g), \;\; \zeta_2 = 4g(1+g), \\ &\zeta_4 = 0 = \mathcal{R}_2, \;\; \zeta_5 = 19(g-2)g^2(1+g)^2(3+g), \\ &B_1 = 0, \;\; B_2 = -648g^5(1+g)^5(1+3g)(2+3g)x^4. \end{aligned} \tag{3.67}$$

Therefore, for systems (3.61), we have:

$$\zeta_1\zeta_2\zeta_5 \neq 0 \;\Rightarrow\; g(1+g)(g-2)(3+g) \neq 0. \tag{3.68}$$

We now discuss two possibilities: $B_2 \neq 0$ and $B_2 = 0$.

1: *The case* $B_2 \neq 0$. In this situation, by Lemma 2.3, systems (3.66) cannot possess any invariant line in other direction than $x = (g+1)/2$.

On the other hand, by Lemma 2.4, these systems could possess an invariant line parallel to the existing one if $\theta = (g-1)(g+2) = 0$. However, a straightforward computation shows that neither $g = 1$ nor $g = -2$ leads to the appearance of an additional parallel invariant line.

Systems (3.66) possess three finite singularities $M_i(x_i, y_i)$ $(i = 1,2,3)$ with coordinates:

$$x_1 = \frac{1+g}{2}, \quad y_1 = \frac{(1+g)^2}{4}; \quad x_2 = \frac{1+g}{2}, \quad y_2 = \frac{1}{4}(1+g)(1+3g);$$
$$x_3 = -\frac{1+3g}{2}, \quad y_3 = \frac{(1+3g)^2}{4}.$$

We observe that the invariant line $x = (g+1)/2$ intersects the invariant parabola at the singular point M_1, and we claim that M_1 is a multiple singularity of systems (3.66). Indeed, applying the corresponding translation, we can place M_1 at the origin of coordinates, resulting in the system:

$$\dot{x} = gx^2 + xy, \quad \dot{y} = g(1+g)^2x - g(1+g)y + (g-1)xy + 2y^2,$$

where $M_0(0,0)$ is the singularity corresponding to M_1.

Following [1], we compute the invariant polynomials: $\mu_4 = \mu_3 = 0$, and:

$$\mu_2 = g^2(1+g)^2(1+2g)x(gx+y).$$

Due to condition (3.68), we have that $\mu_2 = 0$ if and only if $1+2g = 0$. By [1, Lemma 5.2, statement (ii)], the point M_0 has multiplicity exactly 2 if $1+2g \neq 0$, and it is triple if $g = -1/2$.

For systems (3.66), we have $\zeta_3 = 8(1+2g)^2$, so we now consider two cases: $\zeta_3 \neq 0$ and $\zeta_3 = 0$.

1.1: *The subcase* $\zeta_3 \neq 0$. Then $1+2g \neq 0$, and therefore M_1 is a double singular point of the system, with all three singularities distinct.

Moreover, the singularity M_2 lies on the invariant line, while M_3 lies on the invariant parabola. To determine the relative positions of these points with respect to the double singularity M_1, we compute:

$$\begin{aligned} y_2 - y_1 = g(1+g)/2 \;&\Rightarrow\; \operatorname{sign}(y_2 - y_1) = \operatorname{sign}\big(g(g+1)\big), \\ x_3 - x_1 = -(1+2g) \;&\Rightarrow\; \operatorname{sign}(x_3 - x_1) = -\operatorname{sign}(1+2g), \end{aligned}$$

and we observe that for systems (3.66), we have $\zeta_2 = 4g(g+1)$, hence sign $(\zeta_2) =$ sign $\big(g(g+1)\big)$.

Thus, we arrive at the following configurations:

$$\begin{array}{lll}
\zeta_2 < 0,\ 2g+1 < 0 \ \text{(i.e., } -1 < g < -1/2) & \Rightarrow y_2 < y_1,\ x_3 > x_1 & \Rightarrow \textit{Config. } \mathcal{P}.82;\\
\zeta_2 < 0,\ 2g+1 > 0 \ \text{(i.e., } -1/2 < g < 0) & \Rightarrow y_2 < y_1,\ x_3 < x_1 & \Rightarrow \simeq \textit{Config. } \mathcal{P}.82;\\
\zeta_2 > 0,\ 2g+1 < 0 \ \text{(i.e., } g < -1) & \Rightarrow y_2 > y_1,\ x_3 > x_1 & \Rightarrow \textit{Config. } \mathcal{P}.83;\\
\zeta_2 > 0,\ 2g+1 > 0 \ \text{(i.e., } g > 0) & \Rightarrow y_2 > y_1,\ x_3 < x_1 & \Rightarrow \simeq \textit{Config. } \mathcal{P}.83.
\end{array}$$

1.2: *The subcase* $\zeta_3 = 0$. Then $g = -1/2$, leading to the system:

$$\dot{x} = -(4x-1)(-1+8x-16y)/64, \quad \dot{y} = (-x+12y-48xy+64y^2)/32,$$

which possesses the invariant line $x = 1/4$ and the invariant parabola $\Phi_1(x,y) = x^2 - y = 0$. In this case, the singular points M_1 and M_3 coalesce, resulting in the configuration *Config.* $\mathcal{P}.84$.

2: *The case* $B_2 = 0$. Considering (3.67) and the condition (3.68), we conclude that $B_2 = 0$ is equivalent to $(1+3g)(2+3g) = 0$.

If $g = -1/3$, we arrive at the system:

$$\dot{x} = -(3x-1)(x-3y)/9, \quad \dot{y} = 2y(1-6x+9y)/9, \tag{3.69}$$

which possesses the additional invariant line $y = 0$, tangent to the invariant parabola at the singular point $M_3(0,0)$ and intersecting the invariant line $x = 1/3$ at the singular point $M_2(1/3,0)$. Therefore, we obtain the configuration *Config.* $\mathcal{P}.85$.

Assume now $g = -2/3$. This leads to the system:

$$\dot{x} = -(6x-1)(8x-1-12y)/72, \quad \dot{y} = (-x+14y-60xy+72y^2)/36,$$

which, via the affine transformation $x_1 = -x + 1/2$, $y_1 = -x + y + 1/4$, can be brought to system (3.69), also corresponding to configuration *Config.* $\mathcal{P}.85$.

Thus, we have proved the following lemma.

Lemma 3.11. *Assume that for a quadratic system the conditions* $(\mathcal{A}_4^*)$ *are satisfied. Then this system possesses one of the following configurations if and only if the corresponding conditions are satisfied, respectively:*

$$\begin{array}{ll}
B_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_2 < 0 & \Rightarrow \textit{Config. } \mathcal{P}.82;\\
B_2 \neq 0,\ \zeta_3 \neq 0,\ \zeta_2 > 0 & \Rightarrow \textit{Config. } \mathcal{P}.83;\\
B_2 \neq 0,\ \zeta_3 = 0 & \Rightarrow \textit{Config. } \mathcal{P}.84;\\
B_2 = 0 & \Rightarrow \textit{Config. } \mathcal{P}.85.
\end{array}$$

3.1.5 The statement $(\mathcal{A}_5^*)$

According to Proposition 2.7*, the condition $\zeta_2 = 0$ holds. Considering (3.2), we obtain $g(g+1) = 0$.

Following the proof of Lemma 3.1, we conclude that the condition $g + 1 = 0$ can be reduced, via an affine transformation (see formulas (3.12)), to the condition $g = 0$.

Therefore, it suffices to study only the case $g = 0$. In this case, we arrive at the following two-parameter family of systems:

$$\dot{x} = m + nx - y/2 + xy, \quad \dot{y} = 2mx + 2ny - xy + 2y^2, \tag{3.70}$$

which possesses the invariant parabola $\Phi(x,y) = x^2 - y = 0$.

Considering the statement $(\mathcal{A}_5^*)$ for these systems, we calculate:

$$\begin{aligned} &\zeta_1 = -12,\ \ \zeta_2 = 0,\ \ \zeta_6 = (2m+n)/2,\ \ \mathcal{R}_1 = 0,\ \ \mathcal{R}_2 = 6(2m+n),\\ &B_1 = 2m(4m-1-2n)(2m+n)^3. \end{aligned} \tag{3.71}$$

Remark 3.12. Following [1, Lemma 5.2], for systems (3.70), we compute:

$$\mu_0 = 0, \quad \mu_1 = -2(2m+n)y \neq 0,$$

due to the condition $\zeta_6 \neq 0$. Therefore, according to [1, Lemma 5.2, statement (i)], we conclude that one of the singular points of systems (3.70) has gone to infinity and has coalesced with the infinite singularity $N[1:0:0]$, producing an infinite singularity of multiplicity $(1,1)$ (see Remark 2.5).

The case $B_1 \neq 0$. We observe that the family of systems (3.70) is a subfamily of (3.1) defined by the condition $g = 0$. Considering the finite singularities of (3.1) given in (3.4), we remark that in the case $g = 0$, the singular point $M_1(x_1, y_1)$ with coordinates

$$x_1 = -\frac{2m+n+gn}{g(1+g)}, \quad y_1 = \frac{2m}{1+g},$$

has moved to infinity. According to Remark 3.12, this singularity coalesced with the infinite singularity $N[1:0:0]$, producing an infinite singularity of multiplicity $(1,1)$.

Therefore, systems (3.70) possess three finite singularities $M_i(\tilde{x}_i, \tilde{y}_i)$ for $i = 2,3,4$, where, from (3.4), we have

$$\tilde{x}_i = x_i\big|_{g=0}, \quad \tilde{y}_i = y_i\big|_{g=0}, \quad i = 2,3,4.$$

Taking into consideration [1, Proposition 5.1], for systems (3.70), we compute:

$$\mu_0 = 0, \quad \mathbf{D} = 48(2m+n)^4\big(108m^2 - 2m + 36mn - n^2 + 16n^3\big), \quad \mathbf{R} = 12(2m+n)^2y^2.$$

We observe that $\mathbf{R} \neq 0$ due to $\zeta_6 \neq 0$, and by [1, Proposition 5.1], we have three distinct real finite singularities if $\mathbf{D} < 0$, and one real and two complex if $\mathbf{D} > 0$. Considering the point at infinity of multiplicity $(1,1)$, we arrive at *Config. $\mathcal{P}$.86* if $\mathbf{D} < 0$, and *Config. $\mathcal{P}$.87* if $\mathbf{D} > 0$.

Now assume that for systems (3.70), the condition $\mathbf{D} = 48(F_1')^2F_2' = 0$ holds, where, from (3.3), we have:

$$F_1' = -(2m+n)^2, \quad F_2' = -2m + 108m^2 + 36mn - n^2 + 16n^3.$$

Since $F_1' \neq 0$ (due to $\zeta_6 \neq 0$), we conclude that the condition $\mathbf{D} = 0$ is equivalent to $F_2' = 0$.

Introducing a new parameter v, as in the generic case (see page 29), we obtain $n = (1 - v^2)/12$, $m = (1+v)^2(2v-1)/216$, and we arrive at the following one-parameter family of systems:

$$\begin{aligned} \dot{x} &= \frac{(1+v)^2(2v-1)}{216} - \frac{v^2-1}{12}\,x - \frac{1}{2}y + xy,\\ \dot{y} &= \frac{(1+v)^2(2v-1)}{108}\,x - \frac{v^2-1}{6}\,y - xy + 2y^2, \end{aligned} \tag{3.72}$$

which is a subfamily of (3.8) defined by $g = 0$.

The systems (3.5) possess three finite singularities given in (3.7), and M_1 is a multiple singularity (of multiplicity at least two). We observe that for $g = 0$, the singular point M_3

has gone to infinity and, according to Remark 3.12, this singularity coalesced with the infinite singularity $N[1:0:0]$, producing an infinite singularity of multiplicity $(1,1)$.

Thus, the systems (3.72) possess at most two different finite singularities $M_1(\tilde{x}_1,\tilde{y}_1)$ (multiple) and $M_2(\tilde{x}_2,\tilde{y}_2)$, where, from (3.7), we have:

$$\tilde{x}_1=\frac{1+v}{6},\quad \tilde{y}_1=\frac{(1+v)^2}{36};\quad \tilde{x}_2=\frac{1-2v}{6},\quad \tilde{y}_2=\frac{(1-2v)^2}{36}.$$

We observe that M_2 coalesces with the double point M_1 if and only if $v=0$.

Considering that $B_1\neq 0$ (i.e., systems (3.72) do not possess any invariant line), we conclude that the configuration is *Config.* $\mathcal{P}$*.88* if $v\neq 0$, and *Config.* $\mathcal{P}$*.89* if $v=0$.

Moreover, for systems (3.72), we compute:

$$\xi_2=\frac{1}{209952}v^2(v-2)^6(1+v)^2,\quad \zeta_6=\frac{1}{108}(v-2)^2(1+v),$$

and due to $\zeta_6\neq 0$, we conclude that the condition $v\neq 0$ is equivalent to $\xi_2\neq 0$. Therefore, we obtain configuration *Config.* $\mathcal{P}$*.88* if $\xi_2\neq 0$, and *Config.* $\mathcal{P}$*.89* if $\xi_2=0$.

The case $B_1=0$**.** Considering (3.71) and the condition $\zeta_6\neq 0$ (i.e., $2m+n\neq 0$), we deduce that the condition $B_1=0$ is equivalent to $m(4m-1-2n)=0$.

On the other hand, for systems (3.70), we calculate:

$$\xi_1=9(4m-1-2n)(2m+n)^2/4$$

and, due to $\zeta_6\neq 0$, we conclude that the condition $4m-1-2n=0$ is equivalent to $\xi_1=0$. Thus, we discuss two subcases: $\xi_1\neq 0$ and $\xi_1=0$.

1: *The subcase* $\xi_1\neq 0$. In this case, the condition $B_1=0$ yields $m=0$, which leads to the one-parameter family of systems:

$$\dot{x}=\frac{1}{2}(2nx-y+2xy),\quad \dot{y}=y(2n-x+2y),\tag{3.73}$$

possessing the invariant parabola $\Phi(x,y)=x^2-y=0$ and the invariant line $y=0$. Calculations yield:

$$B_2=-324n^2(1+2n)y^4$$

and, according to Lemma 2.3, we discuss two possibilities: $B_2\neq 0$ and $B_2=0$.

1.1: The possibility $B_2\neq 0$. We determine that systems (3.73) possess three finite singularities $M_i(x_i,y_i)$ $(i=1,2,3)$ with coordinates:

$$x_1=0,\quad y_1=0;\quad x_{2,3}=\frac{1}{4}\left(1\pm\sqrt{1-16n}\right),\quad y_{2,3}=\frac{1}{8}\left(1-8n\pm\sqrt{1-16n}\right).\tag{3.74}$$

According to Remark 3.12, the fourth finite singularity has coalesced with an infinite one, resulting in a singular point of multiplicity $(1,1)$.

We observe that M_1 is the tangency point between $y=0$ and the invariant parabola, and that M_2 and M_3 are either real, complex, or coincident, depending on the value of $1-16n$.

To determine the relative position of the real singularities M_2 and M_3 with respect to M_1, we calculate:

$$(x_2-x_1)(x_3-x_1)=n,\quad (x_2-x_1)+(x_3-x_1)=1/2>0.$$

On the other hand, for systems (3.73), we calculate:

$$\mathbf{D} = -48n^6(1-16n), \quad \mathcal{R}_2 = 6n,$$

and therefore, due to $\mathcal{R}_2 \neq 0$, we have $\text{sign}\,(\mathcal{R}_2) = \text{sign}\,(n)$ and $\text{sign}\,(\mathbf{D}) = -\text{sign}\,(1-16n)$.

Thus, in the case $B_2 \neq 0$, we arrive at the following four configurations:

$$\begin{array}{ll} \mathbf{D} < 0, \mathcal{R}_2 < 0 & \Rightarrow \textit{Config. } \mathcal{P}.90; \\ \mathbf{D} < 0, \mathcal{R}_2 > 0 & \Rightarrow \textit{Config. } \mathcal{P}.91; \\ \mathbf{D} > 0 & \Rightarrow \textit{Config. } \mathcal{P}.92; \\ \mathbf{D} = 0 & \Rightarrow \textit{Config. } \mathcal{P}.93. \end{array}$$

1.2: The possibility $B_2 = 0$. This implies that $(1+2n)n = 0$, and since $n \neq 0$ (due to $\zeta_6 = n/2 \neq 0$), we get $1+2n = 0$. Thus, $n = -1/2$, and we obtain the system:

$$\dot{x} = \frac{1}{2}(-x-y+2xy), \quad \dot{y} = y(-1-x+2y), \tag{3.75}$$

possessing two invariant lines: $y = 0$ and $y = x$. Considering (3.74), we get three real finite singularities, leading to configuration *Config.* $\mathcal{P}.94$.

2: *The subcase* $\xi_1 = 0$. This implies $m = (1+2n)/4$, and we arrive at the one-parameter family of systems:

$$\dot{x} = \frac{1}{4}(1+2n+4nx-2y+4xy), \quad \dot{y} = \frac{1}{2}(x+2nx+4ny-2xy+4y^2), \tag{3.76}$$

possessing the invariant parabola $\Phi(x,y) = x^2 - y = 0$ and the invariant line $y = x - (2n+1)/2$. Calculations yield:

$$B_2 = -81(1+2n)(1+4n)^2(x-y)^4$$

and, considering Lemma 2.3, we examine two possibilities: $B_2 \neq 0$ and $B_2 = 0$.

2.1: The possibility $B_2 \neq 0$. The above systems possess three finite singularities $M_i(x_i, y_i)$ $(i = 1,2,3)$ with coordinates:

$$x_1 = -\frac{1}{2}, \quad y_1 = \frac{1}{4}; \quad x_{2,3} = \frac{1}{2}\left(1 \pm \sqrt{-(1+4n)}\right), \quad y_{2,3} = \frac{1}{2}\left(-2n \pm \sqrt{-(1+4n)}\right).$$

The singularities M_2 and M_3 are the intersection points between the invariant line $y = x - (2n+1)/2$ and the invariant parabola, and they are real (respectively, complex or coincident) if $1+4n < 0$ (respectively, $1+4n > 0$, $1+4n = 0$).

Again, in the case of real singularities, we calculate:

$$(x_2 - x_1)(x_3 - x_1) = (5+4n)/4, \quad (x_2 - x_1) + (x_3 - x_1) = 2 > 0.$$

Moreover, for systems (3.76), calculations give:

$$\mathbf{D} = 3(1+4n)^5(5+4n)^2/4, \quad \xi_3 = 8164197(1+4n)^3(5+4n)/2,$$

and therefore, for $\mathbf{D} \neq 0$, we have $\text{sign}\,(\mathbf{D}) = \text{sign}\,(1+4n)$ and $\text{sign}\,(\xi_3) = \text{sign}\,\big((1+4n)(5+4n)\big)$.

Thus, in the case $B_2 \neq 0$ and $\mathbf{D} \neq 0$, we arrive at the following configurations:

$$\begin{array}{ll} \mathbf{D} < 0, \xi_3 < 0 & \Rightarrow \textit{Config. } \mathcal{P}.95; \\ \mathbf{D} < 0, \xi_3 > 0 & \Rightarrow \textit{Config. } \mathcal{P}.96; \\ \mathbf{D} > 0 & \Rightarrow \textit{Config. } \mathcal{P}.97. \end{array}$$

Now, assume that $\mathbf{D} = 0$. This implies $(1+4n)(5+4n) = 0$. Since $\zeta_6 = (1+4n)/4 \neq 0$, we get $5+4n = 0$, meaning that one of the singularities M_2 or M_3 coalesces with M_1. Thus, we arrive at configuration *Config. $\mathcal{P}$.98*.

2.2: The possibility $B_2 = 0$. This implies $(1+2n)(1+4n) = 0$, and since $1+4n \neq 0$ (due to $\zeta_6 \neq 0$), we get $1+2n = 0$. Thus, $n = -1/2$, and we arrive again at system (3.75), possessing configuration *Config. $\mathcal{P}$.94*.

Thus, we have proved the following lemma.

Lemma 3.13. *Assume that for a quadratic system the conditions $(\mathcal{A}_5^*)$ are satisfied. Then this system possesses one of the following configurations if and only if the corresponding conditions are satisfied, respectively:*

$$
\begin{array}{ll}
B_1 \neq 0,\ \mathbf{D} < 0 & \Rightarrow \textit{ Config. } \mathcal{P}.86; \\
B_1 \neq 0,\ \mathbf{D} > 0 & \Rightarrow \textit{ Config. } \mathcal{P}.87; \\
B_1 \neq 0,\ \mathbf{D} = 0,\ \xi_2 \neq 0 & \Rightarrow \textit{ Config. } \mathcal{P}.88; \\
B_1 \neq 0,\ \mathbf{D} = 0,\ \xi_2 = 0 & \Rightarrow \textit{ Config. } \mathcal{P}.89; \\
B_1 = 0,\ \xi_1 \neq 0,\ B_2 \neq 0,\ \mathbf{D} < 0,\ \mathcal{R}_2 < 0 & \Rightarrow \textit{ Config. } \mathcal{P}.90; \\
B_1 = 0,\ \xi_1 \neq 0,\ B_2 \neq 0,\ \mathbf{D} < 0,\ \mathcal{R}_2 > 0 & \Rightarrow \textit{ Config. } \mathcal{P}.91; \\
B_1 = 0,\ \xi_1 \neq 0,\ B_2 \neq 0,\ \mathbf{D} > 0 & \Rightarrow \textit{ Config. } \mathcal{P}.92; \\
B_1 = 0,\ \xi_1 \neq 0,\ B_2 \neq 0,\ \mathbf{D} = 0 & \Rightarrow \textit{ Config. } \mathcal{P}.93; \\
B_1 = 0,\ \xi_1 \neq 0,\ B_2 = 0 & \Rightarrow \textit{ Config. } \mathcal{P}.94; \\
B_1 = 0,\ \xi_1 = 0,\ B_2 \neq 0,\ \mathbf{D} < 0,\ \xi_3 < 0 & \Rightarrow \textit{ Config. } \mathcal{P}.95; \\
B_1 = 0,\ \xi_1 = 0,\ B_2 \neq 0,\ \mathbf{D} < 0,\ \xi_3 > 0 & \Rightarrow \textit{ Config. } \mathcal{P}.96; \\
B_1 = 0,\ \xi_1 = 0,\ B_2 \neq 0,\ \mathbf{D} > 0 & \Rightarrow \textit{ Config. } \mathcal{P}.97; \\
B_1 = 0,\ \xi_1 = 0,\ B_2 \neq 0,\ \mathbf{D} = 0 & \Rightarrow \textit{ Config. } \mathcal{P}.98; \\
B_1 = 0,\ \xi_1 = 0,\ B_2 = 0 & \Rightarrow \textit{ Config. } \mathcal{P}.94.
\end{array}
$$

Since all the statements provided by Proposition 2.7* have been considered, this proposition is proved. □

3.2 Systems in QSP$_{(\eta>0)}$ with the condition $\zeta_1 = 0$

In what follows, we examine each of the statements $(\mathcal{B}_1)$ to $(\mathcal{B}_7)$ given by Proposition 2.8.

According to this proposition, a system satisfying the conditions provided by one of the statements $(\mathcal{B}_1)$ to $(\mathcal{B}_7)$ can be brought to the form:

$$\dot{x} = m + nx - \frac{3y}{2} + 2x^2 + xy, \quad \dot{y} = 2mx + 2ny + xy + 2y^2, \tag{3.77}$$

and this system possesses the invariant parabola $\Phi_1(x,y) = x^2 - y = 0$.

3.2.1 The statement $(\mathcal{B}_1)$

According to this statement, for systems (3.77) we calculate $\chi_3 = 0$ and

$$\chi_4 = 61875\,\mathcal{U}_1\mathcal{U}_3, \quad \zeta_7 = -\frac{52875}{2}\,\mathcal{U}_1\mathcal{U}_2\mathcal{U}_3, \quad \mathcal{R}_3 = \quad 3850561006875\,\mathcal{U}_1\mathcal{U}_2\mathcal{U}_3, \tag{3.78}$$

where

$$\mathcal{U}_1 = 1 + 4m + 2n, \quad \mathcal{U}_2 = 4m - 147 - 14n,$$
$$\mathcal{U}_3 = 18m + 1372m^2 - 84mn + 27n^2 + 144n^3.$$

On the other hand, following Lemma 2.3, we calculate:

$$B_1 = m(2m-n)(2m+3n+9)(4m-6n-9)(1+4m+2n) \tag{3.79}$$

and, considering Lemma 2.3, we discuss two cases: $B_1 \neq 0$ and $B_1 = 0$.

The case $B_1 \neq 0$. We observe that the family of systems (3.77) is a subfamily of (3.1) defined by the condition $g = 2$. Therefore, it is clear that systems (3.77) possess four finite singularities $M_i(\tilde{x}_i, \tilde{y}_i)$ $(i = 1,2,3,4)$, where, considering (3.4), we have:

$$\tilde{x}_i = x_i\big|_{\{g=2\}}, \quad \tilde{y}_i = y_i\big|_{\{g=2\}}, \quad i = 1,2,3,4.$$

On the other hand, for systems (3.77), we have:

$$\mathbf{D} = 48\widetilde{F}_1^2\widetilde{F}_2, \quad \widetilde{F}_1 = F_1\big|_{\{g=2\}}, \quad \widetilde{F}_2 = F_2\big|_{\{g=2\}},$$

where F_1 and F_2 are given in (3.3).

As it was proved for the family (3.1), in the case $\mathbf{D} \neq 0$, these systems possess only two distinct configurations: *Config.* $\mathcal{P}.1$ if $\mathbf{D} < 0$, and *Config.* $\mathcal{P}.2$ if $\mathbf{D} > 0$. We obtain the same two configurations in the particular case $g = 2$, because this value of the parameter g is not a bifurcation value for these two configurations.

Assume now that $\mathbf{D} = 0$. This implies $\widetilde{F}_1\widetilde{F}_2 = 0$, and we have to distinguish which factor vanishes. We point out that the invariant polynomial ξ_1, which governed the condition $F_1 = 0$ for systems (3.1) in the generic case (i.e., $g \neq 2$), vanishes for $g = 2$. Therefore, we must use another invariant polynomial, and for systems (3.77) we calculate:

$$\xi_{18} = 17969284698750\, \mathcal{U}_2\, \mathcal{U}_3\, \widetilde{F}_1.$$

Therefore, due to the condition $\zeta_7 \neq 0$, we obtain that the condition $\widetilde{F}_1 = 0$ is equivalent to $\xi_{18} = 0$. Thus, we examine two possibilities: $\xi_{18} \neq 0$ and $\xi_{18} = 0$.

1: The possibility $\xi_{18} \neq 0$. Then $\widetilde{F}_1 \neq 0$ and hence the condition $\mathbf{D} = 0$ implies $\widetilde{F}_2 = 0$. Following the investigation of the family of systems (3.1) in the particular case $g = 2$, we arrive at the systems (3.5), which for $g = 2$ become:

$$\begin{aligned} \dot{x} &= \frac{1}{216}(2v+1)(v-1)^2 - \frac{1}{12}(v^2-1)x - \frac{3y}{2} + 2x^2 + xy, \\ \dot{y} &= \frac{1}{108}(2v+1)(v-1)^2 x - \frac{1}{6}(v^2-1)y + xy + 2y^2. \end{aligned} \tag{3.80}$$

For the above systems, we calculate:

$$\xi_2 = 2^{-5}3^{-8}(v-4)^2(v-1)^2v^2(v^2-20v-8)^2,$$
$$\xi_{18} = 998293594375(v-10)(v-4)^4(v-1)^4(20+v)^2(4+5v)^2(v^2-20v-8)/3188646,$$

and we observe that, due to $\xi_{18} \neq 0$, the condition $\xi_2 = 0$ is equivalent to $v = 0$.

Therefore, following the examination of the two-parameter family of systems (3.1), we conclude that the one-parameter family of systems (3.80), in the case $B_1\xi_{18} \neq 0$, possesses the configuration *Config.* $\mathcal{P}.3$ if $\xi_2 \neq 0$ and *Config.* $\mathcal{P}.4$ if $\xi_2 = 0$.

2: The possibility $\xi_{18} = 0$. Then we have $\widetilde{F}_1 = 0$, which implies $\mathbf{D} = 0$. Following the investigation of the family of systems (3.1) in the particular case $g = 2$, we arrive at the systems (3.8), which for $g = 2$ become:

$$\begin{aligned} \dot{x} =& \frac{3}{8}(u-2)^2 - \frac{1}{4}(u^2-4)x - \frac{3y}{2} + 2x^2 + xy, \\ \dot{y} =& \frac{3}{4}(u-2)^2 x - \frac{1}{2}(u^2-4)y + xy + 2y^2. \end{aligned} \tag{3.81}$$

For the above systems, we calculate:

$$\chi_4 = -556875(u-3)^5(u-2)^2(13+u)/4, \quad \xi_2 = 9(u-3)^2(u-2)^2\widetilde{Z}_1/2,$$
$$\xi_3 = 490484322\,\tilde{\alpha}_1^3\,\widetilde{Z}_1, \quad \widetilde{Z}_1 = Z_1\big|_{\{g=2\}}, \quad \tilde{\alpha}_1 = \alpha_1\big|_{\{g=2\}},$$

where Z_1 and α_1 are the polynomials defined for systems (3.8) (see (3.10) and (3.11)).

We observe that, due to the condition $\chi_4 \neq 0$, we have:

$$\operatorname{sign}(\xi_2) = \operatorname{sign}(\widetilde{Z}_1), \quad \operatorname{sign}(\xi_3) = \operatorname{sign}(\widetilde{Z}_1\tilde{\alpha}_1),$$

and, following the examination of the two-parameter family of systems (3.8), we conclude that the one-parameter family of systems (3.81), in the case $B_1 \neq 0$, possesses the following configurations if and only if the corresponding conditions are satisfied:

$$\begin{array}{ll} \xi_2 < 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.5; \\ \xi_2 > 0,\ \xi_3 < 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.6; \\ \xi_2 > 0,\ \xi_3 > 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.7; \\ \xi_2 = 0 & \Leftrightarrow \textit{Config. } \mathcal{P}.8. \end{array}$$

The case $B_1 = 0$. Considering (3.79) and the condition $\chi_4 \neq 0$ (i.e., $4m + 2n + 1 \neq 0$), we observe that the condition $B_1 = 0$ is equivalent to:

$$m(2m-n)(2m+3n+9)(4m-6n-9) = 0.$$

For systems (3.77), calculations yield:

$$\begin{aligned} \xi_{19} &= -12870000\,m\,(2m-n)\,(2m+3n+9), \\ \xi_{20} &= -540\,m\,(2m-n)\,\mathcal{U}_1\mathcal{U}_3, \quad \xi_{21} = -110106\,m\,\mathcal{U}_1\mathcal{U}_2\mathcal{U}_3, \end{aligned} \tag{3.82}$$

and we consider two subcases: $\xi_{19} \neq 0$ and $\xi_{19} = 0$.

The subcase $\xi_{19} \neq 0$. Then $m(2m-n)(2m+3n+9) \neq 0$, and therefore the condition $B_1 = 0$ yields $4m - 6n - 9 = 0$. This implies $m = \frac{3(3+2n)}{4}$, and we arrive at the one-parameter family of systems:

$$\begin{aligned} \dot{x} &= (9 + 6n + 4nx + 8x^2 - 6y + 4xy)/4, \\ \dot{y} &= (9x + 6nx + 4ny + 2xy + 4y^2)/2, \end{aligned} \tag{3.83}$$

which possesses the invariant line $y = x - \frac{3+2n}{2}$ and four finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with coordinates:

$$x_1 = -\frac{3}{2}, \quad y_1 = \frac{9}{4}; \quad x_2 = -\frac{3+4n}{4}, \quad y_2 = \frac{3+2n}{4};$$
$$x_{3,4} = \frac{1}{2}\left(1 \pm \sqrt{-(5+4n)}\right), \quad y_{3,4} = \frac{1}{2}\left(-2-2n \pm \sqrt{-(5+4n)}\right).$$

We determine that the singularities M_1, M_3, and M_4 lie on the invariant parabola. Moreover, M_3 and M_4 are the points of intersection of the invariant line $y = x - (3+2n)/2$ with the invariant parabola $\Phi_1(x,y) = x^2 - y = 0$. We calculate:

$$\Phi_1(x_2,y_2) = \frac{1}{16}(4n-3)(5+4n),$$

and we conclude that M_2 lies on the parabola if and only if $4n-3=0$, because for systems (3.83), we have:

$$\chi_4\zeta_7\mathcal{R}_3 \neq 0 \;\Leftrightarrow\; (5+4n)(9+4n)(69+4n) \neq 0. \tag{3.84}$$

In order to determine the position of the singularity M_1 with respect to M_3 and M_4 (when they are real), we calculate:

$$(x_1-x_3)(x_1-x_4) = (21+4n)/4 \;\Rightarrow\; \operatorname{sign}\big((x_1-x_3)(x_1-x_4)\big) = \operatorname{sign}(21+4n),$$
$$(x_1-x_3)+(x_1-x_4) = -4 < 0.$$

Thus, we observe that for the parameter n, the following possible bifurcation values arise: $n \in \{-21/4, -5/4, 3/4\}$. Moreover, we point out that due to the condition (3.84), the inequality $5+4n \neq 0$ must hold (i.e., $n \neq -5/4$), and hence the singularities M_3 and M_4 cannot coincide.

On the other hand, according to Lemma 2.3, for the existence of an invariant line in a direction different from $y = x$, the condition $B_2 = 0$ is necessary. For systems (3.83), we calculate:

$$B_2 = -729(3+2n)(9+4n)^2(x-y)^4,\;\; \mathbf{D} = 243(4n-3)^2(5+4n)^3(21+4n)^2/4,$$
$$\xi_9 = 16299895407840(9+4n)^2(21+4n),$$

and in the case $\mathbf{D} \neq 0$, we have:

$$\operatorname{sign}(\mathbf{D}) = \operatorname{sign}(5+4n), \quad \operatorname{sign}(\xi_9) = \operatorname{sign}(21+4n).$$

Considering Lemma 2.3, we examine two possibilities: $B_2 \neq 0$ and $B_2 = 0$.

1: *The possibility* $B_2 \neq 0$. We discuss two cases: $\mathbf{D} \neq 0$ and $\mathbf{D} = 0$.

1.1: *The case* $\mathbf{D} \neq 0$. In this case, all four finite singular points of systems (3.83) are distinct. Considering the bifurcation values of the parameter n mentioned above, for systems (3.83) we obtain the following configurations (depending on the parameter n):

$\mathbf{D} < 0$, $\xi_9 < 0$ (i.e., $n < -21/4$) $\Rightarrow \simeq$ *Config.* $\mathcal{P}.17$;
$\mathbf{D} < 0$, $\xi_9 > 0$ (i.e., $-21/4 < n < -5/4$) $\Rightarrow \simeq$ *Config.* $\mathcal{P}.19$;
$\mathbf{D} > 0$ (i.e., $n > -5/4$) $\Rightarrow \simeq$ *Config.* $\mathcal{P}.20$.

1.2: *The case* $\mathbf{D} = 0$. Then, due to the condition (3.84), we get $(4n-3)(21+4n) = 0$, and we observe that the condition $21+4n = 0$ is governed by the invariant polynomial ξ_9. Therefore, we arrive at the configuration *Config.* $\mathcal{P}.21$ if $\xi_9 \neq 0$ and *Config.* $\mathcal{P}.25$ if $\xi_9 = 0$.

2: *The possibility* $B_2 = 0$. Considering the condition (3.84), we get $n = -3/2$, which leads to the system:

$$\dot{x} = \frac{1}{2}(-3x+4x^2-3y+2xy), \quad \dot{y} = y(-3+x+2y),$$

possessing two invariant lines $y = x$ and $y = 0$, in addition to the invariant parabola. Therefore, in this case, we obtain an equivalent configuration to *Config.* $\mathcal{P}.52$.

The subcase $\xi_{19} = 0$. Then $m(2m-n)(2m+3n+9) = 0$, and we examine two possibilities: $\xi_{20} \neq 0$ and $\xi_{20} = 0$.

1: *The possibility* $\xi_{20} \neq 0$. In this case, considering (3.82), we obtain $m(2m-n) \neq 0$, and therefore $2m+3n+9 = 0$. This implies $m = -3(3+n)/2$, and we arrive at the one-parameter family of systems:

$$\dot{x} = \frac{1}{2}(2x-3)(3+n+2x+y), \quad \dot{y} = -3(3+n)x + 2ny + xy + 2y^2, \tag{3.85}$$

which is a subfamily of (3.14) defined by the condition $g = 2$. The family (3.14) was investigated earlier, and considering (3.15), (3.16) and (3.17) for $g = 2$ (i.e., for systems (3.85)), we have:

$$\begin{gathered} Z_2 = -4(2+n), \quad \alpha_2 = 21+4n, \quad \beta_2 = 33+4n, \\ B_2 = -5832(3+n)(9+4n)^2(17+4n)x^4, \quad \mathbf{D} = -972Z_2\alpha_2^2\beta_2^2, \\ B_3 = -9(9+4n)x^2(12x^2+4nx^2-24xy-8nxy-5y^2)/2, \\ \xi_7 = 1057164750000Z_2\alpha_2^2\beta_2, \quad \xi_8 = 55640250000Z_2\alpha_2\beta_2^2, \\ \xi_{18} = -7277560302993750(6+n)(9+4n)(57+4n)\alpha_2\beta_2. \end{gathered}$$

We observe that for the parameter n, the following possible bifurcation values arise: $n \in \{-33/4, -21/4, -2\}$. Considering (3.78) for systems (3.85), we obtain:

$$\chi_4\zeta_7\mathcal{R}_3 \neq 0 \;\Leftrightarrow\; (6+n)(9+4n)(17+4n)(57+4n)\beta_2 \neq 0, \tag{3.86}$$

and therefore $\beta_2 B_3 \neq 0$. Moreover, from the above condition we deduce that $\xi_{18} = 0$ if and only if $\alpha_2 = 0$.

Thus, in the case $B_2 \neq 0$, and following the investigation of the family (3.14) for $g = 2$, we get the following configurations (depending on the parameter n):

$\mathbf{D} < 0$, $\xi_7 < 0$ (i.e., $n < -33/4$)	$\Rightarrow$ *Config.* $\mathcal{P}.9$;
$\mathbf{D} < 0$, $\xi_7 > 0$, $\xi_8 < 0$ (i.e., $-33/4 < n < -21/4$)	$\Rightarrow$ *Config.* $\mathcal{P}.11$;
$\mathbf{D} < 0$, $\xi_7 > 0$, $\xi_8 > 0$ (i.e., $-21/4 < n < -2$)	$\Rightarrow$ *Config.* $\mathcal{P}.12$;
$\mathbf{D} > 0$ (i.e., $n > -2$)	$\Rightarrow$ *Config.* $\mathcal{P}.13$;
$\mathbf{D} = 0$, $\xi_{18} \neq 0$ (i.e., $n = -2$)	$\Rightarrow$ *Config.* $\mathcal{P}.14$;
$\mathbf{D} = 0$, $\xi_{18} = 0$ (i.e., $n = -21/4$)	$\Rightarrow$ *Config.* $\mathcal{P}.16$.

Assuming $B_2 = 0$, and considering the condition (3.86), we get $n = -3$ and arrive at the system:

$$\dot{x} = \frac{1}{2}(2x-3)(2x+y), \quad \dot{y} = y(-6+x+2y),$$

which possesses two invariant lines $x = 3/2$ and $y = 0$, in addition to the invariant parabola. Therefore, for this system, we obtain the configuration *Config.* $\mathcal{P}.47$.

2: *The possibility* $\xi_{20} = 0$. Then, from (3.82), we obtain $m(2m-n) = 0$, and we discuss two cases: $\xi_{21} \neq 0$ and $\xi_{21} = 0$.

2.1: *The case* $\xi_{21} \neq 0$. Then $m \neq 0$, and we obtain $m = n/2$. This leads to the following one-parameter family of systems:

$$\dot{x} = \frac{n}{2} + nx - \frac{3y}{2} + 2x^2 + xy, \quad \dot{y} = (n+y)(x+2y), \tag{3.87}$$

which is a subfamily of (3.19) defined by the condition $g = 2$. The family (3.19) was investigated earlier, and considering (3.21) for $g = 2$ (i.e., for systems (3.87)), we conclude that these systems possess four singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with coordinates:

$$x_1 = \sqrt{-n}, \quad y_1 = -n; \quad x_2 = -\sqrt{-n}, \quad y_2 = -n;$$
$$x_3 = -\frac{1}{2}, \quad y_3 = \frac{1}{4}; \quad x_4 = -\frac{2n}{3}, \quad y_4 = \frac{n}{3}.$$

For these systems, we calculate:

$$\theta = -32 \neq 0, \quad B_2 = -162(1+4n)(9+4n)^2y^4, \quad \chi_4 = 61875n(1+4n)(9+4n)(1+36n),$$

and therefore $B_2 \neq 0$ due to $\chi_4 \neq 0$. Following the examination of the configurations of systems (3.19) for $g = 2$, we obtain:

$$\alpha_3 = 4n - 3, \quad \beta_3 = 1 + 4n, \quad \mathbf{D} = 768n^3\alpha_3^2\beta_3^2, \quad \xi_9 = 3219732426240(9+4n)^2\beta_3,$$

and due to $\chi_4 \neq 0$, in the case $\mathbf{D} \neq 0$, we have:

$$\operatorname{sign}(\mathbf{D}) = \operatorname{sign}(n), \quad \operatorname{sign}(\xi_9) = \operatorname{sign}(\beta_3),$$

and the condition $\alpha_3 = 0$ is equivalent to $\mathbf{D} = 0$.

Thus, we arrive at the following configurations (depending on the parameter n):

$$\begin{aligned}
&\mathbf{D} < 0, \xi_9 < 0 \text{ (i.e., } n < -1/4) && \Rightarrow \textit{ Config. } \mathcal{P}.17;\\
&\mathbf{D} < 0, \xi_9 > 0 \text{ (i.e., } -1/4 < n < 0) && \Rightarrow \textit{ Config. } \mathcal{P}.19;\\
&\mathbf{D} > 0 \text{ (i.e., } n > 0, n \neq 3/4) && \Rightarrow \textit{ Config. } \mathcal{P}.20;\\
&\mathbf{D} = 0 \text{ (i.e., } n = 3/4) && \Rightarrow \textit{ Config. } \mathcal{P}.21.
\end{aligned}$$

2.2: *The case* $\xi_{21} = 0$. Then $m = 0$, and we obtain the one-parameter family of systems:

$$\dot{x} = nx - \frac{3y}{2} + 2x^2 + xy, \quad \dot{y} = y(2n + x + 2y), \tag{3.88}$$

which is a subfamily of (3.25) defined by the condition $g = 2$. The family (3.25) was investigated earlier, and considering (3.28) for $g = 2$ (i.e., for systems (3.88)), we have:

$$Z_3 = 1 - 16n, \quad B_2 = -1458(3+n)(1+2n)(3+2n)y^4, \quad \theta = -32 \neq 0,$$
$$B_3 = -9n(7+4n)x^2y^2/2 - 9(3+n)xy^3 + 9(3+n)y^4/2 \neq 0,$$
$$\mathbf{D} = -3888n^6Z_3, \quad \xi_{22} = 1050n, \quad \chi_4 = 556875n^2(1+2n)(3+16n).$$

So, due to the condition $\chi_4 \neq 0$, in the case $\mathbf{D} \neq 0$, we have:

$$\operatorname{sign}(\mathbf{D}) = -\operatorname{sign}(Z_3), \quad \operatorname{sign}(\xi_{22}) = \operatorname{sign}(n).$$

Thus, in the case $B_2 \neq 0$, and following the investigation of the family (3.25) for $g = 2$, we get the following configurations (depending on the parameter n):

$$\begin{aligned}
&\mathbf{D} < 0, \xi_{22} < 0 \text{ (i.e., } n < 0) && \Rightarrow \textit{ Config. } \mathcal{P}.32;\\
&\mathbf{D} < 0, \xi_{22} > 0 \text{ (i.e., } 0 < n < 1/16) && \Rightarrow \textit{ Config. } \mathcal{P}.31;\\
&\mathbf{D} > 0 \text{ (i.e., } n > 1/16) && \Rightarrow \textit{ Config. } \mathcal{P}.34;\\
&\mathbf{D} = 0 \text{ (i.e., } n = 1/16) && \Rightarrow \textit{ Config. } \mathcal{P}.37.
\end{aligned}$$

Assume now $B_2 = 0$. The condition $\chi_4 \neq 0$ implies $1 + 2n \neq 0$, and we get $(3+2n)(3+n) = 0$. Since for systems (3.88) we have $\xi_{23} = -225(3+n)/4$, we arrive at configuration *Config.* $\mathcal{P}.52$ in the case $\xi_{23} \neq 0$ (i.e., $n = -3/2$), and *Config.* $\mathcal{P}.47$ in the case $\xi_{23} = 0$ (i.e., $n = -3$).

3.2.2 The statements $(\mathcal{B}_2)$, $(\mathcal{B}_3)$, and $(\mathcal{B}_4)$

According to Proposition 2.8, all these three statements share the common condition $\zeta_7 = 0$. Considering (3.78) and the requirement $\chi_4 \neq 0$, we must impose the condition $\mathcal{U}_2 = 4m - 147 - 14n = 0$, leading to $m = 7(21 + 2n)/4$. This gives rise to the following one-parameter family:

$$\begin{aligned} \dot{x} &= (147 + 14n + 4nx + 8x^2 - 6y + 4xy)/4, \\ \dot{y} &= (147x + 14nx + 4ny + 2xy + 4y^2)/2, \end{aligned} \tag{3.89}$$

for which we calculate:

$$\begin{aligned} \chi_4 &= 61875(37 + 4n)(69 + 4n)(357 + 4n)(301 + 36n), \\ \zeta_8 &= 5(21 + 4n)^2/4, \quad \mathcal{R}_4 = 19500(33 + 4n). \end{aligned} \tag{3.90}$$

Thus, following Proposition 2.8, we distinguish three possibilities: $\zeta_8\mathcal{R}_4 \neq 0$ (statement $(\mathcal{B}_2)$), $\zeta_8 = 0$ (statement $(\mathcal{B}_3)$), and $\mathcal{R}_4 = 0$ (statement $(\mathcal{B}_4)$). We examine each possibility in turn.

The possibility $\zeta_8\mathcal{R}_4 \neq 0$. Then $33 + 4n \neq 0$, and systems (3.89) possess the following two invariant parabolas:

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = -(21+2n)(21+4n) + 6(21+4n)x + 24x^2 - 2(33+4n)y = 0.$$

We observe that systems (3.89) form a subfamily of (3.37) defined by the condition $g = 2$. The family (3.37) was investigated earlier, and considering (3.40) and (3.43) for $g = 2$ (i.e., for systems (3.89)), we have:

$$\begin{gathered} Z_4 = -(33 + 4n), \quad \alpha_4 = 133 + 4n, \quad \beta_4 = 861 + 100n, \quad \theta = -32 \neq 0, \\ \mathbf{D} = -3(21 + 4n)^2 Z_4 \alpha_4^2 \beta_4^2/4, \quad \zeta_2 = 24 > 0, \quad \xi_{14} = 1235\,\alpha_4\beta_4/2, \\ B_1 = 105(21 + 2n)(33 + 4n)(37 + 4n)(49 + 4n)(69 + 4n)/2. \end{gathered}$$

We observe that due to $\zeta_8\mathcal{R}_4 \neq 0$, we have $Z_4(21 + 4n) \neq 0$, and, in the case $\mathbf{D} \neq 0$, we obtain:

$$\operatorname{sign}(\mathbf{D}) = -\operatorname{sign}(Z_4), \quad \operatorname{sign}(\xi_{14}) = \operatorname{sign}(\alpha_4\beta_4).$$

Moreover, the direction of the invariant parabola $\Phi_2(x, y) = 0$ depends on $\operatorname{sign}(33 + 4n)$.

According to Lemma 2.3, the existence of an invariant line in systems (3.89) requires $B_1 = 0$. Thus, we consider two cases: $B_1 \neq 0$ and $B_1 = 0$.

The case $B_1 \neq 0$. Then no invariant line exists. For the parameter n, we have three possible bifurcation values: $n \in \{-133/4, -861/100, -33/4\}$. However, due to $\mathcal{R}_4 \neq 0$, we must have $Z_4 \neq 0$, i.e., $n \neq -33/4$.

Considering these possible bifurcation values, in the case $B_1 \neq 0$, systems (3.89) lead to the following configurations (depending on the parameter n):

$$\begin{array}{ll} \mathbf{D} < 0,\ \xi_{14} < 0 \text{ (i.e., } -133/4 < n < -861/100) & \Rightarrow \textit{ Config. } \mathcal{P}.58; \\ \mathbf{D} < 0,\ \xi_{14} > 0,\ \beta_4 < 0 \text{ (i.e., } n < -133/4) & \Rightarrow \textit{ Config. } \mathcal{P}.59; \\ \mathbf{D} < 0,\ \xi_{14} > 0,\ \beta_4 > 0 \text{ (i.e., } -861/100 < n < -33/4) & \Rightarrow \textit{ Config. } \mathcal{P}.59; \\ \mathbf{D} > 0 \text{ (i.e., } n > -33/4) & \Rightarrow \textit{ Config. } \mathcal{P}.61; \\ \mathbf{D} = 0,\ \beta_4 \neq 0 \text{ (i.e., } n = -133/4) & \Rightarrow \textit{ Config. } \mathcal{P}.64; \\ \mathbf{D} = 0,\ \beta_4 = 0 \text{ (i.e., } n = -861/100) & \Rightarrow \textit{ Config. } \mathcal{P}.64. \end{array}$$

We may summarize the above as:

$$\begin{array}{ll} \mathbf{D} < 0, \xi_{14} < 0 & \Rightarrow \textit{Config. } \mathcal{P}.58; \\ \mathbf{D} < 0, \xi_{14} > 0 & \Rightarrow \textit{Config. } \mathcal{P}.59; \\ \mathbf{D} > 0 & \Rightarrow \textit{Config. } \mathcal{P}.61; \\ \mathbf{D} = 0 & \Rightarrow \textit{Config. } \mathcal{P}.64. \end{array}$$

The case $B_1 = 0$. Considering (3.90) and the condition $\chi_4\zeta_8\mathcal{R}_4 \neq 0$, the condition $B_1 = 0$ is equivalent to $49 + 4n = 0$, i.e., $n = -49/4$. The corresponding system (3.89) possesses the invariant line $y = 49/4$, leading to a configuration equivalent to *Config.* $\mathcal{P}.69$.

The possibility $\zeta_8 = 0$. From (3.90), this condition implies $n = -21/4$, and we arrive at the system:

$$\begin{aligned} \dot{x} &= (147 - 42x - 12y + 16x^2 + 8xy)/8, \\ \dot{y} &= (147x - 42y + 4xy + 8y^2)/4. \end{aligned} \tag{3.91}$$

For $n = -21/4$, we find:

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = 24(x^2 - y) = 0,$$

i.e., the system has a double invariant parabola. Moreover, in this case, there is one real singular point $M_1(x_1, y_1)$ and two complex singularities $M_{2,3}(x_{2,3}, y_{2,3})$, with:

$$x_1 = -\frac{7}{2}, \quad y_1 = \frac{49}{4}; \quad x_{2,3} = \frac{3}{2} \pm i\sqrt{3}, \quad y_{2,3} = -\frac{3}{4} \pm 3i\sqrt{3}.$$

We point out that M_1 is a double singularity of system (3.91), located on the double invariant parabola $\Phi_1(x, y) = x^2 - y = 0$. Therefore, we arrive at configuration *Config.* $\mathcal{P}.79$.

The possibility $\mathcal{R}_4 = 0$. From (3.90), this condition implies $n = -33/4$, and we obtain the system:

$$\dot{x} = (2x - 3)(-21 + 8x + 4y)/8, \quad \dot{y} = (63x - 66y + 4xy + 8y^2)/4.$$

For $n = -33/4$, the second invariant parabola becomes the reducible conic $\Phi_2(x, y) = 6(2x - 3)^2 = 0$. Thus, the system possesses the invariant line $x = 3/2$ and the invariant parabola $\Phi_1(x, y) = x^2 - y = 0$, yielding a configuration equivalent to *Config.* $\mathcal{P}.83$.

3.2.3 The statement $(\mathcal{B}_5)$

According to Proposition 2.8, we must have the condition $\chi_4 = 0$ and $\zeta_5\zeta_9 \neq 0$. Thus, for systems (3.77) we compute:

$$\begin{aligned} \chi_4 = 61875(1 + 4m + 2n)\mathcal{V}, \quad \xi_{24} = 140625(4m - 14n - 147)\mathcal{V}/16, \\ \zeta_5 = 25(196m - 46n - 3)(4m - 14n - 147)/16, \\ \zeta_9 = -2970000(4m - 14n - 147)\mathcal{W}, \end{aligned} \tag{3.92}$$

where

$$\mathcal{V} = 18m + 1372m^2 - 84mn + 27n^2 + 144n^3, \quad \mathcal{W} = 10m + 196m^2 - 88mn + 15n^2.$$

We consider two cases: $\xi_{24} \neq 0$ and $\xi_{24} = 0$.

The case $\xi_{24} \neq 0$. Then $\mathcal{V} \neq 0$ and the condition $1+4m+2n=0$ implies $m=-(1+2n)/4$. This leads to the one-parameter family of systems

$$\dot{x} = -\frac{1}{4}(2n+1) + nx - \frac{3y}{2} + 2x^2 + xy, \quad \dot{y} = -\frac{1}{2}(2n+1)x + 2ny + xy + 2y^2, \tag{3.93}$$

which possess the invariant line $y = x - \frac{1}{4}$ and two invariant parabolas:

$$\Phi_1(x,y) = x^2 - y = 0, \quad \Phi_2(x,y) = -1 - 2n + 2(1+4n)x - 2(-1+4n)y - 8y^2 = 0.$$

For these systems, we have

$$\begin{gathered}\zeta_5 = 25(37+4n)(13+36n), \quad \xi_{24} = -140625(5+4n)^2(37+4n)(13+36n)/16,\\ \zeta_9 = 11\cdot 30^4(1+4n)(37+4n)(13+36n), \quad B_1 = 0, \quad \theta = -32 \neq 0,\\ B_2 = -81(1+2n)(1+4n)(17+4n)(x-y)^4, \quad \mathbf{D} = 3(1+4n)(5+4n)^6/4.\end{gathered} \tag{3.94}$$

Following Lemma 2.3, we consider two subcases: $B_2 \neq 0$ and $B_2 = 0$.

1: *The subcase $B_2 \neq 0$.* Then, by Lemmas 2.3 and 2.4 (since $\theta \neq 0$), we conclude that systems (3.93) can have only one invariant line (namely, $y = x - 1/4$).

Systems (3.93) have four finite singularities $M_i(x_i, y_i)$, $i = 1, \ldots, 4$, with coordinates

$$\begin{gathered}x_1 = \frac{1}{2}, \quad y_1 = \frac{1}{4}; \quad x_2 = \frac{1-4n}{12}, \quad y_2 = -\frac{1+2n}{6};\\ x_{3,4} = -\frac{1}{2}\left(1 \pm \sqrt{-1-4n}\right), \quad y_{3,4} = \frac{1}{2}\left(-2n \pm \sqrt{-1-4n}\right).\end{gathered}$$

Note that the invariant parabolas intersect at three points: M_1, M_3, and M_4. The singularities M_3 and M_4 may be real or complex depending on $1+4n \neq 0$ (due to $\zeta_9 \neq 0$). Moreover, the direction of the parabola $\Phi_2(x,y) = 0$ also depends on $1+4n$.

It is easy to verify that the invariant line $y = x - 1/4$ is tangent to both invariant parabolas at M_1. The singularity M_2 lies on this invariant line, and

$$\Phi_1(x_2, y_2) = \frac{1}{144}(5+4n)^2 \neq 0, \quad \Phi_2(x_2, y_2) = -\frac{1}{18}(5+4n)^2 \neq 0,$$

due to $\xi_{24} \neq 0$. Considering (3.94), $\mathbf{D} \neq 0$ since $\zeta_9\xi_{24} \neq 0$ and $\operatorname{sign}(\mathbf{D}) = \operatorname{sign}(5+4n)$.

To understand the position of M_2 relative to M_1, we compute

$$x_2 - x_1 = \frac{1-4n}{12} - \frac{1}{2} = -\frac{5+4n}{12} \quad \Rightarrow \quad \operatorname{sign}(x_2 - x_1) = -\operatorname{sign}(5+4n).$$

Hence, all finite singularities except M_2 are fixed as intersection points of the invariant curves, and their positions depend on n. In the case $B_2 \neq 0$, the possible bifurcation values for n are $-5/4$ and $-1/4$.

Thus, for $B_2 \neq 0$ in systems (3.93) we have the following configurations:

$$\begin{aligned}&\mathbf{D} < 0 \text{ and } n < -5/4 && \Rightarrow \textit{Config. } \mathcal{P}.99;\\ &\mathbf{D} < 0 \text{ and } n > -5/4 && \Rightarrow \simeq \textit{Config. } \mathcal{P}.99;\\ &\mathbf{D} > 0 \text{ (i.e., } n > -1/4) && \Rightarrow \textit{Config. } \mathcal{P}.100.\end{aligned}$$

So, *Config.* $\mathcal{P}.99$ occurs if $\mathbf{D} < 0$, and *Config.* $\mathcal{P}.100$ if $\mathbf{D} > 0$.

2: *The subcase $B_2 = 0$.* From $\zeta_9 \neq 0$, we get $(1+2n)(17+4n) = 0$.

If $1+2n=0$, then $n=-1/2$, yielding the system

$$\dot{x}=(-x+4x^2-3y+2xy)/2,\quad \dot{y}=y(-1+x+2y),$$

which has four invariant curves (two parabolas and two lines):

$$\Phi_1(x,y)=x^2-y=0,\quad \Phi_2(x,y)=x-3y+4y^2=0,\quad y=x-1/4,\quad y=0.$$

This corresponds to configuration *Config. $\mathcal{P}$.101*.

If $n=-17/4$, we get

$$\dot{x}=(-3+2x)(-5+8x+4y)/8,\quad \dot{y}=(15x-34y+4xy+8y^2)/4,$$

which has invariant lines $y=x-1/4$ and $x=3/2$, and invariant parabolas

$$\Phi_1(x,y)=x^2-y=0,\quad \Phi_2(x,y)=15-64x+72y-16y^2=0.$$

The line $x=3/2$ is tangent to $\Phi_2(x,y)=0$ at $M_4(3/2,9/4)$. Thus, in this case, we get a configuration equivalent to *Config. $\mathcal{P}$.101*.

The case $\zeta_{24}=0$. This implies $\mathcal{V}=0$ and we calculate

$$\text{Discrim}\,[\mathcal{V},m]=36(1-28n)(3+28n)^2\equiv\gamma(n).$$

Since $m,n\in\mathbb{R}$, the condition $\gamma(n)\geq 0$ is necessary.

We claim that $\zeta_5\neq 0$ implies $3+28n\neq 0$. Indeed, setting $n=-3/28$ we get

$$\mathcal{V}=\frac{(2744m+27)^2}{5488}=0\quad\Rightarrow\quad m=-\frac{27}{2744},$$

which implies $\zeta_5=0$. Thus, the claim is proved.

Therefore, the condition $1-28n\geq 0$ is necessary for $\mathcal{V}$ to have real roots. Setting a new parameter u as $1-28n=u^2\geq 0$, we have $n=(1-u^2)/28$ and

$$\mathcal{V}=\frac{1}{5488}(15+2744m+24u+3u^2-6u^3)(15+2744m-24u+3u^2+6u^3)=0.$$

By symmetry ($u\mapsto -u$), we may assume the second factor vanishes, yielding

$$m=-3(u-1)^2(5+2u)/2744.$$

This leads to the one-parameter family of systems

$$\begin{aligned}\dot{x}&=-\frac{3(u-1)^2(5+2u)}{2744}-\frac{u^2-1}{28}x-\frac{3}{2}y+2x^2+xy,\\ \dot{y}&=-\frac{3(u-1)^2(5+2u)}{1372}x-\frac{u^2-1}{14}y+xy+2y^2,\end{aligned}\tag{3.95}$$

which possess two invariant parabolas:

$$\Phi_1(x,y)=x^2-y=0,\quad \Phi_2(x,y)=3(u-1)^4+112(u-1)^3x+1176(u-1)^2y-38416y^2=0.$$

For these systems,

$$\begin{gathered}\zeta_5 = 25(u-50)(u-22)(u^2-4)(3u-10)(3u+46)/38416,\\ \zeta_9 = 2227500(u-50)(u-22)(u^2-4)(u-1)^3(3u-10)(3u+46)/823543,\\ \zeta_{10} = -15(354160+48u-1336u^2+64u^3+27u^4-19u^5+3u^6)/38416,\\ \mathbf{D} = -3^5 7^{-18}(u-1)^6(6+u)^8(34+u)^2(2+5u)^2.\end{gathered} \tag{3.96}$$

Also, for (3.95) we have

$$B_1 = -3^3 2^{-5} 7^{-15}(u-22)(u-8)^3(u-1)^3(6+u)^3(13+u)(20+u)(5+2u)(3u-10)(4+3u). \tag{3.97}$$

Following Lemma 2.3, we consider two subcases: $B_1 \neq 0$ and $B_1 = 0$.

1: *The subcase* $B_1 \neq 0$. Then, by Lemma 2.3, systems (3.95) cannot possess any invariant line.

The systems (3.95) have four finite singularities $M_i(x_i, y_i)$, $i = 1,2,3,4$, with coordinates

$$\begin{gathered}x_1 = -\frac{5+2u}{14}, \quad y_1 = \frac{(5+2u)^2}{196}; \quad x_2 = \frac{(u-1)(22+26u+u^2)}{1372}, \quad y_2 = -\frac{(u-1)^2(5+2u)}{1372};\\ x_3 = \frac{1-u}{14}, \quad y_3 = \frac{(1-u)^2}{196}; \quad x_4 = \frac{3(u-1)}{14}, \quad y_4 = \frac{9(u-1)^2}{196}.\end{gathered} \tag{3.98}$$

The invariant parabolas intersect at points M_3 and M_4. The singularities M_1 and M_2 lie on $\Phi_1 = 0$ and $\Phi_2 = 0$, respectively. The direction of $\Phi_2 = 0$ depends on $u-1$, and since $\zeta_9 \neq 0$, we have $u \neq 1$.

Because $\mathbf{D} = 0$ indicates a multiple singularity, we consider the possibilities $\mathbf{D} \neq 0$ and $\mathbf{D} = 0$.

1.1: *The possibility* $\mathbf{D} \neq 0$. Then all singularities are distinct. To determine the relative positions of M_1 and M_2 with respect to M_3 and M_4 (intersection points of the parabolas), we compute:

$$\begin{aligned}x_3 - x_1 &= \frac{6+u}{14}, & x_3 - x_2 &= -\frac{(u-1)(6+u)(20+u)}{1372},\\ x_4 - x_1 &= \frac{2+5u}{14}, & x_4 - x_2 &= -\frac{(u-8)(u-1)(34+u)}{1372}.\end{aligned}$$

Moreover, the singular point M_2, which lies on the parabola $\Phi_2(x,y) = 0$, can be located either above or below its axis $y = y_v$, where y_v is the ordinate of the vertex of this parabola. For $\Phi_2(x,y) = 0$, we have $y_v = 3(u-1)^2/196$ and then we calculate

$$y_2 - y_v = -(u-1)^2(13+u)/686 \quad \Rightarrow \quad \operatorname{sign}(y_2 - y_v) = -\operatorname{sign}(13+u).$$

Additionally,

$$\Phi_1(x_2, y_2) = \frac{(u-1)^2(6+u)^3(34+u)}{1882384}, \quad \Phi_2(x_1, y_1) = -(6+u)^3(2+5u).$$

Possible bifurcation values for u are $\{-34, -20, -13, -6, -\frac{2}{5}, 1, 8\}$. Since $\zeta_5\zeta_9 B_1 \mathbf{D} \neq 0$, we have:

$$(u-8)(u-1)(u+20)(u+13)(u+6)(u+34)(2+5u) \neq 0.$$

Thus, in the case $B_1 \neq 0$ and $\mathbf{D} \neq 0$, systems (3.95) yield the following configurations:

$$\begin{array}{lll}
u<-34 & \Rightarrow x_3>x_4,\ x_1>x_3,\ x_2<x_4,\ y_2>y_v & \Rightarrow \textit{Config. } \mathcal{P}.102;\\
-34<u<-20 & \Rightarrow x_3>x_4,\ x_1>x_3,\ x_4<x_2<x_3,\ y_2>y_v & \Rightarrow \textit{Config. } \mathcal{P}.103;\\
-20<u<-13 & \Rightarrow x_3>x_4,\ x_1>x_3,\ x_4<x_3<x_2,\ y_2>y_v & \Rightarrow \simeq \textit{Config. } \mathcal{P}.103;\\
-13<u<-6 & \Rightarrow x_3>x_4,\ x_1>x_3,\ x_4<x_3<x_2,\ y_2<y_v & \Rightarrow \simeq \textit{Config. } \mathcal{P}.103;\\
-6<u<-2/5 & \Rightarrow x_3>x_4,\ x_4<x_1<x_3,\ x_4<x_2<x_3,\ y_2<y_v & \Rightarrow \simeq \textit{Config. } \mathcal{P}.103;\\
-2/5<u<1 & \Rightarrow x_3>x_4,\ x_1<x_3,\ x_4<x_2<x_3,\ y_2<y_v & \Rightarrow \simeq \textit{Config. } \mathcal{P}.102;\\
1<u<8 & \Rightarrow x_3>x_4,\ x_1<x_3,\ x_4<x_2<x_3,\ y_2<y_v & \Rightarrow \textit{Config. } \mathcal{P}.104;\\
u>8 & \Rightarrow x_3>x_4,\ x_1<x_3,\ x_4<x_2<x_3,\ y_2<y_v & \Rightarrow \simeq \textit{Config. } \mathcal{P}.104.
\end{array}$$

We can summarize these as

$$\begin{array}{lll}
\textit{Config. } \mathcal{P}.103 & \Leftrightarrow & (u+34)(5u+2)<0;\\
\textit{Config. } \mathcal{P}.102 & \Leftrightarrow & (u+34)(5u+2)>0 \text{ and } u-1<0;\\
\textit{Config. } \mathcal{P}.104 & \Leftrightarrow & (u+34)(5u+2)>0 \text{ and } u-1>0.
\end{array}$$

On the other hand, for systems (3.95) we have

$$\xi_{25}=2^{-3}7^{-9}5913(u-1)^3(6+u)^4(34+u)(2+5u),$$
$$\zeta_5\zeta_9=2^{-2}7^{-11}3^45^611(u-1)^3(-50+u)^2(-22+u)^2(-2+u)^2(2+u)^2(-10+3u)^2(46+3u)^2,$$

and due to $\mathbf{D}\zeta_5\zeta_9\neq 0$ we have

$$\xi_{25}\neq 0,\quad \operatorname{sign}(\xi_{25})=\operatorname{sign}\big((u-1)(34+u)(2+5u)\big),\quad \operatorname{sign}(\zeta_5\zeta_9)=\operatorname{sign}(u-1).$$

This leads to the following invariant conditions:

$$\begin{array}{lll}
\xi_{25}<0 & \Leftrightarrow & \textit{Config. } \mathcal{P}.102;\\
\xi_{25}>0,\ \zeta_5\zeta_9<0 & \Leftrightarrow & \textit{Config. } \mathcal{P}.103;\\
\xi_{25}>0,\ \zeta_5\zeta_9>0 & \Leftrightarrow & \textit{Config. } \mathcal{P}.104.
\end{array}$$

1.2: *The possibility* $\mathbf{D}=0$. Considering the condition $B_1\neq 0$, this implies $(34+u)(2+5u)=0$. Taking into consideration the position of the invariant parabolas and the coordinates (3.98) of the singularities of systems (3.95), we obtain:

$$\begin{array}{lll}
u=-34 & \Rightarrow x_3>x_4,\ x_1>x_3,\ x_2=x_4,\ y_2>y_v & \Rightarrow \textit{Config. } \mathcal{P}.105;\\
u=-2/5 & \Rightarrow x_3>x_4,\ x_1=x_4,\ x_4<x_2<x_3,\ y_2<y_v & \Rightarrow \simeq \textit{Config. } \mathcal{P}.105.
\end{array}$$

So, we deduce that in the case $B_1\neq 0$ and $\mathbf{D}=0$ we get the unique configuration *Config. $\mathcal{P}$.105*.

2: *The subcase* $B_1=0$. Considering (3.97) and (3.96), we conclude that due to $\zeta_9\neq 0$ the condition $B_1=0$ is equivalent to

$$(u-8)(6+u)(13+u)(20+u)(5+2u)(4+3u)=0.$$

However, we could decrease the number of factors.

Remark 3.14. We remark that in the case $u-1\neq 0$ (i.e., when the second parabola exists), applying the transformation

$$x_1=\frac{343}{(u-1)^3}y-\frac{21}{4(u-1)},\quad y_1=\frac{343}{(u-1)^3}x+\frac{147}{4(u-1)^2},\quad t_1=\frac{(u-1)^3}{343}t,$$

we arrive at a family of systems of the same form (3.95):

$$\dot{x}_1=-\frac{3(u_1-1)^2(5+2u_1)}{2744}-\frac{u_1^2-1}{28}x_1-\frac{3y_1}{2}+2x_1^2+x_1y_1,$$
$$\dot{y}_1=-\frac{3(u_1-1)^2(5+2u_1)}{1372}x_1-\frac{u_1^2-1}{4}y_1+x_1y_1+2y_1^2,$$

with the new parameter $u_1=(48+u)/(u-1)$ (then $u=(48+u_1)/(u_1-1)$).

Considering Remark 3.14 and the relation $u = (48 + u_1)/(u_1 - 1)$, we calculate

$$u + 13 = \frac{7(5 + 2u_1)}{u_1 - 1}, \qquad u + 20 = \frac{7(3u_1 + 4)}{u_1 - 1}.$$

So, to determine the configurations given by the condition $B_1 = 0$, it is sufficient to consider the conditions provided by the equality

$$(u - 8)(6 + u)(5 + 2u)(4 + 3u) = 0.$$

2.1: *The possibility* $u = -4/3$. This leads to the system

$$\dot{x} = (-1 - 2x + 144x^2 - 108y + 72xy)/72, \quad \dot{y} = (x + 2y)(-1 + 36y)/36,$$

possessing the invariant line $y = 1/36$ and two invariant parabolas:

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = 1 - 16x + 72y - 432y^2.$$

We determine that the configuration of the above system corresponds to *Config.* $\mathcal{P}$*.106*.

2.2: *The possibility* $u = 8$. This leads to the system

$$\dot{x} = (2x - 3)(3 + 8x + 4y)/8, \quad \dot{y} = (x + 2y)(4y - 9)/4,$$

possessing three invariant lines $y = 9/4$, $y = x + 3/4$ and $x = 3/2$ and two invariant parabolas:

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = 3 + 16x + 24y - 16y^2.$$

We observe that all five invariant curves intersect at the singular point $M_4(3/2, 9/4)$. So we get the configuration *Config.* $\mathcal{P}$*.107*.

2.3: *The possibility* $u = -5/2$. In this case we arrive at the system

$$\dot{x} = (-3x + 32x^2 - 24y + 16xy)/16, \quad \dot{y} = y(-3 + 8x + 16y)/4,$$

possessing the invariant line $y = 0$ and two invariant parabolas:

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = 3 - 32x + 96y - 256y^2.$$

We observe that the invariant line $y = 0$ is tangent to the parabola $\Phi_1(x, y) = 0$ at the point $M_1(0, 0)$ and intersects the second parabola at $M_2(3/32, 0)$. In this case, we have the configuration *Config.* $\mathcal{P}$*.108*.

2.4: *The possibility* $u = -6$. In this case we get the system

$$\dot{x} = (3 - 10x + 16x^2 - 12y + 8xy)/8, \quad \dot{y} = (3x - 10y + 4xy + 8y^2)/4,$$

possessing the invariant line $y = x - 1/4$ and the invariant parabolas

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = 3 - 16x + 24y - 16y^2 = 0.$$

Considering the coordinates (3.98) of the singularities of systems (3.95), we observe that for $u = -6$ the singular points M_2, M_3 and M_1 coalesce producing a triple singular point. Moreover, this triple singularity is a point of tangency of the invariant line $y = x - 1/4$ with both parabolas. As a result, we get the configuration *Config.* $\mathcal{P}$*.109*.

On the other hand, for systems (3.95) we have

$$\zeta_9 = \frac{2227500}{823543}(u-50)(u-22)(u^2-4)(u-1)^3(3u-10)(3u+46),$$
$$\zeta_6 = -\frac{3}{1372}(6+u)(292-52u+5u^2), \quad \text{Discrim}\,[292-52u+5u^2] = -3136 < 0,$$
$$\xi_{26} = \frac{3}{941192}(u-50)(u^2-4)(u-1)(3u+46)(6+u)(13+u)(5+2u),$$
$$\xi_{27} = \frac{1}{2744}(u-8)(380+52u+9u^2), \quad \text{Discrim}\,[380+52u+9u^2] = -10976 < 0.$$

We observe that, due to $\zeta_9 \neq 0$, the condition $\xi_{26} \neq 0$ is equivalent to $(6+u)(13+u)(5+2u) \neq 0$. Moreover, considering Remark 3.14, we conclude that for $\xi_{26} = 0$ we may assume $(6+u)(5+2u) = 0$ because the condition $13+u = 0$ could be brought to $5+2u = 0$ via an affine transformation and time rescaling.

Thus, in the case $B_1 = 0$, systems (3.95) possess the following configurations if and only if the corresponding conditions are satisfied:

$$\begin{array}{lcl}
\xi_{26} \neq 0,\ \xi_{27} \neq 0\ (\text{then } u = -4/3) & \Leftrightarrow & \textit{Config. } \mathcal{P}.106;\\
\xi_{26} \neq 0,\ \xi_{27} = 0\ (\text{then } u = 8) & \Leftrightarrow & \textit{Config. } \mathcal{P}.107;\\
\xi_{26} = 0,\ \zeta_6 \neq 0\ (\text{then } u = -5/2) & \Leftrightarrow & \textit{Config. } \mathcal{P}.108;\\
\xi_{26} = 0,\ \zeta_6 = 0\ (\text{then } u = -6) & \Leftrightarrow & \textit{Config. } \mathcal{P}.109.
\end{array}$$

3.2.4 The statement $(\mathcal{B}_6)$

In this case the condition $\chi_4 = \zeta_9 = 0$ must be fulfilled. Considering (3.92), due to the condition $\zeta_5 \neq 0$, we obtain that $\zeta_9 = 0$ is equivalent to $\mathcal{W} = 0$. Straightforward calculations give us that the systems of equations $\chi_4 = 0$ and $\mathcal{W} = 0$ could have only the following solutions $\mathcal{S}_i = (m_i, n_i)$ $(i = 1,2,3,4)$:

$$\mathcal{S}_1 = (0,0), \quad \mathcal{S}_2 = \left(-\frac{1}{8}, -\frac{1}{4}\right), \quad \mathcal{S}_3 = \left(-\frac{5}{72}, -\frac{13}{36}\right), \quad \mathcal{S}_4 = \left(-\frac{27}{2944}, -\frac{3}{8}\right).$$

However, we have

$$\chi_4(\mathcal{S}_i) = \zeta_9(\mathcal{S}_i) = 0, \quad i = 1,2,3,4,$$
$$\zeta_5(\mathcal{S}_1) \neq 0, \quad \zeta_5(\mathcal{S}_2) \neq 0, \quad \zeta_5(\mathcal{S}_3) = \zeta_5(\mathcal{S}_4) = 0,$$

and hence only the solutions $\mathcal{S}_1$ and $\mathcal{S}_2$ satisfy the conditions of statement $(\mathcal{B}_6)$. Therefore, we examine only these two solutions.

We observe that each one of them gives us a concrete system (without parameters), and it remains to construct the corresponding system having a single fixed configuration of the invariant parabolas and lines.

For systems (3.77), we calculate:

$$\begin{aligned}
\xi_9 = 3^6 17252510\big[&65536m^4 - 32m^3(6131+3252n) - 16m^2(-32110-7953n+484n^2)\\
&+ 6m(10221-53292n+5540n^2+4336n^3)\\
&- 9(-2304-7857n-12140n^2+836n^3+240n^4)\big].
\end{aligned}$$

We obtain that $\xi_9(\mathcal{S}_2) = 0$ and $\xi_9(\mathcal{S}_1) \neq 0$, and then we examine two cases: $\xi_9 \neq 0$ and $\xi_9 = 0$.

The case $\xi_9 \neq 0$. Then we consider the solution $\mathcal{S}_1$, i.e., $m = n = 0$. In this case, we arrive at the system

$$\dot{x} = -\frac{3y}{2} + 2x^2 + xy, \quad \dot{y} = y(x + 2y), \tag{3.99}$$

possessing the invariant line $y = 0$ and the invariant parabola $\Phi(x, y) = x^2 - y = 0$.

This system possesses the following two singular points: $M_1(0, 0)$ and $M_2(-1/2, 1/4)$. We observe that the point M_1 is the point of tangency of the invariant line with the parabola. Moreover, this point is a triple singularity of system (3.99), because we have

$$\mu_4 = \mu_3 = \mu_2 = 0, \quad \mu_1 = -3(x + 2y) \neq 0,$$

and, by [1, Lemma 5.2, statement (ii)], the point M_1 is of multiplicity exactly 3. As a result, we get the configuration *Config.* $\mathcal{P}.40$.

The case $\xi_9 = 0$. In this case we get the solution $\mathcal{S}_2$, i.e., $m = -1/8$ and $n = -1/4$. Then, we arrive at the system

$$\dot{x} = -\frac{1}{8} - \frac{x}{4} - \frac{3y}{2} + 2x^2 + xy, \quad \dot{y} = \frac{1}{4}(4y - 1)(x + 2y),$$

possessing the invariant lines $y = 1/4$ and $y = x - 1/4$ and the invariant parabola $\Phi(x, y) = x^2 - y = 0$.

As a result, we get the configuration *Config.* $\mathcal{P}.110$.

3.2.5 The statement $(\mathcal{B}_7)$

In this case, the condition $\chi_4 = \zeta_5 = 0$ and $\zeta_6 \neq 0$ must be fulfilled. Straightforward calculations give us that the systems of equations $\chi_4 = 0$ and $\zeta_5 = 0$ could have only the following solutions $\widetilde{\mathcal{S}}_i = (m_i, n_i)$ $(i = 1, \ldots, 6)$:

$$\widetilde{\mathcal{S}}_1 = \left(-\frac{27}{2744}, -\frac{3}{28}\right), \quad \widetilde{\mathcal{S}}_2 = \left(-\frac{2205}{8}, -\frac{357}{4}\right), \quad \widetilde{\mathcal{S}}_3 = \left(\frac{539}{72}, -\frac{301}{36}\right),$$
$$\widetilde{\mathcal{S}}_4 = \left(\frac{35}{8}, -\frac{37}{4}\right), \quad \widetilde{\mathcal{S}}_5 = \left(-\frac{5}{72}, -\frac{13}{36}\right), \quad \widetilde{\mathcal{S}}_6 = \left(-\frac{189}{8}, -\frac{69}{4}\right).$$

We split these solutions into two sets:

$$\mathcal{G}_1 = \{\widetilde{\mathcal{S}}_1, \widetilde{\mathcal{S}}_2, \widetilde{\mathcal{S}}_3\}, \quad \mathcal{G}_2 = \{\widetilde{\mathcal{S}}_4, \widetilde{\mathcal{S}}_5, \widetilde{\mathcal{S}}_6\}.$$

Lemma 3.15. *Assume that the conditions of statement* $(\mathcal{B}_7)$ *are satisfied and then the system of equations* $\chi_4 = \zeta_5 = 0$ *generates six solutions* $\widetilde{\mathcal{S}}_i = (m_i, n_i)$ $(i = 1, \ldots, 6)$ *given above. In this case, the invariant polynomial* ξ_6 *distinguishes the set* $\mathcal{G}_1$ *from the set* $\mathcal{G}_2$.

Proof. To prove this lemma it is sufficient to evaluate ξ_6 for the elements of each one of the sets. For systems (3.77), we calculate:

$$\xi_6 = 2^9 3^4 2877985 m(1 + 4m + 2n)(-147 + 50m + 61n + 8n^2),$$

and we obtain

$$\xi_6(\widetilde{\mathcal{S}}_i) \neq 0, \quad i = 1, 2, 3, \qquad \xi_6(\widetilde{\mathcal{S}}_j) = 0, \quad j = 4, 5, 6,$$

and we complete the proof of the lemma. □

According to the above lemma, we discuss two cases: $\xi_6 \neq 0$ and $\xi_6 = 0$.

The case $\xi_6 \neq 0$. Then we have to examine the elements of the first set $\mathcal{G}_1$.

1: *The subcase* $\widetilde{\mathcal{S}}_1$. Then we have $m = -27/2744$ and $n = -3/28$, and we get the system

$$\dot{x} = 2x^2 + xy - \frac{3x}{28} - \frac{3y}{2} - \frac{27}{2744}, \quad \dot{y} = xy - \frac{27x}{1372} + 2y^2 - \frac{3y}{14}, \tag{3.100}$$

possessing the following three invariant parabolas: $\Phi_1(x,y) = x^2 - y = 0$ and

$$\Phi_2(x,y) = 3 + 112x + 1176y - 38416y^2 = 0, \quad \Phi_3(x,y) = -243 + 3024x - 10584y + 38416y^2 = 0.$$

We observe that the singular point $M_1(3/14, 9/196)$ is the point of intersection of all three invariant parabolas. So we get the configuration *Config.* $\mathcal{P}$*.111*.

Next, we prove that the systems generated by $\widetilde{\mathcal{S}}_2$ and $\widetilde{\mathcal{S}}_3$ could be brought to system (3.100) via an affine transformation and a time rescaling.

Consider first the solution $\widetilde{\mathcal{S}}_2$, i.e., $m = -2205/8$ and $n = -357/4$. This leads to the system

$$\dot{x} = 2x^2 + xy - \frac{357x}{4} - \frac{3y}{2} - \frac{2205}{8}, \quad \dot{y} = xy - \frac{2205x}{4} + 2y^2 - \frac{357y}{2},$$

which via the transformation

$$x_1 = -\frac{3}{28} + \frac{y}{343}, \quad y_1 = \frac{3}{196} + \frac{x}{343}, \quad t_1 = 343t,$$

is brought to the system (3.100).

Analogously, taking the solution $\widetilde{\mathcal{S}}_3$, i.e., $m = 539/72$ and $n = -301/36$, we arrive at the system

$$\dot{x} = 2x^2 + xy - \frac{301x}{36} - \frac{3y}{2} + \frac{539}{72}, \quad \dot{y} = xy + \frac{539x}{36} + 2y^2 - \frac{301y}{18},$$

which via the transformation

$$x_1 = \frac{9}{28} - \frac{27y}{343}, \quad y_1 = \frac{27}{196} - \frac{27x}{343}, \quad t_1 = -\frac{343t}{27},$$

is brought to the system (3.100).

The case $\xi_6 = 0$. Then we have to examine the elements of the second set $\mathcal{G}_2$.

1: *The subcase* $\widetilde{\mathcal{S}}_4$. Then we have $m = 35/8$ and $n = -37/4$, and we get the system

$$\dot{x} = 2x^2 + xy - \frac{37x}{4} - \frac{3y}{2} + \frac{35}{8}, \quad \dot{y} = xy + \frac{35x}{4} + 2y^2 - \frac{37y}{2}, \tag{3.101}$$

possessing the invariant line $y = x - 1/4$ and three invariant parabolas: $\Phi_1(x,y) = x^2 - y = 0$ and

$$\Phi_2(x,y) = 5 - 12x + 3x^2 + y = 0, \quad \Phi_3(x,y) = -35 + 144x - 152y + 16y^2 = 0.$$

We observe that the singular point $M_1(1/2, 1/4)$ is the point of intersection of all four invariant curves. So we get the configuration *Config.* $\mathcal{P}$*.112*.

Next, we prove that the systems generated by $\widetilde{\mathcal{S}}_5$ and $\widetilde{\mathcal{S}}_6$ could be brought to system (3.101) via an affine transformation and a time rescaling.

Consider first the solution $\widetilde{\mathcal{S}}_5$, i.e., $m = -5/72$ and $n = -13/36$. This leads to the system

$$\dot{x} = 2x^2 + xy - \frac{13x}{36} - \frac{3y}{2} - \frac{5}{72}, \quad \dot{y} = -\frac{5x}{36} - \frac{13y}{18} + xy + 2y^2,$$

which via the transformation

$$x_1 = \frac{11}{4} - 9y, \quad y_1 = \frac{19}{4} - 9x, \quad t_1 = -\frac{t}{9},$$

is brought to the system (3.101).

Analogously, taking the solution $\widetilde{\mathcal{S}}_6$, i.e., $m = -189/8$ and $n = -69/4$, we arrive at the system

$$\dot{x} = 2x^2 + xy - \frac{69x}{4} - \frac{3y}{2} - \frac{189}{8}, \quad \dot{y} = xy - \frac{189x}{4} + 2y^2 - \frac{69y}{2},$$

which via the transformation

$$x_1 = 2 - \frac{x}{3}, \quad y_1 = 7 - \frac{y}{3}, \quad t_1 = -3t,$$

is brought to the system (3.101).

3.3 Configurations of systems in $\mathbf{QSP}_{(\eta<0)}$

In what follows, we examine the configurations of the systems in $\mathbf{QSP}_{(\eta<0)}$ for each of the cases provided by Proposition 2.9. According to this proposition, we consider the canonical form (2.5), i.e., the systems

$$\dot{x} = m + (2n-1)x/2 + gx^2 - gy/2 - xy, \quad \dot{y} = 2mx - x^2 + 2ny + gxy - 2y^2, \tag{3.102}$$

with $C_2 = x(x^2+y^2)$, possessing the invariant parabola $\Phi(x,y) = x^2 - y = 0$.

3.3.1 The statement $(\mathcal{E}_1)$

For systems (3.102), we calculate

$$\begin{aligned} \zeta_4 &= (25+g^2)(3g+9g^3-4m-6gn)/16, \\ \mathcal{R}_1 &= 15(1+g^2)(25+g^2)(3g+9g^3-4m-6gn)/2. \end{aligned} \tag{3.103}$$

The case $B_1 \neq 0$**.** Then, according to Lemma 2.3, systems (3.102) cannot possess any invariant line.

Let us examine the finite singularities of these systems. Following [1, Proposition 5.1], we calculate the invariant polynomial $\mathbf{D} = 12F_1'^2F_2'$, where

$$\begin{aligned} F_1' &= -2gm - 2g^3m + 4m^2 - n - g^2n - 4gmn + g^2n^2, \\ F_2' &= 8 - g^2 - 72gm + 8g^3m + 432m^2 - 48n + 4g^2n + 144gmn + 96n^2 - 4g^2n^2 - 64n^3, \end{aligned} \tag{3.104}$$

and we discuss two subcases: $\mathbf{D} \neq 0$ and $\mathbf{D} = 0$.

The subcase $\mathbf{D} \neq 0$. The systems (3.102) possess four finite singularities $M_i(x_i, y_i)$, $(i = 1, 2, 3, 4)$, with coordinates

$$x_1 = -\frac{gn-2m}{g^2+1},\ y_1 = \frac{2gm+n}{g^2+1};\quad x_2 = \frac{1}{6\mathcal{Y}^{1/3}}\left[\mathcal{Y}^{2/3} + \mathcal{Y}^{1/3}g - 3g^2 + 2\mathcal{Z}\right],$$

$$y_2 = \frac{1}{6\left(\sqrt[3]{\mathcal{W}}\,(2\mathcal{Z}-3g^2) + 4g\mathcal{W}^{2/3} + \mathcal{W}\right)}\Big[3\sqrt{3F_2'}\mathcal{Z} + 3\mathcal{W}^{2/3}\left(g^3 + 10gn - 5g + 12m\right)$$
$$+ \mathcal{W}^{1/3}\mathcal{Z}\left(2\mathcal{Z} - 3g^2\right) + 3\Big(g\left(g^4 + 22g^2n - 11g^2 + 84n^2 - 84n + 21\right) + 36m\mathcal{Z}\Big) + g\mathcal{W}^{4/3}\Big];$$

$$x_3 = \frac{1}{12\mathcal{Y}^{1/3}}\left[\left(-1 + i\sqrt{3}\right)\mathcal{Y}^{2/3} + 2g\mathcal{Y}^{1/3} - \left(1 + i\sqrt{3}\right)\left(2\mathcal{Z} - 3g^2\right)\right],$$

$$y_3 = \frac{1}{-48g\mathcal{Y}^{2/3} + 6\left(1+i\sqrt{3}\right)\mathcal{Y}^{1/3}\left(2\mathcal{Z}-3g^2\right) + 6\left(1-i\sqrt{3}\right)\mathcal{Y}}\Big[-6\mathcal{Y}^{2/3}\left(g^3 + 10gn - 5g + 12m\right)$$
$$+ \left(1 + i\sqrt{3}\right)\mathcal{Y}^{4/3}g + \left(1 + i\sqrt{3}\right)\mathcal{Y}^{1/3}\mathcal{Z}\left(2\mathcal{Z} - 3g^2\right)$$
$$+ \left(1 - i\sqrt{3}\right)\mathcal{Y}\mathcal{Z} + \left(1 - i\sqrt{3}\right)g\left(2\mathcal{Z} - 3g^2\right)^2\Big];$$

$$x_4 = \frac{1}{12\mathcal{Y}^{1/3}}\left[\left(-1 - i\sqrt{3}\right)\mathcal{Y}^{2/3} + 2g\mathcal{Y}^{1/3} - \left(1 - i\sqrt{3}\right)\left(2\mathcal{Z} - 3g^2\right)\right],$$

$$y_4 = \frac{1}{-48g\mathcal{Y}^{2/3} + 6\left(1-i\sqrt{3}\right)\mathcal{Y}^{1/3}\left(2\mathcal{Z}-3g^2\right) + 6\left(1+i\sqrt{3}\right)\mathcal{Y}}\Big[-6\mathcal{Y}^{2/3}\left(g^3 + 10gn - 5g + 12m\right)$$
$$+ \left(1 - i\sqrt{3}\right)\mathcal{Y}^{4/3}g + \left(1 - i\sqrt{3}\right)\mathcal{Y}^{1/3}\mathcal{Z}\left(2\mathcal{Z} - 3g^2\right)$$
$$+ \left(1 + i\sqrt{3}\right)\mathcal{Y}\mathcal{Z} + \left(1 + i\sqrt{3}\right)g\left(2\mathcal{Z} - 3g^2\right)^2\Big].$$

In the above expressions for the singularities, we use the following notations:

$$\mathcal{Y} = g^3 + 18gn - 9g + 108m + 3\sqrt{\mathcal{X}},\quad \mathcal{Z} = -3 + 2g^2 + 6n,$$
$$\mathcal{W} = -9g + g^3 + 108m + 18gn + 3\sqrt{3F_2'},$$

where

$$\mathcal{X} = 24 - 3g^2 - 216gm + 24g^3m + 1296m^2 - 144n + 12g^2n + 432gmn + 288n^2 - 12g^2n^2 - 192n^3.$$

Calculations yield:

$$\Phi(x_2, y_2) = \Phi(x_3, y_3) = \Phi(x_4, y_4) = 0,\quad \Phi(x_1, y_1) = \frac{F_1'}{(1+g^2)^2},$$

and therefore the three singularities M_2, M_3, and M_4 of systems (3.102) lie on the invariant parabola. Moreover, M_1 is located outside the parabola and would belong to the parabola if and only if the condition $F_1' = 0$ holds, where F_1' is given in (3.104). However, we have $\mathbf{D} = 12F_1'^2F_2' \neq 0$, and hence there are always exactly three simple singularities on the parabola.

On the other hand, according to [1, Proposition 5.1], if $\mathbf{D} > 0$, systems (3.102) possess two real and two complex finite singularities. For $\mathbf{D} < 0$, we could have either four real or four complex finite singularities. However, since M_1 is a real singular point for these systems, we conclude that in the case $\mathbf{D} < 0$, we must have four real finite distinct singularities.

Thus, since the real singularity M_1 is outside the invariant parabola and all three finite singularities on the parabola (whether real or complex) are distinct, and furthermore we cannot have any invariant line, we arrive at the configuration *Config.* $\mathcal{P}$.113 if $\mathbf{D} < 0$, and at *Config.* $\mathcal{P}$.114 if $\mathbf{D} > 0$.

The subcase D = 0. This implies that $F_1'F_2' = 0$, and we calculate:

$$\xi_1 = -6\zeta_4 F_1'.$$

Therefore, we deduce that, due to $\zeta_4 \neq 0$, the condition $F_1' = 0$ is equivalent to $\xi_1 = 0$. Thus, we examine two possibilities: $\xi_1 \neq 0$ and $\xi_1 = 0$.

1: *The possibility* $\xi_1 \neq 0$. In this case, the condition $\mathbf{D} = 0$ implies $F_2' = 0$. Since this polynomial is quadratic in the parameter m, we calculate

$$\text{Discrim}\,[F_2', m] = 64(g^2 + 12n - 6)^3.$$

Therefore, as the parameters m, n, and g of systems (3.102) must be real, the condition $g^2 + 12n - 6 \geq 0$ must hold. Introducing a new parameter v such that $g^2 + 12n - 6 = v^2 \geq 0$, we get $n = (6 - g^2 + v^2)/12$. Then, we compute

$$F_2' = \frac{1}{108}\left[216m - (g+v)^2(g-2v)\right]\left[216m - (g-v)^2(g+2v)\right] = 0,$$

and, due to the symmetry under the change $v \mapsto -v$, we may assume the first factor vanishes. This yields:

$$m = (g-2v)(g+v)^2/216.$$

Considering the expressions for the parameters m and n, we arrive at the following two-parameter family of systems:

$$\begin{aligned} \dot{x} &= \frac{(g-2v)(g+v)^2}{216} - \frac{g^2-v^2}{12}\,x - \frac{g}{2}y + gx^2 - xy, \\ \dot{y} &= \frac{(g-2v)(g+v)^2}{108}\,x + \frac{6-g^2+v^2}{6}\,y + gxy - 2y^2, \end{aligned} \tag{3.105}$$

possessing the invariant parabola $\Phi(x,y) = x^2 - y = 0$.

We observe that for the above systems, the following conditions on the parameters g and v hold:

$$\begin{aligned} &\xi_1 \neq 0 \;\Leftrightarrow\; (8g-v)^2(4g+v)\left(2g^2 - 8gv - v^2 + 18\right)\left(g^2 + 2gv + v^2 + 9\right) \neq 0; \\ &B_1 \neq 0 \;\Leftrightarrow\; (2g-v)(4g+v)(36 + 4g^2 - 4gv + v^2)(g^2 + 2gv + v^2 + 9) \\ &\qquad \times (g^2 - 4gv + 4v^2 + 9) \neq 0. \end{aligned} \tag{3.106}$$

We determine that systems (3.105) possess three finite singularities $M_i(x_i, y_i)$ $(i = 1,2,3)$ with coordinates:

$$\begin{gathered} x_1 = \frac{-27g + 5g^3 - 6gv^2 - v^3}{54(1+g^2)}, \quad y_1 = \frac{54 - 9g^2 + g^4 + 9v^2 - 3g^2v^2 - 2gv^3}{108(1+g^2)}, \\ x_2 = \frac{g-2v}{6}, \quad y_2 = \frac{(g-2v)^2}{36}, \quad x_3 = \frac{g+v}{6}, \quad y_3 = \frac{(g+v)^2}{36}. \end{gathered}$$

We calculate:

$$\Phi(x_2, y_2) = \Phi(x_3, y_3) = 0, \quad \Phi(x_1, y_1) = -\frac{\left(2g^2 - 8gv - v^2 + 18\right)\left(g^2 + 2gv + v^2 + 9\right)^2}{2916(1+g^2)^2},$$

and conclude that the singular points M_2 and M_3 lie on the invariant parabola, while M_1 lies outside the parabola due to the conditions (3.106).

We claim that M_3 is a multiple singularity of systems (3.105). Indeed, applying the corresponding translation, we can place M_3 at the origin, arriving at the systems:

$$\begin{aligned}\dot{x} &= \frac{1}{18}(g+v)(4g+v)x - \frac{1}{6}(4g+v)y + gx^2 - xy,\\ \dot{y} &= \frac{1}{54}(g+v)\left(2g^2+gv-v^2-18\right)x + \frac{1}{18}\left(v^2-2g^2-gv+18\right)y + gxy - x^2 - 2y^2,\end{aligned}$$

where $M_0(0,0)$ corresponds to the singularity M_3.

Following [1], we calculate the following invariant polynomials: $\mu_4 = \mu_3 = 0$, and

$$\mu_2 = \frac{1}{324}v\left[(g+v)^2+9\right]\left[(v-2g)x+6y\right]\left[(3-g^2-gv)x+(4g+v)y\right].$$

By [1, Lemma 5.2, statement (ii)], the point M_0 has multiplicity at least 2. We observe that, due to the condition $B_1 \neq 0$, we have $\mu_2 = 0$ if and only if $v = 0$. In this case, we calculate:

$$\mu_2 = 0, \quad \mu_1 = -\frac{1}{27}\left[(5g^4+27)x - 32g^3y\right] \neq 0.$$

Thus, according to [1, Lemma 5.2, statement (ii)], we have a double point if $v \neq 0$ and a triple point if $v = 0$.

On the other hand, for systems (3.105), we calculate:

$$\xi_2 = \frac{1}{209952}v^2\left(18+2g^2-8gv-v^2\right)^2\left(9+g^2+2gv+v^2\right)^2,$$

and due to (3.106), we conclude that the condition $v = 0$ is equivalent to $\xi_2 = 0$.

Thus, for systems (3.105), we obtain configuration *Config. $\mathcal{P}$.115* if $\xi_2 \neq 0$ and *Config. $\mathcal{P}$.116* if $\xi_2 = 0$.

2: *The possibility* $\xi_1 = 0$. We obtain $F_1' = 0$, and since this polynomial is quadratic in the parameter m, we calculate:

$$\text{Discrim}\,[F_1', m] = 4(1+g^2)^2(g^2+4n).$$

It is clear that for the existence of real solutions of the equation $F_1' = 0$, the condition $g^2+4n \geq 0$ must hold.

Thus, we introduce a new parameter u such that $g^2+4n = u^2 \geq 0$, leading to $n = (u^2-g^2)/4$. Then, calculations yield:

$$F_1' = -\frac{1}{16}\left[8m-(g-u)(2+g^2-gu)\right]\left[8m-(g+u)(2+g^2+gu)\right] = 0,$$

and, due to symmetry under $u \mapsto -u$, we may assume the first factor vanishes. This gives:

$$m = (g-u)(2+g^2-gu)/8.$$

Considering the expressions for m and n, we arrive at the following two-parameter family of systems:

$$\begin{aligned}\dot{x} &= \frac{(g-u)(2+g^2-gu)}{8} + \frac{u^2-g^2-2}{4}x - \frac{g}{2}y + gx^2 - xy,\\ \dot{y} &= \frac{(g-u)(2+g^2-gu)}{4}x - \frac{g^2-u^2}{2}y + gxy - 2y^2,\end{aligned} \tag{3.107}$$

possessing the invariant parabola $\Phi(x,y) = x^2 - y = 0$.

The systems (3.107) possess three finite singularities $M_i(x_i, y_i)$ $(i = 1,2,3)$ with coordinates:

$$x_1 = \frac{g-u}{2}, \quad y_1 = \frac{(g-u)^2}{4};$$
$$x_{2,3} = \frac{1}{4}\left(u \pm \sqrt{Y_1}\right), \quad y_{2,3} = \frac{1}{8}\left[u^2 + 2gu - 2g^2 - 4 \pm u\sqrt{Y_1}\right],$$
$$Y_1 = u^2 + 4gu - 4g^2 - 8.$$

We calculate:

$$\Phi(x_1, y_1) = \Phi(x_2, y_2) = \Phi(x_3, y_3) = 0,$$

and therefore all three singularities are located on the invariant parabola.

Moreover, we point out that M_1 is a singularity of systems (3.107) with multiplicity at least 2. Indeed, applying a translation that places M_1 at the origin, we arrive at the system:

$$\dot{x} = \frac{1}{2}(g^2 - gu - 1)x + \frac{1}{2}(u - 2g)y + gx^2 - xy,$$
$$\dot{y} = \frac{1}{2}(g-u)(g^2 - gu - 1)x + \frac{1}{2}(g-u)(2g-u)y - x^2 + gxy - 2y^2,$$

where $M_0(0,0)$ is the singularity corresponding to M_1.

Following [1], we calculate the following invariant polynomials: $\mu_4 = \mu_3 = 0$, and:

$$\mu_2 = \frac{1}{2}(g^2+1)\left[(g-u)^2 + 1\right]\left[(g^2 - gu + 1)x^2 + (u - 2g)xy + 2y^2\right].$$

We observe that $\mu_2 \neq 0$, and by [1, Lemma 5.2, statement (ii)], the point M_0 has multiplicity exactly 2.

On the other hand, the singularities M_2 and M_3 may be either real or complex, depending on the value of Y_1. To determine the position of the double singularity M_1 relative to M_2 and M_3 when they are real (i.e., $Y_1 > 0$), we calculate:

$$(x_2 - x_1)(x_3 - x_1) = \frac{(g-u)^2 + 1}{2} > 0.$$

Therefore, in the case $Y_1 > 0$, both singularities M_2 and M_3 lie on the same side of the double point M_1.

It is clear that for $Y_1 = 0$, the points M_2 and M_3 coalesce, and we obtain two double points located on the invariant parabola.

For systems (3.107), calculations yield:

$$\xi_2 = \frac{1}{8}(1+g^2)^2\left[1 + (g-u)^2\right]^2 Y_1,$$

and hence $\operatorname{sign}(\xi_2) = \operatorname{sign}(Y_1)$ whenever $\xi_2 \neq 0$.

Thus, we conclude that systems (3.107) possess configuration *Config. $\mathcal{P}$.117* if $\xi_2 < 0$, *Config. $\mathcal{P}$.118* if $\xi_2 > 0$, and *Config. $\mathcal{P}$.119* if $\xi_2 = 0$.

The case $B_1 = 0$. For systems (3.102), we calculate:

$$B_1 = -\frac{1}{64}\left[g + g^3 + 4m - 2gn\right]\left[(g - 8m)^2 + (1 - 4n)^2\right]\Psi(g,m,n),$$

where

$$\Psi(g,m,n) = 16m^2 + 8gm(3+2n) + (4+g^2)(1+g^2+4n+4n^2).$$

On the other hand, we calculate:

$$\xi_4 = \frac{13125}{2}(25+g^2)\left(3g+9g^3-4m-6gn\right)\left[(g-8m)^2+(1-4n)^2\right],$$
$$\zeta_4 = \frac{(25+g^2)\left(3g+9g^3-4m-6gn\right)}{16},$$

and, due to $\zeta_4 \neq 0$, we deduce that $\xi_4 = 0$ is equivalent to $(g-8m)^2+(1-4n)^2 = 0$.

Thus, we examine two subcases: $\xi_4 \neq 0$ and $\xi_4 = 0$.

The subcase $\xi_4 \neq 0$. Then, the condition $B_1 = 0$ implies either:

$$g + g^3 + 4m - 2gn = 0, \quad \text{or} \quad \Psi(g,m,n) = 0.$$

We state the following lemma.

Lemma 3.16. *For systems (3.102), if $\xi_4 \neq 0$, then the condition $B_1 = B_2 = 0$ is equivalent to $\Psi(g,m,n) = 0$.*

Proof. Assume first that the condition $\Psi(g,m,n) = 0$ holds. We calculate the discriminant of Ψ with respect to m:

$$\text{Discrim}\,[\Psi, m] = -64(g^2-4n-2)^2 \leq 0.$$

Thus, for real solutions in m, the necessary condition is $g^2-4n-2 = 0$, which gives $n = (g^2-2)/4$. Substituting back, we obtain:

$$\Psi(g,m) = \frac{1}{4}\left(4g+g^3+8m\right)^2, \quad B_2 = \left(4g+g^3+8m\right)^2\phi(g,m,x,y),$$

where $\phi(g,m,x,y)$ is a quartic polynomial in x and y. Thus, clearly, $\Psi(g,m,n) = 0$ implies $B_2 = 0$.

Conversely, assume now that for systems (3.102), the conditions $B_1 = B_2 = 0$ and $\xi_4 \neq 0$ hold, but suppose (for contradiction) that $\Psi(g,m,n) \neq 0$. Then, the condition $B_1 = 0$ yields $g + g^3 + 4m - 2gn = 0$, and solving for m, we get $m = -g(g^2-2n+1)/4$.

Next, we calculate:

$$\Psi(g,n) = (1+g^2)\left(g^2-4n-2\right)^2,$$
$$B_2 = -\frac{81}{2}(1+g^2)^2\left(g^2-4n-2\right)^2\left[4g^4+g^2(8-16n)+(1-4n)^2\right]x^4,$$
$$\text{Discrim}\left[4g^4+g^2(8-16n)+(1-4n)^2, n\right] = -256g^2 < 0,$$

where the last inequality holds because $\zeta_4 = g(g^2+25)(5g^2-4n+2)/8 \neq 0$. Therefore, for $B_2 = 0$, it must follow that $\Psi(g,n) = 0$, leading to a contradiction with our assumption that $\Psi(g,m,n) \neq 0$. This completes the proof of Lemma 3.16. □

Therefore, in what follows we discuss two possibilities: $B_2 \neq 0$ and $B_2 = 0$.

1: *The possibility* $B_2 \neq 0$. Then, by Lemma 3.16, we have $\Psi(g,m,n) \neq 0$, and the condition $B_1 = 0$ implies $g + g^3 + 4m - 2gn = 0$. Solving for m, we obtain $m = -g(g^2 - 2n + 1)/4$, leading to the two-parameter family of systems:

$$\begin{aligned} \dot{x} &= -\frac{1}{4}g(g^2 - 2n + 1) + \frac{1}{2}(2n-1)x - \frac{g}{2}y + gx^2 - xy, \\ \dot{y} &= -\frac{1}{2}g(g^2 - 2n + 1)x + 2ny - x^2 + gxy - 2y^2, \end{aligned} \tag{3.108}$$

possessing the invariant line $L_1(x,y) = 2x + g = 0$, in addition to the invariant parabola $\Phi(x,y) = x^2 - y = 0$.

For these systems, we calculate:

$$\zeta_4 = \frac{g(g^2+25)(5g^2 - 4n + 2)}{8}, \quad \theta = -8(g^2+9).$$

Since $\theta \neq 0$, by Lemma 2.4, systems (3.108) cannot have an invariant line parallel to $2x + g = 0$. Moreover, by Lemma 2.3, there cannot be invariant lines in other directions because $B_2 \neq 0$.

The systems (3.108) possess four finite singularities $M_i(x_i, y_i)$, $i = 1,2,3,4$, with coordinates:

$$x_1 = -\frac{g}{2}, \quad y_1 = \frac{g^2}{4}; \quad x_2 = -\frac{g}{2}, \quad y_2 = \frac{2n - g^2}{2};$$
$$x_{3,4} = \frac{1}{2}\left(g \pm \sqrt{Y_2}\right), \quad y_{3,4} = \frac{1}{2}\left(2n - 1 \pm g\sqrt{Y_2}\right), \quad Y_2 = 4n - g^2 - 2.$$

We compute:

$$\Phi(x_1,y_1) = \Phi(x_3,y_3) = \Phi(x_4,y_4) = L_1(x_1,y_1) = L_1(x_2,y_2) = 0,$$
$$\Phi(x_2,y_2) = (3g^2 - 4n)/4,$$

therefore, M_1 is the intersection point of the invariant line with the invariant parabola. Moreover, M_2 lies on the invariant line and belongs to the invariant parabola if and only if $3g^2 - 4n = 0$. Finally, M_3 and M_4 may be real, complex, or coinciding, depending on the value of Y_2, and they always lie on the invariant parabola.

To determine the relative positions of the finite singularities, we calculate:

$$(x_3 - x_1)(x_4 - x_1) = (5g^2 - 4n + 2)/4 = \gamma_1/4, \quad y_2 - y_1 = (4n - 3g^2)/4 = \delta_1/4.$$

Thus, when $Y_2 > 0$, M_2 and M_3 lie on the same side (respectively, on opposite sides) of M_1 if $\gamma_1 > 0$ (respectively, $\gamma_1 < 0$). Notice that $\gamma_1 \neq 0$ due to $\zeta_4 \neq 0$.

Also, $y_2 > y_1$ if $\delta_1 > 0$, $y_2 < y_1$ if $\delta_1 < 0$, and $y_2 = y_1$ if $\delta_1 = 0$, in which case the intersection point of the invariant line and the parabola is a double singular point of systems (3.108).

We compute the invariant polynomial $\mathbf{D}$ responsible for the existence of multiple finite singularities:

$$\mathbf{D} = -3(g^2+1)^4 Y_2 \gamma_1^2 \delta_1^2/4, \quad \zeta_4 = g(25 + g^2)\gamma_1/8,$$
$$\xi_7 = 4698510000\, g^2(1+g^2)^2 Y_2 \gamma_1 \delta_1^2, \quad \xi_8 = -247290000\, g^2(1+g^2)^2 Y_2 \delta_1 \gamma_1^2.$$

Thus, since $\zeta_4 \neq 0$, in the case $\mathbf{D} \neq 0$ we have:

$$\operatorname{sign}(\mathbf{D}) = -\operatorname{sign}(Y_2), \quad \operatorname{sign}(\xi_7) = \operatorname{sign}(Y_2\gamma_1), \quad \operatorname{sign}(\xi_8) = -\operatorname{sign}(Y_2\delta_1),$$

and we examine two cases: $\mathbf{D} \neq 0$ and $\mathbf{D} = 0$.

1.1: *The case* $\mathbf{D} \neq 0$. Then $Y_2 \neq 0$, and systems (3.108) have four distinct finite singularities.

Remark 3.17. We observe that $\gamma_1 + \delta_1 = 2(g^2+1) > 0$. Therefore, the conditions $\gamma_1 < 0$ and $\delta_1 < 0$ are incompatible.

Considering Remark 3.17, in the case $\mathbf{D} \neq 0$, systems (3.108) exhibit the following configurations:

$$\begin{array}{lll}
\mathbf{D} < 0, \xi_7 < 0 & \Rightarrow\ (x_3 - x_1)(x_4 - x_1) < 0,\ y_2 > y_1 & \Rightarrow\ \textit{Config. } \mathcal{P}.120; \\
\mathbf{D} < 0, \xi_7 > 0, \xi_8 < 0 & \Rightarrow\ (x_3 - x_1)(x_4 - x_1) > 0,\ y_2 > y_1 & \Rightarrow\ \textit{Config. } \mathcal{P}.121; \\
\mathbf{D} < 0, \xi_7 > 0, \xi_8 > 0 & \Rightarrow\ (x_3 - x_1)(x_4 - x_1) > 0,\ y_2 < y_1 & \Rightarrow\ \textit{Config. } \mathcal{P}.122; \\
\mathbf{D} > 0, \xi_8 < 0 & \Rightarrow\ y_2 < y_1 & \Rightarrow\ \textit{Config. } \mathcal{P}.123; \\
\mathbf{D} > 0, \xi_8 > 0 & \Rightarrow\ y_2 > y_1 & \Rightarrow\ \textit{Config. } \mathcal{P}.124.
\end{array}$$

1.2: *The case* $\mathbf{D} = 0$. Since $\gamma_1 \neq 0$ (due to $\zeta_4 \neq 0$), this condition implies $Y_2\delta_1 = 0$, and we calculate:

$$\xi_1 = -3g(1+g^2)^2(25+g^2)\gamma_1\delta_1/16.$$

Thus, since $\gamma_1 \neq 0$, the condition $\delta_1 = 0$ is equivalent to $\xi_1 = 0$. We consider two subcases: $\xi_1 \neq 0$ and $\xi_1 = 0$.

1.2.1: *The subcase* $\xi_1 \neq 0$. Then $Y_2 = 0$ (i.e., $n = (g^2+2)/4$), so M_3 and M_4 coalesce into a double singular point on the parabola. Moreover, the position of M_2 is determined by δ_1. For these systems, with $n = (g^2+2)/4$, we calculate:

$$\xi_1\zeta_8 = -3g^4(1+g^2)^3(25+g^2)\delta_1/2, \quad \zeta_4 = g^3(25+g^2)/2.$$

Since $\zeta_4 \neq 0$, we have $\operatorname{sign}(\xi_1\zeta_8) = -\operatorname{sign}(\delta_1)$. Therefore, in the case $\mathbf{D} = 0$ and $\xi_1 \neq 0$, we have configuration *Config.* $\mathcal{P}.125$ if $\xi_1\zeta_8 < 0$, and *Config.* $\mathcal{P}.126$ if $\xi_1\zeta_8 > 0$.

1.2.2: *The subcase* $\xi_1 = 0$. This condition implies $n = (3g^2)/4$, where M_2 and M_1 coalesce. Note that in this case, $\gamma_1 = 2(g^2+1) > 0$.

For $n = 3g^2/4$, we have:

$$Y_2 = 2(g^2-1), \quad \xi_2 = (g^2-1)(1+g^2)^4,$$

and clearly, $\xi_2 = 0$ if and only if $Y_2 = 0$, which corresponds to M_3 and M_4 also coalescing, yielding two double singularities on the invariant parabola.

Thus, for $\mathbf{D} = \xi_1 = 0$, we get *Config.* $\mathcal{P}.127$ if $\xi_2 \neq 0$, and *Config.* $\mathcal{P}.128$ if $\xi_2 = 0$.

2: *The possibility* $B_2 = 0$. Thus, $B_1 = B_2 = 0$, and by Lemma 3.16, the condition $\Psi(g,m,n) = 0$ holds. Referring to the proof of Lemma 3.16, we get:

$$g^2 - 4n - 2 = 0 \quad \Rightarrow \quad n = (g^2-2)/4, \qquad 4g + g^3 + 8m = 0 \quad \Rightarrow \quad m = -g(g^2+4)/8.$$

This leads to the one-parameter family of systems:

$$\begin{aligned}
\dot{x} &= -\frac{1}{8}g(g^2+4) + \frac{1}{4}(g^2-4)x - \frac{g}{2}y + gx^2 - xy, \\
\dot{y} &= -\frac{1}{4}g(g^2+4)x + \frac{1}{2}(g^2-2)y - x^2 + gxy - 2y^2,
\end{aligned} \tag{3.109}$$

possessing three invariant lines:

$$L_1(x,y) = 2x + g = 0, \quad L_{2,3}(x,y) = 4(y \pm ix) - g(g \mp 2i) = 0,$$

besides the invariant parabola.

We find that systems (3.109) possess four finite singularities $M_i(x_i, y_i)$, $i = 1,2,3,4$, with coordinates:

$$x_1 = -\frac{g}{2}, \quad y_1 = \frac{g^2}{4}; \quad x_2 = -\frac{g}{2}, \quad y_2 = -\frac{g^2+2}{4};$$
$$x_{3,4} = \frac{1}{2}(g \pm 2i), \quad y_{3,4} = \frac{1}{4}(g \pm 2i)^2.$$

We calculate:

$$\Phi(x_1, y_1) = \Phi(x_3, y_3) = \Phi(x_4, y_4) = 0, \quad \Phi(x_2, y_2) = (g^2+1)/2,$$
$$L_1(x_1, y_1) = L_1(x_2, y_2) = L_2(x_1, y_1) = L_2(x_3, y_3) = L_3(x_4, y_4) = 0.$$

Thus, M_1 is the intersection point of all three invariant lines with the invariant parabola. Additionally, M_2 lies on the invariant line but not on the parabola, since $g^2+1 \neq 0$. Moreover, since $y_2 - y_1 = -(g^2+1)/2 < 0$, M_2 lies below M_1 along the vertical line $L_1 = 0$.

Hence, systems (3.109) possess the unique configuration *Config.* $\mathcal{P}$*.129*.

The subcase $\zeta_4 = 0$. This condition implies $(g - 8m)^2 + (1 - 4n)^2 = 0$, yielding $m = g/8$ and $n = 1/4$. Thus, we obtain the following one-parameter family of systems:

$$\begin{aligned} \dot{x} &= \frac{g}{8} - \frac{x}{4} - \frac{gy}{2} + gx^2 - xy, \\ \dot{y} &= \frac{gx}{4} + \frac{y}{2} - x^2 + gxy - 2y^2, \end{aligned} \tag{3.110}$$

which, in addition to the invariant parabola $\Phi(x, y) = x^2 - y = 0$, possess two complex invariant lines given by $L_{1,2}(x, y) = 4(y \pm ix) - 1 = 0$.

For these systems, we calculate:

$$\zeta_4 = g(25+g^2)(1+9g^2)/16, \qquad B_3 = -3g(1+g^2)(x^2+y^2)^2/4,$$

and since $\zeta_4 \neq 0$ (i.e., $g \neq 0$), we have $B_3 \neq 0$. Thus, according to Lemma 2.3, these systems cannot have an invariant line in the third (real) direction.

The systems (3.110) possess four finite singularities $M_i(x_i, y_i)$, $i = 1,2,3,4$, with coordinates:

$$x_1 = 0, \quad y_1 = \frac{1}{4}; \qquad x_2 = \frac{g}{2}, \quad y_2 = \frac{g^2}{4}; \qquad x_{3,4} = \pm\frac{i}{2}, \quad y_{3,4} = -\frac{1}{4}.$$

We compute:

$$\Phi(x_2, y_2) = \Phi(x_3, y_3) = \Phi(x_4, y_4) = 0, \quad \Phi(x_1, y_1) = -\frac{1}{4},$$

and observe that the real singularity M_1 is the intersection point of the two complex invariant lines and lies outside the invariant parabola. The second real singular point M_2 lies on the parabola, and its position depends on the real parameter $g \neq 0$.

As a result, we arrive at a single configuration: *Config.* $\mathcal{P}$*.130*.

3.3.2 The statement $(\mathcal{E}_2)$

According to Proposition 2.9, in this case the conditions $\zeta_4 = 0$ and $\mathcal{R}_7\zeta_5 \neq 0$ must hold. From (3.103), the condition $\zeta_4 = 0$ implies:

$$3g + 9g^3 - 4m - 6gn = 0 \quad \Rightarrow \quad m = 3g(3g^2 - 2n + 1)/4,$$

which leads to the following family of systems:

$$\begin{aligned}\dot{x} &= \frac{3}{4}g\left(3g^2-2n+1\right)+\frac{1}{2}(2n-1)x-\frac{gy}{2}+gx^2-xy,\\ \dot{y} &= \frac{3}{2}g\left(3g^2-2n+1\right)x+2ny-x^2+gxy-2y^2,\end{aligned} \tag{3.111}$$

possessing two invariant parabolas: the canonical one, $\Phi_1(x,y)=x^2-y=0$, and a second parabola,

$$\Phi_2(x,y)=(3g^2-4n)(1+3g^2-2n)+2g(3g^2-4n)x-4(1+g^2)x^2+2(2+5g^2-4n)y=0.$$

For the systems (3.111), we calculate:

$$\begin{aligned}\zeta_5 &= \frac{19}{4}(g^2+25)(3g^2-4n)^2, \quad \mathcal{R}_7=16120(3g^2+1)(5g^2-4n+2),\\ \theta &= -8(g^2+9), \quad B_1=-g(g^2+1)(9g^2+1)(5g^2-4n+2)\Psi_2\Psi_3/32,\end{aligned} \tag{3.112}$$

where

$$\Psi_2(g,n)=81g^4+g^2(28-72n)+4(1+2n)^2, \quad \Psi_3(g,n)=36g^4+g^2(16-48n)+(1-4n)^2.$$

According to Lemma 2.3, systems (3.111) may possess at least one invariant line only if $B_1=0$. Thus, we proceed to examine two possibilities: $B_1\neq 0$ and $B_1=0$.

The possibility $B_1\neq 0$. The systems (3.111) possess four finite singularities $M_i(x_i,y_i)$ $(i=1,2,3,4)$ with coordinates:

$$\begin{gathered}x_1=\frac{3g}{2}, \quad y_1=\frac{9g^2}{4};\\ x_2=\frac{g(3+9g^2-8n)}{2(1+g^2)}, \quad y_2=\frac{9g^4+g^2(3-6n)+2n}{2(1+g^2)};\\ x_{3,4}=\frac{1}{2}\left(-g\pm\sqrt{Y_3}\right), \quad y_{3,4}=\frac{1}{2}\left(2n-1-2g^2\mp g\sqrt{Y_3}\right),\\ Y_3=4n-5g^2-2.\end{gathered} \tag{3.113}$$

We calculate:

$$\Phi_1(x_1,y_1)=\Phi_1(x_3,y_3)=\Phi_1(x_4,y_4)=0, \quad \Phi_2(x_2,y_2)=\Phi_2(x_3,y_3)=\Phi_2(x_4,y_4)=0,$$

therefore, the singularities M_3 and M_4 are the points of intersection of both invariant parabolas. Moreover, the point M_1 lies on the parabola $\Phi_1=0$, while M_2 lies on $\Phi_2=0$.

To determine the relative positions of M_1 and M_2 with respect to M_3 and M_4 (when $Y_3>0$), we calculate:

$$\begin{gathered}(x_3-x_1)(x_4-x_1)=(2+21g^2-4n)/4=\gamma_2/4,\\ (x_3-x_2)(x_4-x_2)=-\frac{Y_3}{4(1+g^2)^2}\left[21g^4+2g^2(5-8n)+1\right]=-\frac{Y_3}{4(1+g^2)^2}\delta_2,\\ (x_3-x_1)+(x_4-x_1)=-4g, \quad (x_3-x_2)+(x_4-x_2)=\frac{2gY_3}{1+g^2}.\end{gathered}$$

We observe the following sign relations:

$$\operatorname{sign}\big((x_3-x_1)+(x_4-x_1)\big)=-\operatorname{sign}(g),\quad \operatorname{sign}\big((x_3-x_2)+(x_4-x_2)\big)=\operatorname{sign}(gY_3). \tag{3.114}$$

Thus, we deduce that the point M_1 (respectively M_2) lies on the invariant parabola $\Phi_1=0$ (respectively $\Phi_2=0$) between M_3 and M_4 if and only if $\gamma_2<0$ (respectively $Y_3\delta_2>0$).

From these relations, we state the following remark.

Remark 3.18. Assume that, for the singularities given in (3.113), the following conditions hold:

$$(x_3-x_1)(x_4-x_1)>0,\quad (x_3-x_2)(x_4-x_2)>0.$$

Then, when $Y_3>0$, the condition

$$\big[(x_3-x_1)+(x_4-x_1)\big]\big[(x_3-x_2)+(x_4-x_2)\big]>0$$

is impossible.

This follows directly from the sign relations in (3.114).

For systems (3.111), we also calculate:

$$\mathbf{D}=-3(3g^2-4n)^2Y_3\gamma_2^2\delta_2^2/4,\quad \xi_{14}=1235\gamma_2\delta_2/2,\quad \xi_{30}=1235\left[Y_3\delta_2-(1+g^2)^2\gamma_2\right]/2. \tag{3.115}$$

We observe that, when $\mathbf{D}\neq 0$,

$$\operatorname{sign}(\mathbf{D})=-\operatorname{sign}(Y_3),\quad \operatorname{sign}(\xi_{14})=\operatorname{sign}(\gamma_2\delta_2).$$

Moreover, in the case where $\xi_{14}<0$ (i.e., $\gamma_2\delta_2<0$) and $\mathbf{D}<0$ (i.e., $Y_3>0$), we find:

$$\operatorname{sign}(\xi_{30})=\operatorname{sign}\left[Y_3\delta_2-(1+g^2)^2\gamma_2\right]=\operatorname{sign}(\delta_2).$$

Thus, we proceed to analyze two cases: $\mathbf{D}\neq 0$ and $\mathbf{D}=0$.

The case $\mathbf{D}\neq 0$. We observe that, in the case $\mathbf{D}>0$, the singular points M_3 and M_4 are complex, and therefore in this situation it is not necessary to distinguish the signs of the polynomials γ_2 and δ_2.

Thus, taking into account Remark 3.18 and the information discussed above, we detect that in the case $\mathbf{D}\neq 0$ the systems admit the following configurations:

$\mathbf{D}<0,\ \gamma_2<0,\ \delta_2>0 \Rightarrow (x_3-x_1)(x_4-x_1)<0,\ (x_3-x_2)(x_4-x_2)<0 \Rightarrow$ *Config.* $\mathcal{P}.132$;
$\mathbf{D}<0,\ \gamma_2>0,\ \delta_2<0 \Rightarrow (x_3-x_1)(x_4-x_1)>0,\ (x_3-x_2)(x_4-x_2)>0 \Rightarrow$ *Config.* $\mathcal{P}.131$;
$\mathbf{D}<0,\ \gamma_2<0,\ \delta_2<0 \Rightarrow (x_3-x_1)(x_4-x_1)<0,\ (x_3-x_2)(x_4-x_2)>0 \Rightarrow$ *Config.* $\mathcal{P}.133$;
$\mathbf{D}<0,\ \gamma_2>0,\ \delta_2>0 \Rightarrow (x_3-x_1)(x_4-x_1)>0,\ (x_3-x_2)(x_4-x_2)<0 \Rightarrow \simeq$ *Config.* $\mathcal{P}.133$;
$\mathbf{D}>0 \Rightarrow$ *Config.* $\mathcal{P}.134$.

Note that in the case $\gamma_2\delta_2>0$, both conditions lead to equivalent configurations to *Config.* $\mathcal{P}.133$. Thus, we deduce that for $\mathbf{D}\neq 0$, the systems (3.111) realize the following configurations if and only if the corresponding invariant conditions hold:

$\mathbf{D}<0,\ \xi_{14}<0,\ \xi_{30}<0 \Rightarrow$ *Config.* $\mathcal{P}.131$;
$\mathbf{D}<0,\ \xi_{14}<0,\ \xi_{30}>0 \Rightarrow$ *Config.* $\mathcal{P}.132$;
$\mathbf{D}<0,\ \xi_{14}>0 \Rightarrow$ *Config.* $\mathcal{P}.133$;
$\mathbf{D}>0 \Rightarrow$ *Config.* $\mathcal{P}.134$.

The case D = 0. Considering the values of the invariant polynomials obtained above and the conditions $\zeta_5 \neq 0$ (i.e., $3g^2 - 4n \neq 0$) and $\mathcal{R}_7 \neq 0$ (i.e., $Y_3 \neq 0$), we deduce that the condition $\mathbf{D} = 0$ implies $\gamma_2\delta_2 = 0$. From (3.115), this is equivalent to $\xi_{14} = 0$.

We claim that, in the case $\xi_{14} = 0$, the systems (3.111) exhibit configuration *Config. $\mathcal{P}$.135* if $\xi_{30} < 0$, configuration *Config. $\mathcal{P}$.136* if $\xi_{30} > 0$, and configuration *Config. $\mathcal{P}$.137* if $\xi_{30} = 0$.

Indeed, assume $\xi_{14} = 0$, that is, $\gamma_2\delta_2 = 0$. To prove our claim, we examine both possible subcases.

1: *The subcase $\delta_2 = 0$.* This condition implies:

$$n = \frac{1 + 10g^2 + 21g^4}{16g^2}, \quad \gamma_2 = \frac{(7g^2 - 1)(9g^2 + 1)}{4g^2}.$$

We determine that, under this condition, the singular point M_2 coalesces with M_4. If in addition $\gamma_2 = 0$, then M_1 coalesces with M_3, producing two double singularities on the parabola.

Thus, for systems (3.111), if $\gamma_2 > 0$, they realize *Config. $\mathcal{P}$.135*, if $\gamma_2 < 0$, they realize *Config. $\mathcal{P}$.136*, and if $\gamma_2 = 0$, they realize *Config. $\mathcal{P}$.137*.

Considering (3.115), for $\delta_2 = 0$ we observe that $\operatorname{sign}(\xi_{30}) = -\operatorname{sign}(\gamma_2)$, which confirms the claim for this subcase.

2: *The subcase $\gamma_2 = 0$.* This implies $n = (2 + 21g^2)/4$, and under this condition, the singular point M_1 coalesces with M_3. We calculate:

$$\delta_2 = (1 - 7g^2)(1 + 9g^2).$$

It is straightforward to verify that, in this case, if $\delta_2 < 0$, the configuration is *Config. $\mathcal{P}$.135*, if $\delta_2 > 0$, the configuration is *Config. $\mathcal{P}$.136*, and if $\delta_2 = 0$, the configuration is *Config. $\mathcal{P}$.137*.

Finally, from (3.115), for $\gamma_2 = 0$ we find $Y_3 = 16g^2 > 0$, so $\operatorname{sign}(\xi_{30}) = \operatorname{sign}(\delta_2)$, which completes the proof of our claim.

The possibility $B_1 = 0$. From (3.112), this condition implies $g(5g^2 - 4n + 2)\Psi_2\Psi_3 = 0$. We claim that, due to the condition $\mathcal{R}_7 \neq 0$, the equality $B_1 = 0$ is equivalent to $g = 0$.

Indeed, assuming $g \neq 0$, we compute:

$$\operatorname{Discrim}[\Psi_2, n] = -4096g^2 < 0, \quad \operatorname{Discrim}[\Psi_3, n] = -256g^2 < 0,$$

and hence the equations $\Psi_2 = 0$ and $\Psi_3 = 0$ cannot have real solutions with respect to the parameter n. This completes the proof of our claim.

Thus, we conclude $g = 0$ and arrive at the following one-parameter family of systems:

$$\dot{x} = \frac{1}{2}x\,(2n - 2y - 1), \quad \dot{y} = -x^2 + 2n\,y - 2y^2, \tag{3.116}$$

which possess the invariant line $x = 0$ and the invariant parabolas:

$$\Phi_1(x, y) = x^2 - y = 0, \quad \Phi_2(x, y) = x^2 + (2n - 1)y - n(2n - 1) = 0.$$

For these systems, we calculate:

$$\zeta_5 = 1900n^2, \quad \mathcal{R}_7 = -32240(2n - 1), \quad B_2 = -162(2n + 1)^2(4n - 1)^2x^4.$$

We now discuss two cases: $B_2 \neq 0$ and $B_2 = 0$.

The case $B_2 \neq 0$**.** By Lemma 2.3, in this case the system cannot possess invariant lines in any other direction. Considering the condition $g = 0$ in (3.113), we find that the systems (3.116) possess four finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3, 4)$ with coordinates:

$$x_1 = 0, \quad y_1 = 0; \quad x_2 = 0, \quad y_2 = n;$$
$$x_{3,4} = \frac{1}{2}\big(\pm\sqrt{Y_3}\big), \quad y_{3,4} = \frac{1}{2}(2n-1), \quad Y_3 = 2(2n-1).$$

We observe that the invariant line $x = 0$ intersects the invariant parabola $\Phi_1 = 0$ at point M_1, and intersects the parabola $\Phi_2 = 0$ at point M_2.

For these systems we have:

$$\mathbf{D} = -12n^2Y_3^3 \quad \Rightarrow \quad \text{sign}\,(\mathbf{D}) = -\text{sign}\,(Y_3).$$

Since all singular points are fixed as intersection points of invariant curves, and $\mathbf{D} \neq 0$ (due to $\zeta_5\mathcal{R}_7 \neq 0$), we conclude that these systems realize configuration *Config.* $\mathcal{P}$*.138* if $\mathbf{D} < 0$, and configuration *Config.* $\mathcal{P}$*.139* if $\mathbf{D} > 0$.

The case $B_2 = 0$**.** This condition implies $(2n+1)(4n-1) = 0$.

Assume first $4n - 1 = 0$, that is, $n = 1/4$. Then, we arrive at the system:

$$\dot{x} = -\frac{1}{4}x(4y+1), \quad \dot{y} = \frac{1}{2}\left(-2x^2 - 4y^2 + y\right), \tag{3.117}$$

which possesses three invariant lines: $L_1(x, y) = x = 0$ and $L_{2,3}(x, y) = y \pm ix - 1/4 = 0$, along with the invariant parabolas $\Phi_1(x, y) = x^2 - y = 0$ and $\Phi_2(x, y) = -4x^2 + 2y - 1/2 = 0$.

We observe that the point $M_2(0, 1/4)$ corresponds to the intersection of the above complex lines. As a result, this system exhibits the configuration *Config.* $\mathcal{P}$*.140*.

Now, if $2n + 1 = 0$ (i.e., $n = -1/2$), we arrive at the system:

$$\dot{x} = -x(1+y), \quad \dot{y} = -x^2 - y - 2y^2,$$

which can be transformed into system (3.117) via the affine transformation and time rescaling:

$$x_1 = x/2, \quad y_1 = y/2 + 1/4, \quad t_1 = 2t,$$

and hence also realizes *Config.* $\mathcal{P}$*.140*.

3.3.3 The statement $(\mathcal{E}_3)$

According to Proposition 2.9, in this case the conditions $\zeta_4 = \zeta_5 = 0$ and $\mathcal{R}_7 \neq 0$ hold. Considering (3.112), the condition $\zeta_5 = 0$ implies:

$$3g^2 - 4n = 0 \quad \Rightarrow \quad n = \frac{3g^2}{4},$$

and we obtain the following one-parameter family of systems:

$$\begin{aligned} \dot{x} &= \frac{3}{8}g\,(3g^2+2) + \frac{1}{4}(3g^2-2)x - \frac{g\,y}{2} + g\,x^2 - x\,y, \\ \dot{y} &= \frac{3}{4}g\,(3g^2+2)x + \frac{3g^2}{2}y - x^2 + g\,x\,y - 2y^2, \end{aligned} \tag{3.118}$$

which, according to Proposition 2.9, possess $\Phi(x,y) = x^2 - y = 0$ as a double invariant parabola.

For these systems we compute:

$$\zeta_4 = \zeta_5 = 0, \quad \mathcal{R}_7 = 32240(1+g^2)(1+3g^2) \neq 0,$$
$$\theta = -8(g^2+9) \neq 0, \quad B_1 = -\frac{g\,(1+g^2)^4\,(1+9g^2)^3}{4}.$$

According to Lemma 2.3, systems (3.118) can possess at least one invariant line only if $B_1 = 0$. Thus, we discuss two cases: $B_1 \neq 0$ and $B_1 = 0$.

The case $B_1 \neq 0$. Systems (3.118) possess the following three finite singularities $M_i(x_i, y_i)$ $(i = 1,2,3)$ with coordinates:

$$\begin{gathered} x_1 = \frac{3g}{2}, \quad y_1 = \frac{9g^2}{4}; \\ x_{2,3} = -\frac{1}{2}\left[g \pm i\sqrt{2(1+g^2)}\right], \quad y_{2,3} = \frac{1}{4}\left[-2 - g^2 \pm 2gi\sqrt{2(1+g^2)}\right]. \end{gathered} \tag{3.119}$$

It is clear that the real singular point M_1 is a double point, as it lies on the double invariant parabola. This fact can be checked directly.

Moreover, the complex singular points M_2 and M_3 also lie on the invariant parabola, though this is not relevant for the classification of the configuration. We deduce that in the case $B_1 \neq 0$, systems (3.118) realize a single configuration: *Config.* $\mathcal{P}$*.141*.

The case $B_1 = 0$**.** This condition implies $g = 0$. Thus, system (3.118) with $g = 0$ possesses an additional invariant line: $x = 0$. Considering the singularities (3.119) evaluated at $g = 0$, we arrive at the unique configuration *Config.* $\mathcal{P}$*.142*.

3.3.4 The statement $(\mathcal{E}_4)$

According to Proposition 2.9, in this case the conditions $\zeta_4 = \mathcal{R}_7 = 0$ and $\zeta_5 \neq 0$ hold. Considering (3.112), the condition $\mathcal{R}_7 = 0$ implies:

$$5g^2 - 4n + 2 = 0 \quad \Rightarrow \quad n = \frac{2+5g^2}{4}.$$

Thus, we arrive at the following one-parameter family of systems:

$$\begin{aligned} \dot{x} &= \frac{1}{8}(g+2x)\left(3g^2 + 4g\,x - 4y\right), \\ \dot{y} &= \frac{3g^3 x}{4} + \frac{1}{2}(5g^2+2)y - x^2 + g\,x\,y - 2y^2, \end{aligned} \tag{3.120}$$

which possess the invariant parabola $\Phi(x,y) = x^2 - y = 0$ and the invariant line $2x + g = 0$. For these systems we calculate:

$$B_2 = -648(1+g^2)^5(1+9g^2)x^4 \neq 0,$$

and by Lemma 2.3, no additional invariant lines can exist.

Systems (3.120) have three finite singularities $M_i(x_i, y_i)$ $(i = 1, 2, 3)$ with coordinates:

$$x_1 = -\frac{g}{2}, \quad y_1 = \frac{g^2}{4}; \quad x_2 = -\frac{g}{2}, \quad y_2 = \frac{1}{4}(3g^2 + 2); \quad x_3 = \frac{3g}{2}, \quad y_3 = \frac{9g^2}{2}.$$

We claim that the singular point M_1 is a multiple singularity of systems (3.120). Indeed, applying a suitable translation to place M_1 at the origin, we arrive at the system:

$$\begin{aligned} \dot{x} &= x(gx - y), \\ \dot{y} &= g(1 + g^2)x - x^2 + (1 + g^2)y + g\,x\,y - 2y^2, \end{aligned}$$

where $M_0(0, 0)$ corresponds to the singularity M_1.

Following [1], we compute the following invariant polynomials:

$$\mu_4 = \mu_3 = 0, \quad \mu_2 = 2g(1 + g^2)^2 x(gx - y),$$
$$\mu_1 = -(1 + g^2)(x + 5g^2 x - 4gy),$$

and by [1, Lemma 5.2, statement (ii)], the point M_0 has multiplicity at least 2. Notice that $\mu_2 = 0$ if and only if $g = 0$, but in this case $\mu_1 \neq 0$. Therefore, according to [1, Lemma 5.2, statement (ii)], M_1 is a double point if $g \neq 0$ and a triple point if $g = 0$. This classification is governed by the invariant polynomial $\zeta_3 = 32g^2$.

We also note that the multiple singularity M_1 is the intersection point between the invariant line $2x + g = 0$ and the invariant parabola. Moreover, the singularity M_3 lies on the same invariant parabola, and M_3 coalesces with M_1 when $g = 0$, producing a triple finite singularity in systems (3.120).

On the other hand, the singularity M_2 lies on the invariant line above the point M_1, since $y_2 - y_1 = (g^2 + 1)/2 > 0$. Therefore, we conclude that systems (3.120) realize configuration *Config.* $\mathcal{P}$*.143* if $\zeta_3 \neq 0$, and *Config.* $\mathcal{P}$*.144* if $\zeta_3 = 0$.

As all the cases have now been examined, we conclude that statement $(\boldsymbol{B})$ of the Main Theorem is fully proved.

3.4 Geometric invariants and the proof of the statement (C)

In this subsection, we complete the proof of the Main Theorem by showing that all 144 configurations of invariant parabolas and invariant lines that we have constructed are non-equivalent according to Definition 1.3. To achieve this, we define the invariants that distinguish the configurations within the family $\mathbf{QSP}_{(\eta \neq 0)}$ into 144 *distinct* cases. We believe that these invariants are among the most suitable for describing the geometric phenomena specific to this class.

The basic algebraic-geometric notions that we will use here include the concept of an integer-valued r-cycle and its type:

Definition 3.19. Let V be an irreducible algebraic variety of dimension n over a field K. A *cycle of dimension* r, or an *r-cycle*, on V is a formal sum

$$\sum_W m(W)W,$$

where each W is a subvariety of V of dimension r that is not contained in the singular locus of V, $m(W) \in \mathbb{Z}$, and only finitely many of the coefficients $m(W)$ are nonzero. The *degree of an r-cycle* is the sum $\sum_W m(W)$. An $(n-1)$-cycle is called a *divisor*.

Definition 3.20. The *type of an r-cycle* is the set of all ordered pairs (n_1, n_2), where n_1 is a coefficient appearing in the r-cycle (i.e., $n_1 = m(W)$ for some W), and n_2 is the number of subvarieties W in the cycle for which $m(W) = n_1$.

Definition 3.21. We define a set of numerical and geometric invariants that allow us to distinguish the obtained configurations:

(a) $(M_{\mathcal{P}}, m_{\mathcal{L}})$ = (total multiplicity of invariant parabolas, total multiplicity of invariant affine lines);

(b) $\tau^f_{\mathcal{P}}$ = the type of the divisor of the multiplicities of finite singularities of the system located on the parabolas;

(c) $t^f_{\mathcal{P}\cap\mathcal{L}}$ = the type of the divisor of the intersection multiplicities (in the finite plane) between $\mathcal{P}$ and $\mathcal{L}$;

(d) τ^{∞}_s = the type of the divisor of the multiplicities of singularities on the line at infinity;

(e) $M^n_{\mathcal{L}\cap\mathcal{P}}$ = the maximum number of real finite intersection points between an invariant line and a parabola;

(f) $M^m_{\mathcal{P}}$ = the maximum multiplicity among the invariant parabolas;

(g) Consider the finite segment of a parabola delimited by two singularities s_1 and s_2 of the system, having inside another singularity s_0. Let $m(s_0)$ denote the multiplicity of s_0. We define the invariant $I(s_0)$ for this configuration, assigning it the value 1 if s_0 is an intersection point between the parabola and a line, and 0 otherwise;

(h) $m^f(\mathcal{P}\cap\mathcal{L})$ = the multiplicity of the intersection point (considered as a singularity of the system) between the parabola and an affine line;

(i) Consider an invariant line passing through the infinite point of the parabola. This line has another finite intersection point with the parabola, splitting it into two branches. We introduce the invariant $\{n^1_{\mathcal{P}}, n^2_{\mathcal{P}}\}$, where $n^i_{\mathcal{P}}$ denotes the number of singularities of the system located on each open branch of the parabola;

(j) $m^{\mathbb{R}}_s(\mathcal{P})$ = the total multiplicity of real singularities of the system located on the parabola;

(k) $n^s_{in}(\mathcal{P})$ = the total number of real singularities located inside the union of all domains delimited by the parabolas;

(l) If an invariant line intersects a parabola at two distinct real finite points, we obtain a domain $\mathcal{D}^f_{\mathcal{P}\cap\mathcal{L}}$ bounded by the line segment and the arc of the parabola not passing through its infinite point. We denote by $\tau(\mathcal{D}^f_{\mathcal{P}\cap\mathcal{L}})$ the type of the divisor of the of the multiplicities of singularities of the system located on the boundary of $\mathcal{D}^f_{\mathcal{P}\cap\mathcal{L}}$;

(m) $n^f_s(\mathcal{F})$: the number of finite singular points of the curve

$$\mathcal{F} : \mathcal{P}(X, Y, Z) \cdot L_1(X, Y, Z) \cdot L_2(X, Y, Z) = 0$$

that have multiplicity at least 2.

(n) Suppose an affine line intersects the parabola $x^2 - y = 0$ at two finite points or has a point of tangency with it. Let Δ^b denote the curvilinear triangle on the Poincaré disk, with vertex at the infinite point of the parabola, bounded by the closed branch of the parabola, the adjacent segment of the invariant line, and the open arc a_∞ containing a singular point at infinity in its interior. We denote by $n(\Delta^b)$ (respectively, $m(\Delta^b)$) the number (respectively, the total multiplicity) of singularities located on Δ^b;

(o) Assume we have a real system possessing two real invariant parabolas. In this case, two distinct possibilities occur in the real projective plane:

(1) The points at infinity of the two parabolas are distinct,

(2) The points at infinity coincide.

Clearly, the positions of the points at infinity (P_1^∞, P_2^∞) separate these two cases. If $P_1^\infty \neq P_2^\infty$, we are in case (1). If $P_1^\infty = P_2^\infty$, we are in case (2), which further splits into two subcases on the Poincaré disk (PD):

(i) The two points at infinity coincide on PD,

(ii) The two points are opposite on PD.

We define the invariant $J(P_1^\infty, P_2^\infty)$ of the group acting on the systems viewed on the Poincaré disk, assigning the value 0 to case (1), the value 1 to case $(2.i)$, and the value 2 to case $(2.ii)$;

(p) If two invariant parabolas intersect at two distinct finite points, we obtain a finite domain $\mathcal{D}^f_{\mathcal{P}_1\cap\mathcal{P}_2}$ delimited by the closed branches of the parabolas. We denote by $\tau(\mathcal{D}^f_{\mathcal{P}_1\cap\mathcal{P}_2})$ the type of the divisor of the multiplicities of singularities of the system located on the boundary of $\mathcal{D}^f_{\mathcal{P}_1\cap\mathcal{P}_2}$;

(q) Assume that two real invariant parabolas have two distinct points at infinity, $\mathcal{P}_1^\infty$ and $\mathcal{P}_2^\infty$, which are not opposite on PD. Let a_1^∞ and a_2^∞ denote the open arcs on the circumference of PD determined by $\mathcal{P}_1^\infty$ and $\mathcal{P}_2^\infty$. Assume that within the interior of arc a_1^∞ (respectively, a_2^∞), there are n_1 (respectively, n_2) singularities at infinity. We define a new invariant: $m(\mathcal{P}_1^\infty, \mathcal{P}_2^\infty) = \min\{n_1, n_2\}$.

The set of numerical and geometric invariants introduced in Definition 3.21 provides the necessary criteria to distinguish all 144 non-equivalent configurations of systems in the family **QSP**. Each invariant encodes specific geometric information regarding the arrangement of invariant parabolas, affine lines, and singularities, both finite and at infinity.

Figures 3.1 and 3.2 illustrate the complete bifurcation diagram associated with the Main Theorem. The diagrams are organized according to the sign of the parameter η, with Figure 3.1 representing the case $\eta > 0$ and Figure 3.2 corresponding to $\eta < 0$.

Each branch in these diagrams reflects a bifurcation step governed by one or more of the invariants from Definition 3.21, capturing the sequence of geometric changes that distinguish one configuration from another. Together, the invariants and the diagrams provide a complete and systematic classification of all phase portraits in the family **QSP**.

Abstract. In this paper, we discuss the resonance phenomena in linear and weakly nonlinear impulsive differential equations. Using a topological approach, we obtain the Landesman–Lazer type necessary and sufficient conditions for the existence of periodic solutions and extend the Fredholm alternative for linear equations with impulses. Moreover, we show the coexistence of periodic and unbounded solutions of weakly nonlinear impulsive differential equations through the use of the successor map and a Lyapunov function.

Keywords: impulsive differential equations, resonance phenomena, periodic solutions, Fredholm alternative, Lyapunov function.

2020 Mathematics Subject Classification: 34C25, 34C11.

1 Introduction

In this paper, we focus on the second-order impulsive ordinary differential equations

$$\begin{cases} u'' + f(t,u) = 0, \\ \Delta u(t_j) = J_j(u(t_j^-), u'(t_j^-)), \\ \Delta u'(t_j) = Q_j(u(t_j^-), u'(t_j^-)), \ j = \pm 1, \pm 2, \dots, \end{cases} \tag{1.1}$$

where $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ is continuous, 2π-periodic with respect to first variable, $0 \le t_1 < \cdots < t_k < 2\pi$, $\Delta u(t_j) = u(t_j^+) - u(t_j^-)$, $\Delta u'(t_j) = u'(t_j^+) - u'(t_j^-)$, J_j, $Q_j : \mathbb{R}^2 \to \mathbb{R}$ are continuous for $j = \pm 1, \pm 2, \dots$ Moreover, we assume that the impulsive time is 2π-periodic, that is, $t_{j+k} = t_j + 2\pi$, for $j = \pm 1, \pm 2, \dots$

There are many interesting results on the existence and multiplicity of periodic solutions of impulsive differential equations. Various methodologies include fixed point theory [12–14], the Leray–Schauder continuation method of topological degree [5,19], the variational method

✉Corresponding author. Email: fan7ch@gmail.com

[4, 15, 21, 22], the Poincaré–Birkhoff twist theorem [8, 18], and Moser's twist theorem for the Lagrange stability of impulsive differential equations [16, 20].

Regarding the existence of periodic solutions for impulsive differential equations, several significant results have been achieved. However, compared to non-impulsive differential equations, many unresolved issues remain that are worthy of further investigation. For the linear equation

$$u'' + n^2 u = p(t), \tag{1.2}$$

where $p(t) \in C([0, 2\pi])$ is 2π-period. The so-called phenomenon of linear resonance arises whenever n is a positive integer. In other words, periodic solutions and unbounded solutions cannot coexist for the linear equation (1.2). This implies that all solutions of (1.2) are either periodic or unbounded. This is also known as the Fredholm alternative. However, slightly different equations do not have such strong conclusions. For instance, Alonso and Ortega [2] proved that similar results fail to hold for piecewise linear equations

$$u'' + au^+ - bu^- = p(t),$$

where $u^+ = \max\{u, 0\}$, $u^- = \max\{-u, 0\}$ and a, b are different and satisfy

$$\frac{1}{\sqrt{a}} + \frac{1}{\sqrt{b}} \in \mathbb{Q}. \tag{1.3}$$

They deduced that periodic and unbounded solutions can coexist when (1.3) holds and $a \neq b$ in [2].

Meanwhile, under the influence of impulses, the resonance phenomenon in linear equations has attracted significant attention. Similarly, the coexistence of periodic solutions with unbounded solutions in weakly linear equations has been a focus of recent studies. Recently, Drábek and Langerová [6] obtained the Fredholm alternative type results for linear equations with bounded impulses. They applied critical point theory to provide the necessary and sufficient conditions for the existence of a solution when solutions satisfying the impulse conditions in the derivative:

$$\Delta u(t_j) = 0, \qquad \Delta u'(t_j) = \tilde{I}_j(u(t_j^-)),$$

$$\lim_{s \to \pm\infty} \tilde{I}_j(s) = \tilde{I}_j(\pm\infty), \qquad \tilde{I}_j(+\infty) < \tilde{I}_j(s) < \tilde{I}_j(-\infty), \qquad j = 1, \ldots, k.$$

In their work [15], they also mentioned employing similar approaches to analyze the necessary and sufficient conditions for the periodic solutions of linear equations. However, we note that when applying variational methods or critical point theory to impulsive equations, due to the limitations of these methods, it is necessary to transform the periodic solution or boundary value problem into a functional critical point. In such cases, the impulses must satisfy

$$\Delta u(t_j) = 0, \qquad \Delta u'(t_j) = \tilde{I}_j(u(t_j^-)).$$

An interesting question is whether we can overcome this limitation and obtain the necessary and sufficient conditions for the existence of periodic solutions of linear equations under more general impulsive conditions. One of the main results of this paper is to relax the impulse restrictions established in [6], via topological framework, allowing for impulses in both the function and its derivative.

We consider the following impulsive equation

$$\begin{cases} u''(t) + n^2 u(t) = p(t), \quad t \in [0, 2\pi],\ t \neq t_j; \\ \Delta u(t_j) = J_j(u'(t_j^-)), \quad \Delta u'(t_j) = Q_j(u(t_j^-)), \quad j = 1, \dots, k; \\ u(0) = u(2\pi), \quad u'(0) = u'(2\pi). \end{cases} \tag{1.4}$$

Suppose that

(H_1) For $j = 1, \dots, k$, there exist limits

$$\lim_{s \to \pm\infty} J_j(s) = J_j(\pm\infty), \qquad \lim_{s \to \pm\infty} Q_j(s) = Q_j(\pm\infty),$$

and the following inequalities hold:

$$J_j(+\infty) < J_j(s) < J_j(-\infty), \qquad Q_j(-\infty) < Q_j(s) < Q_j(+\infty), \qquad s \in \mathbb{R}.$$

That gives our Landesman–Lazer type condition.

(H_2) For any $\theta \in \mathbb{R}$, $p(t)$ satisfies

$$\begin{aligned} & n \sum_{j=1}^{k} J_j(-\infty) \cos^+(nt_j + \theta) - n \sum_{j=1}^{k} J_j(+\infty) \cos^-(nt_j + \theta) + \sum_{j=1}^{k} Q_j(+\infty) \sin^-(nt_j + \theta) \\ & - \sum_{j=1}^{k} Q_j(-\infty) \sin^+(nt_j + \theta) > \int_0^{2\pi} \sin(nt + \theta) p(t) dt > n \sum_{j=1}^{k} J_j(+\infty) \cos^+(nt_j + \theta) \\ & - n \sum_{j=1}^{k} J_j(-\infty) \cos^-(nt_j + \theta) - \sum_{j=1}^{k} Q_j(+\infty) \sin^+(nt_j + \theta) + \sum_{j=1}^{k} Q_j(-\infty) \sin^-(nt_j + \theta). \end{aligned}$$

Theorem 1.1. *Assume that* (H_1) *holds. Then* (1.4) *has a* 2π*-periodic solution if and only if* $p(t)$ *satisfies* (H_2)*. Moreover, if* (1.4) *has no periodic solutions then every solution must be unbounded.*

Remark 1.2. Theorem 1.1 provides the necessary and sufficient conditions for impulses in both the function and its derivative, and also discusses unbounded solutions, extending the results in [6].

And we illustrate our results with an example.

Example 1.3. Let $n = 2$ in (1.4), the impulse time $t_1 = \frac{\pi}{4}$, $t_2 = \frac{\pi}{2}$ and the impulse condition is of the form $J_j(u') = -\arctan u'$, $Q_j(u) = \arctan u$, $j = 1, 2$. Then (1.4) has a 2π-periodic solution if $p(t) = \cos 2t + \sin 2t$.

Furthermore, the Fredholm alternative does not hold for nonlinear equations. There is no similar theorem even for piecewise linear equations, as shown by Alonso and Ortega [2]. Fonda and Mawhin [7] proved all solutions of $J\dot{u} = \nabla \mathcal{H}(u) + f(u) + p(t)$ are bounded in the past, and those with sufficiently large amplitude are unbounded in the future. Qian [17] showed that the coexistence of periodic solution and unbounded solution, the infinity of large amplitude subharmonics for asymmetric weakly nonlinear oscillator There is no similar theorem even for piecewise linear equations by Alonso and Ortega [2]. Fonda and Mawhin [7] proved all solutions of $J\dot{u} = \nabla \mathcal{H}(u) + f(u) + p(t)$ are bounded in the past, and those with sufficiently large amplitude are unbounded in the future. Qian [17] showed that the coexistence

of periodic solution and unbounded solution, the infinity of large amplitude subharmonics for asymmetric weakly nonlinear oscillator

$$x'' + a^2x^+ - b^2x^- + h(x) = p(t),$$

with $h(\pm\infty) = 0$ and $xh(x) \to +\infty (x \to \infty)$. For the other discussion of the coexistence of unbounded solutions and periodic solutions, we refer the reader to [3, 9, 10]. Thus the coexistence of periodic solution and unbounded solution is a typical nonlinear phenomenon. We consider the following weakly nonlinear impulsive equation

$$\begin{cases} u''(t) + n^2u(t) + h(u(t)) = p(t), \quad t \in [0, 2\pi],\ t \neq t_j; \\ \Delta u(t_j) = J_j(u(t_j^-), u'(t_j^-)), \quad \Delta u'(t_j) = Q_j(u(t_j^-), u'(t_j^-)), \quad j = 1, \dots, k, \end{cases} \tag{1.5}$$

where $0 < t_1 < \cdots < t_k < 2\pi$, $h : C[0, 2\pi] \to C[0, 2\pi]$, $p(t) \in C([0, 2\pi])$ is 2π-periodic and $J_j, Q_j : \mathbb{R}^2 \to \mathbb{R}$ are continuous, $j = 1, \dots, k$. Suppose that

(D_1) $h(u)$ satisfies

(i) $h(\pm\infty) = \lim_{u\to\pm\infty} h(u) = 0$,

(ii) $\lim_{|u|\to\infty} uh(u) = +\infty$.

(D_2) Impulsive terms satisfy

$$J_j(u, u') = O\left(\frac{1}{r}\right), \qquad Q_j(u, u') = O\left(\frac{1}{r}\right), \qquad j = 1, \dots, k,$$

where $r = \sqrt{|u|^2 + |u'|^2}$. $f = O\left(\frac{1}{r}\right)$ for $r \to \infty$ means that $f/\left(\frac{1}{r}\right)$ is bounded for all sufficiently large r.

Theorem 1.4. *Assume that (D_1) and (D_2) hold. Then there exists $q_0 > 0$, such that (1.5) has both 2π-periodic solution and unbounded solution provided that $p(t)$ satisfies*

$$0 < M_p < q_0,$$

where

$$M_p = \max_{\theta\in[0,2\pi]} \left| \int_0^{2\pi} p(t) \sin(nt + \theta) dt \right|.$$

Example 1.5. Let $h(u) = u^{-\frac{1}{3}}$ and the impulse condition is given by $Q_j(u, u') = J_j(u, u') = \frac{1}{\sqrt{u^2+u'^2}}$. Then (1.5) has both 2π-periodic solution and unbounded solution.

The rest of the paper is organized as follows. In Section 2, we discuss the necessary and sufficient conditions for the existence of periodic solutions of linear impulsive equations via constant variation method and degree theory. Moreover, we prove that all solutions are unbounded when the periodic solution does not exist by the method of variation of constants. In Section 3, we consider weakly nonlinear impulsive equations and introduce the successor map to prove the existence of a periodic solution. The proof of the existence of the unbounded solution is mainly using Poincaré map to construct a Liapunov function that makes the solution grow infinitely along the orbit. So that the solution of the equation is unbounded.

2 Resonance and the existence of periodic solutions

In this section, we discuss a linear equation with impulses and provide necessary and sufficient conditions for the existence of a 2π-periodic solution under assumptions (H_1) and (H_2). Furthermore, we prove the existence of unbounded solutions and then complete the proof of Theorem 1.1.

Consider the linear periodic boundary value problem

$$\begin{cases} u''(t) + n^2 u(t) = p(t), \quad t \in [0, 2\pi],\ t \neq t_j; \\ \Delta u(t_j) = J_j(u(t_j^-), u'(t_j^-)), \quad \Delta u'(t_j) = Q_j(u(t_j^-), u'(t_j^-)),\ j = 1, \dots, k; \\ u(0) = u(2\pi), \quad u'(0) = u'(2\pi). \end{cases} \tag{2.1}$$

where $0 < t_1 < \cdots < t_k < 2\pi$, $p(t) \in C(\mathbb{R}, \mathbb{R})$, $p(t)$ is 2π-periodic and the impulses J_j, $Q_j : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$, $j = 1, \dots, k$, are continuous.

2.1 The necessary condition

For a general case, we consider the following impulsive equation

$$\begin{cases} x'(t) = Ax(t) + P(t), \quad t \neq t_j; \\ \Delta x(t_j) = I_j(x(t_j^-)), \quad j = 1, \dots, k; \\ x(0) = x(2\pi), \end{cases} \tag{2.2}$$

where 2×2 matrix A is constant, two-dimensional vector $P(t)$ is continuous, $\Delta x(t_j) = x(t_j^+) - x(t_j^-)$, I_j are continuous, $j = 1, \dots, k$.

For simplicity, we set $t_0 = 0$ and $t_{k+1} = 2\pi$. It is well known that the solutions of (2.2) which include instantaneous impulses result in jump discontinuities in both velocity and position at times $t = t_j$, $j = 1, \dots, k$. In other words, any motion of the solution is the same as the motion of the corresponding equation without impulses until it meets the next impulse time. Hence, we first consider the differential equation without impulses

$$x'(t) = Ax(t) + P(t). \tag{2.3}$$

Fixed any $j \in \{0, 1, \dots, k\}$. Suppose that equation (2.3) satisfies the initial condition $x(t_j) = x(t_j^+)$. By the method of variation of parameters, we have

$$x(t) = \Phi(t) \left(\Phi^{-1}(t_j^+) x(t_j^+) + \int_{t_j}^{t} \Phi^{-1}(s) P(s) ds \right), \qquad t \in (t_j^+, t_{j+1}^-),$$

where $\Phi(t)$ is the fundamental matrix of (2.3) that satisfies $\Phi(0) = \Phi(2\pi) = E$. In particular,

$$x(t_{j+1}^-) = \Phi(t_{j+1}^-) \left(\Phi^{-1}(t_j^+) x(t_j^+) + \int_{t_j}^{t_{j+1}^-} \Phi^{-1}(s) P(s) ds \right).$$

Next, we present the expression for the solutions of the impulsive differential equation (2.2). Note that $\Phi(t_j^+) = \Phi(t_j) = \Phi(t_j^-)$, since $\Phi(t)$ is continuous. Substituting $x(t_1^-)$ into the

expression for $x(t_2^-)$ yields

$$\begin{aligned} x(t_2^-) &= \Phi(t_2^-)\left(\Phi^{-1}(t_1^+)x(t_1^+) + \int_{t_1^+}^{t_2^-} \Phi^{-1}(s)P(s)ds\right) \\ &= \Phi(t_2^-)\left(\Phi^{-1}(t_1^+)\left(x(t_1^-) + x(t_1^+) - x(t_1^-)\right) + \int_{t_1^+}^{t_2^-} \Phi^{-1}(s)P(s)ds\right) \\ &= \Phi(t_2^-)\left(x(0) + \int_0^{t_2^-} \Phi^{-1}(s)P(s)ds + \Phi^{-1}(t_1^+)I_1(x(t_1^-))\right). \end{aligned}$$

Repeating the above steps by substituting $x(t_2^-)$ into the expression for $x(t_3^-)$, and so on, we obtain

$$x(t) = \Phi(t)\left(x(0) + \int_0^t \Phi^{-1}(s)P(s)ds + \sum_{t>t_j} \Phi^{-1}(t_j)I_j(x(t_j^-))\right). \tag{2.4}$$

In particular,

$$\begin{aligned} x(2\pi) &= \Phi^{-1}(2\pi)\left(x(0) + \int_0^{2\pi} \Phi^{-1}(s)P(s)ds + \sum_{j=1}^{k} \Phi^{-1}(t_j)I_j(x(t_j^-))\right) \\ &= x(0) + \int_0^{2\pi} \Phi^{-1}(s)P(s)ds + \sum_{j=1}^{k} \Phi^{-1}(t_j)I_j(x(t_j^-)). \end{aligned} \tag{2.5}$$

Since $x(0) = x(2\pi)$, it follows that

$$\int_0^{2\pi} \Phi^{-1}(s)P(s)ds + \sum_{j=1}^{k} \Phi^{-1}(t_j)I_j(x(t_j^-)) = 0. \tag{2.6}$$

Recall that the equation (2.1). We set $x_1(t) = u(t)$, $x_2(t) = u'(t)$, $x(t) = (x_1(t), x_2(t))^T$, $P(t) = (0, p(t))^T$, $I_j = (J_j, Q_j)^T$, $j = 1, \ldots, k$, and $A = \begin{pmatrix} 0 & 1 \\ -n^2 & 0 \end{pmatrix}$. Obviously,

$$\Phi(t) = \begin{pmatrix} \cos nt & \frac{1}{n}\sin nt \\ -n\sin nt & \cos nt \end{pmatrix}.$$

Then, plugging these expression back into (2.6), we obtain

$$\begin{aligned} \int_0^{2\pi} p(t)\sin nt dt &= n\sum_{j=1}^{k} J_j(u(t_j^-), u'(t_j^-))\cos nt_j - \sum_{j=1}^{k} Q_j(u(t_j^-), u'(t_j^-))\sin nt_j, \\ \int_0^{2\pi} p(t)\cos nt dt &= -n\sum_{j=1}^{k} J_j(u(t_j^-), u'(t_j^-))\sin nt_j - \sum_{j=1}^{k} Q_j(u(t_j^-), u'(t_j^-))\cos nt_j. \end{aligned}$$

We now assume that the impulses affect only one component of the system. Consider the following linear periodic boundary value problem

$$\begin{cases} u''(t) + n^2u(t) = p(t), \quad t \in [0, 2\pi],\ t \neq t_j; \\ \Delta u(t_j) = J_j(u'(t_j^-)), \quad \Delta u'(t_j) = Q_j(u(t_j^-)), \quad j = 1, \ldots, k; \\ u(0) = u(2\pi), \quad u'(0) = u'(2\pi). \end{cases} \tag{2.7}$$

where the impulses satisfies (H_1).

Similarly, we have

$$\int_0^{2\pi} p(t)\sin ntdt = n\sum_{j=1}^{k} J_j(u'(t_j^-))\cos nt_j - \sum_{j=1}^{k} Q_j(u(t_j^-))\sin nt_j,$$
$$\int_0^{2\pi} p(t)\cos ntdt = -n\sum_{j=1}^{k} J_j(u'(t_j^-))\sin nt_j - \sum_{j=1}^{k} Q_j(u(t_j^-))\cos nt_j.$$

Choose any $\theta \in \mathbb{R}$. Multiplying the above two expressions by $\cos\theta$ and $\sin\theta$, respectively, and adding them together, we obtain

$$\begin{aligned}\int_0^{2\pi} p(t)\sin(nt+\theta)dt &= n\sum_{j=1}^{k} J_j(u'(t_j^-))\cos(nt_j+\theta) - \sum_{j=1}^{k} Q_j(u(t_j^-))\sin(nt_j+\theta)\\ &= n\sum_{j=1}^{k} J_j(u'(t_j^-))(\cos^+(nt_j+\theta) - \cos^-(nt_j+\theta))\\ &\quad - \sum_{j=1}^{k} Q_j(u(t_j^-))(\sin^+(nt_j+\theta) - \sin^-(nt_j+\theta)),\end{aligned}$$

where $f^+ = \max\{f,\ 0\}$ and $f^- = \max\{0,\ -f\}$.

By combining (H_1), we finally obtain

$$\begin{aligned}&n\sum_{j=1}^{k} J_j(-\infty)\cos^+(nt_j+\theta) - n\sum_{j=1}^{k} J_j(+\infty)\cos^-(nt_j+\theta)\\ &\qquad + \sum_{j=1}^{k} Q_j(+\infty)\sin^-(nt_j+\theta) - \sum_{j=1}^{k} Q_j(-\infty)\sin^+(nt_j+\theta)\\ &> \int_0^{2\pi} \sin(nt+\theta)p(t)dt\\ &> n\sum_{j=1}^{k} J_j(+\infty)\cos^+(nt_j+\theta) - n\sum_{j=1}^{k} J_j(-\infty)\cos^-(nt_j+\theta)\\ &\qquad - \sum_{j=1}^{k} Q_j(+\infty)\sin^+(nt_j+\theta) + \sum_{j=1}^{k} Q_j(-\infty)\sin^-(nt_j+\theta),\end{aligned}$$

which is exactly assumption (H_2).

2.2 The sufficient condition

For the Banach space

$$X = \{x : [0,2\pi] \to \mathbb{R}^2 :\ x(t) \text{ is continuous for } t \neq t_j,\ x(t_j^-),\ x(t_j^+) \text{ exist,}\\ \text{and } x(t_j^-) = x(t_j),\ j = 1,\dots,k,\ x(0) = x(2\pi)\},$$

we define the norm as

$$\|x\|_X = \sup_{t\in B}\left(\sum_{i=1}^{2} x_i(t)^2\right)^{\frac{1}{2}},$$

where $B = [0,2\pi]\backslash\{t_1, t_2, \ldots, t_k\}$.

The Banach space X is reflexive. Indeed, for any $x \in X$, since the interval $[0,2\pi]$ is measurable, $x(t)$ is a measurable function in it. It is obvious that $\int_0^{2\pi} x^2(t)dt < \infty$ which implies $X \subset L^2[0,2\pi]$. $L^2[0,2\pi]$ is a reflexive Banach space and so is X.

To establish the existence of a periodic solution to (2.7), we make use the homotopy invariance property of Leray–Schauder degree. Consider the following equation

$$\begin{cases} u''(t) + (n^2 - (1-\lambda)\delta)u(t) = \lambda p(t), \quad t \in [0,2\pi],\ t \neq t_j; \\ \Delta u(t_j) = \lambda J_j(u'(t_j^-)), \quad \Delta u'(t_j) = \lambda Q_j(u(t_j^-)), \quad j = 1, \ldots, k; \\ u(0) = u(2\pi), \quad u'(0) = u'(2\pi). \end{cases} \tag{2.8}$$

and the corresponding homotopy $F_\lambda : X \to X$, defined as

$$F_\lambda x = x(0) + \frac{2\pi - t}{2\pi}\left(\int_0^{2\pi} (\lambda P(s) + A_\lambda x(s))ds + \sum_{j=1}^{k} \lambda I_j(x(t_j^-))\right)$$
$$+ \int_0^t (\lambda P(s) + A_\lambda x(s))ds + \sum_{t>t_j}^{k} \lambda I_j(x(t_j^-)),$$

where $A_\lambda = \begin{pmatrix} 0 & 1 \\ -(n^2-(1-\lambda)\delta) & 0 \end{pmatrix}$, $\lambda \in [0,1]$ and $\delta \in (0, \frac{1}{2})$ is sufficiently small so that

$$(n-1)^2 < n^2 - (1-\lambda)\delta < n^2.$$

It is well known that the 2π-periodic solutions of (2.8) correspond to the fixed points of the operator F_λ.

Indeed, $F_\lambda(M)$ is an equicontinuous family of functions. Let $M \subset X$ be a bounded set. For any $x \in M$, $F_\lambda(x(t))$ is continuous, for $t \neq t_j$, $j = 1, \ldots, k$. Thus, $F_\lambda(x(t))$ is uniformly continuous on each closed subinterval with $0, t_1, \ldots, t_k, 2\pi$ as the end point. For any $x \in M$, $x(t)$ is bounded since $x(t)$ is continuous in $[0,2\pi]$, $t \neq t_j$. Clearly, $P(t)$ is bounded. Note that the boundedness of $J_j(x(t))$ and $Q_j(x(t))$ implies the boundedness of $I_j(x(t))$, $j = 1, \ldots, k$. We conclude from (2.8) that $F_\lambda x$ is bounded and hence uniformly bounded. By the Arzelà–Ascoli's theorem, we conclude that $F_\lambda(M)$ is relatively compact and, in consequence, the operator F_λ is completely continuous.

It remains to show that there exists $R_0 > 0$, such that for all $R \geq R_0$ and $\lambda \in [0,1]$, if $x \in X$, $\|x\| = R$, then $x - F_\lambda x \neq 0$.

We perform the proof via contradiction. Assume that there exist sequences $x_m \in X$, $\|x_m\| \to \infty$, $m \to \infty$ and $\lambda_m \in [0,1]$ such that $x_m = F_{\lambda_m} x_m$. Define $y_m = \frac{x_m}{\|x_m\|}$. Then the equation is equivalent to

$$F_{\lambda_m} y_m = \frac{x(0)}{\|x_m\|} + \frac{2\pi - t}{2\pi}\left(\int_0^{2\pi} \left(\lambda_m \frac{P(s)}{\|x_m\|} + A_{\lambda_m} y_m(s)\right) ds + \sum_{j=1}^{k} \lambda_m \frac{I_j(x_m(t_j^-))}{\|x_m\|}\right)$$
$$+ \int_0^t \left(\lambda_m \frac{P(s)}{\|x_m\|} + A_{\lambda_m} y_m(s)\right) ds + \sum_{t>t_j}^{k} \lambda_m \frac{I_j(x_m(t_j^-))}{\|x_m\|} = y_m. \tag{2.9}$$

Clearly, $\frac{x(0)}{\|x_m\|} \to 0$ and $\frac{P(t)}{\|x_m\|} \to 0$. By (H_1), we see that $\frac{J_j(u_m'(t_j^-))}{\|x_m\|} \to 0$, $\frac{Q_j(u_m(t_j^-))}{\|x_m\|} \to 0$ and so $\frac{I_j(x_m(t_j^-))}{\|x_m\|} \to 0$.

Since the Banach space X is reflexive and the boundedness of $\{y_m\}$, there exists a weakly convergence subsequence which is still denoted by $\{y_m\}$. Assume that $y_m \rightharpoonup y \in X$ and $\lambda_m \to \lambda \in [0,1]$. Since F_λ is compact, we have $F_\lambda y_m \to F_\lambda y$. It then follows from (2.9) that $y_m \to y$ strongly in X.

Passing to the limit as $m \to \infty$, we obtain from (2.9) that

$$F_\lambda y = \frac{2\pi - t}{2\pi} \int_0^{2\pi} A_\lambda y(t)dt + \int_0^t A_\lambda y(t)dt = y,$$

and equivalent to

$$\begin{cases} u'' + (n^2 - (1-\lambda)\delta)u = 0, \\ u(0) = u(2\pi), \quad u'(0) = u'(2\pi). \end{cases}$$

where $y = (u, u')$, $\|y\| = 1$, $\lambda \in [0,1]$. By the fact that $(n-1)^2 < n^2 - (1-\lambda)\delta < n^2$, the above equation has a solution if and only if $\lambda = 1$ and $u(t) = c_0 \sin(nt + \theta_0)$ where $c_0 > 0$, $\theta_0 \in \mathbb{R}$. The condition $c_0 > 0$ can be ensured by choosing an appropriate θ_0. Therefore, we obtain

$$\frac{u_m}{\|x_m\|} \to c_0 \sin(nt + \theta_0), \qquad m \to \infty.$$

We have

$$u_m''(t) + (n^2 - (1-\lambda_m)\delta)u_m(t) = \lambda_m p(t), \tag{2.10}$$

$$u_m(t_j^+) - u_m(t_j^-) = \lambda_m J_j(u_m'(t_j^-)),\ u_m'(t_j^+) - u_m'(t_j^-) = \lambda_m Q_j(u_m(t_j^-)),\ j = 1, \dots, k, \tag{2.11}$$

which follows from $x_m - F_{\lambda_m} x_m = 0$.

Choose the test function $v : [0, 2\pi] \to R$ that is continuously differentiable and satisfies $v(0) = v(2\pi)$, $v'(0) = v'(2\pi)$. Multiplying equation (2.10) by $v(t)$ and integrating over B, we get

$$\int_0^{2\pi} u_m''(t)v(t)dt + (n^2 - (1-\lambda_m)\delta) \int_0^{2\pi} u_m(t)v(t)dt = \int_0^{2\pi} \lambda_m p(t)v(t)dt, \tag{2.12}$$

where

$$\int_0^{2\pi} u_m''(t)v(t)dt = \int_0^{t_1^-} u_m''(t)v(t)dt + \sum_{j=1}^{k-1} \int_{t_j^+}^{t_{j+1}^-} u_m''(t)v(t)dt + \int_{t_k^+}^{2\pi} u_m''(t)v(t)dt.$$

Then, using integration by parts, we obtain

$$\begin{aligned} \int_{t_j^+}^{t_{j+1}^-} u_m''(t)v(t)dt &= u_m'(t)v(t) \,|_{t_j^+}^{t_{j+1}^-} - \int_{t_j^+}^{t_{j+1}^-} u_m'(t)v'(t)dt \\ &= u_m'(t_{j+1}^-)v(t_{j+1}) - u_m'(t_j^+)v(t_j) - u_m(t_{j+1}^-)v'(t_{j+1}) \\ &\quad + u_m(t_j^+)v'(t_j) + \int_{t_j^+}^{t_{j+1}^-} u_m(t)v''(t)dt. \end{aligned} \tag{2.13}$$

Combining (2.11), (2.12) and (2.13), we obtain

$$\begin{aligned} &\int_0^{2\pi} u_m(t)v''(t)dt + (n^2 - (1-\lambda_m)\delta) \int_0^{2\pi} u_m(t)v(t)dt + \lambda_m \sum_{j=1}^{k} J_j(u'(t_j^-))v'(t_j) \\ &\quad - \lambda_m \sum_{j=1}^{k} Q_j(u_m(t_j^-))v(t_j) = \int_0^{2\pi} \lambda_m p(t)v(t)dt. \end{aligned}$$

Now, choose $v(t) = c_0 \sin(nt + \theta_0)$, then,

$$\begin{aligned} &-(1-\lambda_m)\delta \int_0^{2\pi} u_m(t)\sin(nt+\theta_0)dt + n\lambda_m \sum_{j=1}^{k} J_j(u'_m(t_j^-))\cos(nt_j+\theta_0) \\ &\quad -\lambda_m \sum_{j=1}^{k} Q_j(u_m(t_j^-))\sin(nt_j+\theta_0) = \int_0^{2\pi} \lambda_m p(t)\sin(nt+\theta_0)dt. \end{aligned} \tag{2.14}$$

Notice that $\dfrac{u_m}{\|x_m\|} \to c_0 \sin(nt+\theta_0),\ c_0 > 0$, which implies that

$$\int_0^{2\pi} u_m(t)\sin(nt+\theta_0)dt > 0, \qquad m \gg 1. \tag{2.15}$$

From (2.14) and (2.15), it follows that

$$\int_0^{2\pi} p(t)\sin(nt+\theta_0)dt \le n\sum_{j=1}^{k} J_j(u'_m(t_j^-))\cos(nt_j+\theta_0) - \sum_{j=1}^{k} Q_j(u_m(t_j^-))\sin(nt_j+\theta_0).$$

Passing to the limit as $m \to \infty$, we finally obtain

$$\begin{aligned} \int_0^{2\pi} p(t)\sin(nt+\theta_0)dt \le{}& n\sum_{j=1}^{k} J_j(+\infty)\cos^+(nt_j+\theta_0) - n\sum_{j=1}^{k} J_j(-\infty)\cos^-(nt_j+\theta_0) \\ &-\sum_{j=1}^{k} Q_j(+\infty)\sin^+(nt_j+\theta_0) + \sum_{j=1}^{k} Q_j(-\infty)\sin^-(nt_j+\theta_0), \end{aligned}$$

a contradiction with the assumption (H_2).

We can now choose an appropriate $R > 0$, such that $x - F_\lambda x \neq 0$, for $x \in X$ with $\|x\| = R$. Define $B_R = \{x \in X \mid \|x\| < R\}$. We say that $x(t) \in \partial B_R$ if there exists a $t_0 \in [0, 2\pi]$, such that $x(t_0) = R$.

Let $x_1(t) = r\cos\varphi,\ x_2(t) = r\sin\varphi$, we have

$$|r'(t)| = \left|\frac{x_1x'_1 + x_2x'_2}{\sqrt{x_1^2+x_2^2}}\right| = \left|\frac{(1-n^2+(1-\lambda)\delta)x_1(t)x_2(t) + \lambda p(t)x_2(t)}{\sqrt{x_1^2+x_2^2}}\right| \le n^2 r(t) + P,$$

where $P = \max_{t\in[0,2\pi]}|p(t)|$, which implies that for sufficiently large $x_1^2 + x_2^2$, there exists a $B_P > 0$, such that

$$(r(t_0)+B_P)\mathrm{e}^{-n^2(t-t_0)} \le r(t) + B_P \le (r(t_0)+B_P)\mathrm{e}^{n^2(t-t_0)}, \qquad t \in [t_0, t_0+2\pi].$$

This shows that $x(t_0) \to +\infty \Leftrightarrow \|x\| \to +\infty$.

To summarize: there exists a $B_R > 0$ such that for each $x(t) \in \partial B_R$, $x - F_\lambda x \neq 0$, $\lambda \in [0,1]$. Now, by the Theorem 3 of [11], we have

$$\deg(I - F_1; B_R, 0) = \deg(I - F_0; B_R, 0) = (-1)^2 \deg_{\mathrm{B}}(A_0|_{\mathbb{R}^2}; B_R \cap \mathbb{R}^2, 0),$$

where $\deg(I - F_0; B_R, 0)$ denotes the Leray–Schauder degree, and $\deg_{\mathrm{B}}(A_0|_{\mathbb{R}^2}; B_R \cap \mathbb{R}^2, 0)$ denotes the Brouwer degree.

Let

$$A_0x : \mathbb{R}^2 \to \mathbb{R}^2, \qquad (x_1, x_2) \longmapsto (x_2, -(n^2-\delta)x_1),$$

where $x = (x_1, x_2)^T$.

It is easy to verify that $A_0 x$ has exactly one zero in $B_R \cap \mathbb{R}^2$. Therefore,

$$\deg_B(A_0|_{\mathbb{R}^2}; B_R \cap \mathbb{R}^2, 0) = \operatorname{sgn}(\det(A_0)) = \operatorname{sgn}(n^2 - \delta) = 1,$$

and consequently,

$$\deg(I - F_1; B_R, 0) = \deg(I - F_0; B_R, 0) = \deg_B(I - F_0; B_R, 0) = 1.$$

Hence, the original system has at least one 2π-periodic solution.

Finally, we have the following result.

Proposition 2.1. *Assume that* (H_1) *holds. Then* (2.7) *has a* 2π*-periodic solution if and only if* $p(t)$ *satisfies* (H_2).

Remark 2.2. Suppose that

(H_1') For $j = 1, \ldots, k$, there exist limits

$$\lim_{s \to \pm\infty} J_j(s) = J_j(\pm\infty), \qquad \lim_{s \to \pm\infty} Q_j(s) = Q_j(\pm\infty),$$

and the following inequalities hold:

$$J_j(-\infty) < J_j(s) < J_j(+\infty), \quad Q_j(+\infty) < Q_j(s) < Q_j(-\infty).$$

(H_2') For any $\theta \in \mathbb{R}$, $p(t)$ satisfies

$$\begin{aligned}
