&n \sum_{j=1}^{k} J_j(-\infty) \cos^+(nt_j + \theta) - n \sum_{j=1}^{k} J_j(+\infty) \cos^-(nt_j + \theta) \\
&\quad + \sum_{j=1}^{k} Q_j(+\infty) \sin^-(nt_j + \theta) - \sum_{j=1}^{k} Q_j(-\infty) \sin^+(nt_j + \theta) \\
&< \int_0^{2\pi} \sin(nt + \theta) p(t) dt \\
&< n \sum_{j=1}^{k} J_j(+\infty) \cos^+(nt_j + \theta) - n \sum_{j=1}^{k} J_j(-\infty) \cos^-(nt_j + \theta) \\
&\quad - \sum_{j=1}^{k} Q_j(+\infty) \sin^+(nt_j + \theta) + \sum_{j=1}^{k} Q_j(-\infty) \sin^-(nt_j + \theta).
\end{aligned}$$

Proposition 2.3. *Assume that* (H_1') *holds. Then* (2.7) *has a* 2π*-periodic solution if and only if* $p(t)$ *satisfies* (H_2').

The proof of this proposition can be completed using a method similar to the one presented above.

2.3 The existence of unbounded solutions

This section is to prove that all solutions of (2.7) are unbounded when the periodic solution does not exist, namely

Proposition 2.4. *Assume that (H_1) holds. There exists $\theta_0 \in \mathbb{R}$ such that $p(t)$ satisfies either*

$$\begin{aligned}\int_0^{2\pi} p(t)\sin(nt+\theta_0)dt \geq\ & n\sum_{j=1}^{k} J_j(-\infty)\cos^+(nt_j+\theta_0) - n\sum_{j=1}^{k} J_j(+\infty)\cos^-(nt_j+\theta_0)\\ & + \sum_{j=1}^{k} Q_j(+\infty)\sin^-(nt_j+\theta_0) - \sum_{j=1}^{k} Q_j(-\infty)\sin^+(nt_j+\theta_0),\end{aligned}$$

or

$$\begin{aligned}\int_0^{2\pi} p(t)\sin(nt+\theta_0)dt \leq\ & n\sum_{j=1}^{k} J_j(+\infty)\cos^+(nt_j+\theta_0) - n\sum_{j=1}^{k} J_j(-\infty)\cos^-(nt_j+\theta_0)\\ & - \sum_{j=1}^{k} Q_j(+\infty)\sin^+(nt_j+\theta_0) + \sum_{j=1}^{k} Q_j(-\infty)\sin^-(nt_j+\theta_0).\end{aligned}$$

Then all solutions of (2.7) are unbounded (in the phase plane).

Proof. We denote by $u(t)$ a solution of (2.7). Setting $x(t) = (u(t), u'(t))^T$. Then for any $m \in \mathbb{N}$, by (2.4) we get

$$\begin{aligned}nu(2m\pi) &= nu(0) - \int_0^{2m\pi} p(t)\sin ntdt + n\sum_{j=1}^{mk} J_j(u'(t_j^-))\cos nt_j - \sum_{j=1}^{mk} Q_j(u(t_j^-))\sin nt_j,\\ u'(2m\pi) &= u'(0) + \int_0^{2m\pi} p(t)\cos ntdt + n\sum_{j=1}^{mk} J_j(u'(t_j^-))\sin nt_j + \sum_{j=1}^{mk} Q_j(u(t_j^-))\cos nt_j.\end{aligned}$$

Multiply the two equations above by $-\cos\theta_0, \sin\theta_0$, respectively, and add them together to get

$$\begin{aligned}&u'(2m\pi)\sin\theta_0 - nu(2m\pi)\cos\theta_0\\ &\quad= u'(0)\sin\theta_0 - nu(0)\cos\theta_0 + \int_0^{2m\pi} p(t)\sin(nt+\theta_0)dt\\ &\qquad - n\sum_{j=1}^{mk} J_j(u'(t_j^-))\cos(nt_j+\theta_0) + \sum_{j=1}^{mk} Q_j(u(t_j^-))\sin(nt_j+\theta_0).\end{aligned}$$

Hence, we immediately deduce that

$$\begin{aligned}&\left|u'(2m\pi)\sin\theta_0 - nu(2m\pi)\cos\theta_0\right|\\ &\quad\geq \left|\int_0^{2m\pi} p(t)\sin(nt+\theta_0)dt - n\sum_{j=1}^{mk} J_j(u'(t_j^-))\cos(nt_j+\theta_0) + \sum_{j=1}^{mk} Q_j(u(t_j^-))\sin(nt_j+\theta_0)\right|\\ &\qquad - \left|u'(0)\sin\theta_0 - nu(0)\cos\theta_0\right|.\end{aligned}$$

Note that

$$\int_0^{2m\pi} p(t)\sin(nt+\theta_0)dt = m\int_0^{2\pi} p(t)\sin(nt+\theta_0)dt,$$

since $p(t)\sin(nt+\theta_0)$ is 2π-periodic.

Assume that the $u(t)$ is bounded. By (H_1), for all t_j, $j = 1, 2, \ldots$, we have

$$J_j(+\infty) < J_j(u'(t_j^-)) < J_j(-\infty), \qquad Q_j(-\infty) < Q_j(u(t_j^-)) < Q_j(+\infty).$$

and

$$\xi_0 = \min\left\{ n\sum_{j=1}^{k} |J_j(\pm\infty) - J_j(u'(t_j^-))|,\ \sum_{j=1}^{k} |Q_j(\pm\infty) - Q_j(u(t_j^-))| \right\} > 0.$$

For $t \in [2l\pi, 2(l+1)\pi]$, $l = 1, 2, \ldots, m-1$,

$$\begin{aligned}
\int_0^{2\pi} \sin(nt+\theta_0)p(t)dt &= \int_{2l\pi}^{2(l+1)\pi} \sin(nt+\theta_0)p(t)dt \\
&\geq n\sum_{j=(l-1)k}^{lk} J_j(-\infty)\cos^+(nt_j+\theta_0) - n\sum_{j=(l-1)k}^{lk} J_j(+\infty)\cos^-(nt_j+\theta_0) \\
&\quad + \sum_{j=(l-1)k}^{lk} Q_j(+\infty)\sin^-(nt_j+\theta_0) - \sum_{j=(l-1)k}^{lk} Q_j(-\infty)\sin^+(nt_j+\theta_0) \\
&> n\sum_{j=(l-1)k}^{lk} J_j(u'(t_j^-))\cos(nt_j+\theta_0) - \sum_{j=(l-1)k}^{lk} Q_j(u(t_j^-))\sin(nt_j+\theta_0),
\end{aligned}$$

it follows that

$$\int_0^{2\pi} p(t)\sin(nt+\theta_0)dt - n\sum_{j=(l-1)k}^{lk} J_j(u'(t_j^-))\cos(nt_j+\theta_0) + \sum_{j=(l-1)k}^{lk} Q_j(u(t_j^-))\sin(nt_j+\theta_0) > \xi_0.$$

Adding the m inequalities above, we get

$$m\int_0^{2\pi} p(t)\sin(nt+\theta_0)dt - n\sum_{j=1}^{mk} J_j(u'(t_j^-))\cos(nt_j+\theta_0) + \sum_{j=1}^{mk} Q_j(u(t_j^-))\sin(nt_j+\theta_0) > m\xi_0,$$

therefore,

$$|u'(2m\pi)\sin\theta_0 - nu(2m\pi)\cos\theta_0| \geq m\xi_0 - |u'(0)\sin\theta_0 - nu(0)\cos\theta_0|.$$

Since

$$n\|x(2m\pi)\|_X \geq n(u^2(2m\pi) + u'^2(2m\pi))^{\frac{1}{2}} \geq |u'(2m\pi)\sin\theta_0 - nu(2m\pi)\cos\theta_0|,$$

which yields

$$n||x(2m\pi)||_X \geq m\xi_0 - |u'(0)\sin\theta_0 - nu(0)\cos\theta_0|,$$

hence

$$n\|x(2m\pi)\|_X \to +\infty, \qquad m \to +\infty,$$

which implies that $x(t)$ is unbounded in $[0, +\infty)$. □

By combining Proposition 2.1 and Proposition 2.4, we have thus proved the Theorem 1.1.

3 Coexistence of periodic and unbounded solutions

In this section, we consider the coexistence of periodic and unbounded solutions of the following weakly nonlinear impulsive differential equations

$$\begin{cases} u''(t) + n^2u(t) + h(u(t)) = p(t), \quad t \in [0, 2\pi],\ t \neq t_j; \\ \Delta u(t_j) = J_j(u(t_j^-), u'(t_j^-)), \quad \Delta u'(t_j) = Q_j(u(t_j^-), u'(t_j^-)), \quad j = 1, \ldots, k; \end{cases} \tag{3.1}$$

where $0 < t_1 < \cdots < t_k < 2\pi$, $p(t)$ is 2π-periodic and continuous, h is continuous and J_j, $Q_j : \mathbb{R}^2 \to \mathbb{R}$, $j = 1, \ldots, k$, are continuous. Assume that (D_1), (D_2) hold.

Let $P(t) = (0, p(t) - h(u(t)))^T$ and initial value $(u(\tau;\tau,w), u'(\tau;\tau,w)) = (0, w)$. We conclude from (2.4) that

$$\begin{aligned} u(t) =& \frac{w}{n}\sin(nt - n\tau) + \frac{1}{n}\int_\tau^t \sin(nt - ns)(p(s) - h(u(s)))ds \\ &+ \sum_{t>t_j} J_j(u(t_j^-), u'(t_j^-))\cos(nt - nt_j) + \frac{1}{n}\sum_{t>t_j} Q_j(u(t_j^-), u'(t_j^-))\sin(nt - nt_j), \\ u'(t) =& w\cos(nt - n\tau) + \int_\tau^t \cos(nt - ns)(p(s) - h(u(s)))ds \\ &- n\sum_{t>t_j} J_j(u(t_j^-), u'(t_j^-))\sin(nt - nt_j) + \sum_{t>t_j} Q_j(u(t_j^-), u'(t_j^-))\cos(nt - nt_j). \end{aligned} \tag{3.2}$$

The proof of Theorem 1.4 is presented as following. We divide the proof in two steps. The first one is to prove the existence of the periodic solution using the successor map. The second step is to construct an auxiliary Lyapunov function that makes the solution grow infinitely along the orbit, which is motivated by [1]. So that the solution is unbounded.

3.1 The existence of a periodic solution

We assume that $h(u)$ is locally Lipschitzian which guarantees the uniqueness of the solutions for the initial value problem associated with (3.1), if necessary. Write $g(u) = n^2u + h(u)$, $G(u) = \int_0^u g(s)ds$. Consider the following equation

$$\begin{cases} u' = v, \\ v' = -g(u) + \lambda p(t), \quad t \in [0, 2\pi],\ t \neq t_j; \\ \Delta u(t_j) = \lambda J_j(u(t_j^-), v(t_j^-)), \\ \Delta v(t_j) = \lambda Q_j(u(t_j^-), v(t_j^-)),\ j = 1, \ldots, k, \end{cases} \tag{3.3}$$

where $\lambda \in [0, 1]$. Notice that (3.3) is equivalent to (3.1) when $\lambda = 1$.

Let $(u(t;\tau,w), v(t;\tau,w))$ denote the solution of (3.3) with the initial point $(0, w)$, $w \gg 1$. We define τ_1 as the time when $(u(t;\tau,w), v(t;\tau,w))$ intersects the positive v-axis again, and write $w(\tau_1;\tau,w) = w_1$.

The successor map is defined as $S : (\tau, v) \mapsto (\tau_1, w_1)$. S is well defined for $|w| \gg 1$, and the uniqueness of the solution for the initial value problem guarantees that S is continuous and one to one. The periodicity of $p(t)$ implies that $S(\tau + 2\pi, w) = S(\tau, w) + (2\pi, 0)$.

By the boundedness of J_j, Q_j and h, we have

Lemma 3.1. $\tau_1 - \tau = \frac{2\pi}{n} + O(\frac{1}{r})$.

Now, let $u(t) = u(t;\tau,v)$, $v(t) = v(t;\tau,v)$, $H(t) = \frac{1}{2}v^2(t) + G(u(t))$, and $l(t) = \sqrt{2H(t)}$. Then we have

$$|l'(t)| = \left|\frac{v(t)}{l(t)}p(t)\right| \leq |p(t)| < P, \qquad t \neq t_j,\ j = 1, \ldots, k,$$

where $P = \max_{t\in[0,2\pi]}\{|p(t)|\}$.

From this, it follows that

$$|l(t) - l(t')| \leq P|t - t'|,$$

when $t, t' \in (t_j, t_{j+1})$, $j = 1, \ldots, k-1$, or $t, t' \in (0, t_1)$, or $t, t' \in (t_k, 2\pi)$.

When $t = t_j$, by (D_2), $u(t_j^+) - u(t_j^-) = O(\frac{1}{r})$ and $v(t_j^+) - v(t_j^-) = O(\frac{1}{r})$ for large w. Then for sufficiently small $\varepsilon > 0$, there exists $w_0' > 0$, such that for $w > w_0'$, $u(t_j^+) = u(t_j^-) \pm \varepsilon, v(t_j^+) = v(t_j^-) \pm \varepsilon$. Therefore,

$$\begin{aligned} H(t_j^+) &= \frac{1}{2}v^2(t_j^+) + G(u(t_j^+)) = \frac{1}{2}(v(t_j^-) \pm \varepsilon)^2 + G(u(t_j^-) \pm \varepsilon) \\ &= H(t_j^-) + \varepsilon_1, \end{aligned}$$

where $\varepsilon_1 = \pm v(t_j^-)\varepsilon + \int_{u(t_j^-)}^{u(t_j^-)\pm\varepsilon} g(s)ds + \varepsilon^2$.

In conclusion, for sufficiently large $|l(\tau)|$, we have

$$|l(t) - l(\tau)| \le 2(P+1)|t - \tau|.$$

Thus, we obtain the following

Lemma 3.2.

$$|l(t) - w| \le 2(P+1)T, \qquad |t - \tau| \le T,\ w \ge w_0.$$

Further, we can prove the following lemma.

Lemma 3.3.

$$w_1 - w = \int_\tau^{\tau + \frac{2\pi}{n}} \cos(ns - n\tau)p(s) + O\left(\frac{1}{r}\right), \qquad w \gg 1;$$

$$\begin{aligned} \tau_1 - \tau = {} & \frac{\pi}{n} - \frac{1}{nw}\int_\tau^{\tau+\frac{2\pi}{n}} \sin(n\tau - ns)(h - p(s))ds \\ & - \frac{1}{w}\lambda \sum_{t>t_j} J_j(u(t_j^-), u'(t_j^-)) \cos(n\tau_1 - nt_j) \\ & - \frac{1}{nw}\lambda \sum_{t>t_j} Q_j(u(t_j^-), u'(t_j^-)) \sin(nt - nt_j) + O\left(\frac{1}{r^2}\right), \qquad w \gg 1. \end{aligned}$$

Proof. Without loss of generality, we can assume that there are $k_1 \le k$ impulses in the interval $[\tau, \tau_1]$. The corresponding impulse times are denoted by $t_1, t_2, \ldots, t_{k_1}$.

Step 1. We estimate $w_1 - w$.

By the nature of definite integral, we have

$$w_1 - w = l(\tau_1) - l(\tau) = \int_\tau^{\tau_1} \frac{v(s)p(s)}{l(s)}ds + \sum_{j=1}^{k_1} l(t_j^+) - l(t_j^-).$$

We now begin by estimating $\sum_{j=1}^{k_1} l(t_j^+) - l(t_j^-)$. By definition, we have

$$\begin{aligned} l(t_j^+) - l(t_j^-) &= \sqrt{v^2(t_j^+) + 2G(u(t_j^+))} - \sqrt{v^2(t_j^-) + 2G(u(t_j^-))} \\ &= \frac{(v(t_j^+) + v(t_j^-))(v(t_j^+) - v(t_j^-)) + 2\int_{u(t_j^-)}^{u(t_j^+)} g(s)ds}{\sqrt{v^2(t_j^+) + 2G(u(t_j^+))} + \sqrt{v^2(t_j^-) + 2G(u(t_j^-))}}. \end{aligned}$$

According to the mean value theorem for integrals and (i) of (D_1), there exists M_j such that $\int_{u(t_j^-)}^{u(t_j^+)} h(s)ds = M_j(u(t_j^+) - u(t_j^-))$. Hence, we have

$$\int_{u(t_j^-)}^{u(t_j^+)} g(s)ds = \int_{u(t_j^-)}^{u(t_j^+)} n^2 u + h(s)ds = \left(\frac{1}{2}n^2(u(t_j^+) + u(t_j^-)) + M_j\right)(u(t_j^+) - u(t_j^-)\Big),$$

it follows that

$$\begin{aligned}\sum_{j=1}^{k_1} l(t_j^+) - l(t_j^-) = &\sum_{j=1}^{k_1} \frac{(v(t_j^+) + v(t_j^-))\lambda Q_j(u(t_j^-), u'(t_j^-))}{\sqrt{v^2(t_j^+) + 2G(u(t_j^+))} + \sqrt{v^2(t_j^-) + 2G(u(t_j^-))}} \\ &+ \frac{2(\frac{1}{2}n^2(u(t_j^+) + u(t_j^-)) + M_j)\lambda J_j(u(t_j^-), u'(t_j^-))}{\sqrt{v^2(t_j^+) + 2G(u(t_j^+))} + \sqrt{v^2(t_j^-) + 2G(u(t_j^-))}}.\end{aligned}$$

This implies that

$$\sum_{j=1}^{k_1} l(t_j^+) - l(t_j^-) = O\left(\frac{1}{r}\right), \qquad w \gg 1, \tag{3.4}$$

by (D_2).

Combining (3.4), Lemma 3.1 and Lemma 3.2, the further estimate for $w_1 - w$ is given by

$$\begin{aligned}w_1 - w &= \int_\tau^{\tau_1} \frac{v(s)p(s)}{l(s)}ds + O\left(\frac{1}{r}\right) \\ &= \int_\tau^{\tau_1} \left(w\cos(ns - n\tau) + \int_\tau^s (\cos(ns - n\xi)(p(\xi) - h))\, d\xi\right)\frac{p(s)}{l(s)}ds + O\left(\frac{1}{r}\right) \\ &= \int_\tau^{\tau_1} \frac{w\cos(ns - n\tau)p(s)}{l(s)}ds + O\left(\frac{1}{r}\right) \\ &= \int_\tau^{\tau + \frac{2\pi}{n}} \cos n(s - \tau)p(s)ds + O\left(\frac{1}{r}\right), \qquad w \gg 1.\end{aligned}$$

Step 2. The estimation of $\tau_1 - \tau$ is given below.

By the definition of τ_1 and (3.2), we have

$$\begin{aligned}\frac{w}{n}\sin(n\tau_1 - n\tau) = &\frac{1}{n}\int_\tau^{\tau_1} \sin(n\tau_1 - ns)(h - p(s))ds \\ &- \lambda\sum_{t>t_j} J_j(u(t_j^-), u'(t_j^-))\cos(n\tau_1 - nt_j) \\ &- \frac{\lambda}{n}\sum_{t>t_j} Q_j(u(t_j^-), u'(t_j^-))\sin(nt - nt_j).\end{aligned}$$

Using the Taylor expansion, we obtain

$$\begin{aligned}\frac{w}{n}\sin(n\tau_1 - n\tau) &= \frac{w}{n}\sin n\left(\frac{\pi}{n} - \tau_1 + \tau\right) \\ &= w\left(\frac{\pi}{n} - \tau_1 + \tau + O\left(\frac{1}{r^3}\right)\right).\end{aligned}$$

It follows from Lemma 3.1 that

$$\begin{aligned}\tau_1 - \tau = &\frac{\pi}{n} - \frac{1}{nw}\int_\tau^{\tau + \frac{2\pi}{n}} \sin(n\tau - ns)(h - p(s))ds - \frac{1}{w}\lambda\sum_{t>t_j} J_j(u(t_j^-), u'(t_j^-))\cos(n\tau_1 - nt_j) \\ &- \frac{1}{nw}\lambda\sum_{t>t_j} Q_j(u(t_j^-), u'(t_j^-))\sin(nt - nt_j) + O\left(\frac{1}{r^2}\right), \qquad w \gg 1.\end{aligned}$$

The proof of Lemma 3.2 is then completed. □

Let

$$\phi(t-\tau) = \frac{1}{n}\sin(nt-n\tau),$$

$$\psi(t) = \frac{1}{n}\int_\tau^t \sin(nt-ns)(p(s)-h)ds + \sum_{t>t_j} J_j(u(t_j^-),u'(t_j^-))\cos(nt-nt_j)$$

$$+\frac{1}{n}\sum_{t>t_j} Q_j(u(t_j^-),u'(t_j^-))\sin(nt-nt_j).$$

It is easy to observe that $\psi(t)$ is bounded by (D_1) and (D_2).

Lemma 3.4. *Assume that (ii) of (D_1) holds. For any $K>0$, there exists $w_0 = w(K) > 0$, such that*

$$\int_\tau^{\tau+\frac{2\pi}{n}} h(w\phi(s-\tau)+\psi(s))\sin n(s-\tau)ds \geq \frac{K}{w}, \qquad w \geq w_0.$$

Proof. Without loss of generality, we take $\tau = 0$. It is sufficient to prove the inequality:

$$\int_0^{\frac{2\pi}{n}} h\left(\frac{\omega}{n}\sin ns+\psi(s)\right)\sin nsds \geq \frac{K}{w}, \qquad w \geq w_0.$$

By definition of ψ, $\psi(t)$ is bounded and $\psi(t)\to 0$ as $t\to 0$.

By condition (D_2), there exists $\delta = O(\frac{1}{r}) > 0$, such that, for $\frac{2\pi}{n} > t > \frac{2\pi}{n}-\delta$, $h(\frac{\omega}{n}\sin nt+\psi(t))\sin nt > 0$, which together with (D_1) yields

$$\int_0^{\frac{2\pi}{n}} h\left(\frac{\omega}{n}\sin ns+\psi(s)\right)\sin nsds \geq \int_\delta^{\frac{2\pi}{n}-\delta} h\left(\frac{\omega}{n}\sin ns+\psi(s)\right)\sin nsds - O\left(\frac{1}{r}\right).$$

Introducing the transformation $\frac{\omega}{n}\sin nt+\psi(t) = \frac{\omega}{n}\sin n\xi$. Then, there exists $\omega \gg 1$, such that

$$h\left(\frac{\omega}{n}\sin n\xi\right)\frac{\omega}{n}\sin n\xi \geq 4M_h.$$

Therefore,

$$\begin{aligned}\int_\delta^{\frac{2\pi}{n}-\delta} h\left(\frac{\omega}{n}\sin ns+\psi(s)\right)\sin nsds &= \frac{1}{\omega}\int_{\xi^-}^{\xi^+} h\left(\frac{\omega}{n}\sin n\xi\right)\frac{\omega\sin n\xi - n\psi(t)}{\omega\cos nt+\psi'(t)}\omega\cos n\xi d\xi\\ &\geq \frac{n}{4\omega}\int_{\xi^-}^{\xi^+} h\left(\frac{\omega}{n}\sin n\xi\right)\frac{\omega}{n}\sin n\xi\cos n\xi d\xi\\ &\geq \frac{\bar{M}M_h}{\omega} := \frac{K}{\omega}\end{aligned}$$

where $\bar{M} = \int_{\frac{\pi}{8}}^{\frac{3\pi}{8}}\cos n\xi d(n\xi)$. □

Introduce the Banach space

$$X = \{x:\ [0,2\pi]\to\mathbb{R}^2:\ x(t) \text{ is continuous for } t\neq t_j,\ x(t_j^-),\ x(t_j^+)\text{exist,}\\ \text{and } x(t_j^-) = x(t_j) j = 1,\dots,k,\ x(0) = x(2\pi)\},$$

and the operator $F_\lambda : X \to X$

$$F_\lambda x = x(0) + \frac{2\pi - t}{2\pi}\left(\int_0^{2\pi}(\lambda P(t) + Ax(t) - H(x(t)))dt + \lambda\sum_{j=1}^{k} I_j(x(t_j^-))\right)$$
$$+ \int_0^t (\lambda P(s) + Ax(s) - H(x(s)))ds + \lambda\sum_{t>t_j} I_j(x(t_j^-)),$$

where $H(x(t)) = (0, h(u(t)))^T$. According to the above we can know F_λ is completely continuous.

It is clear that (3.3) is equivalent to a fixed point problem, that is $x = F_\lambda x$. We now apply the topological degree to prove the existence of periodic solutions. Let

$$\Sigma = \{(x, \lambda) \in X \times [0,1] \mid F_\lambda x = x\}.$$

Lemma 3.5. *If there is a bounded open set $\Omega \subset X$, such that*

$$\Sigma \cap \partial\Omega = \emptyset,$$

then $\deg(F_\lambda, \Omega, 0) = \deg(F_0, \Omega, 0) = 1$, *and thus, the equation* (3.3) *has at least one 2π-periodic solution.*

Similar to the proof of proposition 2.1, we have $\deg(F_0, \Omega, 0) = 1$. We now seek an appropriate bounded open set. Let

$$\Omega(k) = \left\{(u, v) \in X \mid \omega(u, v) = \frac{1}{2}v^2(t) + G(u(t)) < k\right\}.$$

On the one hand, $(u(t), v(t)) \in \Sigma \cap \partial(\Omega(k))$, for sufficiently large k, then there exists $t_0 \in [0, 2\pi]$, such that $\frac{1}{2}v^2(t_0) + G(u(t_0)) = k$. By Lemma 3.2, $(u(t), v(t)) \in \mathbb{R}^2$ is in a bounded set by

$$\left\{(u, v) \in X \mid k_- < \frac{1}{2}v^2(t) + G(u(t)) < k_+\right\},$$

where $\sqrt{k_\pm} = \sqrt{k} \pm 4(P+1)\pi$. Thus $(u(t), v(t))$ starts from $u(\tau) = 0$, $v(\tau) = w$, $\tau \in [0, 2\pi]$, $w \in [k_-, k_+]$. The 2π-periodicity implies that $u(\tau + 2\pi) = 0$, $v(\tau + 2\pi) = w$. Thus,

$$\tau_m = \tau + 2\pi,$$

for some $m \in \mathbb{N}$.

On the other hand, by using the variation of constant formula, we obtain $u(t) = w\phi(t) + \psi(t)$. Combining this with Lemma 3.4, we have

$$\tau_n - \tau = 2\pi - \frac{1}{nw}\int_\tau^{\tau+2\pi} \sin(n\tau_1 - ns)(h - p(s))ds + O\left(\frac{1}{w^2}\right)$$
$$\leq 2\pi - \frac{K}{w^2} + \frac{M_p'}{w} + O\left(\frac{1}{w^2}\right) < 2\pi,$$

where K is sufficiently large, M_p' is sufficiently small, such that for some k,

$$\frac{K}{w^2} - \frac{M_p'}{w} - O\left(\frac{1}{w^2}\right) > 0,$$

for $w \in [k_-, k_+]$.

Thus, we find that the bounded open set $\Omega(k)$ satisfies the condition of Lemma 3.5 and we have

Proposition 3.6. *Assume that* (D_1) *and* (D_2) *hold. Then there exists* $q_0 > 0$*, such that the equation* (1.5) *has* 2π*-periodic solution provided that* $p(t)$ *satisfies*

$$M_p < q_0,$$

where

$$M_p = \max_{\theta\in[0,2\pi]} \left| \int_0^{2\pi} p(t)\sin(nt+\theta)dt \right|.$$

3.2 The existence of unbounded solutions

Let us continue our analysis about the above equation. Given a function $p(t)$, we shown in the previous section that there exists 2π-periodic solution with

$$\max\left\{ \int_0^{2\pi} p(t)\sin(nt+\phi)dt \ : \ \phi\in\mathbb{R} \right\} > 0,$$

within a sufficiently large disk in the phase plane. Accordingly, we fix some $\phi\in\mathbb{R}$ such that

$$d_* := \frac{1}{2}\int_0^{2\pi} p(t)\sin(nt+\phi)dt > 0.$$

Let $(u(t;\zeta), u'(t;\zeta))$ be the solution of (3.1) with the initial condition $\zeta = (\omega, v)\in\mathbb{R}^2$. The associated Poincaré map is defined by $\mathcal{P} : (\omega, v) \to (u(2\pi;\zeta), u'(2\pi;\zeta))$. To investigate the existence of unbounded solutions, we introduce the auxiliary function

$$V : \ \mathbb{R}^2 \to \mathbb{R}, \qquad V(\zeta) := v\sin\phi - n\omega\cos\phi.$$

First, we verify the following property of V: there exists a constant $r_* > 0$, such that, for $|\zeta| \geq r_*$,

$$V(\mathcal{P}(\zeta)) \geq V(\zeta) + d_*. \tag{3.5}$$

Multiplying both sides of (3.1) by $\sin(nt+\phi)$ and integrating both sides at $[0, 2\pi]$, we get

$$\begin{aligned}\int_0^{2\pi} u''(t;\zeta)\sin(nt+\phi)dt = &\int_0^{2\pi} p(t)\sin(nt+\phi)dt - n^2\int_0^{2\pi} u(t;\zeta)\sin(nt+\phi)dt\\ &- \int_0^{2\pi} h(u(t;\zeta))\sin(nt+\phi)dt.\end{aligned}$$

Using integration by parts we obtain

$$\begin{aligned}\int_0^{2\pi} u''(t;\zeta)\sin(nt+\phi)dt = V(F(\zeta)) - V(\zeta) + n\sum_{j=1}^{k} J_j(u(t_j^-), u'(t_j^-))\cos(nt_j+\phi)\\ - \sum_{j=1}^{k} Q_j(u(t_j^-), u'(t_j^-))\sin(nt_j+\phi) - n^2\int_0^{2\pi} u(t;\zeta)\sin(nt+\phi)dt.\end{aligned}$$

It follows that

$$\begin{aligned}V(F(\zeta)) - V(\zeta) = &\int_0^{2\pi} p(t)\sin(nt+\phi)dt - \int_0^{2\pi} h(u(t;\zeta))\sin(nt+\phi)dt\\ &- n\sum_{j=1}^{k} J_j(u(t_j^-), u'(t_j^-))\cos(nt_j+\phi) + \sum_{j=1}^{k} Q_j(u(t_j^-), u'(t_j^-))\sin(nt_j+\phi).\end{aligned}$$

We now estimate the second term on the right-hand side of the above equation.

Lemma 3.7. *There exists a sufficiently large $r_* > 0$, such that $\zeta = (\omega, v) > r_*$ satisfying*

$$\left| \int_0^{2\pi} h(u(t;\zeta)) \sin(nt + \phi) dt \right| < \frac{d_*}{2}. \tag{3.6}$$

Proof. By (D_1), there exists $u_* > 0$, such that for $|u(t;\zeta)| > u_*$, $|h(u(t;\zeta))| < \frac{d_*}{8\pi}$. Denote the upper bound of $|h|$ by M_h.

We take the transformation

$$u(t;\zeta) = r(t;\zeta)\cos\theta(t;\zeta), \qquad u'(t;\zeta) = r(t;\zeta)\sin\theta(t;\zeta).$$

For $r(t;\zeta) \geq 1$, we have

$$|r'(t;\zeta)| \leq (n^2 + M_h) r(t;\zeta), \qquad \frac{1}{2} \leq \theta'(t;\zeta) \leq (n^2 + M_h), \qquad t \neq t_1, \ldots, t_k.$$

Analysis similar to that in the proof of Lemma 3.1 shows that, for $t \in [0, 2\pi], t \neq t_1, \ldots, t_k$,

$$\mathrm{e}^{-2(n^2+M_h)\pi} r(0;\zeta) \leq r(t;\zeta) \leq \mathrm{e}^{2(n^2+M_h)\pi} r(0;\zeta), \tag{3.7}$$

$$-2(n^2 + M_h)\pi < \theta(2\pi;\zeta) - \theta(0;\zeta) < 0. \tag{3.8}$$

Let $\delta_* > 0$ be sufficiently small such that $|\cos\theta(t;\zeta)| \leq \cos(\frac{\pi}{2} - \delta_*)$ for $\theta(t;\zeta) \in [m\pi + \frac{\pi}{2} - \delta_*, m\pi + \frac{\pi}{2} + \delta_*]$, $m \in \mathbb{Z}$. Define

$$E_* = \left\{ t \in [0, 2\pi] : \theta(t;\zeta) \in \left[m\pi + \frac{\pi}{2} - \delta_*, m\pi + \frac{\pi}{2} + \delta_* \right], m \in \mathbb{Z} \right\}.$$

By (3.8), we have $\mathrm{mes}(E_*) \leq 8(n^2 + M_h)\delta_*$ and

$$|u(t;\zeta)| \geq r(t;\zeta)\cos\left(\frac{\pi}{2} - \delta_*\right), \qquad t \in [0, 2\pi] \setminus E_*.$$

By (3.7), we take

$$\delta_* = \frac{d_*}{32(n^2 + M_h)M_h}, \qquad r = |\zeta| \geq r_* = \frac{u_* \mathrm{e}^{2(n^2+M_h)\pi}}{\cos(\frac{\pi}{2} - \delta_*)},$$

then

$$\begin{aligned}
&\left| \int_0^{2\pi} h(u(t;\zeta)) \sin(nt + \phi) dt \right| \\
&\quad \leq \left| \int_{t \in E_*} h(u(t;\zeta)) \sin(nt + \phi) dt \right| + \left| \int_{t \in [0,2\pi] \setminus E_*} h(u(t;\zeta)) \sin(nt + \phi) dt \right| \\
&\quad \leq \mathrm{mes}(E_*) M_h + 2\pi \cdot \frac{d_*}{8\pi} \leq \frac{d_*}{4} + \frac{d_*}{4} = \frac{d_*}{2}.
\end{aligned}$$

□

On the other hand, from (D_2), it follows that

$$\left| -n \sum_{j=1}^{k} J_j(u(t_j^-), u'(t_j^-)) \cos(nt_j + \phi) + \sum_{j=1}^{k} Q_j(u(t_j^-), u'(t_j^-)) \sin(nt_j + \phi) \right| \leq \frac{d_*}{2},$$

for $r(t;\zeta)$ large enough.

Combining (3.7) and the boundedness of impulses, we can take $|\zeta| \geq r_*$ large enough such that the above inequality holds. Then

$$V(\mathcal{P}(\zeta)) - V(\zeta) \geq 2d_* - \frac{d_*}{2} - \frac{d_*}{2} = d_*.$$

Furthermore, we notice that V is bounded above on the bounded set $|\zeta| \leq r_*$, i.e.

$$\overline{V_*} := \sup\{V(\zeta) : |\zeta| \leq r_*\} < +\infty.$$

Write $r^* = n\overline{V_*}^{1/2}\mathrm{e}^{4(n^2+M_h)\pi}$. For $|\zeta_0| \geq r^*$ and $\zeta_0 = (-\cos\phi, \sin\phi)|\zeta_0|$, we can see (3.5) holds. It follows that

$$V(\mathcal{P}(\zeta_0)) \geq V(\zeta_0) + d_* > V(\zeta_0) = \cos^2\phi + n\sin^2\phi > \overline{V_*},$$

hence that $|\mathcal{P}(\zeta_0)| \geq r_*$ by the definition of $\overline{V_*}$.

Then let us denote by $\zeta_1 = \mathcal{P}(\zeta_0)$ the new initial point. Likewise,

$$V(\mathcal{P}(\zeta_1)) \geq V(\zeta_1) + d_* \geq V(\zeta_0) + 2d_*.$$

Similar arguments apply to the case $m \in \mathbb{N}$. Then we have

$$V(\mathcal{P}(\zeta_{m+1})) \geq V(\zeta_m) + d_* \geq V(\zeta_0) + (m+1)d_*,$$

which implies that $\zeta_m \to \infty$, $m \to \infty$. If otherwise, then this contradicts the fact that V is bounded above on the bounded set. From this, we conclude that if $|\zeta_0| \geq r^*$ and $\zeta_0 = (-\cos\phi, \sin\phi)|\zeta_0|$, then $(u(t;\zeta_0), u'(t;\zeta_0))$ is an unbounded solution of (3.1).

If $|\zeta_0| \geq r^*$ but $\zeta_0 \neq (-\cos\phi, \sin\phi)|\zeta_0|$, by $\theta'(t;\zeta_0) \geq \frac{1}{2}$ and $r^* = n\overline{V_*}^{1/2}\mathrm{e}^{4(n^2+M_h)\pi}$, then we find a $\tau_0 \in [0, 4\pi)$ such that $(u(\tau_0;\zeta_0), u'(\tau_0;\zeta_0)) = (-\cos\phi, \sin\phi)r(\tau_0;\zeta_0)$ and $r(\tau_0;\zeta_0) \geq r_*$. Similarly, let $\bar{\zeta}_m = \mathcal{P}^m(\bar{\zeta}_0)$. By the same method as shown before, we have $\bar{\zeta}_m \to \infty$, $m \to \infty$, which implies that $(u(t;\zeta_0), u'(t;\zeta_0))$ is also an unbounded solution. Therefore, we have the following assertion.

Proposition 3.8. *Assume that (D_1) and (D_2) hold. Then there exists $q_0 > 0$, such that the equation (3.1) has an unbounded solution provided that $p(t)$ satisfies*

$$0 < M_p < q_0.$$

Combining Proposition 3.6 and Proposition 3.8, we have thus proved the Theorem 1.4.

Abstract. In our work, we prove the existence and uniqueness of positive 1-periodic solutions of a first order differential equation that contains a piecewise constant term. Such equations admit periodic solutions and hence they can be used for numerical modelling of temperature changes in a space surrounded by environment with different temperature. For some types of functional equations, it is possible to use the comparison principle method of differential equations to obtain existence, uniqueness, and asymptotic stability results.

Keywords: functional differential equations, periodic solutions, existence, uniqueness.

2020 Mathematics Subject Classification: 34K13, 39B22.

1 Introduction

In our paper, we analyze positive 1-periodic solutions of functional differential equation

$$x'(t) = f(x(t)) + x(\lfloor t \rfloor)g(t - \lfloor t \rfloor), \qquad t \geq 0 \tag{1.1}$$

where $\lfloor . \rfloor : [0, \infty) \to \mathbb{N} \cup \{0\}$ is the standard floor function, i.e. $\lfloor t \rfloor = n$ if $t \in [n, n+1)$ for some $n \in \mathbb{N} \cup \{0\}$. We will assume that the function f is negative for positive x, and equals zero at zero, and g is positive over the interval $[0, 1]$ (see conditions 1) and 2) below for more precise assumptions).

The problem (1.1) represents a numeric model that describes temperature changes in a space bounded by outside environment. A solution of problem represents temperature of the space cooled by colder environment; the negative function f represents cooling up to zero. The space is simultaneously warmed by a heating agent inside; the positive function g represents heating. Moreover, the function g is multiplied by the temperature values at discrete points so that the actual temperature is affected by previous temperature.

In this work, we use the comparison principle for differential equations to prove the existence, uniqueness and asymptotic stability (see Theorem 3.6) of positive 1-periodic solution of

✉ Corresponding author. Email: Michal.Feckan@fmph.uniba.sk

the equation (1.1) under certain assumptions on the functions f and g. In some other works (e.g. [6]), authors analyzed an explicit form of solutions of a similar problem. In [5], a special type of Gronwall lemma was used. For more results and methods used regarding analyzing functional equations of this type, we refer to [4] and references therein. Next, linear functional equations similar to (1.1) have been studied by many authors. The floor function $\lfloor . \rfloor$ that appears in (1.1) was used in the automatic control theory in the frame of so-called sampled-data approach; see e.g. [10], [11]. In [3], [8], and [9], formulas of representation of solutions were found using the idea to the direction of the Floquet theory; the idea of such approach is to reduce equations in linear case to equations with finite-dimensional fundamental systems. In some other works (e.g. [6]), authors analyzed an explicit form of solutions. General theory of functional differential equations proposed in the books [1] and [2] was built namely on the idea of finite-dimensional fundamental systems. We also note that in [13], such delays are used in semi-discretization methods for the study of stability analysis of linear time-periodic and time-delay systems.

2 Preliminaries

Throughout the whole paper, for the functions f, g in the equation (1.1), we will assume the following conditions:

1) $f : [0, \infty) \to (-\infty, 0]$ is continuously differentiable, $f(0) = 0$ and $f(x) < 0$ for $x > 0$,

2) $g : [0, 1] \to (0, \infty)$ is continuous.

It is important to note that the derivative of solution x of the equation (1.1) need not exist at $t = n$ for $n \in \mathbb{N}$. In such case, x is not continuously differentiable at these points. However, one-sided derivatives of x at $t = n$ do exist, since in (1.1), one can pass to the limit for $t \to n^+$ or $t \to n^-$. Due to these facts, we state the following definition of solutions of (1.1).

We say that a continuous function $x : [0, \infty) \to \mathbb{R}$ is a solution of the equation (1.1) if for every $n \in \mathbb{N} \cup \{0\}$, the function x is continuously differentiable over $(n, n + 1)$, and the equation (1.1) is satisfied for $t \in (n, n + 1)$. Necessarily, there exist finite one-sided derivatives of x at points n and $n + 1$.

In order to study $1-$periodic solutions of (1.1), we will consider the problem

$$x'(t) = f(x(t)) + x(0)g(t), \qquad t \in [0, 1], \tag{2.1}$$

$$x(0) = x(1), \tag{2.2}$$

where $x'(0)$ and $x'(1)$ are the corresponding one-sided derivatives. Obviously, for every initial condition $x(0) > 0$, there exists a unique positive solution x of the equation (2.1) defined over the whole interval $[0, 1]$. The equation (1.1) has a 1-periodic solution if and only if there exists a solution of problem (2.1)–(2.2).

Let g satisfy the condition 2). We introduce some notation we will use throughout the whole paper. Denote $g_1 = \min_{t\in[0,1]} g(t)$, $g_2 = \max_{t\in[0,1]} g(t)$, and $g_3 = \int_0^1 g(t)\,\mathrm{d}t$. Thus, it holds $g_2 \geq g_3 \geq g_1 > 0$ and if g is nonconstant over $[0, 1]$, then strict inequalities are valid.

3 Results

In this section, we present our results. In the proofs, we use standard methods of analysis of solutions of ODE such as the comparison method.

Lemma 3.1. *Let x be a solution of the equation (2.1), $x(0) > 0$, and g is differentiable and nonincreasing over the interval $[0,1]$. Then the function x attains its minimum either at $t = 0$ or $t = 1$.*

Proof. Observe that since $x(0) > 0$ and $g > 0$ over $[0,1]$, the corresponding solution x of (2.1) remains positive over $[0,1]$ (this is not obviously true for every continuous function g; see Remark 3.3). Also, if there is a continuously differentiable function y such that

$$y'(t) > f(y(t)) + y(0)g(t), \qquad t \in (0,1]$$

with $y(0) = x(0)$, then necessarily $y(t) > x(t)$ for $t \in (0,1]$. These assertions can be proven by using standard methods; see e.g. [12].

First, we assume that $g' < 0$ over $[0,1]$ and proceed by a contradiction. Let $t_0 \in (0,1)$ be the point of minimum of x. Hence $x'(t_0) = 0$ and differentiating (2.1) with respect to t, we obtain

$$x''(t) = f'(x(t))x'(t) + x(0)g'(t). \tag{3.1}$$

This means that $x''(t_0) < 0$ and so t_0 cannot be a point of minimum.

Now, we assume that g is differentiable and nonincreasing over $[0,1]$. Denote $g_n(t) = g(t) - \frac{t}{n}$ for $n \in \mathbb{N}$ large enough so that $g_n > 0$ over $[0,1]$ (say $n \geq n_0$). Let x_n be the corresponding solution of

$$x_n'(t) = f(x_n(t)) + x(0)g_n(t)$$

that satisfies $x_n(0) = x(0)$. Then x_n is bounded by zero from below and by x from above, and the sequence $\{x_n\}_{n \geq n_0}$, x_n converges uniformly to x over $[0,1]$. Since $g_n' < 0$, we have $x_n(t) \geq \min\{x_n(0), x_n(1)\}$ by the previous part of the proof. Hence $x(t) \geq \min\{x(0), x(1)\}$. □

Remark 3.2. Using arguments from the proof of Lemma 3.1, one can prove that if there holds (2.2) and $g' < 0$ over $[0,1]$, then x attains its maximum at a unique point $t_0 \in (0,1)$.

Remark 3.3. It is well known that if g is not positive, then a solution x that starts at some $x(0) > 0$ may cross the zero solution. Necessary and sufficient conditions of this phenomenon for linear delay differential equations were obtained in [7]. For convenience of readers, we can consider the equation

$$x'(t) = -x(t) + x(0)(-2t - 1).$$

Observe that the function $x(t) = \frac{1}{2} - t$ is a solution that crosses zero.

Lemma 3.4. *Let $f(x) = -\eta x$ where $\eta > 0$. Then there exists a unique $\eta^* = \eta^*(g) > 0$ such that for every positive solution x of (2.1), the following assertions are true:*

i) If $\eta > \eta^*$, then $x(1) < x(0)$.

ii) If $\eta < \eta^*$, then $x(1) > x(0)$.

iii) If $\eta = \eta^*$, then $x(1) = x(0)$.

Proof. Let x be a positive solution of the equation

$$x'(t) = -\eta x(t) + x(0)g(t), \qquad t \in [0,1] \tag{3.2}$$

that starts at some $x(0) > 0$. Multiplying the equation with $e^{\eta t}$ and integrating over $[0,1]$, we obtain

$$x(1) = x(0)e^{-\eta}\left(1 + \int_0^1 e^{\eta t} g(t)\,\mathrm{d}t\right).$$

Now, we discuss when there holds

$$e^{-\eta}\left(1+\int_0^1 e^{\eta t}g(t)\,\mathrm{d}t\right)=1 \tag{3.3}$$

or equivalently, $F(\eta):=\int_0^1 e^{\eta t}(g(t)-\eta)\,\mathrm{d}t=0$.

Let us prove that there is a unique solution of the equation $F(\eta)=0$. Note that F is a continuous function and $F(g_1)>0>F(g_2)$. Hence there exists at least one solution $\eta^*\in(g_1,g_2)$ of (3.3) and obviously, there is no solution beyond (g_1,g_2). Thus, every positive solution x of (3.2) for $\eta=\eta^*$ satisfies $x(0)=x(1)$. If there exists a root $\eta_1>\eta^*$ of (3.3) and y is a positive solution of problem

$$y'(t)=-\eta_1 y(t)+y(0)g(t),$$

then $y'(t)<-\eta^* y(t)+y(0)g(t)$. We can choose x, a solution of (3.2) with $\eta=\eta^*$ such that $x(0)=y(0)$, then $y(1)<x(1)=x(0)=y(0)$ what is a contradiction. If $\eta_1<\eta^*$, then a similar argument can be used. We conclude that $\eta_1\neq\eta^*$ cannot be a root of (3.3).

We turn to prove *i*). If $\eta>\eta^*$, then $F(\eta)<0$, hence $e^{-\eta}\left(1+\int_0^1 e^{\eta t}g(t)\,\mathrm{d}t\right)<1$ and $x(1)<x(0)$. The assertions *ii*) and *iii*) can be proven similarly. □

Remark 3.5. From the proof of Lemma 3.4, it is clear that $\eta^*\in(g_1,g_2)$. If moreover, g is nonconstant, nonincreasing and differentiable over $[0,1]$, then $\eta^*\in(g_1,g_3)$. Indeed, integrating by parts, we get

$$F(g_3)=\int_0^1 e^{g_3 t}(g(t)-g_3)\,\mathrm{d}t=\left[e^{g_3 t}\left(G(t)-g_3 t\right)\right]_0^1-g_3\int_0^1 e^{g_3 t}(G(t)-g_3 t)\,\mathrm{d}t,$$

where $G(t)=\int_0^t g(s)\,\mathrm{d}s$. Note that $G(0)=0$ and $G(1)=g_3$. Since G is a function concave over $[0,1]$ and not equal to the line that connects the points $[0,0]$ and $[1,g_3]$, it holds $G(t)>g_3 t$ for $t\in(0,1)$. We conclude that $F(g_3)<0$ and since $F(g_2)<0$, then necessarily, $\eta^*\in(g_1,g_3)$.

Theorem 3.6. *Let f,g satisfy the conditions 1), 2), and let η^* be as in Lemma 3.4. Assume that*

$$\lim_{x\to 0^+}\frac{f(x)}{x}>-\eta^*>\lim_{x\to\infty}\frac{f(x)}{x}. \tag{3.4}$$

Then there exists a positive solution x of problem (2.1)–(2.2), hence a 1-periodic solution of (1.1).

Moreover, if the function $\frac{f(x)}{x}$ is decreasing on interval $(0,\infty)$, then the positive 1-periodic solution x is unique and for every solution y of (1.1) such that $y(0)>0$, it holds

$$\lim_{t\to\infty}(x(t)-y(t))=0. \tag{3.5}$$

Proof. Note that if x,y are two solutions of (2.1) and $x(0)>y(0)>0$, then $x(t)>y(t)$ for $t\in[0,1]$. Indeed, it holds $x'(t)-y'(t)=a(t,x,y)(x(t)-y(t))+(x(0)-y(0))g(t)$ for $a(t,x,y)=\int_0^1 f'(sx(t)+(1-s)y(t))\,\mathrm{d}s$. Thus,

$$x(t)-y(t)=(x(0)-y(0))\left(e^{\int_0^t a(s)\,\mathrm{d}s}+\int_0^t e^{\int_s^t a(v)\,\mathrm{d}v}g(s)\,\mathrm{d}s\right)$$

and hence, $x>y$ over $[0,1]$ due to the condition 2).

Observe that if there exist two positive solutions $x_{-,+}$ of (2.1) such that $x_-<x_+$ over $[0,1]$, $x_-(0)<x_-(1)$, and $x_+(0)>x_+(1)$, then there is a solution of (2.1)–(2.2) that lies between x_-

and x_+. In fact, if we define a sequence $\{x_n\}_{n\in\mathbb{N}}$ such that $x_1(0) = x_-(1)$ and $x_{n+1}(0) = x_n(1)$ for $n \in \mathbb{N}$, then $x_-(t) < x_1(t) < x_2(t) < \ldots < x_+(t)$ for $t \in [0,1]$, since two distinct positive solutions of (2.1) do not intersect each other. The sequence of functions $\{x_n\}_{n\in\mathbb{N}}$ is increasing with respect to n and bounded by x_+ from above hence convergent to some solution of (2.1)-(2.2). In the following, our goal will be to find such functions x_- and x_+.

Due to the assumption $\lim_{x\to 0^+} \frac{f(x)}{x} > -\eta^*$, there holds $f(x) > -\eta x$ for some $\eta < \eta^*$ close to η^* and for all $x \in (0,\varepsilon)$ where $\varepsilon = \varepsilon(\eta) > 0$ is sufficiently small. If $x(0) \in \left(0, \frac{\varepsilon}{2}\min\{1, \frac{1}{g_2}\}\right)$ and x is the corresponding solution of (2.1), then $x' < x(0)g_2 \le \frac{\varepsilon}{2}$. Thus, the function x is bounded by ε. If y is the solution of (2.1) with $f(x) = -\eta x$ and $y(0) = x(0)$, then we can similarly prove that $y(t) \in (0,\varepsilon)$ for $t \in [0,1]$ and so $y < x$ over $(0,1]$. Due to Lemma 3.4, it holds $y(1) > y(0)$ therefore $x(1) > x(0)$ and we can denote $x_- := x$.

Now, we turn to find a solution x_+. Observe that if the initial condition $x(0) > 0$ is arbitrarily large the the value $\min_{t\in[0,1]} x(t)$ is also arbitrarily large where x is the corresponding solution of (2.1). Assume by contradiction that there is a sequence $\{x_n(0)\}_{n\in\mathbb{N}}$ of initial values such that $x_n(0) \to \infty$ as $n \to \infty$ and $\min_{t\in[0,1]} x_n(t)$ is bounded with respect to n. Let $t_n \in [0,1]$ be such that $x_n(t_n) = \min_{t\in[0,1]} x_n(t)$. Clearly, $t_n > 0$ for all n sufficiently large, since $x_n(0)$ is unbounded, and so $x_n'(t_n) \le 0$. On the other hand, the sequence $\{f(x_n(t_n))\}_{n\in\mathbb{N}}$ is bounded from below by some negative constant K and we conclude that

$$0 \ge x_n'(t_n) = f(x_n(t_n)) + x_n(0)g(t_n) \ge K + x_n(0)g_1.$$

This is not true if n is large enough.

The assumption (3.4) implies that $f(x) < -\eta^* x$ for all $x \in (x_0,\infty)$ for some x_0 large enough. We choose $x(0) > x_0$ large enough so that $x(t) > x_0$ for $t \in [0,1]$ where x is the corresponding solution of (2.1). Let y be the solution of equation

$$y'(t) = -\eta^* y(t) + y(0)g(t)$$

with $y(0) = x(0)$. Lemma 3.4 implies that $y(1) = y(0)$ and y lies entirely in (x_0,∞) (increasing $x(0)$ if necessary). Consequently, $y > x$ over $(0,1]$, $x(1) < y(1) = x(0)$, and we can choose $x_+ = x$.

Let x be a fixed positive solution of problem (2.1)–(2.2). We prove that x is unique. Let $\alpha \in (0,1)$ and denote $z(t) = \alpha x(t)$ for $t \in [0,1]$. Since the function $\frac{f(x)}{x}$ is decreasing on $(0,\infty)$, it holds

$$\frac{f(\alpha\xi)}{\alpha\xi} > \frac{f(\xi)}{\xi} \quad \text{for } \xi > 0$$

and so $\alpha f(x(t)) < f(\alpha x(t))$. Thus, we obtain

$$z'(t) = \alpha(f(x(t)) + x(0)g(t)) < f(z(t)) + z(0)g(t).$$

If y is the solution of (2.1) equipped with $y(0) = z(0) = \alpha x(0)$, then $y(t) > z(t)$ over $(0,1]$. Hence $y(1) > \alpha x(1) = \alpha x(0) = y(0)$. Thus, any solution of (2.1) that lies between x and the zero solution cannot be extended to a 1-periodic solution of (1.1).

If $\alpha > 1$, then similar arguments imply that $y(1) < y(0)$ where y is the solution of (2.1) satisfying $y(0) = \alpha x(0)$. Hence the solution x is the unique positive 1-periodic solution.

The assertion (3.5) is a consequence of above arguments. Let y be as in the previous part of the proof. If $y(0) < x(0)$, then the sequence $\{y(n)\}_{n\in\mathbb{N}}$ is increasing and necessarily converges to $x(0)$ so there holds (3.5). Otherwise y would converge to a 1-periodic solution different from x which is not possible. The case $y(0) > x(0)$ is similar. □

Remark 3.7. If $f(x) > -\eta^* x$ or $f(x) < -\eta^* x$ for all $x > 0$, then one can use arguments as in the proof of Theorem 3.6 and Lemma 3.4 to prove that there is no positive solution of problem (2.1)–(2.2).

Theorem 3.8. *Let $x_0 > 0$ and assume that one of the cases is true:*

i) It holds either $f(x_0) > -g_1 x_0$ or $f(x_0) < -g_2 x_0$.

ii) It holds $f(x_0) < -g_3 x_0$, f, g are decreasing.

Then there is no solution of the problem (2.1)–(2.2) with $x(0) = x_0$.

Proof. Let $i)$ be valid. Assume first that $f(x_0) > -g_1 x_0$ and there is a solution x of (2.1)–(2.2) satisfying $x(0) = x_0$. Let y be the solution of equation

$$y' = f(y) + x_0 g_1, \qquad y(0) = x_0.$$

Since the equation is autonomous, y is either strict monotone or constant. From $g \geq g_1$, we have $x \geq y$ over $[0,1]$. On the other hand, $f(y(0)) = f(x_0) > -x_0 g_1$ and so y is increasing on some neighbourhood of 0, hence increasing on $[0,1]$. Hence $x(1) > x_0 = x(0)$. The case $f(x_0) < -g_2 x_0$ is analogous.

Assume that $ii)$ is valid. Lemma 3.1 implies that if x is a solution of (2.1)–(2.2), then $x(t) \geq x_0$ for $t \in (0,1)$, hence $f(x(t)) \leq f(x_0)$. Integrating the equation (2.1) over $[0,1]$, it holds

$$0 = \int_0^1 f(x(t))\,\mathrm{d}t + x_0 \int_0^1 g(t)\,\mathrm{d}t \leq f(x_0) + x_0 g_3,$$

a contradiction. □

4 Example

Consider the equation

$$x'(t) = -\frac{x(t)}{3} - x^2(t) + x(\lfloor t \rfloor) e^{-(t - \lfloor t \rfloor)}, \qquad t \geq 0. \tag{4.1}$$

Note that the functions $f(x) = -\frac{x}{3} - x^2$, $x \geq 0$, and $g(t) = e^{-t}$, $t \in [0,1]$ satisfy the conditions 1), 2). One can easily check that all of the assumptions of Theorems 3.6 and 3.8 are true so that there is a unique positive 1-periodic solution x. Due to Remark 3.5, η^* lies in the interval $(e^{-1}, 1 - e^{-1})$. Theorem 3.8 provides us a bound for the starting value $x(0) := x_0$. From the part $i)$, we come to inequality $-\frac{x_0}{3} - x_0^2 > -e^{-1} x_0$, or equivalently, $x_0 > e^{-1} - \frac{1}{3}$. We can use the part $ii)$ and we obtain $-\frac{x_0}{3} - x_0^2 < -(1 - e^{-1}) x_0$, or, $x_0 > \frac{2}{3} - e^{-1}$. Hence for $x(0) \notin [e^{-1} - \frac{1}{3}, \frac{2}{3} - e^{-1}]$, then there is no positive 1-periodic solution of (4.1).

The equation (3.3) can be solved numerically and we find that $\eta^* \approx 0.601$. In the Figure 4.1, we see two solutions $x_{-,+}$ of (4.1) over the interval $[0, 100]$. For x_-, we choose $x_-(0) = 0.03 < e^{-1} - \frac{1}{3}$ and for x_+, $x_-(0) = 0.3 > \frac{2}{3} - e^{-1}$. From the proof of Theorem 3.6, we know that the values $x_-(n)$ and $x_+(n)$ for integer n converge to a value that is the initial condition for the periodic solution. Numerical computations show that $x_-(100) \approx 0.256$ and $x_+(100) - x_-(100) \approx 1.64 \times 10^{-9}$. This means that $x_-(100)$ approximates the initial value of the 1-periodic solution with error 1.64×10^{-9}. As observed in Remark 3.2, the graphs of both solutions consist of smooth parts of solutions of (1.1) defined on intervals $[n-1, n]$

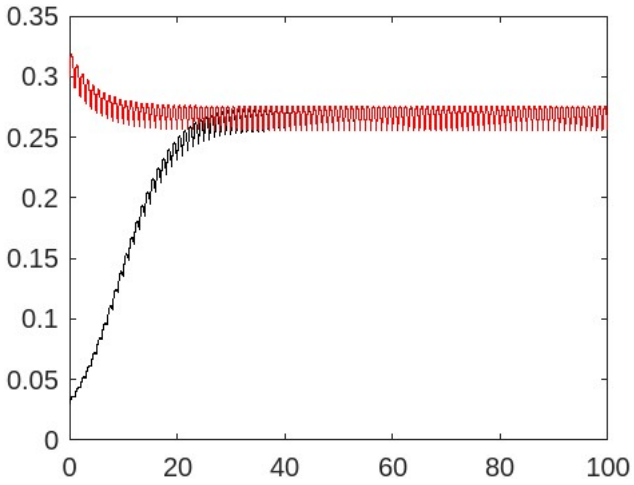

Figure 4.1: Comparison of solutions x_- (black line) and x_+ (red line).

for $n = 1, \dots, 100$ that attain local maximum at exactly one interior point on each interval $[n-1, n]$ and attain local minima at points $n-1$ and n.

The problem (4.1) describes temperature changes in a space bounded by outside cold environment for particular functions f and g. We see that for such f, g, the optimal initial temperature is approximately equal to 0.256 and repeats regularly at every positive integer point. If the initial temperature is higher or lower, then, after some time, it becomes close to optimal due to the asymptotic stability of the periodic solution in sense of (3.5).

Abstract. In this paper, we consider the following Schrödinger–Poisson system with critical-concave nonlinearity:

$$\begin{cases} -\Delta u + l(x)\phi u = |u|^4 u + \mu h(x)|u|^{q-2}u & \text{in } \mathbb{R}^3, \\ -\Delta \phi = l(x)u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $\mu > 0$, $1 < q < 2$ and the functions l, h satisfy some mild conditions. By constraining the energy functional of the above problem on a closed subset of the sign-changing Nehari manifold, we obtain a sign-changing solution with positive energy for $\mu > 0$ small enough.

Keywords: Schrödinger–Poisson system, critical-concave nonlinearity, Nehari manifold, sign-changing solution.

1 Introduction and main results

This paper focuses on standing waves of the following nonlinear Schrödinger–Poisson system:

$$\begin{cases} i\psi_t = -\Delta\psi + \phi(x)\psi - g(x,\psi), \\ -\Delta\phi = |\psi|^2, \end{cases} \tag{1.1}$$

where $g \in C(\mathbb{R}^3 \times \mathbb{C}, \mathbb{R})$ and $\psi : \mathbb{R}^3 \times [0,T] \to \mathbb{C}$. Such systems arise as electromagnetic field models in quantum mechanics and has a strong physical background. The first equation of system (1.1) describes the evolution of the quantum state of microscopic particles (such as electrons) over time, while the second equation (i.e. Poisson equation) is often used to describe the relationship between the electrostatic potential and the charge distribution. The interaction of charge particles with electromagnetic field can be described by coupling the

nonlinear Schrödinger equation and the Poisson equation. For more physical backgrounds of Schrödinger–Poisson system, we recommend readers to refer to [2,6].

In the past decades, many mathematicians studied the standing wave solution of type $\psi(x,t) = e^{i\lambda t}u(x)$ for system (1.1), which corresponds to a solution u of the elliptic system

$$\begin{cases} -\Delta u + u + \phi u = g(x,u) & \text{in } \mathbb{R}^3, \\ -\Delta \phi = u^2 & \text{in } \mathbb{R}^3. \end{cases} \tag{1.2}$$

For the case of $g(x,u) = |u|^{p-2}u$, D'Aprile and Mugnai [7] showed that system (1.2) has no nontrivial solution once $p \geq 6$ or $p \leq 2$ by establishing a related Pohožaev identity, Ruiz [18] showed that system (1.2) does not admit any nontrivial solution if $p \leq 3$ and has positive solution if $p \in (3,6)$, in this case ground state solution was further proved by Azzollini and Pomponio in [1]. Afterwards, Schrödinger–Poisson systems with Sobolev critical exponent and subcritical perturbation were investigated by many scholars. For example, see the cases of superlinear perturbations in [1, 25], the cases of sublinear perturbations in [13] and the references therein. As we will recall below, various existence results of sign-changing solutions for Schrödinger–Poisson systems were widely studied in [4,5,8–12,15,17,19–21,23,24,26,27]. More precisely, for the Schrödinger–Poisson system

$$\begin{cases} -\Delta u + V(x)u + \phi u = K(x)f(u) & \text{in } \mathbb{R}^3, \\ -\Delta \phi = u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.3}$$

Ianni [10] studied the case of $V = K = 1$, $f(u) = |u|^{p-2}u$ and $p \in [4,6)$, by the heat flow method he got a radially nodal solution changing sign exactly $k-1$ times for every integer $k \geq 2$. Meanwhile, Kim and Seok [12] proved the similar results to [10] for $p \in (4,6)$ by using the variational methods. Wang and Zhou assumed $K = 1$, $f(u) = |u|^{p-2}u$, $p \in (4,6)$ and V satisfies compactness condition in [21], where they proved a sign-changing solution of system (1.3) by combining the constraint minimization argument and the Brouwer degree theory. In [19], by using a quantitative deformation lemma, Shuai and Wang extended the results in [21] to the case of general nonlinearity f, which satisfies an increasing condition. If V, K satisfy some vanishing conditions, Liang et al. [15] proved system (1.3) has a sign-changing solution. Chen and Tang [4] assumed that $f \in C(\mathbb{R},\mathbb{R})$ satisfies a weaker condition than the increasing condition, by using a direct approach they obtained a ground state sign-changing solution with precisely two nodal domains. After this, Chen and Tang assumed that f satisfies asymptotically cubic or super-cubic conditions in [5], where they proved a sign-changing solution with precisely two nodal domains under mild assumptions on asymptotic behaviors of V, K. When $K = 1$ and f satisfies super-cubic conditions, via the method of invariant sets of descending flow, Liu et al. [17] proved that system (1.3) has infinitely many sign-changing solutions. In [26], Zhong and Tang studied the system

$$\begin{cases} -\Delta u + V(x)u + \phi u = |u|^2 u + \mu h(x)u & \text{in } \mathbb{R}^3, \\ -\Delta \phi = u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $V \in C(\mathbb{R}^3,\mathbb{R}^+)$ satisfies a compactness condition and $h \in L^{\frac{3}{2}}(\mathbb{R}^3) \setminus \{0\}$ is nonnegative, by using the sign-changing Nehari manifold they got a ground state sign-changing solution for any $\mu \in (0,\mu_1)$, with μ_1 denoting the first eigenvalue of $-\Delta u + u = \mu h(x)u$ in $H^1(\mathbb{R}^3)$. In

[8], Gu et al. considered the following system with subquadratic or quadratic nonlinearity:

$$\begin{cases} -\Delta u + V(x)u + \lambda\phi u = f(u) & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $V \in C(\mathbb{R}^3, \mathbb{R}^+)$ is radial if f is subquadratic and coercive if f is quadratic, by following the ideas of [17] they verified the existence and multiplicity of sign-changing solution for $\lambda > 0$ small enough.

As for the existence of sign-changing solutions for the critical Schrödinger–Poisson system

$$\begin{cases} -\Delta u + V(x)u + K(x)\phi u = |u|^4 u + g(x,u) & \text{in } \mathbb{R}^3, \\ -\Delta\phi = K(x)u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.4}$$

there are seldom results proved in [9, 11, 20, 27]. In [27], Zhong and Tang studied the case of $V = 1$ and $g(x,u) = \mu h(x)u$, under some mild conditions on K, g, by combining the variational methods and sign-changing Nehari manifold they obtained a ground state sign-changing solution of system (1.4) for any $\mu \in (0, \mu_1)$, where μ_1 is the first eigenvalue of $-\Delta u + u = \mu h(x)u$ in $H^1(\mathbb{R}^3)$. When $K = 1$, $f(x,u) = \mu f(u)$ satisfies an increasing condition and V satisfies compactness condition, Wang et al. [20] proved that system (1.4) has a least-energy sign-changing solution for $\mu > 0$ large enough. Later, Kang et al. [11] concerned with the following Schrödinger–Poisson system with steep well potential:

$$\begin{cases} -\Delta u + (\lambda V(x) + 1)u + \phi u = |u|^4 u + |u|^{p-2}u & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $p \in (5, 6)$, by combining constrained minimization arguments and Hofer's deformation lemma, they proved the existence and concentration of ground sign-changing solution for $\lambda > 0$ large enough. Subsequently, Huang et al. [9] extended the results in [11] to the case of general perturbed nonlinearity.

Recently, sign-changing solutions on the Schrödinger–Poisson systems with concave-convex nonlinearity have attracted wide attention. Yang and Ou [24] studied the Schrödinger–Poisson system

$$\begin{cases} -\Delta u + \dfrac{1}{4\pi}\displaystyle\int_\Omega \frac{u^2(y)}{|x-y|}dy u = |u|^{q-2}u + \mu|u|^{p-2}u & \text{in } \Omega, \\ u(x) = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.5}$$

where $\Omega \subset \mathbb{R}^3$ is a bounded domain with smooth boundary $\partial\Omega$, $1 < p < 2$ and $4 < q < 6$. By using constrained variational method and quantitative deformation lemma, they proved that there exists some constant $\mu^* > 0$ such that system (1.5) has a sign-changing solution with positive energy for any $\mu < \mu^*$. After this work, Yang and Tang [23] studied the Schrödinger–Poisson system

$$\begin{cases} -\Delta u + V(x)u + \phi u = |u|^{p-2}u + \mu K(x)|u|^{q-2}u & \text{in } \mathbb{R}^3, \\ -\Delta\phi = u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $1 < q < 2$, $4 < p < 6$, $K \in L^{\frac{6}{6-q}}(\mathbb{R}^3)$ and $V \in C(\mathbb{R}^3, \mathbb{R})$ satisfies a weakly coercive assumption. By constructing a nonempty closed subset of the sign-changing Nehari manifold,

they obtained a sign-changing solution with positive energy provided $\mu < \mu^*$ for some $\mu^* > 0$. Inspired by the above works, we are interested in whether the critical-concave Schrödinger–Poisson system has sign-changing solution. In this paper, we consider sign-changing solution of the following Schrödinger–Poisson system:

$$\begin{cases} -\Delta u + l(x)\phi u = |u|^4 u + \mu h(x)|u|^{q-2}u & \text{in } \mathbb{R}^3, \\ -\Delta \phi = l(x)u^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.6}$$

where $1 < q < 2$, $\mu > 0$, $0 < l(\cdot) \in L^2(\mathbb{R}^3) \cap L^3(\mathbb{R}^3)$ and the potential function h satisfies the condition

(H) $0 < h(\cdot) \in L^{\frac{6}{6-q}}(\mathbb{R}^3)$ and there exists some $\beta \in \left(3 - \frac{2q}{3}, 3 - \frac{q}{2}\right)$ such that $h(x) \geq \frac{1}{|x|^\beta}$ for all $|x| \leq 1$.

As is well known, the Poisson equation is uniquely solvable. Indeed, for any $u \in D^{1,2}(\mathbb{R}^3)$, define the linear functional

$$L_u(v) = \int_{\mathbb{R}^3} l(x)u^2 v dx, \qquad \forall\, v \in D^{1,2}(\mathbb{R}^3).$$

It follows from $l \in L^2(\mathbb{R}^3)$, the Hölder and Sobolev inequalities that

$$|L_u(v)| \leq |l|_2 |u|_6^2 |v|_6 \leq S^{-\frac{3}{2}} |l|_2 \|u\|^2 \|v\|.$$

Then, by the Lax–Milgram theorem, there exists a unique $\phi_u \in D^{1,2}\left(\mathbb{R}^3\right)$ such that $-\Delta\phi_u = l(x)u^2$ in $\left[D^{1,2}(\mathbb{R}^3)\right]^*$, where

$$\phi_u(x) = \frac{1}{4\pi} \int_{\mathbb{R}^3} \frac{l(y)u^2(y)}{|x-y|} dy.$$

Therefore, system (1.6) can be reduced to the semilinear Schrödinger equation with a non-local term

$$-\Delta u + l(x)\phi_u u = |u|^4 u + \mu h(x)|u|^{q-2}u \quad \text{in } \mathbb{R}^3. \tag{1.7}$$

Then, we say that $u \in D^{1,2}\left(\mathbb{R}^3\right)$ satisfying (1.7) is a weak solution of system (1.6) for short. Moreover, the solution u of system (1.6) is called as a sign-changing solution of system (1.6) once $u^\pm \neq 0$, where

$$u^+(x) := \max\{u, 0\} \quad \text{and} \quad u^-(x) := \min\{u, 0\}.$$

By the variational methods, weak solution of system (1.6) correspond to critical point of the functional

$$\mathcal{I}_\mu(u) = \frac{1}{2}\|u\|^2 + \frac{1}{4}\int_{\mathbb{R}^3} l(x)\phi_u u^2 dx - \frac{1}{6}\int_{\mathbb{R}^3} |u|^6 dx - \frac{\mu}{q}\int_{\mathbb{R}^3} h(x)|u|^q dx, \qquad \forall\, u \in D^{1,2}(\mathbb{R}^3).$$

Based on [14, Lemma 2.3], it is standard to verify that the functional $\mathcal{I}_\mu$ is well-defined in $D^{1,2}(\mathbb{R}^3)$ and is of class C^1. Naturally, we introduce the Nehari manifold of system (1.6) as follows:

$$\mathcal{N}_\mu = \left\{ u \in D^{1,2}\left(\mathbb{R}^3\right) \setminus \{0\} : \left\langle \mathcal{I}'_\mu(u), u \right\rangle = 0 \right\}.$$

As we will see, $\mathcal{N}_\mu$ is closely related to the behavior of the fiber map $\psi_u : t \to \mathcal{I}_\mu(tu)$, which is defined for any $u \in D^{1,2}(\mathbb{R}^3)$ and $t > 0$ by

$$\psi_u(t) = \frac{t^2}{2}\|u\|^2 + \frac{t^4}{4}\int_{\mathbb{R}^3} l(x)\phi_u u^2 dx - \frac{t^6}{6}|u|_6^6 - \frac{\mu t^q}{q}\int_{\mathbb{R}^3} h(x)|u|^q dx.$$

By a simple calculation, we obtain

$$\psi_u'(t) = t\|u\|^2 + t^3\int_{\mathbb{R}^3} l(x)\phi_u u^2 dx - t^5|u|_6^6 - \mu t^{q-1}\int_{\mathbb{R}^3} h(x)|u|^q dx$$

and

$$\psi_u''(t) = \|u\|^2 + 3t^2\int_{\mathbb{R}^3} l(x)\phi_u u^2 dx - 5t^4|u|_6^6 - (q-1)\mu t^{q-2}\int_{\mathbb{R}^3} h(x)|u|^q dx.$$

Clearly, for any $u \in D^{1,2}(\mathbb{R}^3) \setminus \{0\}$, there holds $\psi_u'(t) = 0$ iff $tu \in \mathcal{N}_\mu$. Specially, $\psi_u'(1) = 0$ iff $u \in \mathcal{N}_\mu$. To search for sign-changing solutions of system (1.6), we introduce the sign-changing Nehari manifold

$$\mathcal{M}_\mu = \left\{u \in D^{1,2}(\mathbb{R}^3) : u^\pm \neq 0,\ \langle \mathcal{I}_\mu'(u), u^\pm\rangle = 0\right\}.$$

Now we present our main result of this paper.

Theorem 1.1. *Assume (H) holds, then there exists some $\mu^* > 0$ such that system (1.6) possesses a sign-changing solution u_μ with positive energy for any $\mu \in (0, \mu^*)$.*

Remark 1.2. Our result extends the works [23, 24] to critical-concave Schrödinger–Poisson systems. The methods of studying subcritical concave-convex case in [23, 24] are invalid for critical-concave case, we need to search for a sign-changing Palais–Smale sequence and estimate the corresponding level less than a prescribed threshold to recover the loss of compactness. As we know, the Nehari manifold is a good choice to look for two positive solutions of system (1.6) by splitting the manifold into two parts and using minimization arguments on each parts. However, this idea cannot be directly used to prove sign-changing solutions, since we may not verify that the corresponding parts of the sign-changing Nehari manifold are complete. Thus we work in a closed subset of the one part of $\mathcal{M}_\mu$. Moreover, we propose a question whether system (1.6) has (ground state) sign-changing solution with negative energy.

The rest of this paper focus on proving Theorem 1.1 in Sect. 2. Throughout the present paper, we acknowledge the following notations:

- $L^p(\mathbb{R}^3)$ is the usual Lebesgue space with the norm $|u|_p = \left(\int_{\mathbb{R}^3}|u|^p dx\right)^{\frac{1}{p}}$ for $p \in [1, +\infty)$.
- $C_0^\infty(\mathbb{R}^3)$ consists of infinitely times differentiable functions with compact support in $\mathbb{R}^3$.
- $D^{1,2}(\mathbb{R}^3)$ is the completion of $C_0^\infty(\mathbb{R}^3)$ with respect to the norm $\|u\| = \left(\int_{\mathbb{R}^3}|\nabla u|^2 dx\right)^{\frac{1}{2}}$.
- The best Sobolev constant $S = \inf\left\{\|u\|^2 : u \in D^{1,2}(\mathbb{R}^3) \setminus \{0\}, |u|_6 = 1\right\}$.
- For $r > 0$ and $y \in \mathbb{R}^3$, $\mathbb{B}_r(y) := \left\{x \in \mathbb{R}^3 : |x - y| < r\right\}$ and $\mathbb{B}_r^c(y) = \mathbb{R}^3 \setminus \mathbb{B}_r(y)$.
- C_i $(i \in \mathbb{N}_+)$ denotes positive constant and $\mathbb{R}^+ = (0, +\infty)$.
- $o(1)$ denotes a quantity tending to 0 as $n \to \infty$.

2 Proof of Theorem 1.1

In this section, we will present some preliminary lemmas before completing the proof of our main result. For any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^{\pm} \neq 0$, let the function f_u: $[0,+\infty) \times [0,+\infty) \to \mathbb{R}$ be defined as $f_u(s,t) = \mathcal{I}_\mu(su^+ + tu^-)$. From the Fubini theorem, we get

$$\begin{aligned} f_u(s,t) = {} & \frac{s^2}{2}\|u^+\|^2 + \frac{s^4}{4}\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx - \frac{s^6}{6}|u^+|_6^6 - \frac{\mu s^q}{q}\int_{\mathbb{R}^3} h(x)|u^+|^q dx \\ & + \frac{t^2}{2}\|u^-\|^2 + \frac{t^4}{4}\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx - \frac{t^6}{6}|u^-|_6^6 - \frac{\mu t^q}{q}\int_{\mathbb{R}^3} h(x)|u^-|^q dx \\ & + \frac{1}{2}s^2t^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx. \end{aligned}$$

Through direct computations, we have

$$\begin{aligned} \frac{\partial f_u}{\partial s}(s,t) = {} & s\|u^+\|^2 + s^3\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx + st^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ & - s^5|u^+|_6^6 - \mu s^{q-1}\int_{\mathbb{R}^3} h(x)|u^+|^q dx, \end{aligned} \tag{2.1}$$

$$\begin{aligned} \frac{\partial f_u}{\partial t}(s,t) = {} & t\|u^-\|^2 + t^3\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx + ts^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ & - t^5|u^-|_6^6 - \mu t^{q-1}\int_{\mathbb{R}^3} h(x)|u^-|^q dx, \end{aligned} \tag{2.2}$$

$$\begin{aligned} \frac{\partial^2 f_u}{\partial s^2}(s,t) = {} & \|u^+\|^2 + 3s^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx + t^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ & - 5s^4|u^+|_6^6 - \mu(q-1)s^{q-2}\int_{\mathbb{R}^3} h(x)|u^+|^q dx, \end{aligned} \tag{2.3}$$

$$\begin{aligned} \frac{\partial^2 f_u}{\partial t^2}(s,t) = {} & \|u^-\|^2 + 3t^2\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx + s^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ & - 5t^4|u^-|_6^6 - \mu(q-1)t^{q-2}\int_{\mathbb{R}^3} h(x)|u^-|^q dx \end{aligned} \tag{2.4}$$

and

$$\frac{\partial^2 f_u}{\partial s\partial t}(s,t) = \frac{\partial^2 f_u}{\partial t\partial s}(s,t) = 2st\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx. \tag{2.5}$$

It is easy to see that

$$\frac{\partial f_u}{\partial s}(s,t) = \left\langle \mathcal{I}'_\mu(su^+ + tu^-), u^+ \right\rangle \quad \text{and} \quad \frac{\partial f_u}{\partial t}(s,t) = \left\langle \mathcal{I}'_\mu(su^+ + tu^-), u^- \right\rangle,$$

which indicate that, for any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^{\pm} \neq 0$, $su^+ + tu^- \in \mathcal{M}_\mu$ if and only if $\frac{\partial f_u}{\partial s}(s,t) = 0$ and $\frac{\partial f_u}{\partial t}(s,t) = 0$, that is

$$\mathcal{M}_\mu = \left\{ u \in D^{1,2}(\mathbb{R}^3) : u^{\pm} \neq 0,\ \frac{\partial f_u}{\partial s}(1,1) = 0,\ \frac{\partial f_u}{\partial t}(1,1) = 0 \right\}.$$

Moreover, for any $u \in \mathcal{M}_\mu$, by (2.1)–(2.4) we have

$$\begin{aligned}\frac{\partial^2 f_u}{\partial s^2}(1,1) &= \|u^+\|^2 + 3\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx + \int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ &\quad - 5|u^+|_6^6 - \mu(q-1)\int_{\mathbb{R}^3} h(x)|u^+|^q dx \\ &= (2-q)\|u^+\|^2 + (4-q)\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx \\ &\quad + (2-q)\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - (6-q)|u^+|_6^6 \\ &= -4\|u^+\|^2 - 2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx - 4\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ &\quad - \mu(q-6)\int_{\mathbb{R}^3} h(x)|u^+|^q dx \end{aligned} \tag{2.6}$$

and

$$\begin{aligned}\frac{\partial^2 f_u}{\partial t^2}(1,1) &= \|u^-\|^2 + 3\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx + \int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ &\quad - 5|u^-|_6^6 - \mu(q-1)\int_{\mathbb{R}^3} h(x)|u^-|^q dx \\ &= (2-q)\|u^-\|^2 + (4-q)\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx \\ &\quad + (2-q)\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - (6-q)|u^-|_6^6 \\ &= -4\|u^-\|^2 - 2\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx - 4\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx \\ &\quad - \mu(q-6)\int_{\mathbb{R}^3} h(x)|u^-|^q dx. \end{aligned} \tag{2.7}$$

To begin with, we give some useful properties for the non-local term in the following

Lemma 2.1. *For the unique solution ϕ_u of the Poisson equation, there hold*

(1) $\phi_u(\cdot) \geq 0$ *for any* $u \in D^{1,2}(\mathbb{R}^3)$;

(2) $\phi_{tu} = t^2\phi_u$ *for any* $t > 0$ *and* $u \in D^{1,2}(\mathbb{R}^3)$;

(3) $\int_{\mathbb{R}^3} l(x)\phi_u u^2 dx \leq |\phi_u|_6 \, |lu^2|_{\frac{6}{5}} \leq S^{-1}|l|_2^2|u|_6^4$;

(4) $\int_{\mathbb{R}^3} l(x)\phi_u u^2 dx \leq |\phi_u|_6 \, |lu^2|_{\frac{6}{5}} \leq S^{-1}|l|_3^2|u|_4^4$ *for any* $u \in L^4(\mathbb{R}^3)$;

(5) *if* $u_n \rightharpoonup u$ *in* $D^{1,2}\left(\mathbb{R}^3\right)$, *then* $\phi_{u_n} \rightharpoonup \phi_u$ *in* $D^{1,2}\left(\mathbb{R}^3\right)$;

(6) *if* $u_n \rightharpoonup u$ *in* $D^{1,2}\left(\mathbb{R}^3\right)$, *then* $\int_{\mathbb{R}^3} l(x)\phi_{u_n}u_n^2 dx \to \int_{\mathbb{R}^3} l(x)\phi_u u^2 dx$.

Proof. (1)–(4) are easily verified. (5) and (6) were proved in [14], we omit the details here. □

Lemma 2.2. *There exists some $\mu_1 > 0$ such that, for any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^\pm \neq 0$, there holds that*

(1) *if $\mu \in (0, \mu_1)$, then $f_u(s,t)$ has exactly two critical points $0 < s_1(t) < s_2(t)$ for any fixed $t \geq 0$, where $s_1(t)$ is the minimum point and $s_2(t)$ is the maximum point;*

(2) *if $\mu \in (0, \mu_1)$, then $f_u(s,t)$ has exactly two critical points $0 < t_1(s) < t_2(s)$ for any fixed $s \geq 0$, where $t_1(s)$ is the minimum point and $t_2(s)$ is the maximum point.*

Proof. (1) For any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^{\pm} \neq 0$, by (2.1) we get

$$\frac{\partial f_u}{\partial s}(s,t) = s^{q-1}\bigg(s^{2-q}\|u^+\|^2 + s^{4-q}\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx + s^{2-q}t^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - s^{6-q}|u^+|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u^+|^q dx\bigg).$$

Define the function $\beta_t(s) : [0,+\infty) \to \mathbb{R}$ by

$$\beta_t(s) = s^{2-q}\|u^+\|^2 + s^{4-q}\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx + s^{2-q}t^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - s^{6-q}|u^+|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u^+|^q dx.$$

For any fixed $t \geq 0$, we deduce $\frac{\partial f_u(s,t)}{\partial s} = 0$ iff $\beta_t(s) = 0$ on $(0,+\infty)$. By direct calculation, we derive

$$\begin{aligned}\beta_t'(s) &= (2-q)s^{1-q}\|u^+\|^2 + (4-q)s^{3-q}\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx \\ &\quad + (2-q)s^{1-q}t^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - (6-q)s^{5-q}|u^+|_6^6 \\ &= s^{1-q}\bigg[(2-q)\|u^+\|^2 + (4-q)s^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^+|^2dx \\ &\quad + (2-q)t^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - (6-q)s^4|u^+|_6^6\bigg].\end{aligned}$$

Then, for any fixed $t \geq 0$, it is easy to obtain that $\beta_t(s)$ has exactly one critical point $s_{\max} > 0$ and β_t is increasing in $(0, s_{\max})$ while decreasing in $(s_{\max}, +\infty)$. Moreover, we define $\gamma_t(s) : [0,+\infty) \to \mathbb{R}$ by

$$\gamma_t(s) = s^{2-q}\|u^+\|^2 - s^{6-q}|u^+|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u^+|^q dx.$$

By direct computation, we have

$$\gamma_t'(s) = (2-q)s^{1-q}\|u^+\|^2 - (6-q)s^{5-q}|u^+|_6^6.$$

Obviously, γ_t takes the maximum at $\bar{s} = \big[\frac{(2-q)\|u^+\|^2}{(6-q)|u^+|_6^6}\big]^{\frac{1}{4}}$ and

$$\max_{s>0}\gamma_t(s) = \gamma_t(\bar{s}) = \frac{4}{6-q}\left(\frac{2-q}{6-q}\right)^{\frac{2-q}{4}}\frac{\|u^+\|^{\frac{6-q}{2}}}{|u^+|_6^{\frac{6-3q}{2}}} - \mu\int_{\mathbb{R}^3} h(x)|u^+|^q dx.$$

Denote

$$\mu_1^+ = \frac{4}{6-q}\left(\frac{2-q}{6-q}\right)^{\frac{2-q}{4}}\inf_{u\in D^{1,2}(\mathbb{R}^3),u^+\neq 0}\frac{\|u^+\|^{\frac{6-q}{2}}}{|u^+|_6^{\frac{6-3q}{2}}\int_{\mathbb{R}^3} h(x)|u^+|^q dx}.$$

It follows from (H), the Hölder and Sobolev inequalities that

$$\mu_1^+ \geq \frac{4}{6-q}\left(\frac{2-q}{6-q}\right)^{\frac{2-q}{4}}\frac{S^{\frac{6-q}{4}}}{|h|_{\frac{6}{6-q}}} =: \mu_1. \tag{2.8}$$

Then, once $\mu \in (0, \mu_1)$, we can deduce $\beta_t(s_{\max}) \geq \beta_t(\bar{s}) > \gamma_t(\bar{s}) > 0$ for any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^+ \neq 0$. As a consequence, for any fixed $t \geq 0$, if $\mu \in (0, \mu_1)$, there exist exactly $s_2(t) > s_1(t) > 0$ such that $\beta_t(s_1(t)) = 0$ and $\beta_t(s_2(t)) = 0$, which imply $\frac{\partial f_u}{\partial s}(s_1(t), t) = \frac{\partial f_u}{\partial s}(s_2(t), t) = 0$. Furthermore, we can easily deduce that f_u is decreasing in $s \in (0, s_1(t))$, increasing in $s \in (s_1(t), s_2(t))$ and decreasing in $s \in (s_2(t), +\infty)$. Thus, $s_1(t)$ is the minimum point and $s_2(t)$ is the maximum point, (1) is verified.

(2) Similar to the proof of (1). We define $\beta_s(t) : [0, +\infty) \to \mathbb{R}$ by

$$\begin{aligned}\beta_s(t) = {} & t^{2-q}\|u^-\|^2 + t^{4-q}\int_{\mathbb{R}^3} l(x)\phi_{u^-}|u^-|^2dx \\ & + t^{2-q}s^2\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx - t^{6-q}|u^-|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u^-|^q dx.\end{aligned}$$

For any fixed $s \geq 0$, we deduce $\frac{\partial f_u(s,t)}{\partial t} = 0$ iff $\beta_s(t) = 0$. It can be verified that $\beta_s(t)$ has exactly one critical point $t_{\max} > 0$ and β_s is increasing in $(0, t_{\max})$ while decreasing in $(t_{\max}, +\infty)$. Denote

$$\mu_1^- = \frac{4}{6-q}\left(\frac{2-q}{6-q}\right)^{\frac{2-q}{4}} \inf_{u \in D^{1,2}(\mathbb{R}^3), u^- \neq 0} \frac{\|u^-\|^{\frac{6-q}{2}}}{|u^-|_6^{\frac{6-3q}{2}} \int_{\mathbb{R}^3} h(x)|u^-|^q dx}.$$

It is clear that $\mu_1^+ = \mu_1^- \geq \mu_1$. Repeating the discussion in the proof of (1), we may obtain $\beta_s(t_{\max}) > 0$ for any $\mu \in (0, \mu_1)$. Then, for any fixed $s \geq 0$, if $\mu \in (0, \mu_1)$, there exist exactly $t_2(s) > t_1(s) > 0$ such that $\beta_s(t_1(s)) = \beta_s(t_2(s)) = 0$, which imply $\frac{\partial f_u}{\partial t}(s, t_1(s)) = \frac{\partial f_u}{\partial t}(s, t_2(s)) = 0$. Besides, it is easy to see that f_u is decreasing in $t \in (0, t_1(s))$, increasing in $t \in (t_1(s), t_2(s))$ and decreasing in $t \in (t_2(s), +\infty)$. Naturally, $t_1(s)$ is the minimum point and $t_2(s)$ is the maximum point. Thus, (2) is proved. □

Lemma 2.3. *If $0 < \mu < \mu_1$, then $\frac{\partial^2 f_u}{\partial s^2}(1,1) \neq 0$ and $\frac{\partial^2 f_u}{\partial t^2}(1,1) \neq 0$ for any $u \in \mathcal{M}_\mu$.*

Proof. For any $u \in \mathcal{M}_\mu$, according to Lemma 2.2-(1), $f_u(s,1)$ has exactly two critical points $s_1(1)$ and $s_2(1)$, with $\frac{\partial^2 f_u}{\partial s^2}(s_1(1),1) > 0$ and $\frac{\partial^2 f_u}{\partial s^2}(s_2(1),1) < 0$. Since $u \in \mathcal{M}_\mu$, it follows that $\frac{\partial f_u}{\partial s}(1,1) = 0$. This implies either $s_1(1) = 1$ or $s_2(1) = 1$. Consequently, $\frac{\partial^2 f_u}{\partial s^2}(1,1) \neq 0$. Analogously, by Lemma 2.2-(2) we conclude $\frac{\partial^2 f_u}{\partial t^2}(1,1) \neq 0$. Thus the proof is completed. □

In order to find sign-changing solution of system (1.6), we introduce the following two sets

$$\mathcal{M}_\mu^- = \left\{u \in \mathcal{M}_\mu : \frac{\partial^2 f_u}{\partial s^2}(1,1) < 0,\ \frac{\partial^2 f_u}{\partial t^2}(1,1) < 0\right\}$$

and

$$\mathcal{M}_\mu^* = \left\{u \in \mathcal{M}_\mu : \frac{\partial^2 f_u}{\partial s^2}(1,1) < 0,\ \frac{\partial^2 f_u}{\partial t^2}(1,1) < 0,\ \psi_u''(1) < 0\right\}. \tag{2.9}$$

In the following, we will use the properties of f_u to show that the set $\mathcal{M}_\mu^* \neq \emptyset$ and $\mathcal{M}_\mu^* = \mathcal{M}_\mu^-$.

Lemma 2.4. *There exists some constant $c > 0$, independent of μ, such that $\|u^\pm\| \geq c$ for all $u \in \mathcal{M}_\mu^-$. Moreover, the functional $\mathcal{I}_\mu$ is coercive on $\mathcal{M}_\mu^*$.*

Proof. For any $u \in \mathcal{M}_\mu^-$, from $\frac{\partial^2 f_u}{\partial s^2}(1,1) < 0$, $\frac{\partial^2 f_u}{\partial t^2}(1,1) < 0$, (2.6), (2.7) and the Sobolev inequality, it follows that

$$\begin{aligned}(2-q)\|u^\pm\|^2 &< (2-q)\|u^\pm\|^2 + (4-q)\int_{\mathbb{R}^3} l(x)\phi_{u^\pm}|u^\pm|^2dx + (2-q)\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2dx\\ &< (6-q)|u^\pm|_6^6 \le (6-q)S^{-3}\|u^\pm\|^6,\end{aligned}$$

which shows

$$\|u^\pm\| > \left[\frac{(2-q)S^3}{6-q}\right]^{\frac{1}{4}} =: c > 0.$$

Moreover, for any $u \in \mathcal{M}_\mu^*$, by the Hölder inequality one has

$$\begin{aligned}\mathcal{I}_\mu(u) &= \mathcal{I}_\mu(u) - \frac{1}{4}\langle \mathcal{I}'_\mu(u), u\rangle\\ &= \frac{1}{4}\|u\|^2 + \frac{1}{12}|u|_6^6 - \mu\left(\frac{1}{q}-\frac{1}{4}\right)\int_{\mathbb{R}^3} h(x)|u|^q dx\\ &\ge \frac{1}{4}\|u\|^2 + \frac{1}{12}|u|_6^6 - \mu\left(\frac{1}{q}-\frac{1}{4}\right)|h|_{\frac{6}{6-q}}|u|_6^q\\ &\ge \frac{1}{4}\|u\|^2 + \min_{t\ge 0}\left[\frac{1}{12}t^6 - \mu\left(\frac{1}{q}-\frac{1}{4}\right)|h|_{\frac{6}{6-q}}t^q\right]\\ &\ge \frac{1}{4}\|u\|^2 - \mu^{\frac{6}{6-q}}\frac{6-q}{6}\left[\left(\frac{1}{q}-\frac{1}{4}\right)|h|_{\frac{6}{6-q}}(2q)^{\frac{q}{6}}\right]^{\frac{6}{6-q}}.\end{aligned} \tag{2.10}$$

As a consequence, we deduce that $\mathcal{I}_\mu$ is coercive on $\mathcal{M}_\mu^*$. Thus this lemma is proved. □

Lemma 2.5. *There exists $\mu_2 \in (0,\mu_1)$ such that, once $\mu \in (0,\mu_2)$, for any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^\pm \neq 0$, there exists a unique pair $(s_u,t_u) \in \mathbb{R}^+\times\mathbb{R}^+$ satisfying $s_u u^+ + t_u u^- \in \mathcal{M}_\mu^-$. Moreover,*

$$\mathcal{I}_\mu(s_u u^+ + t_u u^-) = \max_{s,t>0}\mathcal{I}_\mu(su^+ + tu^-).$$

Proof. Let $0 < \mu < \mu_1$. For any $u \in D^{1,2}(\mathbb{R}^3)$ with $u^\pm \neq 0$, by Lemma 2.2, we recall that $\frac{\partial f_u}{\partial s}$ satisfies

(a) $\frac{\partial f_u}{\partial t}(s,t_2(s)) = 0$ for all $s \ge 0$,

(b) $\frac{\partial^2 f_u}{\partial t^2}(s,t_2(s)) < 0$ for all $s \ge 0$,

(c) $\frac{\partial f_u}{\partial t}(s,t)$ is continuous and has continuous partial derivatives in $[0,+\infty)\times[0,+\infty)$.

Then, applying the implicit function theorem, we have that $\frac{\partial f_u}{\partial t}(s,t) = 0$ determines an implicit function $t_2(s)$ with continuous derivative on $[0,+\infty)$. Similarly, we may deduce that $\frac{\partial f_u}{\partial s}(s,t) = 0$ determines an implicit function $s_2(t)$ with continuous derivative on $[0,+\infty)$. For any $s \ge 0$, from $\frac{\partial f_u}{\partial t}(s,t_2(s)) = 0$ and $\frac{\partial f_u}{\partial t}(s,t) \le 0$ for sufficiently large $t > 0$, we claim that

$$t_2(s) < s \quad \text{for } s > 0 \text{ large enough.} \tag{2.11}$$

If not, for some sufficiently large s, it follows from the definition (2.2) that $\frac{\partial f_u}{\partial t}(s,t_2(s)) < 0$, which contradicts $\frac{\partial f_u}{\partial t}(s,t_2(s)) = 0$. Analogously, there holds that

$$s_2(t) < t \quad \text{for } t > 0 \text{ large enough.} \tag{2.12}$$

Hence, by (2.11), (2.12), $t_2(0) > 0$, $s_2(0) > 0$, the continuity of $t_2(s)$ and $s_2(t)$, we conclude the curves of $t_2(s)$ and $s_2(t)$ intersect at some point $(s_u, t_u) \in \mathbb{R}^+ \times \mathbb{R}^+$. Naturally, $\frac{\partial f_u}{\partial s}(s_u, t_u) = \frac{\partial f_u}{\partial t}(s_u, t_u) = 0$. In addition, from (2.5) and (b) it follows that

$$t_2'(s) = -\frac{\frac{\partial^2 f_u}{\partial t \partial s}(s, t_2(s))}{\frac{\partial^2 f_u}{\partial t^2}(s, t_2(s))} > 0 \quad \text{for any } s > 0.$$

Therefore, for any $s > 0$, we obtain that the function t_2 is increasing in $s \in (0, +\infty)$. Similarly, the function s_2 is increasing in $t \in (0, +\infty)$. Hence, there exists unique pair $(s_u, t_u) \in \mathbb{R}^+ \times \mathbb{R}^+$ such that

$$\frac{\partial f_u}{\partial s}(s_u, t_u) = \frac{\partial f_u}{\partial t}(s_u, t_u) = 0$$

and

$$\frac{\partial^2 f_u}{\partial s^2}(s_u, t_u) < 0, \qquad \frac{\partial^2 f_u}{\partial t^2}(s_u, t_u) < 0,$$

that is, $s_u u^+ + t_u u^- \in \mathcal{M}_\mu^-$. Moreover, we prove (s_u, t_u) is the unique maximum point of f_u on $(\mathbb{R}^+)^2$. For this, it suffices to show $(1, 1)$ is the unique maximum point of f_u on $(\mathbb{R}^+)^2$ for any $u \in \mathcal{M}_\mu^-$. Denote

$$\bar{\mu}_2 = \frac{4S^{\frac{q}{2}}}{(6-q)q|h|_{\frac{6}{6-q}}} \left(\frac{qc^2}{2-q}\right)^{\frac{2-q}{2}}.$$

Set $\mu_2 = \min\{\mu_1, \bar{\mu}_2\}$ and let $\mu \in (0, \mu_2)$. For any $u \in \mathcal{M}_\mu^-$, we consider the Hessian matrix

$$H(u) = \begin{pmatrix} \frac{\partial^2 f_u}{\partial s^2}(1,1) & \frac{\partial^2 f_u}{\partial s \partial t}(1,1) \\ \frac{\partial^2 f_u}{\partial t \partial s}(1,1) & \frac{\partial^2 f_u}{\partial t^2}(1,1) \end{pmatrix}.$$

With (2.5)−(2.7) in hand, we deduce from Lemma 2.4 and the Hölder inequality that the determinant

$$\begin{aligned}
\det H(u) = & \left[4\|u^+\|^2 + \int_{\mathbb{R}^3} \left(2l(x)\phi_{u^+}|u^+|^2 + 4l(x)\phi_{u^+}|u^-|^2\right) dx - \mu(6-q)\int_{\mathbb{R}^3} h(x)|u^+|^q dx\right] \\
& \times \left[4\|u^-\|^2 + \int_{\mathbb{R}^3} \left(2l(x)\phi_{u^-}|u^-|^2 + 4l(x)\phi_{u^+}|u^-|^2\right) dx - \mu(6-q)\int_{\mathbb{R}^3} h(x)|u^-|^q dx\right] \\
& - 4\left(\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2 dx\right)^2 \\
\geq & \left[4\|u^+\|^2 + 4\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2 dx - \mu(6-q)S^{-\frac{q}{2}}|h|_{\frac{6}{6-q}}\|u^+\|^q\right] \\
& \times \left[4\|u^-\|^2 + 4\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2 dx - \mu(6-q)S^{-\frac{q}{2}}|h|_{\frac{6}{6-q}}\|u^-\|^q\right] \\
& - 4\left(\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2 dx\right)^2 \\
\geq & \left\{2\|u^+\|^2 + 4\int_{\mathbb{R}^3} l(x)\phi_{u^+}|u^-|^2 dx - \frac{4-2q}{q}\left[\frac{\mu(6-q)q|h|_{\frac{6}{6-q}}}{4S^{\frac{q}{2}}}\right]^{\frac{2}{2-q}}\right\}
\end{aligned}$$

$$
\begin{aligned}
&\times\left\{2\|u^-\|^2+4\int_{\mathbb{R}^3}l(x)\phi_{u^+}|u^-|^2dx-\frac{4-2q}{q}\left[\frac{\mu(6-q)q|h|_{\frac{6}{6-q}}}{4S^{\frac{q}{2}}}\right]^{\frac{2}{2-q}}\right\}\\
&-4\left(\int_{\mathbb{R}^3}l(x)\phi_{u^+}|u^-|^2dx\right)^2\\
\geq\ &4\int_{\mathbb{R}^3}l(x)\phi_{u^+}|u^-|^2dx\left\{2c^2-\frac{4-2q}{q}\left[\frac{\mu(6-q)q|h|_{\frac{6}{6-q}}}{4S^{\frac{q}{2}}}\right]^{\frac{2}{2-q}}\right\}\\
&+4\int_{\mathbb{R}^3}l(x)\phi_{u^+}|u^-|^2dx\left\{2c^2-\frac{4-2q}{q}\left[\frac{\mu(6-q)q|h|_{\frac{6}{6-q}}}{4S^{\frac{q}{2}}}\right]^{\frac{2}{2-q}}\right\}\\
&+\left\{2c^2-\frac{4-2q}{q}\left[\frac{\mu(6-q)q|h|_{\frac{6}{6-q}}}{4S^{\frac{q}{2}}}\right]^{\frac{2}{2-q}}\right\}\times\left\{2c^2-\frac{4-2q}{q}\left[\frac{\mu(6-q)q|h|_{\frac{6}{6-q}}}{4S^{\frac{q}{2}}}\right]^{\frac{2}{2-q}}\right\}\\
>\ &0,
\end{aligned}
$$

which together with $\frac{\partial^2 f_u}{\partial s^2}(1,1)<0$ implies that $H(u)$ is negative definite. Consequently, there holds that $\mathcal{I}_\mu(u^++u^-)=\max_{s,t>0}\mathcal{I}_\mu(su^++tu^-)$ for any $u\in\mathcal{M}_\mu^-$. Therefore, the proof is completed. □

Lemma 2.6. *Once $\mu\in(0,\mu_2)$, then $\mathcal{M}_\mu^*\neq\emptyset$ and $\mathcal{M}_\mu^*=\mathcal{M}_\mu^-$.*

Proof. It is obvious that $\mathcal{M}_\mu^*\subset\mathcal{M}_\mu^-$. Moreover, for any $u\in\mathcal{M}_\mu^-$, it follows from the proof of Lemma 2.5 that $(1,1)$ is the unique maximum point of $f_u(s,t)$. Observe $f_u(r,r)=\psi_u(r)$, we know that 1 is a maximum point of ψ_u. Naturally, $\psi_u''(1)<0$. By the arbitrariness of $u\in\mathcal{M}_\mu^-$, we derive $\mathcal{M}_\mu^-\subset\mathcal{M}_\mu^*$. That is, $\mathcal{M}_\mu^-=\mathcal{M}_\mu^*$. Then, due to Lemma 2.5, we know $\mathcal{M}_\mu^*\neq\emptyset$. Thus the proof is completed. □

In the forthcoming lemmas, we construct a minimizing sequence of Palais–Smale type for

$$m_\mu^*=\inf_{u\in\mathcal{M}_\mu^*}\mathcal{I}_\mu(u).$$

First, we estimate the level m_μ^*. As we know, the extremal functions of the best Sobolev constant S are

$$U_\varepsilon(\cdot)=\frac{3^{\frac{1}{4}}\varepsilon^{\frac{1}{2}}}{(\varepsilon^2+|\cdot|^2)^{\frac{1}{2}}},\qquad \varepsilon>0.$$

Choose two cut-off functions $\varphi,\psi\in C_0^\infty\left(\mathbb{R}^3,[0,1]\right)$ such that,

$$\varphi(x)=\begin{cases}1, & x\in\mathbb{B}_1(0),\\ 0, & x\in\mathbb{B}_2^c(0),\end{cases}$$

and

$$\psi(x)=\begin{cases}0, & x\in\mathbb{B}_2(0),\\ 1, & x\in\mathbb{B}_4(0)\setminus\mathbb{B}_3(0),\\ 0, & x\in\mathbb{B}_5^c(0).\end{cases}$$

Define $u_\varepsilon(x) = \varphi(x)U_\varepsilon(x)$, $v_\varepsilon(x) = -\psi(x)U_\varepsilon(x)$ and $w_\varepsilon(x) = u_\varepsilon(x) + v_\varepsilon(x)$. Clearly, $w_\varepsilon^+(x) = u_\varepsilon(x)$ and $w_\varepsilon^-(x) = v_\varepsilon(x)$. Following the similar calculations to [3], we conclude that, for $\varepsilon > 0$ small enough,

$$\begin{cases} \int_{\mathbb{R}^3} |\nabla u_\varepsilon|^2 dx = S^{\frac{3}{2}} + O(\varepsilon), \\ \int_{\mathbb{R}^3} |u_\varepsilon|^6 dx = S^{\frac{3}{2}} + O(\varepsilon^3), \\ \int_{\mathbb{R}^3} |u_\varepsilon|^4 dx = O(\varepsilon), \\ \int_{\mathbb{R}^3} |\nabla v_\varepsilon|^2 dx = O(\varepsilon), \\ \int_{\mathbb{R}^3} |v_\varepsilon|^6 dx \in \left[C_1\varepsilon^3, C_2\varepsilon^3\right]. \end{cases} \tag{2.13}$$

Lemma 2.7. *There exists $\mu_3 \in (0, \mu_2)$ such that $0 < m_\mu^* < \frac{1}{3}S^{\frac{3}{2}} - D\mu^{\frac{6}{6-q}}$ for any $\mu \in (0, \mu_3)$, where $D = \frac{6-q}{6}\left[\left(\frac{1}{q} - \frac{1}{4}\right)|h|_{\frac{6}{6-q}}(2q)^{\frac{q}{6}}\right]^{\frac{6}{6-q}}$.*

Proof. Firstly, let

$$\mu < \min\left\{\mu_2, \frac{4q}{(4-q)|h|_{\frac{6}{6-q}}(2q)^{\frac{q}{6}}}\left[\frac{3c^2}{4(6-q)}\right]^{\frac{6-q}{6}}\right\}.$$

From (2.10) and Lemma 2.4, it follows that

$$\mathcal{I}_\mu(u) \geq \frac{1}{4}c^2 - \mu^{\frac{6}{6-q}}\frac{6-q}{6}\left[\left(\frac{1}{q} - \frac{1}{4}\right)|h|_{\frac{6}{6-q}}(2q)^{\frac{q}{6}}\right]^{\frac{6}{6-q}} \geq \frac{1}{8}c^2, \quad \forall\, u \in \mathcal{M}_\mu^*,$$

which implies $m_\mu^* > 0$. Due to Lemma 2.5, there exist some $s_\varepsilon, t_\varepsilon > 0$ such that $s_\varepsilon u_\varepsilon + t_\varepsilon v_\varepsilon \in \mathcal{M}_\mu^*$. Observe $\operatorname{spt} u_\varepsilon \cap \operatorname{spt} v_\varepsilon = \emptyset$, we have

$$\begin{aligned} \mathcal{I}_\mu(s_\varepsilon u_\varepsilon + t_\varepsilon v_\varepsilon) = {} & \frac{s_\varepsilon^2}{2}\|u_\varepsilon\|^2 + \frac{s_\varepsilon^4}{4}\int_{\mathbb{R}^3} l(x)\phi_{u_\varepsilon}u_\varepsilon^2 dx - \frac{s_\varepsilon^6}{6}|u_\varepsilon|_6^6 - \frac{\mu s_\varepsilon^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx \\ & + \frac{t_\varepsilon^2}{2}\|v_\varepsilon\|^2 + \frac{t_\varepsilon^4}{4}\int_{\mathbb{R}^3} l(x)\phi_{v_\varepsilon}v_\varepsilon^2 dx - \frac{t_\varepsilon^6}{6}|v_\varepsilon|_6^6 - \frac{\mu t_\varepsilon^q}{q}\int_{\mathbb{R}^3} h(x)|v_\varepsilon|^q dx \\ & + \frac{1}{2}\int_{\mathbb{R}^3} l(x)\phi_{s_\varepsilon u_\varepsilon}|t_\varepsilon v_\varepsilon|^2 dx. \end{aligned} \tag{2.14}$$

By the semigroup property of convolution (see [16, Theorem 5.9]) and the Young inequality, we have

$$\begin{aligned} & \int_{\mathbb{R}^3} l(x)\phi_{s_\varepsilon u_\varepsilon}|t_\varepsilon v_\varepsilon|^2 dx \\ & = \frac{1}{4\pi}\int_{\mathbb{R}^3}\left(\frac{1}{|x|} * l(x)|s_\varepsilon u_\varepsilon|^2\right) l(x)|t_\varepsilon v_\varepsilon|^2 dx \\ & = \frac{1}{4\pi}\int_{\mathbb{R}^3}\left(\frac{1}{|x|^2} * l(x)|s_\varepsilon u_\varepsilon|^2\right)\left(\frac{1}{|x|^2} * l(x)|t_\varepsilon v_\varepsilon|^2\right) dx \\ & \leq \frac{1}{8\pi}\int_{\mathbb{R}^3}\left(\frac{1}{|x|^2} * l(x)|s_\varepsilon u_\varepsilon|^2\right)^2 + \left(\frac{1}{|x|^2} * l(x)|t_\varepsilon v_\varepsilon|^2\right)^2 dx \\ & = \frac{1}{8\pi}\int_{\mathbb{R}^3}\left(\frac{1}{|x|} * l(x)|s_\varepsilon u_\varepsilon|^2\right) l(x)|s_\varepsilon v_\varepsilon|^2 + \left(\frac{1}{|x|} * l(x)|t_\varepsilon u_\varepsilon|^2\right) l(x)|t_\varepsilon v_\varepsilon|^2 dx \\ & = \frac{s_\varepsilon^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{u_\varepsilon}u_\varepsilon^2 dx + \frac{t_\varepsilon^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{v_\varepsilon}v_\varepsilon^2 dx. \end{aligned}$$

Then, (2.14) can be reduced to

$$\mathcal{I}_\mu(s_\varepsilon u_\varepsilon + t_\varepsilon v_\varepsilon) \le \frac{s_\varepsilon^2}{2}\int_{\mathbb{R}^3}|\nabla u_\varepsilon|^2dx + \frac{s_\varepsilon^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{u_\varepsilon}|u_\varepsilon|^2dx - \frac{s_\varepsilon^6}{6}|u_\varepsilon|_6^6 - \frac{\mu s_\varepsilon^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx + \frac{t_\varepsilon^2}{2}\int_{\mathbb{R}^3}|\nabla v_\varepsilon|^2dx + \frac{t_\varepsilon^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{v_\varepsilon}|v_\varepsilon|^2dx - \frac{t_\varepsilon^6}{6}|v_\varepsilon|_6^6. \tag{2.15}$$

For convenience, we introduce

$$\mathcal{J}_1(\varepsilon) = \frac{s_\varepsilon^2}{2}\int_{\mathbb{R}^3}|\nabla u_\varepsilon|^2dx + \frac{s_\varepsilon^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{u_\varepsilon}u_\varepsilon^2dx - \frac{s_\varepsilon^6}{6}|u_\varepsilon|_6^6 - \frac{\mu s_\varepsilon^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx,$$
$$\mathcal{J}_2(\varepsilon) = \frac{t_\varepsilon^2}{2}\int_{\mathbb{R}^3}|\nabla v_\varepsilon|^2dx + \frac{t_\varepsilon^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{v_\varepsilon}v_\varepsilon^2dx - \frac{t_\varepsilon^6}{6}|v_\varepsilon|_6^6.$$

By Lemma 2.1-(3) and (2.13), for $\varepsilon > 0$ small enough, we get

$$\begin{aligned}\mathcal{J}_1(\varepsilon) &\le s_\varepsilon^2 S^{\frac{3}{2}} + s_\varepsilon^4|l|_2^2 - \frac{s_\varepsilon^6}{12}S^{\frac{3}{2}},\\ \mathcal{J}_2(\varepsilon) &\le C_3 t_\varepsilon^2\varepsilon + C_4 t_\varepsilon^4\varepsilon^2 - C_1 t_\varepsilon^6\varepsilon^3\\ &= C_3\left(t_\varepsilon\sqrt{\varepsilon}\right)^2 + C_4\left(t_\varepsilon\sqrt{\varepsilon}\right)^4 - C_1\left(t_\varepsilon\sqrt{\varepsilon}\right)^6.\end{aligned} \tag{2.16}$$

Define $\mathcal{G}(t) = C_3t^2 + C_4t^4 - C_1t^6$ for $t \ge 0$. We infer that $\mathcal{G}$ has exactly one critical point $t_{\max} > 0$ and $\mathcal{G}(t_{\max}) > \mathcal{G}(0) = 0$. Hence,

$$\mathcal{J}_2(\varepsilon) \le \max_{t\ge 0}\mathcal{G}(t) = \mathcal{G}(t_{\max}). \tag{2.17}$$

Noting $m_\mu^* \le \mathcal{I}_\mu(s_\varepsilon u_\varepsilon + t_\varepsilon v_\varepsilon)$, we deduce from (2.15)−(2.17) that s_ε is bounded from above and below by positive constants. Namely, there exist $S_1, S_2 > 0$ such that $S_1 \le s_\varepsilon \le S_2$ for $\varepsilon > 0$ small enough. From Lemma 2.5, we know $t_\varepsilon = t_2(s_\varepsilon)$ and t_ε is continuous on $[0, +\infty)$. Therefore, t_ε is also bounded from above. Then, by (2.15), (2.13) and Lemma 2.1-(4) we can obtain that, for $\varepsilon > 0$ small enough,

$$\begin{aligned}&\mathcal{I}_\mu(s_\varepsilon u_\varepsilon + t_\varepsilon v_\varepsilon)\\ &\le \max_{s>0}\left(\frac{s^2}{2}\|u_\varepsilon\|^2 - \frac{s^6}{6}|u_\varepsilon|_6^6\right) + \frac{S_2^4}{2}\int_{\mathbb{R}^3} l(x)\phi_{u_\varepsilon}u_\varepsilon^2dx - \frac{\mu S_1^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx + O(\varepsilon)\\ &\le \frac{\|u_\varepsilon\|^3}{3|u_\varepsilon|_6^3} + \frac{1}{2}S_2^4S^{-1}|l|_3^2|u_\varepsilon|_4^4 - \frac{\mu S_1^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx + O(\varepsilon)\\ &\le \frac{1}{3}\frac{\left[S^{\frac{3}{2}} + O(\varepsilon)\right]^{\frac{3}{2}}}{\left[S^{\frac{3}{2}} + O(\varepsilon^3)\right]^{\frac{1}{2}}} - \frac{\mu S_1^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx + O(\varepsilon)\\ &\le \frac{1}{3}S^{\frac{3}{2}} + C_5\varepsilon - \frac{\mu S_1^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx.\end{aligned}$$

Recalling that $h(x) \geq \frac{1}{|x|^\beta}$ for all $|x| \leq 1$ and some $\beta > 3 - \frac{2q}{3}$, if letting $\varepsilon = \mu^{\frac{6}{6-q}}$, we conclude

$$\begin{aligned}
&C_5\varepsilon - \frac{\mu S_1^q}{q}\int_{\mathbb{R}^3} h(x)|u_\varepsilon|^q dx \\
&\leq C_5\varepsilon - \frac{\mu S_1^q}{q}\int_{\mathbb{B}_1(0)} \frac{3^{\frac{q}{4}}\varepsilon^{\frac{q}{2}}}{|x|^\beta(\varepsilon^2+|x|^2)^{\frac{q}{2}}}dx \\
&= C_5\varepsilon - \mu\varepsilon^{3-\frac{q}{2}-\beta}\frac{S_1^q}{q}\int_{\mathbb{B}_{\frac{1}{\varepsilon}}(0)} \frac{3^{\frac{q}{4}}}{|x|^\beta(1+|x|^2)^{\frac{q}{2}}}dx \\
&\leq C_5\varepsilon - C_6\mu\varepsilon^{3-\frac{q}{2}-\beta} \\
&= \mu^{\frac{6}{6-q}}\left[C_5 - C_6\mu^{1+\frac{6}{6-q}(2-\frac{q}{2}-\beta)}\right] \\
&< -D\mu^{\frac{6}{6-q}}
\end{aligned}$$

for $\mu > 0$ small enough. Thus, there exists some small

$$\mu_3 < \min\left\{\mu_2, \frac{4q}{(4-q)|h|_{\frac{6}{6-q}}(2q)^{\frac{q}{6}}}\left[\frac{3c^2}{4(6-q)}\right]^{\frac{6-q}{6}}\right\}$$

such that $m_\mu^* \leq \mathcal{I}_\mu(s_\varepsilon u_\varepsilon + t_\varepsilon v_\varepsilon) < \frac{1}{3}S^{\frac{3}{2}} - D\mu^{\frac{2}{2-q}}$ for any $\mu \in (0, \mu_3)$, the proof is completed. □

Lemma 2.8. *There exists some $\mu^* \in (0, \mu_3)$ such that m_μ^* has a minimizing sequence $\{u_n\} \subset \mathcal{M}_\mu^*$ satisfying $\mathcal{I}'_\mu(u_n) \xrightarrow{n} 0$ in $[D^{1,2}(\mathbb{R}^3)]^*$ for any $\mu \in (0, \mu^*)$.*

Proof. Observe that $\mathcal{I}_\mu$ is coercive on $\mathcal{M}_\mu^*$ due to Lemma 2.4, so $\mathcal{I}_\mu$ is bounded from blow on $\mathcal{M}_\mu^*$. It follows from Lemmas 2.3 and 2.4 that $\mathcal{M}_\mu^*$ is complete. Then, by the Ekeland variational principle, there exists a minimizing sequence $\{u_n\} \subset \mathcal{M}_\mu^*$ such that

$$\begin{aligned}
&m_\mu^* \leq \mathcal{I}_\mu(u_n) \leq m_\mu^* + \frac{1}{n}, \\
&\mathcal{I}_\mu(v) \geq \mathcal{I}_\mu(u_n) - \frac{1}{n}\|v - u_n\|, \qquad \forall\, v \in M_\mu^*.
\end{aligned} \tag{2.18}$$

For each n and $\varphi \in D^{1,2}(\mathbb{R}^3)$, we define the functions $h_n^\pm : \mathbb{R}^3 \to \mathbb{R}$ by

$$\begin{aligned}
h_n^\pm(t,s,\tau) = &\int_{\mathbb{R}^3} \left|\nabla(u_n + t\varphi + su_n^+ + \tau u_n^-)^\pm\right|^2 dx \\
&+ \int_{\mathbb{R}^3} l(x)\phi_{u_n+t\varphi+su_n^+\tau u_n^-}|(u_n + t\varphi + su_n^+ + \tau u_n^-)^\pm|^2 dx \\
&- \int_{\mathbb{R}^3} \left|(u_n + t\varphi + su_n^+ + \tau u_n^-)^\pm\right|^6 dx - \mu\int_{\mathbb{R}^3} h(x)\left|(u_n + t\varphi + su_n^+ + \tau u_n^-)^\pm\right|^q dx.
\end{aligned}$$

It is clear that $h_n^\pm(0,0,0) = 0$ and $h_n^\pm(t,s,\tau)$ are of class C^1. Let $v_n = u_n + t\varphi + su_n^+ + \tau u_n^-$. We have

$$\begin{aligned}
\frac{\partial h_n^+(t,s,\tau)}{\partial s} = &2\int_{\mathbb{R}^3} \nabla v_n^+ \cdot \nabla u_n^+ dx + 2\int_{\mathbb{R}^3} l(x)\phi_{v_n}v_n^+u_n^+ dx \\
&+ 2\int_{\mathbb{R}^3} l(x)\phi_{v_n^+}v_n u_n^+ dx - 6\int_{\mathbb{R}^3} |v_n^+|^5 u_n^+ dx - \mu q\int_{\mathbb{R}^3} h(x)|v_n^+|^{q-1}u_n^+ dx.
\end{aligned}$$

Because of $\{u_n\} \subset \mathcal{M}_\mu^*$, there holds

$$\frac{\partial h_n^+(0,0,0)}{\partial s} = 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^+|^2dx - 4|u_n^+|_6^6 + \mu(2-q)\int_{\mathbb{R}^3} h(x)|u_n^+|^q dx.$$

Through direct calculation, we have

$$\begin{aligned}\frac{\partial h_n^+(t,s,\tau)}{\partial \tau} &= 2\int_{\mathbb{R}^3} \nabla v_n^+ \cdot \nabla u_n^- dx + 2\int_{\mathbb{R}^3} l(x)\phi_{v_n} v_n^+ u_n^- dx \\ &\quad + 2\int_{\mathbb{R}^3} l(x)\phi_{v_n^+} v_n u_n^- dx - 6\int_{\mathbb{R}^3} |v_n^+|^5 u_n^- dx - \mu q\int_{\mathbb{R}^3} h(x)|v_n^+|^{q-1}u_n^- dx,\end{aligned}$$

which implies

$$\frac{\partial h_n^+(0,0,0)}{\partial \tau} = 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2dx > 0. \tag{2.19}$$

Analogously, we can obtain

$$\frac{\partial h_n^-(0,0,0)}{\partial \tau} = 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^-|^2dx - 4|u_n^-|_6^6 + \mu(2-q)\int_{\mathbb{R}^3} h(x)|u_n^-|^q dx \tag{2.20}$$

and

$$\frac{\partial h_n^-(0,0,0)}{\partial s} = 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^+|^2dx > 0.$$

Consider the Jacobi determinant

$$\det M = \begin{vmatrix} \frac{\partial h^+(0,0,0)}{\partial s} & \frac{\partial h^+(0,0,0)}{\partial \tau} \\ \frac{\partial h^-(0,0,0)}{\partial s} & \frac{\partial h^-(0,0,0)}{\partial \tau} \end{vmatrix}.$$

It is easy to see that

$$\begin{aligned}\det M &= \left[2\int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^+|^2dx - 4|u_n^+|_6^6 + \mu(2-q)\int_{\mathbb{R}^3} h(x)|u_n^+|^q dx\right] \\ &\quad \times \left[2\int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^-|^2dx - 4|u_n^-|_6^6 + \mu\,(2-q)\int_{\mathbb{R}^3} h(x)|u_n^-|^q dx\right] \\ &\quad - 4\left(\int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^+|^2dx\right)^2.\end{aligned}$$

Since $\{u_n\} \subset \mathcal{M}_\mu^*$, there results that

$$\begin{aligned}\|u_n^+\|^2 + \int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^+|^2dx + \int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^+|^2dx - |u_n^+|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u_n^+|^q dx = 0, \\ \|u_n^-\|^2 + \int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^-|^2dx + \int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2dx - |u_n^-|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u_n^-|^q dx = 0.\end{aligned}$$

Therefore,

$$\begin{aligned}\det M = &\left[-2\|u_n^+\|^2 - 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2dx - 2|u_n^+|_6^6 + \mu(4-q)\int_{\mathbb{R}^3} h(x)|u_n^+|^q dx\right] \\ &\times \left[-2\|u_n^-\|^2 - 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2dx - 2|u_n^-|_6^6 + \mu(4-q)\int_{\mathbb{R}^3} h(x)|u_n^-|^q dx\right] \\ &- 4\left(\int_{\mathbb{R}^3} l(x)\phi_{u_n^-}|u_n^+|^2dx\right)^2 \\ \geq\ &4\|u_n^+\|^2\|u_n^-\|^2 - 2\mu(4-q)\left(\|u_n^-\|^2 + |u_n^-|_6^6 + \int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2dx\right)\int_{\mathbb{R}^3} h(x)|u_n^+|^q dx \\ &- 2\mu(4-q)\left(\|u_n^+\|^2 + |u_n^+|_6^6 + \int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2dx\right)\int_{\mathbb{R}^3} h(x)|u_n^-|^q dx.\end{aligned} \tag{2.21}$$

Since Lemma 2.7 and (2.10) imply

$$\frac{1}{3}S^{\frac{3}{2}} \geq \frac{1}{4}\|u_n\|^2 - \mu_3^{\frac{6}{6-q}}\frac{6-q}{6}\left[\left(\frac{1}{q}-\frac{1}{4}\right)|h|_{\frac{6}{6-q}}(2q)^{\frac{q}{6}}\right]^{\frac{6}{6-q}},$$

there exists some $C_7 > 0$, independent of μ, such that $\sup_n \|u_n\| \leq C_7$. Then, by the Hölder inequality and Lemma 2.1-(3), we have

$$|u_n^{\pm}|_6^6 \leq S^{-3}\|u_n^{\pm}\|^6 \leq S^{-3}C_7^6$$

and

$$\int_{\mathbb{R}^3} h(x)|u_n^{\pm}|^q dx \leq |h|_{\frac{6}{6-q}}|u_n^{\pm}|_6^q \leq S^{-\frac{q}{2}}|h|_{\frac{6}{6-q}}\|u_n^{\pm}\|^q \leq S^{-\frac{q}{2}}|h|_{\frac{6}{6-q}}C_7^q,$$
$$\int_{\mathbb{R}^3} l(x)\phi_{u_n^+}|u_n^-|^2 dx \leq \left|\phi_{u_n^+}\right|_6\left|l(x)|u_n^-|^2\right|_{\frac{6}{5}} \leq S^{-\frac{1}{2}}|l|_2\left\|\phi_{u_n^+}\right\||u_n^-|_6^2 \leq S^{-3}|l|_2^2C_7^4.$$

Then, if letting $\mu < \mu^*$, where

$$\mu^* = \frac{c^4 S^{\frac{q}{2}}}{2(4-q)|h|_{\frac{6}{6-q}}C_7^{2+q}(1+S^{-3}C_7^4+S^{-3}|l|_2^2C_7^2)},$$

by (2.21) and Lemma 2.4, we obtain

$$\det M \geq 2c^4 > 0. \tag{2.22}$$

Therefore, by the implicit function theorem, there exist δ_n and two functions $s_n(t), \tau_n(t) \in C^1((-\delta_n, \delta_n), \mathbb{R})$ such that $s_n(0) = \tau_n(0)$ and for any $t \in (-\delta_n, \delta_n)$,

$$h_n^{\pm}(t, s_n(t), \tau_n(t)) = 0, \tag{2.23}$$

which means that

$$v_n = u_n + t\varphi + s_n(t)u_n^+ + \tau_n(t)u_n^- \in \mathcal{M}_\mu \quad \text{for } t \in (-\delta_n, \delta_n).$$

Further, according to (2.3) and (2.4), by the continuity, there exists some $\delta_n' \in (0, \delta_n)$ such that $\frac{\partial^2 f_{v_n}}{\partial s^2}(1,1) < 0$ and $\frac{\partial^2 f_{v_n}}{\partial t^2}(1,1) < 0$, i.e.

$$v_n = u_n + t\varphi + s_n(t)u_n^+ + \tau_n(t)u_n^- \in \mathcal{M}_\mu^* \quad \text{for } t \in (-\delta_n', \delta_n'). \tag{2.24}$$

We assert that both $\left\{\frac{s_n'(0)}{\|\varphi\|}\right\}$ and $\left\{\frac{\tau_n'(0)}{\|\varphi\|}\right\}$ are bounded for any $\varphi \in D^{1,2}(\mathbb{R}^3) \setminus \{0\}$. It follows from (2.23) that

$$\begin{cases} \dfrac{\partial h_n^+(0,0,0)}{\partial t} + \dfrac{\partial h_n^+(0,0,0)}{\partial s}s_n'(0) + \dfrac{\partial h_n^+(0,0,0)}{\partial \tau}\tau_n'(0) = 0, \\ \dfrac{\partial h_n^-(0,0,0)}{\partial t} + \dfrac{\partial h_n^-(0,0,0)}{\partial s}s_n'(0) + \dfrac{\partial h_n^-(0,0,0)}{\partial \tau}\tau_n'(0) = 0, \end{cases}$$

where

$$\begin{aligned}\frac{\partial h_n^{\pm}(0,0,0)}{\partial t} &= 2\int_{\mathbb{R}^3}\nabla u_n^{\pm}\cdot\nabla\varphi dx + 2\int_{\mathbb{R}^3} l(x)\phi_{u_n^{\pm}}u_n\varphi dx \\ &\quad + 2\int_{\mathbb{R}^3} l(x)\phi_{u_n}u_n^{\pm}\varphi dx - 6\int_{\mathbb{R}^3}|u_n^{\pm}|^5\varphi dx - \mu q\int_{\mathbb{R}^3}h(x)|u_n^{\pm}|^{q-1}\varphi dx.\end{aligned} \tag{2.25}$$

By Cramer's rule, there results

$$s_n'(0) = \frac{1}{\det M}\left(\frac{\partial h_n^-}{\partial t}\frac{\partial h_n^+}{\partial \tau} - \frac{\partial h_n^+}{\partial t}\frac{\partial h_n^-}{\partial \tau}\right)\Big|_{(0,0,0)}. \tag{2.26}$$

Recalling $\sup_n \|u_n\| \le C_7$, from (2.19), (2.20), (2.25), Lemma 2.1 and the Hölder inequality we deduce

$$\left|\left(\frac{\partial h_n^+}{\partial t}\frac{\partial h_n^-}{\partial \tau} - \frac{\partial h_n^-}{\partial t}\frac{\partial h_n^+}{\partial \tau}\right)\Big|_{(0,0,0)}\right| \le C_8\|\varphi\|.$$

Then, (2.22) and (2.26) imply that $|s_n'(0)| \le C_9\|\varphi\|$ for any $\varphi \in D^{1,2}(\mathbb{R}^3)\setminus\{0\}$. Similarly, we deduce that $|\tau_n'(0)| \le C_{10}\|\varphi\|$ for any $\varphi \in D^{1,2}(\mathbb{R}^3)\setminus\{0\}$. Due to (2.18), there holds that

$$\mathcal{I}_\mu(u_n) - \mathcal{I}_\mu\left(u_n + t\varphi + s_n(t)u_n^+ + \tau_n(t)u_n^-\right) \le \frac{1}{n}\|t\varphi + s_n(t)u_n^+ + \tau_n(t)u_n^-\|.$$

Dividing t in both sides of the above inequality and letting $t \to 0^+$, by $\sup_n \|u_n\| \le C_7$, $|s_n'(0)| \le C_9\|\varphi\|$ and $|\tau_n'(0)| \le C_{10}\|\varphi\|$ we have

$$\left\langle \mathcal{I}_\mu'(u_n), \varphi\right\rangle \le \frac{1}{n}\left\|\varphi + s_n'(0)u_n^+ + \tau_n'(0)u_n^-\right\| \le \frac{C_{11}}{n}\|\varphi\|, \quad \forall\ \varphi \in D^{1,2}(\mathbb{R}^3),$$

which implies

$$\left|\left\langle \mathcal{I}_\mu'(u_n), \varphi\right\rangle\right| \le \frac{C_{11}}{n}\|\varphi\|, \quad \forall\ \varphi \in D^{1,2}(\mathbb{R}^3).$$

Consequently, we obtain that $\mathcal{I}_\mu'(u_n) \to 0$ as $n \to \infty$. Thus, the proof is completed. □

Lemma 2.9. *For any $\mu \in (0, \mu^*)$, every sequence $\{u_n\} \subset \mathcal{M}_\mu^*$ such that $\mathcal{I}_\mu(u_n) \xrightarrow{n} m_\mu^*$ and $\mathcal{I}_\mu'(u_n) \xrightarrow{n} 0$ has a convergent subsequence. Moreover, up to a subsequence, $u_n^\pm \xrightarrow{n} u_\mu^\pm$ in $D^{1,2}(\mathbb{R}^3)$.*

Proof. Since Lemma 2.4 implies that $\mathcal{I}_\mu$ is coercive on $\mathcal{M}_\mu^*$ and Lemma 2.7 implies $m_\mu^* < +\infty$, we deduce that $\{u_n\}$ is bounded in $D^{1,2}(\mathbb{R}^3)$. Up to a subsequence, there exists some $u_\mu \in D^{1,2}(\mathbb{R}^3)$ such that, as $n \to \infty$,

$$u_n \rightharpoonup u_\mu \qquad \text{in } D^{1,2}(\mathbb{R}^3)\cap L^6(\mathbb{R}^3), \tag{2.27}$$

$$u_n(x) \to u_\mu(x) \quad \text{a.e. in } \mathbb{R}^3. \tag{2.28}$$

By using standard arguments, we derive $\mathcal{I}_\mu'(u_\mu) = 0$. From (2.28), it easily follows that $|u_n|^q \rightharpoonup |u_\mu|^q$ in $L^{\frac{6}{q}}(\mathbb{R}^3)$ in the sense of subsequence, which and $h \in L^{\frac{6}{6-q}}(\mathbb{R}^3)$ imply

$$\int_{\mathbb{R}^3} h(x)|u_n|^q dx \xrightarrow{n} \int_{\mathbb{R}^3} h(x)|u_\mu|^q dx. \tag{2.29}$$

Let $v_n = u_n - u_\mu$. By the Brézis–Lieb lemma [22, Lemma 1.32], (2.29) and Lemma 2.1-(6), we have

$$\begin{aligned} m_\mu^* + o(1) = \mathcal{I}_\mu(u_n) &= \frac{1}{2}\|u_n\|^2 + \frac{1}{4}\int_{\mathbb{R}^3} l(x)\phi_{u_n}u_n^2 dx - \frac{1}{6}|u_n|_6^6 - \frac{\mu}{q}\int_{\mathbb{R}^3} h(x)|u_n|^q dx \\ &= \frac{1}{2}\|v_n\|^2 - \frac{1}{6}|v_n|_6^6 + \mathcal{I}_\mu(u_\mu) \end{aligned} \tag{2.30}$$

and

$$o(1) = \left\langle \mathcal{I}'_\mu(u_n), u_n \right\rangle = \|u_n\|^2 + \int_{\mathbb{R}^3} l(x)\phi_{u_n}u_n^2 dx - |u_n|_6^6 - \mu\int_{\mathbb{R}^3} h(x)|u_n|^q dx$$
$$= \|v_n\|^2 - |v_n|_6^6. \tag{2.31}$$

Denote $\limsup_{n\to\infty}\|v_n\|^2 = a$. By (2.31) and the definition of the best Sobolev constant, we get $a \le S^{-3}a^3$, which implies either $a = 0$ or $a \ge S^{\frac{3}{2}}$. We claim that $a \ge S^{\frac{3}{2}}$ can't occur. From $\mathcal{I}'_\mu(u_\mu) = 0$, (2.30), (2.31) and (2.10), it follows that

$$m^*_\mu = \lim_{n\to\infty}\left[\frac{1}{3}\|v_n\|^2 + \mathcal{I}_\mu(u_\mu) - \frac{1}{4}\langle \mathcal{I}'_\mu(u_\mu), u_\mu\rangle\right] \ge \frac{1}{3}S^{\frac{3}{2}} - D\mu^{\frac{6}{6-q}},$$

which together with Lemma 2.7 gives a contradiction. Therefore, $a = 0$. That is, $u_n \to u_\mu$ in $D^{1,2}(\mathbb{R}^3)$.

Further, we prove $u_n^\pm \to u_\mu^\pm$ in $D^{1,2}(\mathbb{R}^3)$. It follows from $\{u_n\} \subset \mathcal{M}^*_\mu$ and $\mathcal{I}'_\mu(u_\mu) = 0$ that

$$\begin{cases} \|u_n^\pm\|^2 + \int_{\mathbb{R}^3} l(x)\phi_{u_n}|u_n^\pm|^2 dx = |u_n^\pm|_6^6 + \mu\int_{\mathbb{R}^3} h(x)|u_n^\pm|^q dx, \\ \|u_\mu^\pm\|^2 + \int_{\mathbb{R}^3} l(x)\phi_{u_\mu}|u_\mu^\pm|^2 dx = |u_\mu^\pm|_6^6 + \mu\int_{\mathbb{R}^3} h(x)|u_\mu^\pm|^q dx. \end{cases} \tag{2.32}$$

It is easy to verify that

$$|u_n^\pm(x) - u_\mu^\pm(x)| \le |u_n(x) - u_\mu(x)|, \qquad \forall\, x \in \mathbb{R}^3, \tag{2.33}$$

which and $u_n \to u_\mu$ in $D^{1,2}(\mathbb{R}^3)$ lead to

$$\left||u_n^\pm|_6 - |u_\mu^\pm|_6\right|^6 \le \left|u_n^\pm - u_\mu^\pm\right|_6^6 \le |u_n - u_\mu|_6^6 \le S^{-3}\|u_n - u_\mu\|^6 \xrightarrow{n} 0. \tag{2.34}$$

Noting $u_n \to u_\mu$ in $L^6(\mathbb{R}^3)$, we deduce $|u_n^\pm|^q \rightharpoonup |u_\mu^\pm|^q$ in $L^{\frac{6}{q}}(\mathbb{R}^3)$ in the sense of subsequence. Therefore,

$$\int_{\mathbb{R}^3} h(x)|u_n^\pm|^q dx \xrightarrow{n} \int_{\mathbb{R}^3} h(x)|u_\mu^\pm|^q dx. \tag{2.35}$$

Moreover, since $l \in L^2(\mathbb{R}^3)$ and $|u_n - u_\mu|_6 \to 0$ implies that $\left||u_n^\pm|^2 - |u_\mu^\pm|^2\right|^{\frac{6}{5}} \rightharpoonup 0$ in $L^{\frac{5}{2}}(\mathbb{R}^3)$ up to a subsequence, by the Hölder inequality and Lemma 2.1-(3) we have

$$\begin{aligned}\left|\int_{\mathbb{R}^3} l(x)\phi_{u_n}(|u_n^\pm|^2 - |u_\mu^\pm|^2)dx\right| &\le |\phi_{u_n}|_6\left(\int_{\mathbb{R}^3}|l(x)|^{\frac{6}{5}}\left||u_n^\pm|^2 - |u_\mu^\pm|^2\right|^{\frac{6}{5}}dx\right)^{\frac{5}{6}} \\ &\le S^{-1}|l|_2|u_n|_6^2\left(\int_{\mathbb{R}^3}|l(x)|^{\frac{6}{5}}\left||u_n^\pm|^2 - |u_\mu^\pm|^2\right|^{\frac{6}{5}}dx\right)^{\frac{5}{6}} \\ &\xrightarrow{n} 0. \end{aligned} \tag{2.36}$$

Observe $|lu_\mu^\pm|^2 \in L^{\frac{6}{5}}(\mathbb{R}^3)$, we deduce from (2.27) and Lemma 2.1-(5) that

$$\left|\int_{\mathbb{R}^3} l(x)(\phi_{u_n} - \phi_{u_\mu})|u_\mu^\pm|^2 dx\right| \xrightarrow{n} 0,$$

by which and (2.36) we get

$$\int_{\mathbb{R}^3} l(x)\phi_{u_n}|u_n^{\pm}|^2dx \xrightarrow{n} \int_{\mathbb{R}^3} l(x)\phi_{u_\mu}|u_\mu^{\pm}|^2dx. \tag{2.37}$$

Now, by combining (2.32), (2.34), (2.35) and (2.37) we conclude $\|u_n^{\pm}\|^2 \to \|u_\mu^{\pm}\|^2$, which together with (2.27) implies $u_n^{\pm} \xrightarrow{n} u_\mu^{\pm}$ in $D^{1,2}(\mathbb{R}^3)$. Thus the lemma is proved. □

Next, with the above preliminary lemmas in hand, we end the proof of our main result.

Proof of Theorem 1.1. For any $\mu \in (0, \mu^*)$, due to Lemmas 2.8 and 2.7, there exists a sequence $\{u_n\} \subset \mathcal{M}_\mu^*$ such that, as $n \to \infty$,

$$\mathcal{I}_\mu(u_n) \to m_\mu^* \in \left(0, \frac{1}{3}S^{\frac{3}{2}} - D\mu^{\frac{6}{6-q}}\right) \quad \text{and} \quad \mathcal{I}'_\mu(u_n) \to 0 \text{ in } \left[D^{1,2}(\mathbb{R}^3)\right]^*.$$

According to Lemma 2.9, up to a subsequence, there exists some u_μ satisfying $u_n \to u_\mu$ and $u_n^{\pm} \to u_\mu^{\pm}$ in $D^{1,2}(\mathbb{R}^3)$ as $n \to \infty$. Therefore, we get $\mathcal{I}'_\mu(u_\mu) = 0$ and $\mathcal{I}_\mu(u_\mu) = m_\mu^*$. Moreover, Lemma 2.4 says $\|u_n^{\pm}\| \geq c > 0$, which implies $u_\mu^{\pm} \neq 0$. By combining the above arguments, we know that u_μ is a sign-changing solution of system (1.6) with positive energy. Thus Theorem 1.1 is proved. □

Communicated by Armengol Gasull

Abstract. In this paper, we investigate the existence and uniqueness of crossing periodic solutions for a class of mixed-type second order Duffing equations with discontinuity and asymmetry. By the Poincaré–Bohl theorem, we obtain several existence criteria of regular periodic solutions which are crossing. We also present a uniqueness result.

Keywords: discontinuity, Duffing equation, Poincaré–Bohl theorem, crossing periodic solution, existence and uniqueness.

2020 Mathematics Subject Classification: 34A36, 34A34, 34A12, 34C25.

1 Introduction

Second order Duffing equation

$$x'' + g(x) = p(t), \tag{1.1}$$

is one of the typical models both in ODE and forced vibrations, where g is an elastic force and p is an external excitation. There have been many interesting results reported concerning the existence of periodic solutions. The methods involve the Poincaré–Birkhoff twist theorem, the Poincaré–Bohl theorem, averaging theory, variational method and the Leray–Schauder continuation method of topological degree etc., see for example [3–6, 9, 22–26] and the references therein.

In the paper, we are concerned with Eq. (1.1) with discontinuous vector field, in which g presents a discontinuity at $\alpha \in \mathbb{R}$ and it satisfies asymmetric conditions, and then we called it as discontinuous mixed-type Duffing equations. During the last decades, the amount of publications on the discontinuous differential equations is vast. We refer readers to consult classical monographs [8, 19] for the general theory, and literatures [7, 11, 12, 17, 18] for some related research. In [8], the author extend discontinuous differential equations to differential inclusions, he revealed many aspects of discontinuous differential equations and addressed existence and uniqueness of solutions. More results on the differential inclusion can be found

✉ Email: jiangfangfang87@126.com

in [1]. Inspired by these, we consider the existence and uniqueness of periodic solutions for the following second order Duffing equations allowing for discontinuities at 0

$$x'' + g_{\pm}(x) = p(t), \qquad x \neq 0, \tag{1.2}$$

where $p(t) = p(t + 2\pi)$, $g_{\pm}(x)$ are of class C^1 and satisfy the asymmetric growth condition

$$0 \leq \lim_{x\to-\infty} \frac{g_-(x)}{x} < +\infty, \qquad \lim_{x\to+\infty} \frac{g_+(x)}{x} = +\infty. \tag{1.3}$$

Many existing literatures, whether continuous or not, focused on periodic solution problem of Duffing equations with symmetric growth condition. But there is no study about the discontinuous Duffing equation with the asymmetric condition. According to the relationship of linear growth satisfied by the elastic force g, the Duffing equations can be divided into three categories:

(S_p) Superlinear growth: $\lim_{|x|\to\infty} \frac{g(x)}{x} = +\infty$;

(S_m) Semilinear growth: $0 < \liminf_{|x|\to\infty} \frac{g(x)}{x} \leq \limsup_{|x|\to\infty} \frac{g(x)}{x} < \infty$;

(S_b) Sublinear growth: $\lim_{|x|\to\infty} \frac{g(x)}{x} = 0$.

On the other hand, when g satisfies different linear growth conditions for $x \in \mathbb{R}$, it means that the processing method is also different from the one of symmetric Duffing equations. Recently, there are a few papers on the periodic solution problem of discontinuous symmetric Duffing equations (with impulsive perturbations or discontinuous vector field), in which the elastic force g satisfies one of the above linear growth conditions, see [2,10,12–16,18,20,21] for example and the references therein. However, in this paper we consider the existence criteria of crossing periodic solutions of (1.2) when $g_{\pm}(x)$ satisfy different linear growth conditions (1.3) for $x \in \mathbb{R}$. And a uniqueness theorem is also presented.

To obtain the desirable results, we first assume that $g_{\pm}$ satisfy the following conditions.

$(H1)$ Let $g_+ \in C^1([0, +\infty), \mathbb{R})$, $g_- \in C^1((-\infty, 0], \mathbb{R})$, and the behavior of $g_{\pm}$ at the discontinuity point $x = 0$ satisfies that the left and right limits

$$g_- = \lim_{x\to0^-} g_-(x), \qquad g_+ = \lim_{x\to0^+} g_+(x)$$

exist and are finite, and satisfy $g_- < 0 < g_+$.

$(H2)$ There are two real numbers d_1 and d_2 with $d_1 < 0 < d_2$ such that

$$x \leq d_1 \Rightarrow g_-(x) < 0, \qquad x \geq d_2 \Rightarrow g_+(x) > 0.$$

$(H3)$ There are positive constants l_-, l_+, L_- and A_1 such that the asymptotic growth of $g_{\pm}$ is controlled by

$$l_- \leq \frac{g_-(x)}{x} \leq L_-, \quad x \leq -A_1; \qquad \frac{g_+(x)}{x} \geq l_+, \quad x \geq A_1. \tag{1.4}$$

Moreover, there exists an integer $m > 0$ that satisfies

$$\frac{2}{m+1} < \frac{1}{\sqrt{L_-}} \leq \frac{1}{\sqrt{l_-}} + \frac{1}{\sqrt{l_+}} < \frac{2}{m}. \tag{1.5}$$

Then by applying the Poincaré–Bohl theorem to the discontinuous Duffing equation (1.2) with the asymmetric growth condition, we obtain several existence criteria of crossing periodic solutions as follows.

Theorem 1.1. *Assume that* $(H1)$–$(H3)$ *hold. Then* (1.2) *has at least one* 2π *crossing periodic solution.*

Note that (1.4) means that g_- satisfies semilinear growth for $x \le -A_1$, while g_+ can satisfy both semilinear growth and superlinear growth when $x \ge A_1$. Further we have that

$$\lim_{x\to-\infty} g_-(x) = -\infty, \qquad \lim_{x\to+\infty} g_+(x) = +\infty. \tag{1.6}$$

Theorem 1.2. *In Theorem 1.1, if* $(H3)$ *is replaced as* (1.6) *and*

$(H3)'$ *There exist* $L_- \in (0, \frac{1}{4})$ *and* $A_1 > 0$ *such that*

$$\frac{g_-(x)}{x} \le L_-, \qquad x \le -A_1.$$

Then (1.2) *has at least one* 2π *crossing periodic solution.*

Theorem 1.3. *In Theorem 1.1, if* $(H3)$ *is replaced as*

$(H3)^*$ *There are positive constants* l_-, L_-, A *and an integer* $m > 0$ *such that* $\lim_{x\to+\infty} \frac{g_+(x)}{x} = +\infty$, *and*

$$\frac{1}{4}m^2 < l_- \le \frac{g_-(x)}{x} \le L_- < \frac{1}{4}(m+1)^2, \qquad x \le -A. \tag{1.7}$$

Then (1.2) *has at least one* 2π *crossing periodic solution.*

Moreover, for the completeness of the paper we further provide a uniqueness criterion.

Theorem 1.4. *Assume that* $g_\pm$ *are Lipschitz continuous and satisfy* $0 < \frac{g_\pm(x)-g_\pm(y)}{x-y} < 1$ *for any* $x, y \in \mathbb{R} \setminus \{0\}$. *Then* (1.2) *has at most one* 2π *crossing periodic solution.*

This paper is organized as follows. In Section 2, we present some useful preliminaries. In Sections 3–4, we give the behavior of solutions for the autonomous and non-autonomous systems, respectively. Then by applying the Poincaré–Bohl theorem, we obtain several existence criteria of 2π crossing periodic solutions. And we also prove the uniqueness. Moreover, to demonstrate the effectiveness of the obtained results, we further provide an example in Section 5. Concluding remarks are outlined in Section 6.

2 Preliminaries

Consider the second order Duffing equation

$$x'' + g(x) = p(t), \tag{2.1}$$

where $p : \mathbb{R} \to \mathbb{R}$ is continuous and 2π-periodic, and denote by

$$E = \max_{t\in[0,2\pi]}\{|p(t)|\}, \qquad \overline{E} = \max_{t\in[0,2\pi]}\{p(t)\}, \qquad \underline{E} = \min_{t\in[0,2\pi]}\{p(t)\}. \tag{2.2}$$

While $g : \mathbb{R} \to \mathbb{R}$ is continuous except for a discontinuity point at $x = 0$. Assume that $\Sigma_0 = \{(x,y) \in \mathbb{R}^2 : x = 0\}$ divide $g(x)$ of the form

$$g(x) = \begin{cases} g_+(x), & x > 0, \\ g_-(x), & x < 0. \end{cases} \tag{2.3}$$

Here Σ_0 is called as a discontinuity line on the plane, and we denote by

$$\begin{aligned} \Sigma_0^+ &= \{(x,y) : x = 0, y > 0\}, \qquad & \Sigma_0^- &= \{(x,y) : x = 0, y < 0\}, \\ \Sigma_+ &= \{(x,y) \in \mathbb{R}^2 : x > 0\}, \qquad & \Sigma_- &= \{(x,y) \in \mathbb{R}^2 : x < 0\}. \end{aligned}$$

Then $\Sigma_0 = \Sigma_0^+ \cup \{O\} \cup \Sigma_0^-$, $\mathbb{R}^2 = \Sigma_+ \cup \Sigma_0 \cup \Sigma_-$, and the unit normal vector perpendicular to Σ_0 is taken to be $\mathbf{n}^T = (1,0)$.

We recall an existence result of periodic solutions from the Poincaré–Bohl theorem.

Theorem 2.1 ([26, Theorem 1.2 of Chapter VI]). *Suppose that $\mathcal{F} : \mathbb{D} \to \mathbb{R}^2$ is a continuous mapping, where $\mathbb{D}(\subset \mathbb{R}^2)$ is a closed bounded region including the origin as an interior point, the boundary $\partial\mathbb{D}$ is a piecewise smooth simple closed curve. For any $p \in \partial\mathbb{D}$ then the image $q = \mathcal{F}(p)$ satisfies $\overrightarrow{Oq} \neq \lambda\overrightarrow{Op}$, where $\lambda \geq 1$ is a constant. Then $\mathcal{F}$ has at least one fixed point in $\mathbb{D}$.*

It is sufficient to prove that any orbit which starts from $p = (x(0), x'(0)) \in \partial\mathbb{D}$ and moves to $q = (x(2\pi), x'(2\pi)) \in \mathbb{R}^2 \setminus \mathbb{D}$, then the points p and q are not on the same ray starting from the origin.

In what follows, we consider the equivalent system of (2.1) and (2.3)

$$\begin{cases} x' = y, \\ y' = -g_+(x) + p(t), \quad x > 0; \end{cases} \qquad \begin{cases} x' = y, \\ y' = -g_-(x) + p(t), \quad x < 0. \end{cases} \tag{2.4}$$

Let $\mathbf{V}_\pm(t;x,y) = (y, -g_\pm(x) + p(t))^T$ denote the vector field of (2.4). The second component of $\mathbf{V}_\pm$ is discontinuous on Σ_0, so by using Filippov theory to define orbits of (2.4) when they intersect with Σ_0 such that the orbits can be concatenated in a natural way. Concretely, the set-valued extension as follows

$$z'(t) \in \mathbf{V}(t;x,y) = \begin{cases} \mathbf{V}_+(t;x,y), & x > 0, \\ \overline{co}\{\mathbf{V}_+(t;x,y), \mathbf{V}_-(t;x,y)\}, & x = 0, \\ \mathbf{V}_-(t;x,y), & x < 0, \end{cases} \tag{2.5}$$

where $z(t) \doteq (x(t), y(t))^T$, $\mathbf{V}(t;x,y) \doteq \mathbf{V}(t;x(t),y(t))$, and $\overline{co}(A)$ denotes the smallest closed convex set containing A. The convex set with $\mathbf{V}_-$ and $\mathbf{V}_+$ is of the form

$$\overline{co}\{\mathbf{V}_+, \mathbf{V}_-\} = \{(1-q)\mathbf{V}_- + q\mathbf{V}_+, \ \forall q \in [0,1]\},$$

here q is a parameter which defines the convex combination. The extension of (2.4) into the convex differential inclusion (2.5) is known as the Filippov's convex method. The existence of solutions of (2.5) is guaranteed with an upper semi-continuity of set-valued functions, and the existence of solutions of an initial value problem (IVP for short)

$$z'(t) \in \mathbf{V}(t;x,y), \qquad z(0) = (x_0, y_0)^T$$

combines with Filippov's convex method define the solutions of (2.4). For more details, we refer readers to consult [1,8] and the references therein.

In this paper, we deal with the periodic solutions that appear when the discontinuity line Σ_0 is considered, and the solution $t \to (x(t), x'(t))$ vanishes twice per period. These solutions are built piecewise, from restrictions to some subintervals of solutions of $x'' + g_+(x) = p(t)$ (*resp.* $x'' + g_-(x) = p(t)$) vanishing at the bounds of the corresponding subinterval. Now we give the following definitions concerning what kind of solutions we are looking for.

Definition 2.2 ([12])**.** Let I be an interval of $\mathbb{R}$ and $x : I \to \mathbb{R}$ be any solution of (2.4). We say that x is singular if there exists $t^* \in I$ such that $x(t^*) = x'(t^*) = 0$. A non-singular solution is said to be regular.

Definition 2.3. We say that $x : \mathbb{R} \to \mathbb{R}$ is a regular solution of (2.4) if it is continuous to t, and there exists a strictly increasing sequence $(t_j)_{j\in\mathbb{Z}}$, with no accumulation points, such that $x(t_j) = 0, x'(t_j) \neq 0$ and the restriction of x on each interval $[t_{j-1}, t_j]$ is twice continuously differentiable. Moreover, the limits $\lim_{t\to t_j^-} x''(t)$ and $\lim_{t\to t_j^+} x''(t)$ exist and are finite.

By $(H1)$, we assume the existence of solutions to the IVP of (2.4) with $z(0) = (x_0, y_0)^T$. And from the above statements, any solution of IVP with the initial condition $(x_0, y_0) \notin \Sigma_0$ is locally unique, because $\mathbf{V}_+(t; x, y)$ and $\mathbf{V}_-(t; x, y)$ are of class C^1. While for the uniqueness problem of IVP with the initial condition on Σ_0, there are three basic ways in which the vector field around Σ_0 can behave as follows.

(1) Transversal intersection.

Any solution of IVP with the initial condition $(x_0, y_0) \in \Sigma_+$/or $(x_0, y_0) \in \Sigma_-$, exists and is unique. A necessary condition for the transversal intersection at Σ_0 is

$$[\mathbf{n}^T\mathbf{V}_-(t; x, y)] \cdot [\mathbf{n}^T\mathbf{V}_+(t; x, y)] > 0, \qquad (x, y) \in \Sigma_0,$$

where $\mathbf{n}^T\mathbf{V}_-$ and $\mathbf{n}^T\mathbf{V}_+$ are projections of $\mathbf{V}_-$ and $\mathbf{V}_+$ on the normal vector to Σ_0.

(2) Attraction sliding mode (i.e. Σ_0 attracts the solution). Here the solution will hit Σ_0 but cannot leave it and then move along Σ_0.

Any solution of IVP exists and is unique in the forward time. During the sliding mode, the solution will continue along Σ_0 with the vector field $\widetilde{\mathbf{V}}$ being given by

$$\widetilde{\mathbf{V}} = \alpha\mathbf{V}_+ + (1 - \alpha)\mathbf{V}_-, \qquad \alpha = \frac{n^T\mathbf{V}_-}{n^T(\mathbf{V}_- - \mathbf{V}_+)},$$

where the parameter α is chosen such that the vector field $\widetilde{\mathbf{V}}$ lies along Σ_0. An attraction sliding mode at Σ_0 occurs if

$$\mathbf{n}^T\mathbf{V}_-(t; x, y) > 0, \quad \mathbf{n}^T\mathbf{V}_+(t; x, y) < 0, \qquad (x, y) \in \Sigma_0.$$

(3) Repulsion sliding mode (i.e. the vector field is repulsing from Σ_0). Here the solution is diverging from Σ_0.

The IVP with the initial condition on Σ_0 has three possible solutions. In fact, a solution which starts close to Σ_0 will move away from it, but a solution emanating on Σ_0 can stay on Σ_0, obeying Filippov's solution, or leave Σ_0 by entering either Σ_+ or Σ_-. Hence the solution exists but is not unique in forward time.

Remark 2.4. Note that the solution of (2.4) passing through the origin is not unique. For example, we consider

$$g_+(0) - p(t) < 0, \qquad g_-(0) - p(t) > 0.$$

A qualitative sketch of the dynamics is as shown in Figure 2.1. There are two orbits passing through the origin: one is contained in Σ_+ involving the system with g_+, the other is contained in Σ_- involving the system with g_-, but it is not clear that which one should be the unique solution.

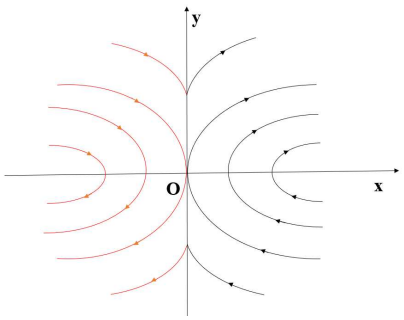

Figure 2.1: Schematic diagram

Definition 2.5. For any given $(0, y) \in \Sigma_0$, if

$$[\mathbf{n}^T \mathbf{V}_-(t; 0^-, y)] \cdot [\mathbf{n}^T \mathbf{V}_+(t; 0^+, y)] \leq 0,$$

$(0, y)$ is called to be *a sliding point*. A set of sliding points is called as a sliding set. We say $(0, y)$ a *crossing point*, if

$$[\mathbf{n}^T \mathbf{V}_-(t; 0^-, y)] \cdot [\mathbf{n}^T \mathbf{V}_+(t; 0^+, y)] > 0.$$

Then the origin is the unique possible sliding point on Σ_0, and it is an isolated and singular sliding point.

Definition 2.6. *A crossing periodic orbit* is defined as a closed orbit with no points in common with the sliding set.

In conclusion, any regular orbit of (2.4) not passing through the origin on the phase plane exists and is unique. In the next text, we focus on the crossing solutions (or orbits) of (2.4) exception for the origin. To be precise, we discuss large-amplitude *crossing periodic orbits* of (2.4). They intersect with Σ_0 transversally, *i.e.* the transversal intersection case. For more information about the existence and uniqueness of solutions of discontinuous differential equations, please see [8, 11, 17] for example and the references therein.

3 Autonomous system

The autonomous equation

$$x'' + g_\pm(x) = 0, \qquad x \neq 0, \tag{3.1}$$

which is equivalent to the system

$$\begin{cases} x' = y, \\ y' = -g_+(x), \quad x > 0; \end{cases} \qquad \begin{cases} x' = y, \\ y' = -g_-(x), \quad x < 0. \end{cases} \tag{3.2}$$

Let $G(x) = \int_0^x g_\pm(u)du$ with $G(0) = 0$, it follows from $(H3)$ that

$$\lim_{x\to-\infty} G(x) = \lim_{x\to+\infty} G(x) = +\infty. \tag{3.3}$$

Then the function G has a minimum on $\mathbb{R}$, by adding a suitable constant we can assume without loss of generality that $G(x) \geq 0$ for every $x \in \mathbb{R}$.

For the system (3.2) we have a Hamiltonian function $H : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ defined as

$$H(x, y) = \frac{1}{2}y^2 + G(x).$$

Note that H is not of class C^1 in $\mathbb{R}^2$, since G is continuous but not differentiable at $x = 0$. The orbits of the crossing solutions are symmetric with respect to the horizontal axis, and they lie on the level sets of the Hamiltonian function, i.e.,

$$L^c = \{(x, y) \in \mathbb{R}^2 : H(x, y) = c\}.$$

The level sets L^c are compact, and consequently the crossing solutions of (3.1) are globally defined.

We are now concentrate on the dynamics both near the origin $O(0, 0)$.

Lemma 3.1. *The origin is a local center for (3.2); if $c > 0$ is small sufficiently, the level set L^c is a closed curve, star-shaped with respect to the origin, corresponding to the crossing periodic solution of (3.2). The same is true for $c > 0$ being large enough.*

Proof. By $(H1)$, there exists a $\delta > 0$ such that for every $x \in [-\delta, 0) \cup (0, \delta]$ we have that

$$xg_\pm(x) > x^2.$$

Let $z(t) = (x(t), y(t))$ be a crossing solution of (3.2) with $x(t) \in [-\delta, 0) \cup (0, \delta]$ for some $t \in \mathbb{R}$. Making the following polar coordinates transformation

$$x(t) = r(t)\cos\theta(t), \qquad y(t) = r(t)\sin\theta(t), \tag{3.4}$$

where $r : [0, 2\pi] \to (0, +\infty)$ and $\theta : [0, 2\pi] \to \mathbb{R}$ are continuous functions, we have that

$$-\theta'(t) = \frac{x'(t)y(t) - x(t)y'(t)}{x^2(t) + y^2(t)} = \frac{x(t)g_\pm(x(t)) + y^2(t)}{x^2(t) + y^2(t)} \geq 1. \tag{3.5}$$

We observe that for $x \in [-\delta, 0) \cup (0, \delta]$,

$$\nabla H(x, y) \cdot (x, y)^T = xg_\pm(x) + y^2 > 0.$$

Hence near the origin, $H(x, y)$ is strictly increasing along the rays emanating from the origin, at least in a small neighborhood of the origin. Then a solution starting with initial point $(x(0), y(0)) \neq (0, 0)$ sufficiently near the origin, on a given ray, will remain in the strip $\{(x, y) : |x| < \delta\}$ for every $t \in [0, 2\pi]$, and during this time it will perform an entire rotation, returning to the initial ray, by (3.5). Since $H(x, y)$ is constant along the orbit, it must indeed return to the same initial point. This proves that the small-amplitude crossing solutions of (3.2) are periodic and from (3.5) they have star-shaped orbits with respect to the origin.

We next consider a large-amplitude crossing solutions of (3.2). From $(H2)$ and set $M = \max\{|xg_{\pm}(x)| : x \in [d_1, d_2]\}$. Let $(x(t), y(t))$ be a crossing solution of (3.2) with $(x(t), y(t)) \neq [d_1, d_2] \times [-\sqrt{M}, \sqrt{M}]$ and $x(t) \neq 0$ for some $t \in \mathbb{R}$. Then it follows from (3.4) that

$$-\theta'(t) \begin{cases} \geq \frac{-M+y^2(t)}{x^2(t)+y^2(t)} > 0, & x(t) \in [d_1, d_2], \\ > \frac{y^2(t)}{x^2(t)+y^2(t)} \geq 0, & x(t) \notin [d_1, d_2]. \end{cases}$$

The same argument shows that far from the origin then $H(x, y)$ is strictly increasing along the rays emanating from the origin. Let

$$\overline{S} = \max\{H(x, y) : (x, y) \in [d_1, d_2] \times [-\sqrt{M}, \sqrt{M}]\},$$

and set $K = \sqrt{2\overline{S}}$. By $(H3)$ there exist $\widehat{d}_1, \widehat{d}_2$ with $\widehat{d}_1 \leq d_1 < 0 < d_2 \leq \widehat{d}_2$ such that

$$x \notin [\widehat{d}_1, \widehat{d}_2] \Rightarrow G(x) > \overline{S}.$$

We claim that if (x, y) is a crossing solution of (3.2) with $(x(0), y(0)) \notin [\widehat{d}_1, \widehat{d}_2] \times [-K, K]$, then $(x(t), y(t)) \notin [d_1, d_2] \times [-\sqrt{M}, \sqrt{M}]$ for every $t \in \mathbb{R}$. Once the claim is proved, the above argument used for the small-amplitude crossing solutions can be applied, and consequently the large-amplitude crossing solutions of (3.2) are periodic and have star-shaped orbits with respect to the origin.

We let (x, y) be a crossing solution of (3.2) such that $(x(0), y(0)) \notin [\widehat{d}_1, \widehat{d}_2] \times [-K, K]$. There are two cases. Either $x(0) \notin [\widehat{d}_1, \widehat{d}_2]$, in which case $G(x(0)) > \overline{S}$, hence

$$H(x(t), y(t)) = H(x(0), y(0)) \geq G(x(0)) > \overline{S}, \qquad t \in \mathbb{R};$$

or $x(0) \in [\widehat{d}_1, \widehat{d}_2]$ and $y(0) \notin [-K, K]$, in which case $\frac{1}{2}y^2(0) > \overline{S}$, hence

$$H(x(t), y(t)) = H(x(0), y(0)) \geq \frac{1}{2}y^2(0) > \overline{S}, \qquad t \in \mathbb{R}.$$

By the definition $\overline{S}$, in both cases then $(x(t), y(t)) \notin [d_1, d_2] \times [-\sqrt{M}, \sqrt{M}]$ for every $t \in \mathbb{R}$. □

For every positive numbers $c_1 < c_2$, define the set

$$A(c_1, c_2) = \left\{(x, y) \in \mathbb{R}^2 : c_1 \leq \frac{1}{2}y^2 + G(x) \leq c_2\right\}.$$

Then it follows from Lemma 3.1 that when $c_1 > 0$ is small enough and $c_2 > c_1$ is large enough, the set $A(c_1, c_2)$ is an annulus with strictly star-shaped boundary curves. Moreover, all crossing solutions of (3.2) with the associated initial value

$$(x(0), y(0)) = (x_0, y_0) \in \mathbb{R} \times \mathbb{R}$$

are regular, with the only exception for $(x_0, y_0) = (0, 0)$, in which case the solution is not defined. Further we agree that the origin will be considered as a singular point defined as in Definition 2.2.

Remark 3.2. If we consider c_1 and c_2 satisfying the above properties as fixed in Lemma 3.1. It is easy to see that we can choose a constant $\rho > 1$ such that for every $(x, y) \in \mathbb{R}^2$

$$\frac{1}{2}y^2 + G(x) \geq c_1 \Rightarrow x^2 + y^2 > \rho^{-1},$$
$$\frac{1}{2}y^2 + G(x) \leq c_2 \Rightarrow x^2 + y^2 < \rho.$$

Lemma 3.1 implies that all regular solutions (or regular orbits) of (3.1), exception for the origin, cross Σ_0 transversally in a clockwise fashion. For example see Figure 3.1: crossing periodic orbits of $x'' + x + \operatorname{sgn}(x) = 0$. It shows that the crossing periodic orbits are nonsmooth but continuous at the intersection points of the orbits and Σ_0.

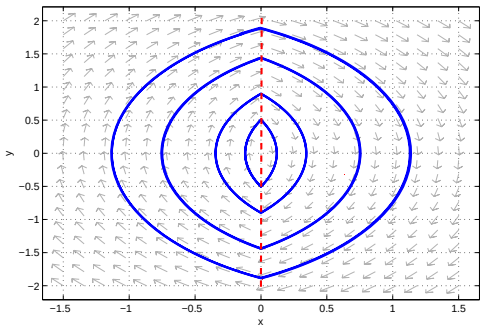

Figure 3.1: Crossing periodic orbits of $x'' + x + \operatorname{sgn}(x) = 0$. Red dashed line denotes Σ_0.

4 Perturbed system

We rewrite the equivalent system associated to (2.1) and (2.3) as follows

$$\begin{cases} x' = y, \\ y' = -g_+(x) + p(t), \quad x > 0; \end{cases} \qquad \begin{cases} x' = y, \\ y' = -g_-(x) + p(t), \quad x < 0. \end{cases} \tag{4.1}$$

Any function $z(t) = (x(t), y(t)) : [0, 2\pi] \to \mathbb{R} \times \mathbb{R}$ such that $(x(t), y(t)) \neq (0,0)$ for every $t \in [0, 2\pi]$. By the polar coordinates transformation (3.4), the resulting equation of (4.1) for $r(t) > 0$ and $\theta(t) \neq \frac{\pi}{2} + k\pi, k \in \mathbb{Z}$ is of the form

$$\begin{cases} \dfrac{dr(t)}{dt} = r\cos\theta\sin\theta + [p(t) - g_\pm(r\cos\theta)]\sin\theta, \\ \dfrac{d\theta(t)}{dt} = -\sin^2\theta + \dfrac{1}{r}[p(t) - g_\pm(r\cos\theta)]\cos\theta. \end{cases} \tag{4.2}$$

Correspondingly, we let $r(t) = r(t; r_0, \theta_0), \theta(t) = \theta(t; r_0, \theta_0)$ be the solution of (4.2), which satisfies $(r(0), \theta(0)) \doteq (r_0, \theta_0) \neq (0,0)$, and $x_0 = r_0\cos\theta_0,\ y_0 = r_0\sin\theta_0$.

Denote by $\mathbb{D}(R_0) \doteq \{(x,y) \in \mathbb{R}^2 : x^2 + y^2 < R_0^2\}$ and $\mathbb{D}[R_0] \doteq \{(x,y) \in \mathbb{R}^2 : x^2 + y^2 \leq R_0^2\}$ are, respectively, the open and closed discs in the plane (*i.e.* two-dimensional balls), and $\mathbb{S}_{R_0} = \{(x,y) \in \mathbb{R}^2 : x^2 + y^2 = R_0^2\}$, with center the origin $O(0,0)$ and radius $R_0 > 0$.

Note that any solution function $z(t) = (x(t), y(t))$ of (4.1) is supposed to be defined on a maximal interval of existence. By (1.6) and the boundedness of $p(t)$, it is easy to show that global existence occurs that $z(t)$ is defined for all $t \in \mathbb{R}$.

Lemma 4.1. *The solution $z(t) = (x(t), y(t))$ of (4.1) is defined on the whole t-axis.*

Proof. Define a function $W(x,y):\mathbb{R}\times\mathbb{R}\to\mathbb{R}$ as

$$W(x,y)=\frac{1}{2}y^2+G(x)-G_{\min}+1,$$

where $G_{\min}=\min\{G(x):x\in\mathbb{R}\}$. It follows that $W(x,y)>\frac{1}{2}y^2+\frac{1}{2}>0$ for every $(x,y)\in\mathbb{R}^2$, and

$$\lim_{x^2+y^2\to+\infty}W(x,y)=+\infty. \tag{4.3}$$

We set $W(t)\doteq W(z(t))=W(x(t),y(t))$ with $W(t_0)=W_0=W(z_0)=W(x_0,y_0)$. When $x(t)\neq 0$ for every $t\in\mathbb{R}$, consider the derivative of W along the solution $z(t)=(x(t),y(t))$ of (4.1) one has that

$$\left|\frac{dW(t)}{dt}\right|=|y(t)p(t)|\le E|y(t)|\le EW(t).$$

Using the elementary differential inequalities we have that

$$W(t)\le W_0e^{E|t-t_0|},$$

for t in a maximal interval containing t_0. Further we have proved that $W(z(t))$ is bounded for t in any bounded interval. And then there is no blow-up at finite time and the global existence is proved. □

Lemma 4.2. *There exists $R_0>0$ such that when $r>R_0$, we have that $\frac{d\theta(t)}{dt}<0$ for all $t\in[0,2\pi]$.*

Proof. By (1.6), there exists $N>0$ sufficiently large such that

$$g_+(x)>\overline{E},\quad x\ge N,\qquad g_-(x)<\underline{E},\quad x\le -N,$$

where $\overline{E}$ and $\underline{E}$ come from (2.2). Let $R_0>N$. When $r>R_0$ and $|r\cos\theta|\ge N$ one has that

$$\frac{d\theta(t)}{dt}=-\sin^2\theta-\frac{[g_\pm(r\cos\theta)-p(t)]\cos^2\theta}{r\cos\theta}<0.$$

While for $r>R_0$ and $|r\cos\theta|<N$ with $r\cos\theta\neq 0$, one has that

$$\frac{d\theta(t)}{dt}<-\sin^2\theta+\frac{|p(t)-g_\pm(r\cos\theta)|}{r}<-\frac{R_0^2-N^2-R_0\delta}{R_0^2},$$

where $\delta=E+\max_{|x|\le N}|g_\pm(x)|$ with E being from (2.2). Further, $\frac{d\theta(t)}{dt}<0$ for $t\in[0,2\pi]$ as long as $R_0>\frac{1}{2}(\delta+\sqrt{4N^2+\delta^2})$. □

Lemma 4.2 implies that there exists $R_0>0$ sufficiently large such that the regular orbits of (4.1) rotate clockwise outside of $\mathbb{S}_{R_0}$ as t ($\in[0,2\pi]$) increases.

Let $|w|=|(a,b)|\doteq\sqrt{a^2+b^2}$, we denote the usual Euclidean norm of the point $w=(a,b)\in\mathbb{R}^2$. Next we prove that any solution $z(t)=(x(t),y(t))$ of (4.1) possesses an elastic property as follows.

Lemma 4.3. *For each $\alpha>0$, there is $\beta=\beta(\alpha)>0$ such that $|z(0)|\ge\beta$ implies that*

$$|z(t)|>\alpha,\qquad t\in[0,2\pi].$$

Proof. Let $W(x,y)=\frac{1}{2}y^2+G(x)$, where $G(x)$ is shown as in (3.3). By (1.6), there exists $X>0$ such that $G(x)>0$ for $|x|>X$. Further, $W(x,y)>0$ for $|x|>X$ and (4.3) holds. We set $G=\min_{x\in\mathbb{R}}\{G(x)\}\le 0$. Consider any solution $z(t;z_0)\doteq(x(t;x_0,y_0),y(t;x_0,y_0))$ of (4.1) passing through $z_0=(x_0,y_0)$, and we denote by $W(t)\doteq W(x(t;x_0,y_0),y(t;x_0,y_0))$ satisfying $W(0)\doteq W_0=W(x_0,y_0)$. When $x(t)\neq 0$, along the solution of (4.1) one has that

$$\frac{dW(t)}{dt}=y(t)p(t)\ge -E\sqrt{2(W(t)-G)},$$

where E is from (2.2). Further

$$\sqrt{2(W(t)-G)}\ge\sqrt{2(W_0-G)}-Et,\qquad t\in[0,2\pi].$$

Let $\gamma(\alpha)=\max\{W(x,y):x^2+y^2\le\alpha^2\}$. By (4.3), there exists $\beta=\beta(\alpha)(>\alpha)$ sufficiently large such that for $x^2+y^2\ge\beta^2$ then

$$2(W(x,y)-G)>(\sqrt{2(\gamma(\alpha)-G)}+2E\pi)^2.$$

Hence $x_0^2+y_0^2\ge\beta^2$, we have that

$$\begin{aligned}\sqrt{2(W(x(t;x_0,y_0),y(t;x_0,y_0))-G)}&\ge\sqrt{2(W_0-G)}-Et\\&>\sqrt{2(\gamma(\alpha)-G)}+2E\pi-Et\ge\sqrt{2(\gamma(\alpha)-G)},\ t\in[0,2\pi].\end{aligned}$$

This implies that $x^2(t;x_0,y_0)+y^2(t;x_0,y_0)>\alpha^2$ for $t\in[0,2\pi]$. □

Lemmas 4.2–4.3 imply that there exists $\alpha>0$ sufficiently large such that the regular orbits of (4.1) rotate clockwise in an annulus as t ($\in[0,2\pi]$) increases.

Consider any solution $(x(t),y(t))$ of (4.1) with the initial point $(x(0),y(0))=(x_0,y_0)\in\Sigma_-$. In the polar coordinates, the solution is denoted by $(r(t),\theta(t))$ satisfying $(r_0,\theta_0)\doteq(r(0),\theta(0))$. By Lemma 4.2, the corresponding regular orbit rotates in a clockwise fashion in Σ_-. Assume that it reaches Σ_0^+ at $t=t_0(>0)$, that is $(x(t_0),y(t_0))=(0,y_{t_0})\in\Sigma_0^+$. Next we present a result, and the discussion for $(x_0,y_0)\in\Sigma_+$ is the same and so omitted here.

Lemma 4.4. *There is $\epsilon_0>0$ such that the solution of (4.1) with $(x(t_0+\epsilon_0),y(t_0+\epsilon_0))\in\Sigma_+$ satisfies*

$$\lim_{\epsilon_0\to 0^+}(x(t_0+\epsilon_0),y(t_0+\epsilon_0))=(0,y_{t_0}).$$

Proof. By (4.2), the solution $(x(t_0+\epsilon_0),y(t_0+\epsilon_0))\in\Sigma_+$ satisfies

$$\int_{\frac{\pi}{2}}^{\theta(t_0+\epsilon_0)}\frac{d\theta}{-\sin^2\theta+\frac{1}{r}[p(t)-g_+(r\cos\theta)]\cos\theta}=\int_{t_0}^{t_0+\epsilon_0}dt=\epsilon_0,\tag{4.4}$$

$$\int_{y_{t_0}}^{r(t_0+\epsilon_0)}\frac{dr}{r\cos\theta\sin\theta+[p(t)-g_+(r\cos\theta)]\sin\theta}=\int_{t_0}^{t_0+\epsilon_0}dt=\epsilon_0.\tag{4.5}$$

We rewrite (4.4) as the form

$$\int_{\frac{\pi}{2}}^{\theta(t_0+\epsilon_0)}\frac{d\theta}{-\sin^2\theta+\frac{1}{r(\theta)}[p(t)-g_+(r(\theta)\cos\theta)]\cos\theta}=\epsilon_0.$$

Further, when ϵ_0 is small enough, (4.4) becomes

$$\int_{\frac{\pi}{2}}^{\theta(t_0+\epsilon_0)} \frac{d\theta}{-\sin^2\theta} = \epsilon_0. \tag{4.6}$$

It is easy to find $\theta^*(t_0+\epsilon_0)$ such that (4.6) holds. And on (r,θ) coordinate plane, $\theta^*(r,t_0+\epsilon_0)$ is a continuous curve close to $\theta=\frac{\pi}{2}$ for a given ϵ_0.

Similarly, we can find the corresponding $r^*(\theta,t_0+\epsilon_0)$ such that (4.5) holds. And on (r,θ) coordinate plane, $r^*(\theta)$ is a continuous curve near $r=y_{t_0}$ for a given ϵ_0.

Put $\theta^*(r,t_0+\epsilon_0)$ and $r^*(\theta,t_0+\epsilon_0)$ into the (r,θ) coordinate plane for the same given ϵ_0. Then there is at least one intersection point $(r^*(t_0+\epsilon_0),\theta^*(t_0+\epsilon_0))$. And the solution of (4.4)–(4.5) with this intersection point as an initial value is the result. □

The above lemmas prompt us to provide the following definition, which can be used to define the Poincaré mapping of (4.1) on the plane.

Definition 4.5. For each $(0,y)\in\Sigma_0^+$, let $(0,-p_R(y))\in\Sigma_0^-$ be the first intersection point of the regular orbit starting from $(0,y)$ and Σ_0. Then the planar mapping $P_R:(0,y)\to(0,-p_R(y))$ is called as a right Poincaré mapping. Similarly, for each $(0,-y)\in\Sigma_0^-$ let $(0,p_L(y))\in\Sigma_0^+$ be the first intersection point of the regular orbit starting from $(0,-y)$ and Σ_0, and we call $P_L:(0,-y)\to(0,p_L(y))$ as a left Poincaré mapping.

By the continuous dependence of solutions on the initial values, P_L and P_R are continuous. Consequently, the component functions p_L and p_R are also continuous. For a regular orbit of (4.1) starting from a given point $(0,y)\in\Sigma_0^+$, by Definition 4.5 it intersects with Σ_0^- at $(0,-p_R(y))$ and Σ_0^+ then at $(0,p_L(p_R(y)))$. Clearly the regular orbit is periodic if and only if $y=p_L(p_R(y))$.

Further, the Poincaré mapping $\mathcal{P}$ of (4.1) is well defined as follows

$$\begin{aligned}\mathcal{P}(\doteq P_L\circ P_R):\mathbb{R}^2\setminus\{O\}&\to\mathbb{R}^2\setminus\{O\},\\ (x_0,y_0)&\to(x(2\pi;x_0,y_0),y(2\pi;x_0,y_0)),\\ (r_0,\theta_0)&\to(r(2\pi;r_0,\theta_0),\theta(2\pi;r_0,\theta_0)),\end{aligned}$$

where $(x_0,y_0)\neq(0,0)$ and $(r_0,\theta_0)\neq(0,0)$. Moreover, note that $\mathcal{P}$ is continuous, and fixed points of $\mathcal{P}$ correspond to the initial points of the regular periodic solutions.

Based on the above several lemmas, we now give the proofs of Theorems 1.1–1.4.

Proof of Theorem 1.1. By $(H3)$, there exists $A\geq A_1$ such that

$$g_+(x)>\overline{E},\quad x\geq A,\qquad g_-(x)<\underline{E},\quad x\leq -A.$$

By Lemmas 4.2–4.3, there exists $R_0>0$ large enough such that regular orbits of (4.1) rotate clockwise outside $\mathbb{S}_{R_0}(\doteq\{(x,y):x^2+y^2=R_0^2\})$. We consider any regular orbit $L_{M_0}(\subset\{(x,y):x^2+y^2>R_0^2\})$ which starts from $M_0(r_0,\theta_0)$ at $t=0$, where $r_0=r(0)$ and $\theta_0=\theta(0)$. Assume that $R_0>A$, $M_0\in\{(x,y):x>A\}$, and L_{M_0} successively intersects with $\{x=A\},\Sigma_0^-,\{x=-A\},\{x=-A\},\Sigma_0^+,\{x=A\}$ and $\{\theta=\theta_0\}$ at points M_1,M_2,M_3,M_4,M_5,M_6 and M_7 (see Figure 4.1), and the corresponding moments and arguments are denoted by $\theta_i=\theta(t_i)$ for $i=1,2,3,4,5,6,7$. We next estimate the time of L_{M_0} rotating clockwise a circle around $\mathbb{S}_{R_0}$ when $R_0>0$ is sufficiently large.

According to Lemmas 4.2–4.3, we choose $\varepsilon > 0$ small sufficiently and $R_0 = \frac{E}{\varepsilon} > A$. Let

$$\begin{aligned}\psi_\pm &= \sin^2\theta + l_\pm \cos^2\theta - \varepsilon,\\ \varphi_- &= \sin^2\theta + L_- \cos^2\theta + \varepsilon.\end{aligned}$$

Then $\psi_\pm > 0$ and $\varphi_- > 0$ when ε is sufficiently small. By the second equality of (4.2),

$$\begin{aligned}-\varphi_- < \theta' < -\psi_-, \qquad & x \le -A,\\ \theta' < -\psi_+, \qquad & x \ge A,\end{aligned}$$

where $\theta' = \frac{d\theta(t)}{dt}$. When $x \ge A$, one has that

$$\begin{aligned}t_1 &= \int_{\theta_0}^{\theta_1} \frac{d\theta}{\theta'} < \int_{\theta_1}^{\theta_0} \frac{d\theta}{\psi_+},\\ t_7 - t_6 &= \int_{\theta_6}^{\theta_7} \frac{d\theta}{\theta'} < \int_{\theta_7}^{\theta_6} \frac{d\theta}{\psi_+} = \int_{\theta_7+2\pi}^{\theta_6+2\pi} \frac{d\theta}{\psi_+}.\end{aligned}$$

Since $\theta_7 + 2\pi = \theta_0$, it follows that

$$t_7 - t_6 + t_1 < \int_{\theta_1}^{\theta_6+2\pi} \frac{d\theta}{\psi_+} < \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \frac{d\theta}{\psi_+} = \frac{\pi}{\sqrt{(l_+ - \varepsilon)(1-\varepsilon)}}.$$

Similarly, for $x \le -A$ then

$$t_4 - t_3 < \int_{-\frac{3\pi}{2}}^{-\frac{\pi}{2}} \frac{d\theta}{\psi_-} = \frac{\pi}{\sqrt{(l_- - \varepsilon)(1-\varepsilon)}}.$$

While for $|x| \le A$, it follows that

$$\begin{aligned}|\theta'| &\ge \sin^2\theta - \frac{|g_\pm(x)| + |p(t)|}{r}\\ &\ge \frac{R_0^2 - A^2}{R_0^2} - \frac{\delta}{R_0} = 1 - \frac{\delta\varepsilon}{E} - \frac{A^2\varepsilon}{E^2},\end{aligned}$$

where $\delta = E + \max_{|x|\le A} |g_\pm(x)|$. Note that the time T that L_{M_0} rotates a circle around $\mathbb{S}_{R_0}$ satisfies

$$T < \frac{\pi}{\sqrt{(l_- - \varepsilon)(1-\varepsilon)}} + \frac{\pi}{\sqrt{(l_+ - \varepsilon)(1-\varepsilon)}} + \left(\int_{\theta_1}^{\theta_2} + \int_{\theta_2}^{\theta_3} + \int_{\theta_4}^{\theta_5} + \int_{\theta_5}^{\theta_6}\right) \frac{d\theta}{\theta'}.$$

It is obvious that $1 - \frac{\delta\varepsilon}{E} - \frac{A^2\varepsilon}{E^2} \to 1$ as $\varepsilon \to 0$. So when $0 < \varepsilon$ is sufficiently small,

$$\begin{aligned}\left|\left(\int_{\theta_1}^{\theta_2} + \int_{\theta_2}^{\theta_3} + \int_{\theta_4}^{\theta_5} + \int_{\theta_5}^{\theta_6}\right) \frac{d\theta}{\theta'}\right| &\le \left(\int_{\theta_1}^{\theta_2} + \int_{\theta_2}^{\theta_3} + \int_{\theta_4}^{\theta_5} + \int_{\theta_5}^{\theta_6}\right) \frac{d\theta}{|\theta'|}\\ &\le \left(\int_{\theta_1}^{\theta_2} + \int_{\theta_2}^{\theta_3} + \int_{\theta_4}^{\theta_5} + \int_{\theta_5}^{\theta_6}\right) \frac{d\theta}{1 - \frac{\delta\varepsilon}{E} - \frac{A^2\varepsilon}{E^2}} \le \frac{4\sigma}{1 - \frac{\delta\varepsilon}{E} - \frac{A^2\varepsilon}{E^2}},\end{aligned}$$

where σ is an angle shown as in Figure 4.1. Since $R_0 = \frac{E}{\varepsilon} \to +\infty$ as $\varepsilon \to 0$, and then $\sigma \to 0$. Hence when R_0 is large sufficiently (*i.e.* $\varepsilon \to 0$), it follows from (1.5) that

$$T < \frac{2\pi}{m}.$$

On the other hand, when $x \le -A$ it follows from $\theta' \ge -\varphi_-$ that

$$T > t_4 - t_3 > \int_{\theta_3}^{\theta_4} \frac{d\theta}{\theta'} > \int_{\theta_4}^{\theta_3} \frac{d\theta}{\varphi_-} = \int_{-\frac{3\pi}{2}}^{-\frac{\pi}{2}} \frac{d\theta}{\varphi_-} - \left(\int_{-\frac{3\pi}{2}}^{\theta_4} + \int_{\theta_3}^{-\frac{\pi}{2}} \right) \frac{d\theta}{\varphi_-}$$
$$= \frac{\pi}{\sqrt{(L_- + \varepsilon)(1+\varepsilon)}} - \left(\int_{-\frac{3\pi}{2}}^{\theta_4} + \int_{\theta_3}^{-\frac{\pi}{2}} \right) \frac{d\theta}{\varphi_-},$$

and

$$\left| \left(\int_{-\frac{3\pi}{2}}^{\theta_4} + \int_{\theta_3}^{-\frac{\pi}{2}} \right) \frac{d\theta}{\varphi_-} \right| \le \frac{2\sigma}{\min\{1, L_-\}} \to 0 \quad \text{as } \varepsilon \to 0.$$

In conclusion, when $R_0 > 0$ is large sufficiently we have that

$$\frac{2\pi}{m+1} < T < \frac{2\pi}{m}.$$

This implies that the number of rotation of any regular orbit of (4.1) in $[0, 2\pi]$ is greater than m but less than $m+1$. Hence by Theorem 2.1, (4.1) has at least one 2π crossing periodic solution. The proof is complete. □

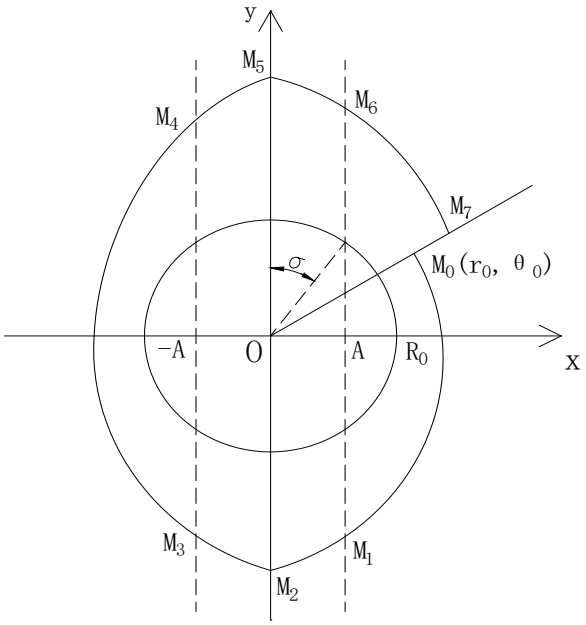

Figure 4.1: Schematic diagram

Proof of Theorem 1.2. By $(H3)'$, there is $A(> A_1)$ large enough such that

$$\theta' \doteq \frac{d\theta}{dt} > -(\sin^2\theta + L_- \cos^2\theta + \varepsilon), \qquad x \le -A.$$

Further, one has that

$$T > \int_{\theta_3}^{\theta_4} \frac{d\theta}{\theta'} > \int_{\theta_4}^{\theta_3} \frac{d\theta}{\sin^2\theta + L_- \cos^2\theta + \varepsilon}$$
$$= \int_{-\frac{3\pi}{2}}^{-\frac{\pi}{2}} \frac{d\theta}{\sin^2\theta + L_- \cos^2\theta + \varepsilon} - \left(\int_{-\frac{3\pi}{2}}^{\theta_4} + \int_{\theta_3}^{-\frac{\pi}{2}} \right) \frac{d\theta}{\sin^2\theta + L_- \cos^2\theta + \varepsilon},$$

and

$$\left|\left(\int_{-\frac{3\pi}{2}}^{\theta_4}+\int_{\theta_3}^{-\frac{\pi}{2}}\right)\frac{d\theta}{\sin^2\theta+L_-\cos^2\theta+\varepsilon}\right|\le\frac{2\sigma}{L_-},$$

where σ is the same as in the proof of Theorem 1.1. Further, by $0<L_-<\frac{1}{4}$, when $R_0>0$ is sufficiently large one has that

$$T>\frac{\pi}{\sqrt{(L_-+\varepsilon)(1+\varepsilon)}}>2\pi.$$

This implies that the number of rotation for any regular orbit rotating clockwise outside $\mathbb{S}_{R_0}$ in $[0,2\pi]$ is less than one. Hence by Theorem 2.1, the conclusion holds. □

Proof of Theorem 1.3. By $\lim\limits_{x\to+\infty}\dfrac{g_+(x)}{x}=+\infty$, there are $A_1(>A)$ and $l_+>0$ large enough such that

$$\frac{g_+(x)}{x}\ge l_+,\qquad x\ge A_1.$$

When $m\ge1$, by (1.7) we can find certain arbitrary large l_+ such that

$$\frac{1}{\sqrt{l_-}}+\frac{1}{\sqrt{l_+}}<\frac{2}{m}.$$

Hence all conditions in Theorem 1.1 hold, and when $m=0$ it is Theorem 1.2. □

Proof of Theorem 1.4. Let $(x_1(t),y_1(t))$ and $(x_2(t),y_2(t))$ be any two 2π crossing periodic solutions, and denote by

$$u(t)=x_1(t)-x_2(t),\qquad v(t)=y_1(t)-y_2(t).$$

When $x_i(t)\neq0$ for $i=1,2$, one has that

$$\begin{aligned}\frac{du(t)}{dt}&=v(t),\\ \frac{dv(t)}{dt}&=-[g_\pm(x_1(t))-g_\pm(x_2(t))],\end{aligned}\tag{4.7}$$

where $g_\pm(x_1(t))-g_\pm(x_2(t))$ are 2π-periodic. Making a polar coordinates transformation

$$u(t)=r(t)\cos\theta(t),\qquad v(t)=r(t)\sin\theta(t),$$

then (4.7) is transformed into the form

$$\begin{aligned}\frac{dr(t)}{dt}&=r\sin\theta\cos\theta-[g_\pm(x_1(t))-g_\pm(x_2(t))]\sin\theta,\\ \frac{d\theta(t)}{dt}&=-\sin^2\theta-\frac{1}{r}[g_\pm(x_1(t))-g_\pm(x_2(t))]\cos\theta.\end{aligned}\tag{4.8}$$

Let $(r(t;\theta_0,r_0),\theta(t;\theta_0,r_0))$ be any regular solution of (4.8) with the initial value condition $(\theta_0,r_0)\neq(0,0)$. Then $r(t)>0$ for $t\in[0,2\pi]$. Note that

$$0<\frac{1}{r}[g_\pm(x_1(t))-g_\pm(x_2(t))]\cos\theta=\frac{g_\pm(x_1(t))-g_\pm(x_2(t))}{x_1(t)-x_2(t)}\cos^2\theta<\cos^2\theta.$$

So we have that

$$-2\pi<\theta(2\pi)-\theta(0)=\int_{\theta(0)}^{\theta(2\pi)}\theta'dt<0.$$

Further (4.7) has no nontrivial 2π crossing periodic solution, and then $u(t)\equiv0$. □

5 An example

Let $g_+(x) = e^x + c_1$ and $g_-(x) = ax - c_2$ in (4.1), where $c_1 \geq 0, c_2 > 0, a \in (\frac{1}{3}, \frac{1}{2})$. Choosing $l_1 = \frac{1}{3}, L_- = \frac{1}{2}$ and $A_1 > 0$ sufficiently large. It is easy to verify $(H1)$–$(H3)$ as follows.

$(H1)$ $g_+ \in C^1([0, +\infty), \mathbb{R})$, $g_- \in C^1((-\infty, 0], \mathbb{R})$, and

$$\lim_{x\to 0^-} (ax - c_2) = -c_2 < 0, \qquad \lim_{x\to 0^+} (e^x + c_1) = 1 + c_1 > 0.$$

$(H2)$ $g_-(x) < 0$ for $x < 0$ and $g_+(x) > 0$ for $x > 0$, and $\lim_{x\to-\infty}(ax - c_2) = -\infty$, $\lim_{x\to+\infty}(e^x + c_1) = +\infty$.

$(H3)$ When $A_1 > 0$ is large sufficiently, there holds

$$\frac{1}{3} < \lim_{x\to-\infty} \frac{g_-(x)}{x} < \frac{1}{2}, \qquad \lim_{x\to+\infty} \frac{g_+(x)}{x} = +\infty.$$

Moreover, we can choose l_+ large arbitrary such that when $m = 1$ we have that

$$1 < \frac{1}{\sqrt{L_-}} \leq \frac{1}{\sqrt{l_-}} + \frac{1}{\sqrt{l_+}} < 2.$$

Hence by using Theorem 1.1, it follows that (4.1) has at least one 2π crossing periodic solution.

6 Concluding remarks

In this paper, we have studied the existence and uniqueness of crossing periodic solutions for a mixed-type second order discontinuous Duffing equation (1.2), where $g_\pm$ satisfy some asymmetric growth conditions for $x \in \mathbb{R}$. However in the existing literatures [2, 10, 12, 13], the authors considered the periodic solution problem of discontinuous symmetric Duffing equation. In [2, 12], the authors considered $g_\pm$ being some specific functions and obtained the existence of periodic solutions. In [2], $g_\pm = x(1 - \frac{1}{\sqrt{a^2+x^2}})$ with $a = 0$ being a discontinuous case; in [12] $g_\pm = \eta\,\mathrm{sgn}(y)$ with $\eta \in \mathbb{R}, \eta > 0$. While in [10, 13], by the Poincaré–Birkhoff theorem, the authors studied the multiplicity of periodic solutions with large-amplitude. So to some sense, our results are improvement and generalization of the ones in the literatures [2, 10, 12, 13].

We first presented the definitions of regular solutions and crossing periodic solutions (or orbits) of (1.2), and state the existence and uniqueness of any regular solution to initial value problem of (1.2) exception for the origin. Next, we analyzed the behavior of regular solutions (or orbits) for the autonomous and non-autonomous systems of (1.2), respectively. After some technical lemmas, by giving the definition of left and right Poincaré mappings, we constructed the Poincaré mapping of (1.2) on the whole plane. Then by using the Poincaré–Bohl theorem (*i.e*, Theorem 2.1), we found a 2π crossing periodic solution. And several corollaries are presented by giving different asymmetric linear growth conditions to $g_\pm$ as $|x| \to +\infty$. Next, to demonstrate the effectiveness of the obtained results, we further provided an example. Finally, a uniqueness criterion of the crossing periodic solution was also given when $g_\pm$ satisfy a kind of Lipschitz condition on the pieces of the nonlinearity.

Abstract. This paper investigates the existence of infinitely many weak solutions for a nonlinear elliptic p-Laplacian equation defined in the whole space $\mathbb{R}^N$. In particular, the equation is parameter-dependent and a range of positive parameters in which the equation admits such solutions is provided. Moreover, some particular cases in which the solutions turn out to be nonnegative are presented. The study is conducted via variational methods and critical points theory.

Keywords: nonlinear p-Laplacian equation, unbounded domain, critical points theory, infinitely many solutions.

2020 Mathematics Subject Classification: 35J20, 58E05.

1 Introduction

The p-Laplacian differential operator, denoted by $\Delta_p(u) = \operatorname{div}(|\nabla u|^{p-2}\nabla u)$, has been studied extensively by many authors in the latest years with various techniques. Precisely, there is a wide literature on elliptic p-Laplacian problems in bounded domains, while the results are fewer when the problems are defined in unbounded domains or in the whole space. Indeed, considering elliptic equations in the whole space $\mathbb{R}^N$ increases the technical difficulties of the study and, among the results, we mention Ambrosetti–García Azorero–Peral [1], Barletta–Candito–Marano–Perera [3], Drábek–Huang [6], Guarnotta–Livrea–Marano [7] and the references therein. Inspired by this issues, the authors of the present paper considered in [2] the following nonlinear elliptic problem

$$\begin{cases} -\Delta_p u + a(x)|u|^{p-2}u = \lambda f(x,u) & \text{in } \mathbb{R}^N, \\ \lim_{|x|\to\infty} u(x) = 0, \end{cases} \tag{1.1}$$

where $p > N$, $\lambda > 0$ is a parameter, $a\colon \mathbb{R}^N \to \mathbb{R}$ is a $L^\infty(\mathbb{R}^N)$-function with $\operatorname{ess\,inf}_{\mathbb{R}^N} a > 0$ and $f : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ is a L^1-Carathéodory function. Despite the lack of compactness of the embedding of Sobolev spaces in appropriate function spaces, the authors are able to obtain

✉Corresponding author. Email: bonanno@unime.it

results in line with the bounded domain case; precisely, some results on the existence of one and two non-zero solutions are presented. As far as we know, [2] is the first note for the case $p > N$ in the whole space.

The present paper is intended to continue the research carried out in [2], studying the existence of infinitely many solutions for problem (1.1) through variational methods and critical points theory. In particular, the main tool of our investigation is a critical points theorem due to Bonanno [4, Theorem 7.4]. By requiring a suitable oscillation of the primitive of the nonlinear term, we get the existence a sequence of pairwise distinct weak solutions that turn out to be nonnegative with an additional assumption on the nonlinearity. To give an idea of the results that we obtain, we present here the following particular case.

Theorem 1.1. *Let $g\colon \mathbb{R} \to \mathbb{R}$ be a continuous nonnegative function and set $G(t) = \int_0^t g(\xi)\mathrm{d}\xi$ for any $t \in \mathbb{R}$. Given $p > N$, assume that*

$$\liminf_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} = 0 \quad \textit{and} \quad \limsup_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} = +\infty.$$

Then, for any $a \in L^\infty(\mathbb{R}^N)$ with $\operatorname{ess\,inf}_{\mathbb{R}^N} a > 0$ and for any non-null and nonnegative function $h \in L^1(\mathbb{R}^N)$, the following problem

$$\begin{cases} -\Delta_p u + a(x)|u|^{p-2}u = h(x)g(u), & x \in \mathbb{R}^N, \\ \lim_{|x|\to\infty} u(x) = 0, \end{cases}$$

admits a sequence of pairwise distinct nonnegative weak solutions.

The paper is organized as follows. In Section 2, we describe the variational setting of the problem and in Theorem 2.2 we recall the abstract theorem that we use in the proof of our main results, which are presented in Section 3. In particular, Theorem 3.1 and Theorem 3.3 ensure the existence of infinitely many weak solutions for problem (1.1) requiring two different behavior on the nonlinearity. Finally, Section 4 deals with the particular case where the nonlinear term is of separable variable type and also provides an example.

2 Variational framework

Given $p > N$, we consider the Sobolev space $W^{1,p}(\mathbb{R}^N)$ endowed with the usual norm

$$\|u\|_{1,p} = \|u\|_p + \|\nabla u\|_p,$$

where $\|\cdot\|_p$ denotes the classical norm in the Lebesgue space $L^p(\mathbb{R}^N)$. It is well known that $W^{1,p}(\mathbb{R}^N)$ is continuously embedded in $L^\infty(\mathbb{R}^N)$ (see Morrey theorem in Brezis [5, Theorem 9.12]). Hence, there exists a constant $c > 0$ such that

$$\|u\|_\infty \le c\|u\|_{1,p} \quad \text{for all } u \in W^{1,p}(\mathbb{R}^N),$$

and an optimal numerical estimate of the embedding constant c can be found in Proposition 2.2 in Amoroso–Bonanno–Perera [2], see also Remark 2.1. However, for our investigation we equip the space with the following equivalent norm

$$\|u\| = \left(\int_{\mathbb{R}^N} |\nabla u(x)|^p dx + \int_{\mathbb{R}^N} a(x)|u(x)|^p dx \right)^{\frac{1}{p}},$$

where $a\colon \mathbb{R}^N \to \mathbb{R}$ is such that

$$a \in L^\infty(\mathbb{R}^N) \quad \text{and} \quad a_- = \operatorname*{ess\,inf}_{\mathbb{R}^N} a > 0.$$

By Amoroso–Bonanno–Perera [2, Lemma 2.1] one has

$$\|u\|_\infty \leq C\|u\| \quad \text{for all } u \in W^{1,p}(\mathbb{R}^N), \tag{2.1}$$

where

$$C = \left(\frac{1}{a_-}\right)^{\frac{p-N}{p^2}} 2^{\frac{p-1}{p}} \left(\frac{\Gamma\left(1+\frac{N}{2}\right)}{\pi^{\frac{N}{2}}}\right)^{\frac{1}{p}} \frac{1}{N^{\frac{N}{p^2}}} \left(\frac{p-1}{p-N}\right)^{\frac{N(p-1)}{p^2}}, \tag{2.2}$$

with $\Gamma(s) = \int_0^\infty e^{-t}t^{s-1}\mathrm{d}t$ being the well known gamma function. Note that $W_0^{1,p}(\mathbb{R}^N)$ coincides with $W^{1,p}(\mathbb{R}^N)$, hence if $u \in W^{1,p}(\mathbb{R}^N)$ then it holds that

$$\lim_{|x|\to\infty} u(x) = 0.$$

Therefore, studying problem (1.1) is equivalent to studying the following one

$$-\Delta_p u + a(x)|u|^{p-2}u = \lambda f(x,u) \quad \text{in } \mathbb{R}^N, \qquad u \in W^{1,p}(\mathbb{R}^N), \tag{P_λ}$$

that means finding $u \in W^{1,p}(\mathbb{R}^N)$ such that

$$\int_{\mathbb{R}^N} \left(|\nabla u|^{p-2}\nabla u\nabla v + a(x)|u|^{p-2}uv\right) dx = \lambda \int_{\mathbb{R}^N} f(x,u)v\,\mathrm{d}x,$$

for all $v \in W^{1,p}(\mathbb{R}^N)$.

To this end, we suppose that $f\colon \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ is a L^1-Carathéodory function, i.e.

(i) $f(\cdot,t)$ is measurable for all $t \in \mathbb{R}$,

(ii) $f(x,\cdot)$ is continuous for almost all $x \in \mathbb{R}^N$,

(iii) for all $\sigma > 0$ the function $\sup_{|t|\leq\sigma} |f(\cdot,t)|$ belongs to $L^1(\mathbb{R}^N)$.

Hence, summarizing our hypotheses, we assume that

(H) $p > N, a \in L^\infty(\mathbb{R}^N)$ such that $a_- = \operatorname{ess\,inf}_{\mathbb{R}^N} a > 0$ and $f : \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}$ is an L^1-Carathéodory function.

Our aim is to find weak solutions for problem (P_λ), more precisely we say that $u \in W^{1,p}(\mathbb{R}^N)$ is a weak solution of (P_λ) if

$$\int_{\mathbb{R}^N} \left(|\nabla u|^{p-2}\nabla u\nabla v + a(x)|u|^{p-2}uv\right)\,\mathrm{d}x = \lambda \int_{\mathbb{R}^N} f(x,u)v\,\mathrm{d}x$$

for any $v \in W^{1,p}(\mathbb{R}^N)$. Consider the functionals $\Phi, \Psi\colon W^{1,p}(\mathbb{R}^N) \to \mathbb{R}$ defined by

$$\Phi(u) = \frac{1}{p}\|u\|^p, \qquad \Psi(u) = \int_{\mathbb{R}^N} F(x,u(x))\,\mathrm{d}x,$$

where $F(x,t) = \int_0^t f(x,\xi)\,\mathrm{d}\xi$ for any $(x,t) \in \mathbb{R}^N \times \mathbb{R}$. Then, the functional $I_\lambda = \Phi - \lambda\Psi$ is the so-called energy functional associated to problem (P_λ). It is well known that Φ, Ψ, I_λ are Gâteaux differentiable functionals and it holds that

$$\Phi'(u)(v) = \int_{\mathbb{R}^N} \left(|\nabla u|^{p-2}\nabla u\nabla v + a(x)|u|^{p-2}uv\right)\,\mathrm{d}x,$$
$$\Psi'(u)(v) = \int_{\mathbb{R}^N} f(x,u)v\,\mathrm{d}x,$$

for every $u, v \in W^{1,p}(\mathbb{R}^N)$. Hence, $u \in W^{1,p}(\mathbb{R}^N)$ is a weak solution for (P_λ) if and only if u is a critical point of I_λ, i.e. $I'_\lambda(u)(v) = 0$ for all $v \in W^{1,p}(\mathbb{R}^N)$. Therefore, our aim is to find critical points of the energy functional I_λ, for some $\lambda > 0$.

Our approach is based on variational methods and critical point theory. In particular, our main tool is Theorem 7.4 of Bonanno [4], that we recall here together with the definition of $(PS)^{[r]}$-condition.

Definition 2.1. Let $(X, \|\cdot\|)$ be a Banach space, X^* its dual and $I_\lambda : X \to \mathbb{R}$ a Gâteaux differentiable functional, with $\lambda > 0$. Fix $r \in]-\infty, \infty]$. We say that I_λ satisfies the Palais–Smale condition cut-off upper at r (in short, $(PS)^{[r]}$-condition), if any sequence $\{u_n\} \subseteq X$ such that

(P_1) $I_\lambda(u_n)$ is bounded,

(P_2) $\lim_{n\to\infty} \|I_\lambda(u_n)\|_{X^*} = 0$,

(P_3) $\Phi(u_n) < r$,

has a convergent subsequence in X.

Clearly, if I_λ satisfies the classical (PS)-condition, which involves only conditions (P_1)–(P_2), then it satisfies also the $(PS)^{[r]}$-condition.

Now, let $\Phi, \Psi : X \to \mathbb{R}$ be two functions and for all $r > \inf_X \Phi$, set

$$\varphi(r) = \inf_{u \in \Phi^{-1}((-\infty, r))} \frac{\left(\sup_{v \in (\Phi^{-1}(-\infty, r))} \Psi(v)\right) - \Psi(u)}{r - \Phi(u)}, \tag{2.3}$$

and

$$\alpha := \liminf_{r \to +\infty} \varphi(r), \qquad \beta := \liminf_{r \to (\inf_X \Phi)^+} \varphi(r). \tag{2.4}$$

Theorem 2.2. *Let X be a real Banach space and let $\Phi, \Psi : X \to \mathbb{R}$ be two continuously Gâteaux differentiable functions with Φ bounded from below.*

(a) *If $\alpha < +\infty$ and for each $\lambda \in \left(0, \frac{1}{\alpha}\right)$ the function $I_\lambda = \Phi - \lambda\Psi$ satisfies $(PS)^{[r]}$-condition for all $r \in \mathbb{R}$, then, for each $\lambda \in \left(0, \frac{1}{\alpha}\right)$, the following alternative holds:*

either

(a_1) *I_λ possesses a global minimum, or*

(a_2) *there is a sequence $\{u_n\}$ of critical points (local minima) of I_λ such that $\lim_{n\to+\infty} \Phi(u_n) = +\infty$.*

(b) *If $\beta < +\infty$ and for each $\lambda \in \left(0, \frac{1}{\beta}\right)$ the function $I_\lambda = \Phi - \lambda\Psi$ satisfies $(PS)^{[r]}$-condition for some $r > \inf_X \Phi$, then, for each $\lambda \in \left(0, \frac{1}{\beta}\right)$, the following alternative holds:*

either

(b_1) *there is a global minimum of Φ which is a local minimum of I_λ, or*

(b_2) *there is a sequence of pairwise distinct critical points (local minima) of I_λ sucht that $\lim_{n\to+\infty} \Phi(u_n) = \inf_X \Phi$.*

3 Main results

In this section, we present our main result on the existence of infinitely many weak solutions for problem (P_λ), by requiring an appropriate oscillation of the primitive of the nonlinearity and providing also a range for the parameter λ for which the problem admits such solutions.

Fix an arbitrary open ball $B(x_0, R)$ of center x_0 and radius $R > 0$ and set

$$K_R = \frac{1}{C^p} \frac{\Gamma\left(1+\frac{N}{2}\right)}{\pi^{\frac{N}{2}}} \left(\frac{R^{p-N}}{2^p - 2^{p-N} + R^p \|a\|_\infty} \right), \tag{3.1}$$

where C is given in (2.2); we underline that K_R does not depend on the choice of x_0. Furthermore, put

$$A = \liminf_{\xi \to +\infty} \frac{\int_{\mathbb{R}^N} \max_{|t| \le \xi} F(x,t)\, \mathrm{d}x}{\xi^p},$$

$$B = \limsup_{\xi \to +\infty} \frac{\int_{B\left(x_0, \frac{R}{2}\right)} F(x,\xi)\, \mathrm{d}x}{\xi^p},$$

and

$$\lambda_1 = \frac{1}{B} \frac{1}{p\, C^p K_R}, \qquad \lambda_2 = \frac{1}{A} \frac{1}{p\, C^p}. \tag{3.2}$$

Theorem 3.1. *Let* (H) *be satisfied and assume that*

(h_1) $F(x,t) \ge 0$ *for all* $x \in \mathbb{R}^N, t \ge 0$;

(h_2) $\liminf_{\xi \to +\infty} \frac{\int_{\mathbb{R}^N} \max_{|t| \le \xi} F(x,t)\, \mathrm{d}x}{\xi^p} < K_R \limsup_{\xi \to +\infty} \frac{\int_{B(x_0, \frac{R}{2})} F(x,\xi)\, \mathrm{d}x}{\xi^p}$.

Then, for each $\lambda \in (\lambda_1, \lambda_2)$ *the problem* (P_λ) *admits a sequence of pairwise distinct weak solutions.*

Proof. Our aim is to find a sequence of weak solutions for problem (P_λ), that are critical points of the energy functional $I_\lambda = \Phi - \lambda \Psi$ defined in Section 2, by using part (a) of Theorem 2.2. The functionals Φ and Ψ satisfy the regularity assumptions requested in Theorem 2.2 and in [2, Lemma 2.3] we already proved that I_λ satisfies the $(PS)^{[r]}$-condition for every $r > 0$. So, first we need to verify that $\alpha < +\infty$, where α is given in (2.4). Fix $\lambda \in (\lambda_1, \lambda_2)$ and let $\{s_n\}_{n \in \mathbb{N}} \subseteq \mathbb{R}$ be a sequence such that $\lim_{n \to +\infty} s_n = +\infty$ and

$$A = \lim_{n \to +\infty} \frac{\int_{\mathbb{R}^N} \max_{|t| \le s_n} F(x,t)\, \mathrm{d}t}{s_n^p}.$$

Set $r_n = \frac{s_n^p}{pC^p}$ for all $n \in \mathbb{N}$. From (2.1) it follows that for any $u \in W^{1,p}(\mathbb{R}^N)$ such that $\Phi(u) = \frac{1}{p}\|u\|^p < r_n$, one has

$$\|u\|_\infty \le C\|u\| \le C(pr_n)^{\frac{1}{p}} = s_n \quad \text{for all } n \in \mathbb{N}.$$

Hence, we have that

$$\Phi^{-1}((-\infty, r_n)) \subset \left\{ u \in W^{1,p}(\mathbb{R}^N) : \|u\|_\infty \le s_n \right\} \quad \text{for all } n \in \mathbb{N}.$$

Therefore, by (2.3) it holds that

$$\begin{aligned}\varphi(r_n) &= \inf_{u\in\Phi^{-1}((-\infty,r_n))} \frac{\left(\sup_{v\in(\Phi^{-1}(-\infty,r_n))}\Psi(v)\right)-\Psi(u)}{r_n-\Phi(u)}\\ &\leq \frac{\left(\sup_{v\in(\Phi^{-1}(-\infty,r_n))}\Psi(v)\right)-\Psi(0)}{r_n-\Phi(0)} \leq \frac{\sup_{\|v\|_\infty\leq s_n}\int_{\mathbb{R}^N}F(x,v)\,\mathrm{d}x}{r_n}\\ &\leq p\,C^p\,\frac{\int_{\mathbb{R}^N}\max_{|t|\leq s_n}F(x,t)\,\mathrm{d}x}{s_n^p}.\end{aligned}$$

So, we get

$$\alpha=\liminf_{n\to+\infty}\varphi(r_n)\leq p\,C^p\,A.$$

From assumption (h_2), that can be read as $A<K_RB$, it follows that $A<+\infty$ and so $\alpha<+\infty$. Consequently, either (a_1) or (a_2) holds.

In order to get the existence of a sequence of critical points of I_λ, we prove that it does not posses a global minimum, i.e. that it is unbounded from below. Consider the fixed open ball $B(x_0,R)$ of center x_0 and radius $R>0$ (see (3.1)) and let $\{b_n\}_{n\in\mathbb{N}}\subseteq$ be a sequence such that $\lim_{n\to+\infty}b_n=+\infty$ and

$$B=\lim_{n\to+\infty}\frac{\int_{B\left(x_0,\frac{R}{2}\right)}F(x,b_n)\,\mathrm{d}x}{b_n^p}. \tag{3.3}$$

Set $S=B\left(x_0,R\right)\setminus B\left(x_0,\frac{R}{2}\right)$ and for any $n\in\mathbb{N}$ consider the following function

$$w_n(t)=\begin{cases}0 & \text{if}\quad x\in\mathbb{R}^N\setminus B\left(x_0,R\right),\\ \dfrac{2b_n}{R}(R-|x-x_0|) & \text{if}\quad x\in S,\\ b_n & \text{if}\quad x\in B\left(x_0,\frac{R}{2}\right).\end{cases}$$

Clearly, for every $n\in\mathbb{N}$ it holds that $w_n\in W^{1,p}(\mathbb{R}^N)$ (see Brezis [5, Remark 4(ii), p. 265] or Motreanu–Motreanu–Papageorgiou[8, Proposition 1.10, p. 3]) and

$$\begin{aligned}\|w_n\|^p &= \int_{\mathbb{R}^N}\left(|\nabla w_n|^p+a(x)|w_n|^p\right)\mathrm{d}x\\ &= \int_S\left(\left|\frac{2b_n}{R}\right|^p+a(x)\left|\frac{2b_n}{R}(R-|x-x_0|^p)\right|\right)\mathrm{d}x+\int_{B\left(x_0,\frac{R}{2}\right)}a(x)b_n^p\mathrm{d}x\\ &\leq \int_S\left(\left|\frac{2b_n}{R}\right|^p+\|a\|_\infty\left|\frac{2b_n}{R}\frac{R}{2}\right|^p\right)\mathrm{d}x+\|a\|_\infty\int_{B\left(x_0,\frac{R}{2}\right)}b_n^p\mathrm{d}x\\ &\leq b_n^p\left[\left(\frac{2^p}{R^p}+\|a\|_\infty\right)\mathrm{meas}(S)+\|a\|_\infty\,\mathrm{meas}\left(B\left(x_0,\frac{R}{2}\right)\right)\right],\end{aligned}$$

where

$$\begin{aligned}\mathrm{meas}(S) &= \mathrm{meas}\left(B\left(x_0,R\right)\right)-\mathrm{meas}\left(B\left(x_0,\frac{R}{2}\right)\right)\\ &= \frac{\pi^{\frac{N}{2}}}{\Gamma\left(1+\frac{N}{2}\right)}R^N-\frac{\pi^{\frac{N}{2}}}{\Gamma\left(1+\frac{N}{2}\right)}\left(\frac{R}{2}\right)^N\\ &= \frac{2^N-1}{2^N}\frac{\pi^{\frac{N}{2}}}{\Gamma\left(1+\frac{N}{2}\right)}R^N.\end{aligned}$$

Hence, we obtain

$$\begin{aligned}\|w_n\|^p &\leq b_n^p \frac{\pi^{\frac{N}{2}}}{\Gamma\left(1+\frac{N}{2}\right)}\left[\left(\frac{2^p}{R^p}+\|a\|_\infty\right)\frac{2^N-1}{2^N}R^N+\|a\|_\infty\frac{R^N}{2^N}\right]\\ &= b_n^p \frac{\pi^{\frac{N}{2}}}{\Gamma\left(1+\frac{N}{2}\right)}\left[\frac{2^p-2^{p-N}+R^p\|a\|_\infty}{R^{p-N}}\right],\end{aligned}$$

which leads to

$$\Phi(w_n)=\frac{1}{p}\|w_n\|^p \leq \frac{b_n^p}{p}\frac{\pi^{\frac{N}{2}}}{\Gamma\left(1+\frac{N}{2}\right)}\left[\frac{2^p-2^{p-N}+R^p\|a\|_\infty}{R^{p-N}}\right]=\frac{b_n^p}{p}\frac{1}{K_R C^p}, \tag{3.4}$$

see (3.1). On the other hand, by (h_1) we know that

$$\begin{aligned}\Psi(w_n) &= \int_{\mathbb{R}^N} F(x,w_n)\mathrm{d}x\\ &= \int_S F\left(x,\frac{2b_n}{R}(R-|x-x_0|)\right)\mathrm{d}x+\int_{B\left(x_0,\frac{R}{2}\right)} F(x,b_n)\mathrm{d}x\\ &\geq \int_{B\left(x_0,\frac{R}{2}\right)} F(x,b_n)\mathrm{d}x.\end{aligned} \tag{3.5}$$

Combining together (3.4) and (3.5), we get

$$I_\lambda(w_n)=\Phi(w_n)-\lambda\Psi(w_n)\leq \frac{b_n^p}{p}\frac{1}{K_R C^p}-\lambda\int_{B\left(x_0,\frac{R}{2}\right)} F(x,b_n)\mathrm{d}x, \tag{3.6}$$

for all $\lambda>0, n\in\mathbb{N}$. Now, taking (3.3) into account we have two possibilities:

1. $B=+\infty$
   In this case, fix $M>\frac{1}{\lambda}\frac{1}{p}\frac{1}{K_R C^p}$; from (3.3) there exists $\nu_M>0$ such that
   $$\int_{B\left(x_0,\frac{R}{2}\right)} F(x,b_n)\mathrm{d}x > Mb_n^p \quad \text{for all } n>\nu_M.$$
   Then, from (3.6) it holds that
   $$I_\lambda(w_n)\leq b_n^p\left(\frac{1}{p}\frac{1}{K_R C^p}-\lambda M\right) \quad \text{for all } n>\nu_M.$$
   By the choice of M, one has
   $$\lim_{n\to+\infty} I_\lambda(w_n)=-\infty.$$

2. $B<+\infty$
   In this case, fix $\varepsilon\in\left(0,B-\frac{1}{\lambda p}\frac{1}{K_R C^p}\right)$; from (3.3) there exists $\nu_\varepsilon>0$ such that
   $$\int_{B\left(x_0,\frac{R}{2}\right)} F(x,b_n)\mathrm{d}x > (B-\varepsilon)b_n^p \quad \text{for all } n>\nu_\varepsilon.$$
   Therefore, from (3.6) one has
   $$I_\lambda(w_n)\leq b_n^p\left(\frac{1}{p}\frac{1}{K_R C^p}-\lambda(B-\varepsilon)\right) \quad \text{for all } n>\nu_\varepsilon.$$
   By the choice of ε, it follows that
   $$\lim_{n\to+\infty} I_\lambda(w_n)=-\infty.$$

We underline that the choices of M and ε are allowed thanks to assumption (h_2), which also implies that (λ_1, λ_2) is nonempty and

$$(\lambda_1, \lambda_2) \subseteq \left(0, \frac{1}{\alpha}\right).$$

So, we get that the energy functional I_λ is unbounded from below and part (a_2) of Theorem 2.2 ensures that for each $\lambda \in (\lambda_1, \lambda_2)$ the functional $I_\lambda = \Phi - \lambda\Psi$ admits a sequence $\{u_n\}_{n\in\mathbb{N}} \subset W^{1,p}(\mathbb{R}^N)$ of critical points such that $\lim_{n\to+\infty} \|u_n\| = +\infty$, which are weak solutions of the problem (P_λ). □

Requiring an additional assumption, we can get the existence of nonnegative weak solutions, as the following result ensures.

Theorem 3.2. *Let (H) be satisfied. Suppose that $f(x,0) \geq 0$ for any $x \in \mathbb{R}^N$ and assume that (h_1)–(h_2) hold. Then, for each $\lambda \in (\lambda_1, \lambda_2)$, where λ_1, λ_2 are defined in (3.2), the problem (P_λ) admits a sequence of pairwise distinct nonnegative weak solutions.*

Proof. By applying Theorem 3.1 we get the existence of a sequence of pairwise distinct weak solutions and [2, Lemma 2.2] ensures that the solutions are nonnegative. □

Clearly, being $\Phi(\cdot) = \frac{1}{p}\|\cdot\|^p$, one has that

$$\inf_{W^{1,p}(\mathbb{R}^N)} \Phi = \min_{W^{1,p}(\mathbb{R}^N)} \Phi = \Phi(0) = 0.$$

Hence, exploiting part (b) of Theorem 2.2 and arguing as in the proof of Theorem 3.1, we can state the following alternative result.

Theorem 3.3. *Let (H) be satisfied and assume that*

(h_1') $F(x,t) \geq 0$ *for all* $x \in \mathbb{R}^N, t \geq 0$;

(h_2') $\liminf_{\xi\to 0^+} \frac{\int_{\mathbb{R}^N} \max_{|t|\leq\xi} F(x,t)\,dx}{\xi^p} < K_R \limsup_{\xi\to 0^+} \frac{\int_{B\left(x_0,\frac{R}{2}\right)} F(x,\xi)\,dx}{\xi^p}$.

Then, for each $\lambda \in (\lambda_1', \lambda_2')$, with

$$\lambda_1' = \frac{1}{p\,C^p K_R} \limsup_{\xi\to 0^+} \frac{\xi^p}{\int_{B\left(x_0,\frac{R}{2}\right)} F(x,\xi)\,dx}, \quad \lambda_2' = \frac{1}{p\,C^p} \liminf_{\xi\to 0^+} \frac{\xi^p}{\int_{\mathbb{R}^N} \max_{|t|\leq\xi} F(x,t)\,dx},$$

the problem (P_λ) admits a sequence of pairwise distinct weak solutions which uniformly converges to zero.
In addition, if $f(x,0) \geq 0$ for any $x \in \mathbb{R}^N$, the solutions are nonnegative.

4 Particular cases

This section deals with some consequences of the main results, depending on particular nonlinear terms. Precisely, when the nonlinear term is with separated variables, i.e. of the type $f(x,u) = h(x)g(u)$, the problem (P_λ) becomes the following one

$$-\Delta_p u + a(x)|u|^{p-2}u = \lambda h(x)g(u) \quad \text{in}\mathbb{R}^N, \qquad u \in W^{1,p}(\mathbb{R}^N), \tag{$\tilde{P}_\lambda$}$$

where we suppose that

($\tilde{\mathrm{H}}$) $p > N, a \in L^\infty(\mathbb{R}^N)$ such that $a_- = \operatorname{ess\,inf}_{\mathbb{R}^N} a > 0$, $h \in L^1(\mathbb{R}^N)$ such that $h \not\equiv 0, h \geq 0$ and $g \in C(\mathbb{R}), g \geq 0$.

In this case, the energy functional related to problem ($\tilde{\mathrm{P}}_\lambda$) is

$$\tilde{I}_\lambda(u) = \Phi(u) - \lambda\tilde{\Psi}(u) \quad \text{for all } u \in W^{1,p}(\mathbb{R}^N),$$

where Φ is defined in Section 2 and

$$\tilde{\Psi}(u) = \int_{\mathbb{R}^N} h(x)G(u(x))\mathrm{d}x, \quad \text{with} \quad G(t) = \int_0^t g(\xi)\mathrm{d}\xi \quad \text{for all } t \in \mathbb{R}.$$

Clearly, $u \in W^{1,p}(\mathbb{R}^N)$ is a critical point of $\tilde{I}_\lambda$ if and only if is a weak solution for problem ($\tilde{\mathrm{P}}_\lambda$). Set

$$\tilde{K}_R = K_R \int_{B\left(x_0, \frac{R}{2}\right)} h(x)\mathrm{d}x, \tag{4.1}$$

where K_R is given by (3.1), and put

$$\tilde{\lambda}_1 = \frac{1}{p\,C^p\tilde{K}_R} \limsup_{\xi\to+\infty} \frac{\xi^p}{G(\xi)}, \qquad \tilde{\lambda}_2 = \frac{1}{p\,C^p\|h\|_1} \liminf_{\xi\to+\infty} \frac{\xi^p}{G(\xi)}.$$

Theorem 4.1. *Let* ($\tilde{H}$) *be satisfied and assume that*

($\tilde{h}_2$) $\liminf_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} < \frac{\tilde{K}_R}{\|h\|_1} \limsup_{\xi\to+\infty} \frac{G(\xi)}{\xi^p}$.

Then, for each $\lambda \in \left(\tilde{\lambda}_1, \tilde{\lambda}_2\right)$ *the problem* ($\tilde{\mathrm{P}}_\lambda$) *admits a sequence of pairwise distinct nonnegative weak solutions.*

Proof. Arguing as in the proof of Theorem 3.1, taking into account that g is nonnegative, we get that

$$\alpha = \liminf_{n\to+\infty} \varphi(r_n) \leq p\,C^p\,\|h\|_1 \lim_{n\to+\infty} \frac{G(s_n)}{s_n},$$

and $\alpha < +\infty$ from hypothesis ($\tilde{h}_2$). Furthermore, one has that

$$\tilde{I}_\lambda(w_n) \leq \frac{b_n^p}{p} \frac{1}{K_R\,C^p} - \lambda G(b_n) \int_{B\left(x_0, \frac{R}{2}\right)} h(x)\mathrm{d}x,$$

for all $\lambda > 0, n \in \mathbb{N}$. So, it yields to $\tilde{I}_\lambda(w_n) \to -\infty$ as $n \to +\infty$ thanks to the following:

1. choose $M > \frac{1}{\lambda}\frac{1}{p}\frac{1}{\tilde{K}_R C^p}$ if $\limsup_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} = +\infty$;
2. fix $\varepsilon \in \left(0, \limsup_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} - \frac{1}{\lambda p}\frac{1}{\tilde{K}_R C^p}\right)$ if $\limsup_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} < +\infty$.

Then, we obtain that for each $\lambda \in \left(\tilde{\lambda}_1, \tilde{\lambda}_2\right)$ the problem ($\tilde{\mathrm{P}}_\lambda$) admits a sequence $\{u_n\}_{n\in\mathbb{N}} \subset W^{1,p}(\mathbb{R}^N)$ of weak solutions such that $\lim_{n\to+\infty} \|u_n\| = +\infty$. Finally, since h and g are nonnegative functions, by [2, Lemma 2.2] we know that the weak solutions are nonnegative. □

Clearly, Theorem 1.1 is a special case of Theorem 4.1. In the following, we give a version of Theorem 3.3.

Theorem 4.2. *Let* ($\tilde{H}$) *be satisfied and assume that*

$(\tilde{h}_2')$ $\liminf_{\xi\to 0^+} \frac{G(\xi)}{\xi^p} < \frac{\tilde{K}_R}{\|h\|_1} \limsup_{\xi\to 0^+} \frac{G(\xi)}{\xi^p}$.

Then, for each $\lambda \in \left(\tilde{\lambda}_1', \tilde{\lambda}_2'\right)$, *with*

$$\tilde{\lambda}_1' = \frac{1}{p\, C^p \tilde{K}_R} \limsup_{\xi\to 0^+} \frac{\xi^p}{G(\xi)}, \qquad \tilde{\lambda}_2' = \frac{1}{p\, C^p \|h\|_1} \liminf_{\xi\to 0^+} \frac{\xi^p}{G(\xi)}.$$

the problem ($\tilde{P}_\lambda$) *admits a sequence of pairwise distinct nonnegative weak solutions which uniformly converges to zero.*

Finally, we provide an example of applicability of our results.

Example 4.3. Let $k > 1$ be an arbitrary constant and consider

$$h(x) = e^{-|x|^2} \quad \text{for all } x \in \mathbb{R}^N,$$

and

$$g(t) = \begin{cases} p(1+t)^{p-1}\left(1+k-\cos(k\ln(1+t)) + \frac{k}{p}\sin(k\ln(1+t))\right) & \text{if } t \geq 0, \\ pk & \text{if } t < 0. \end{cases}$$

Clearly, $h\colon \mathbb{R}^N \to \mathbb{R}$ is non-null, positive and $h \in L^1(\mathbb{R}^N)$ with $\|h\|_1 = \pi^{\frac{N}{2}}$, while $g\colon \mathbb{R} \to \mathbb{R}$ is continuous and positive. Moreover, one has

$$G(t) = \begin{cases} (1+t)^p\,(1+k-\cos(k\ln(1+t))) - k & \text{if } t \geq 0, \\ pkt & \text{if } t < 0. \end{cases}$$

By choosing the arbitrary ball $B(0,1)$, see (3.1) and (4.1), we have that

$$\tilde{K}_1 = \frac{N\,\gamma\left(\frac{N}{2}, \frac{1}{4}\right)}{C^p\,(2^{p+1} - 2^{p+1-N} + 2\|a\|_\infty)},$$

where $\gamma(s,x) = \int_0^x e^{-t} t^{s-1} \mathrm{d}t$ is the lower incomplete gamma function. Furthermore, it holds that

$$\liminf_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} = 1-k, \qquad \limsup_{\xi\to+\infty} \frac{G(\xi)}{\xi^p} = 1+k.$$

Then, it is easy to verify that hypothesis ($\tilde{h}_2$) holds and Theorem 4.1 ensures that for any $\lambda \in \left(\frac{2^{p+1}-2^{p+1-N}+2\|a\|_\infty}{Np(1+k)\gamma(\frac{N}{2},\frac{1}{4})}, \frac{1}{pC^p\pi^{\frac{N}{2}}(1-k)}\right)$ and for any $a \in L^\infty(\mathbb{R}^N)$ with $\operatorname{ess\,inf}_{\mathbb{R}^N} a > 0$, the following equation

$$-\Delta_p u + a(x)|u|^{p-2}u = \lambda h(x) g(u), \quad x \in \mathbb{R}^N,$$

admits a sequence of pairwise distinct nonnegative weak solutions in $W^{1,p}(\mathbb{R}^N)$.

Abstract. After the linear differential systems in the plane the easiest ones are the quadratic polynomial differential systems. Due to their nonlinearity and also to their many applications these systems have been studied by many authors. Let **QS** denote the set of all planar quadratic polynomial differential systems, or simply *quadratic systems*, and let **QSR2P** denote the subset of **QS** having two finite invariant real straight lines and an invariant parabola. We classify the phase portraits in the Poincaré disc of all the quadratic systems in the class **QSR2P**.

Keywords: quardratic systems, planar polynomial differential systems, global phase portrait, Poincaré disc.

2020 Mathematics Subject Classification: 34C05, 34C20.

1 Introduction

The study of the quadratic systems started at the early twentieth century. Coppel in [10] mentions that in 1904 Büchel [3] published the first article on quadratic systems. Two classical surveys on quadratic systems were published in 1966 by Coppel [10], and in 1982 by Chicone and Tian [8].

Quadratic systems have been studied intensively during these last decades obtaining many good results on them, see for instance the books [1,28] and the references cited therein. More than one thousand papers have been published on the quadratic systems, but we are still far from completely understanding them.

We consider the following class of planar polynomial differential systems

$$\dot{x} = P(x,y), \quad \dot{y} = Q(x,y), \tag{1.1}$$

where $P, Q \in \mathbb{R}[x,y]$, being $\mathbb{R}[x,y]$ the ring of real polynomials in the two variables x and y. System (1.1) is said to be quadratic if the highest degree of the polynomials P and Q is two, that is, if $\max\{\deg P, \deg Q\} = 2$. Such quadratic systems include a wide range of planar

✉Corresponding author. Email: huaxin.ou@autonoma.cat

dynamical models, including classical examples such as certain Lotka–Volterra systems in population dynamics and Liénard-type systems in control theory.

In this work we restrict our attention to non-degenerate quadratic systems, meaning that the polynomials P and Q are coprime. This assumption guarantees that the quadratic system cannot be reduced to linear or constant differential systems.

The study of quadratic systems has been a central topic in the qualitative theory of dynamical systems, because they exhibit structurally rich dynamics despite their relatively simple algebraic form. These systems may admit multiple invariant algebraic curves, limit cycles, and different types of equilibria. The classification and characterisation of such systems remains an active area of research.

Quadratic systems having invariant conics, i.e., invariant algebraic curves of degree 2, have been studied by several authors, see [2, 5, 14, 16–18, 24–27]. Quadratic systems having invariant algebraic curves of degree 3 have been analysed in [4, 7, 12]. Quadratic systems having invariant straight lines with multiplicity 4 have been classified in [22, 23]. Quadratic systems having invariant straight lines with multiplicity 5 have been classified in [20, 21].

The objective of this paper is to classify the quadratic systems possessing two invariant real straight lines and an invariant parabola. Building on previous classifications of quadratic systems with invariant algebraic curves of degrees two and three [6, 12], this study forms part of a broader effort to investigate systems possessing degree-four invariant curves. Within this framework, we focus on a specific subclass and contribute to its classification. By deriving normal forms, analysing equilibria, and classifying their global phase portraits via Poincaré compactification, we integrate algebraic, geometric, and topological methods to provide all their different topological phase portraits in the Poincaré disc.

2 Preliminaries

We begin by recalling some fundamental notions used throughout the paper.

Let $X = P\frac{\partial}{\partial x} + Q\frac{\partial}{\partial y}$ be the polynomial vector field associated with the polynomial differential system (1.1).

2.1 First integrals and integrating factors.

Let U be an open subset of $\mathbb{R}^2$ and let $H : U \to \mathbb{R}$ be a non-constant C^1 function. We say that H is a *first integral* of the vector field X or of the system (1.1) if $H(x(t), y(t))$ is constant on all the solutions $(x(t), y(t))$ of system (1.1) contained in U. Note that H is a first integral if and only if

$$\frac{dH}{dt} = \frac{\partial H}{\partial x}P(x,y) + \frac{\partial H}{\partial y}Q(x,y) = 0.$$

Let $R : U \to \mathbb{R}$ be a C^1 non-zero function. The function R is an *integrating factor* of the vector field X or of the system (1.1) on U if one of the following three equivalent conditions holds on U:

$$\frac{\partial(RP)}{\partial x} = -\frac{\partial(RQ)}{\partial y}, \qquad \operatorname{div}(RP, RQ) = 0, \qquad XR = -R\operatorname{div}(P,Q).$$

Here $\operatorname{div}(P,Q) = \dfrac{\partial P}{\partial x} + \dfrac{\partial Q}{\partial y}$. The *first integral H associated to the integrating factor R* is given by

$$H(x,y) = \int R(x,y)P(x,y)\,dy + h(x),$$

where the function h is chosen such that $\frac{\partial H}{\partial x} = -RQ$. Then

$$\dot{x} = RP = \frac{\partial H}{\partial y}, \qquad \dot{y} = RQ = -\frac{\partial H}{\partial x}.$$

2.2 Invariant algebraic curves.

We recall that system (1.1) admits an *invariant algebraic curve* $f = f(x,y) = 0$ if

$$Xf = \frac{\partial f}{\partial x}P(x,y) + \frac{\partial f}{\partial y}Q(x,y) = K(x,y)f(x,y) = Kf, \tag{2.1}$$

where K is a polynomial called the *cofactor* of the invariant algebraic curve $f(x,y) = 0$. This terminology reflects the fact that if an orbit of the system has a point on the algebraic curve $f(x,y) = 0$, then the equality (2.1) forces that the entire orbit is contained in the algebraic curve $f(x,y) = 0$.

2.3 Extactic polynomial.

Let X be the vector field associated with the polynomial differential system (1.1) of degree m. The *n–th extactic polynomial of* X, $E_n(X)$, is defined by the determinant

$$\det \begin{pmatrix} v_1 & v_2 & \cdots & v_l \\ X(v_1) & X(v_2) & \cdots & X(v_l) \\ \vdots & \vdots & \ddots & \vdots \\ X^{l-1}(v_1) & X^{l-1}(v_2) & \cdots & X^{l-1}(v_l) \end{pmatrix},$$

where $v_1, v_2, \ldots, v_l$ form a basis of $\mathbb{R}_n[x,y]$, the $\mathbb{R}$–vector space of polynomials in $\mathbb{R}[x,y]$ of degree at most n, $l = (n+1)(n+2)/2$, $X^0(v_i) = v_i$ and $X^j(v_i) = X^{j-1}(X(v_i))$.

Note that the definition of the extactic polynomial is independent of the choice of basis in $\mathbb{R}_n[x,y]$.

Proposition 2.1 (Proposition 5.2 in [9]). *Let $f = 0$ be an invariant algebraic curve of degree n of the vector field X. Then the polynomial f divides the polynomial $E_n(X)$.*

If the invariant algebraic curve $f = f(x,y) = 0$ in Proposition 2.1 satisfies that f^k divides the polynomial $E_n(X)$ but f^{k-1} does not divide it, then by definition the *multiplicity* of the invariant algebraic curve f is k. Geometrically, this means that within the class of all polynomial vector fields of degree m, one can perturb the vector field X into a family X_ε, such that each X_ε admits k invariant algebraic curves, all of them tending to the curve $f = 0$ when $\varepsilon \to 0$. For further details see [9].

2.4 Poincaré compactification.

The Poincaré compactification is a classical tool for analysing the dynamics of planar polynomial differential systems in a neighbourhood of infinity.

Let X be a polynomial vector field of degree d and

$$\mathbb{S}^2 = \{(y_1, y_2, y_3) \in \mathbb{R}^3 : y_1^2 + y_2^2 + y_3^2 = 1\}$$

be the unit sphere in $\mathbb{R}^3$. Let π_0 be the plane tangent to $\mathbb{S}^2$ at $(0,0,1)$, then we identify the plane π_0 with $\mathbb{R}^2$. Consider the central projection $f : \mathbb{R}^2 \to \mathbb{S}^2$, which maps the point $(x,y,1)$ in plane π_0 to the two intersection points of the straight line through $(x,y,1)$ and $(0,0,0)$ with the sphere $\mathbb{S}^2$. Then $\mathbb{S}^1 = \{y \in \mathbb{S}^2 : y_3 = 0\}$ corresponds to the infinity of $\mathbb{R}^2$. Thus the differential Df maps the vector field X in $\mathbb{R}^2$ to X' in $\mathbb{S}^2 \setminus \mathbb{S}^1$. The new vector field X' consists of two symmetric copies of X with respect to the origin of coordinates.

Next we multiply X' by y_3^d to get a vector field $p(X)$ defined in the whole sphere $\mathbb{S}^2$. This process is called the *Poincaré compactification*. Furthermore, the dynamical behavior of $p(X)$ near $\mathbb{S}^1$ corresponds to behavior of X in a neighborhood of infinity.

Since $\mathbb{S}^2$ is a curved manifold we use local charts on the surface of $\mathbb{S}^2$ to facilitate the computations. More precisely, we map the surface of $\mathbb{S}^2$ into a group of local charts (U_i, ϕ_i) and (V_i, ψ_i) that are identical to $\mathbb{R}^2$ for $i = 1,2,3$, where

$$U_i = \{(y_1,y_2,y_3) \in \mathbb{S}^2 : y_i > 0\}, \quad V_i = \{(y_1,y_2,y_3) \in \mathbb{S}^2 : y_i < 0\},$$
$$\phi_i(y_1,y_2,y_3) = \psi_i(y_1,y_2,y_3) = \left(\frac{y_j}{y_i}, \frac{y_k}{y_i}\right), \text{ with } j < k, j,k \neq i.$$

The expressions of $p(X)$ in the local charts (U_1,ϕ_1), (U_2,ϕ_2), and (U_3,ϕ_3) are

$$\dot{u} = v^d\left[-uP\left(\frac{1}{v},\frac{u}{v}\right) + Q\left(\frac{1}{v},\frac{u}{v}\right)\right], \quad \dot{v} = -v^{d+1}P\left(\frac{1}{v},\frac{u}{v}\right).$$
$$\dot{u} = v^d\left[P\left(\frac{u}{v},\frac{1}{v}\right) - uQ\left(\frac{u}{v},\frac{1}{v}\right)\right], \quad \dot{v} = -v^{d+1}Q\left(\frac{u}{v},\frac{1}{v}\right),$$
$$\dot{u} = P(u,v), \quad \dot{v} = Q(u,v),$$

respectively. In the local chart (V_i,ψ_i) the expression of $p(X)$ is the same as in (U_i,ϕ_i) multiplied by $(-1)^{d-1}$ for $i = 1,2,3$. Furthermore, the straight line $v = 0$ in local charts U_1, U_2, V_1, V_2 corresponds to the equator $\mathbb{S}^1$ of $\mathbb{S}^2$, i.e., to the infinity of $\mathbb{R}^2$.

We note that an *infinite equilibrium* of X under the Poincaré compactification is an equilibrium of $p(X)$ in $\mathbb{S}^1$. Moreover, if y is an equilibrium in $\mathbb{S}^1$, then $-y$ is also an equilibrium. When the degree d of X is odd, these two equilibria have the same stability, and if d is even they have opposite stability. Due to the symmetry of $p(X)$ in $\mathbb{S}^2$, it is sufficient to investigate equilibria at infinity in the chart (U_1,ϕ_1) and checking if the origin of chart (U_2,ϕ_2) is also an equilibrium or not.

Since the integral curves in $\mathbb{S}^2$ are symmetric with respect to the origin, we only need to study the flow of $p(X)$ in the closed northern hemisphere, i.e., when $y_3 \geqslant 0$, projecting this part of $\mathbb{S}^2$ onto plane $y_3 = 0$ via a projection $\pi : (y_1,y_2,y_3) \mapsto (y_1,y_2,0)$ gives the so-called *Poincaré disc* $\mathbb{D}$.

For more details on the Poincaré compactification see Chapter 5 of [11].

2.5 Topological equivalence of two polynomial vector fields.

Two Poincaré compactifications $p(X_1)$ and $p(X_2)$ on $\mathbb{D}$ are *topologically equivalent* if there exists a homomorphism $h : \mathbb{D} \to \mathbb{D}$ preserving $\mathbb{S}^1$ and mapping the orbits of $\pi(p(X_1))$ onto the orbits of $\pi(p(X_2))$ preserving or reversing orientation of all the orbits.

The set of separatrices Σ_X of a Poincaré compactification $\pi(p(X))$ consists of all the orbits on $\mathbb{S}^1$, finite equilibria, limit cycles, and the two orbits of the boundary of all hyperbolic sectors associated with the finite and infinite equilibria. For more details, see [13,15].

The open connected regions of $\mathbb{D} \setminus \Sigma_X$ are called *canonical regions* of $\pi(p(X))$. The set Σ_X and one orbit inside each canonical region form the *separatrix configuration* Σ'_X. We denote by S the number of separatrices in the phase portrait of $\pi(p(X))$ on $\mathbb{D}$, and by R the number of its canonical regions. When the circle at infinity in the Poincaré disc is filled with equilibria we do not compute them in the number S.

Two separatrix configurations Σ'_1 and Σ'_2 are *topologically equivalent* if and only if there exists a homomorphism $h : \Sigma'_1 \to \Sigma'_2$ such that $h(\Sigma'_1) = \Sigma'_2$. Hence by the following theorem which was proved by Markus [13], Neumann [15] and Peixoto [19] independently, it suffices to determine when two phase portraits in the Poincaré disc are topologically equivalent by analysing their separatrix configurations.

Theorem 2.2. *Two Poincaré compactified polynomial vector fields $\pi(p(X_1))$ and $\pi(p(X_2))$ with finitely many separatrices are topologically equivalent if and only if their separatrix configurations Σ'_{X_1} and Σ'_{X_2} are topologically equivalent.*

2.6 Quadratic systems with an invariant parabola

The following proposition provides the classification of the quadratic systems having an invariant parabola.

Lemma 2.3 (Proposition 4 in [6])**.** *A quadratic system having an invariant parabola after an affine change of coordinates and a rescaling of the time can be written in the following form*

$$\dot{x} = \frac{b}{2}xy - \frac{a}{2}\left(y - x^2\right) - (p + qx + ry), \quad \dot{y} = by^2 + c\left(y - x^2\right) - 2x(p + qx + ry), \qquad \text{(P)}$$

where a, b, c, p, q, r are real parameters.

3 Main results

In the following two theorems, we present the normal forms of all planar quadratic systems possessing two invariant real straight lines and an invariant parabola, together with their corresponding phase portraits in the Poincaré disc.

Theorem 3.1. *By doing an affine change of variables and a rescaling of the time all the quadratic systems having either two invariant real straight lines and an invariant parabola $f_j = f_j(x, y) = 0$ with cofactors $K_j = K_j(x, y)$ for $j = 1, 2, 3$, or having one real straight line of multiplicity two and an invariant parabola, can be written as one of the following systems, where $H = H(x, y)$ is a first integral and $R = R(x, y)$ is an integrating factor of the corresponding quadratic system.*

$S(1)$ $\dot{x} = x + 1, \quad \dot{y} = x^2 + 2x + y,$
$f_1 = y - x^2, \quad K_1 = 1,$
$f_2 = x + 1, \quad$ *with multiplicity two,* $\quad K_2 = 1,$
$H = \frac{f_1}{f_2}.$

$S(2)$ $\dot{x} = -4x^2 - 2ax + 2y - a + \frac{1}{2}, \quad \dot{y} = -4xy + (1 - 2a)\,x - 4ay,$
$f_1 = y - x^2, \quad K_1 = -4(2x + a),$
$f_2 = 4x + 4y + 1, \quad K_2 = -4x - 4a + 2,$
$f_3 = 4ax + 4y + 2a - 1, \quad K_3 = -2(2x + a), \quad H = \frac{f_1}{f_3^2}.$

$S(3)$ $\dot{x} = -x^2 + (a+b)\,x - ab, \quad \dot{y} = (2b-1)\,x^2 - 2xy + (2a+1)\,y - 2abx,$
$f_1 = y - x^2, \quad K_1 = -2x + 2a + 1,$
$f_2 = x - a, \quad K_2 = b - x,$
$f_3 = x - b, \quad K_3 = a - x, \quad H = f_1^{a-b}\, f_2\, f_3^{2b-2a-1},$
where $(2a - 2b + 1) \neq 0$.

$S(4)$ $\dot{x} = 8(a+1)\,x^2 + 8xy + 2(4ab + 4a + 4b + 3)\,x + 4(2b+1)\,y + (4ab + 2a + 2b + 1),$
$\dot{y} = 8(a + 2b + 1)\,x^2 + 8(2a + 2b + 3)\,xy + 2(4ab + 2a + 2b + 1)\,x + 4(4ab + 2a + 1)\,y + 16y^2,$
$f_1 = y - x^2, \quad K_1 = 16(a+1)\,x + 16y + 4(4ab + 2a + 1),$
$f_2 = 4x + 4y + 1, \quad K_2 = 16(a + b + 1)\,x + 16y + 4(4ab + 2a + 2b + 1),$
$f_3 = 2x + 2b + 1, \quad K_3 = 8(a+1)\,x + 8y + 2(2a+1),$
$R = \frac{f_2^{(a-2b)/(2b)}}{f_1^{(a+b)/(2b)} f_3^2},$
where $ab \neq 0$.

$S(5)$ $\dot{x} = 4(a - b + 2)\,x^2 + 8xy + 2(b+3)\,x - 4(a - b - 1)\,y + (b+1),$
$\dot{y} = 4(2 - a + b)\,x^2 + 24xy + 16y^2 + 2(b+1)\,x + 4(a+1)\,y,$
$f_1 = y - x^2, \quad K_1 = 8(a - b + 2)\,x + 16y + 4(a+1),$
$f_2 = 4x + 4y + 1, \quad K_2 = 4(4x + 4y + b + 1),$
$f_3 = 4x + 4y + b + 1, \quad K_3 = 4(4x + 4y + 1),$
$R = \frac{1}{f_1 \sqrt{f_2 f_3}},$
where $a - b \neq 0$.

$S(6)$ $\dot{x} = 8(ab + 2a - b^2 + 4)\,x^2 + 8(b+2)^2\,xy - 2(b^2 - 4a - 12)\,x - 4(ab - 2b^2 - 6b + 2a - 4)\,y - (ab - 2a + 2b - 4),$
$\dot{y} = 16(2 + b)\,x^2 + 8(ab + 2a + 6b + 12)\,xy + 16(b+2)^2\,y^2 - 2(ab - 2a + 2b - 4)\,x - 4(b^2 - 4a + 4b - 4)\,y,$
$f_1 = y - x^2, \quad K_1 = 16(ab + 2a - b^2 + 4)\,x + 16(b+2)^2\,y - 4(b^2 - 4a + 4b - 4),$
$f_2 = 4x + 4y + 1, \quad K_2 = 8(ab + 2a + 2b - b^2 + 8)\,x + 16(b+2)^2\,y - 4(ab - 2a + 2b - 4),$
$f_3 = 8x + 4(b+2)\,y + (2 - b), \quad K_3 = 8(a+4)(b+2)\,x + 16(b+2)^2\,y + 8(a+2),$
$R = \frac{f_1^{(a-3b)/(2b-2a)}\, f_2^{b/(b-a)}}{f_3^2},$
where $(a - b)(b + 2) \neq 0$.

$S(7)$ $\dot{x} = 8(a+1)\,x^2 + 8xy + 2(ab + 2a + 2b + 3)\,x - 4(a - b - 1)\,y + (ab + a + b + 1),$
$\dot{y} = 8(b+1)\,x^2 + 8(a + b + 3)\,xy + 16y^2 + (2ab + 2a + 2b + 2)\,x + 4(ab + 2a + 1)\,y,$
$f_1 = y - x^2, \quad K_1 = 16(a+1)\,x + 16y + 4(ab + 2a + 1),$
$f_2 = 4x + 4y + 1, \quad K_2 = 8(a + b + 2)\,x + 16y + 4(ab + a + b + 1),$
$f_3 = 4(b+1)\,x + 4y + (b+1)^2, \quad K_3 = 8(a+2)\,x + 16y + 4(a+1),$
$R = \frac{1}{\sqrt{f_1 f_2 f_3}},$
where $a(a - b) \neq 0$.

$S(8)$ $\dot{x} = 8(a - b + 1)\,x^2 + 8xy - 2(4b^2 - 4a - 3)\,x + 4(2b+1)\,y - (2a+1)(4b^2 - 1),$
$\dot{y} = 8(a + b + 1)\,x^2 + 8(2a + 3)\,xy + 16y^2 - 2(8ab^2 + 4b^2 - 2a - 1)\,x - 4(4b^2 + 2b - 2a - 1)\,y,$
$f_1 = y - x^2, \quad K_1 = 16(a - b + 1)\,x + 16y - 4(4b^2 + 2b - 2a - 1),$
$f_2 = 4b^2 - 1 - 4x - 4y, \quad K_2 = 16(a+1)\,x + 16y + 4(2a+1),$

$f_3 = 2x + 2b + 1, \quad K_3 = 8(a - b + 1)\,x + 8y - 2(4ab - 2a + 2b - 1),$
$R = f_1^{-(a+3b)/(2b)} f_2^{(a-3b)/(2b)} f_3,$
where $b(a - b) \neq 0$.

Here $a, b \in \mathbb{R}$.

Theorem 3.2. *The global phase portrait of each system from Theorem 3.1 in the Poincaré disc is topologically equivalent to one of the phase portraits shown in Figure 3.1. Below each phase portrait in the Poincaré disc appear its name, the number of its separatrices S, the number of its canonical regions R, and the system associated with this phase portrait.*

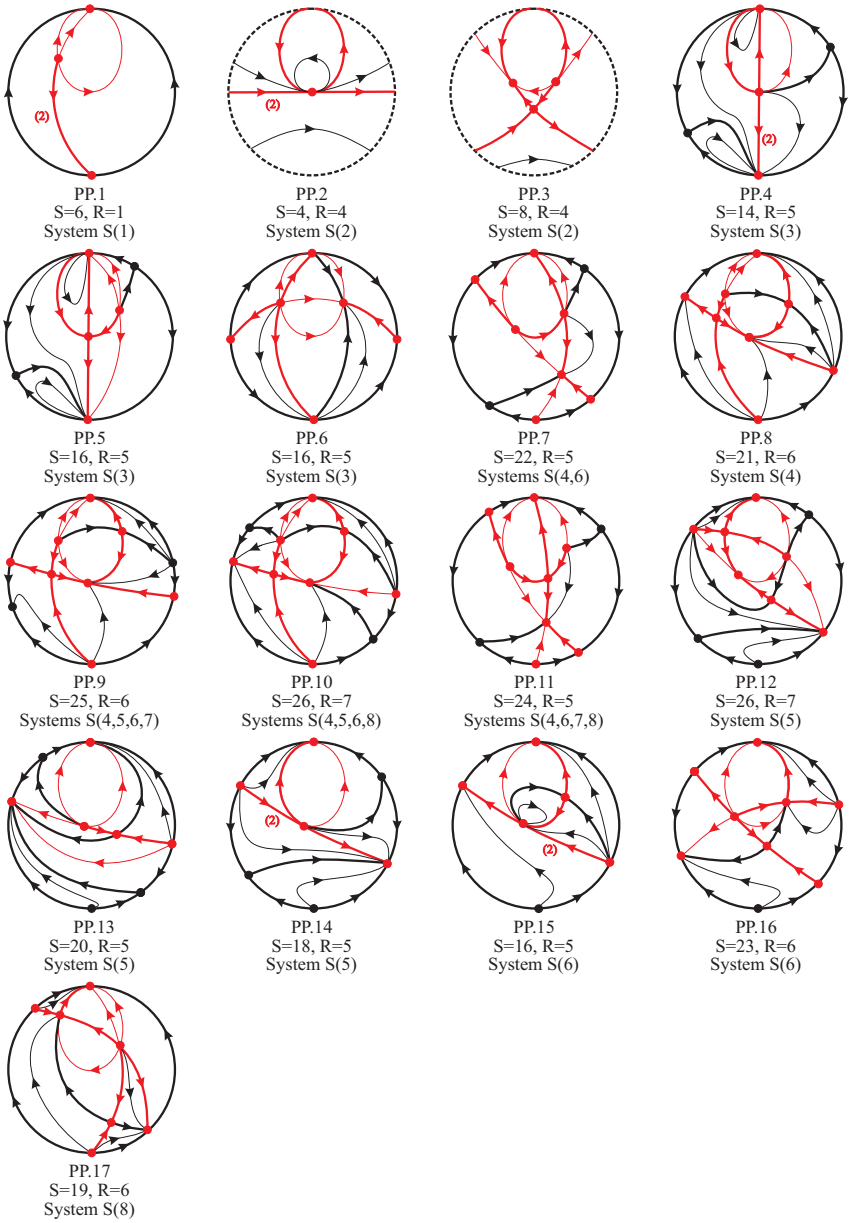

Figure 3.1: Phase portraits in the Poincaré disc of the systems in Theorem 3.1. Separatrices are represented by thick black or red lines, invariant curves are drawn in red, while trajectories within canonical regions are drawn with thin black lines.

4 Structure of the proof

To simplify the proofs of Theorems 3.1 and 3.2 we divide the original system (P) into two separate cases: $b = 0$ and $b = 1$. The overall structure of the analysis for each case is summarised in Figures 4.1 and 4.2.

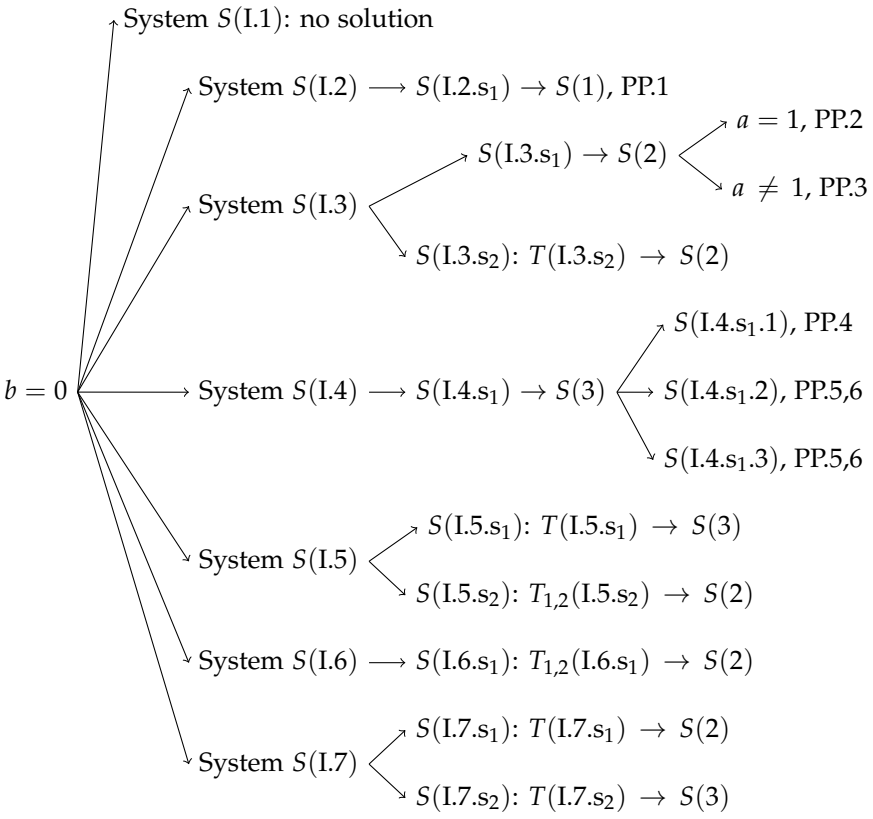

Figure 4.1: Structure of the proof of Theorem 3.1 when $b = 0$.

For each system in Theorem 3.1 we first impose the existence of one invariant straight line to the system, obtaining in total 12 systems, denoted by $S(\text{I}.i)$ and $S(\text{II}.i)$ for $b = 0$ and $b = 1$, respectively. Then, for each of these systems, we impose the existence of a second invariant straight line, obtaining new systems denoted by $S(\text{I}.i.\text{s}_j)$ and $S(\text{II}.i.\text{s}_j)$ which already have an invariant parabola and two invariant straight lines.

Sometimes one of those systems having an invariant parabola and two invariant straight lines is particular cases of another system having an invariant parabola and two invariant straight lines. For example, the notation

$$S(\text{I}.3.\text{s}_2) : T(\text{I}.3.\text{s}_2) \to S(2)$$

indicates that the system $S(\text{I}.3.\text{s}_2)$ can be obtained from system $S(2)$ via the transformation $T(\text{I}.3.\text{s}_2)$, and can therefore be regarded as a particular or an equivalent case. Consequently, when computing the phase portraits, it suffices to consider only the systems that cannot be obtained from other systems.

We shall identify only eight distinct systems whose phase portraits need to be studied. For each of these systems we list the relevant parameter conditions corresponding to different combinations of equilibria, along with the associated phase portrait labels. For instance, under system $S(2)$, the condition "$a = 1$, PP.2" means that when $a = 1$, the corresponding phase portrait is labelled as PP.2.

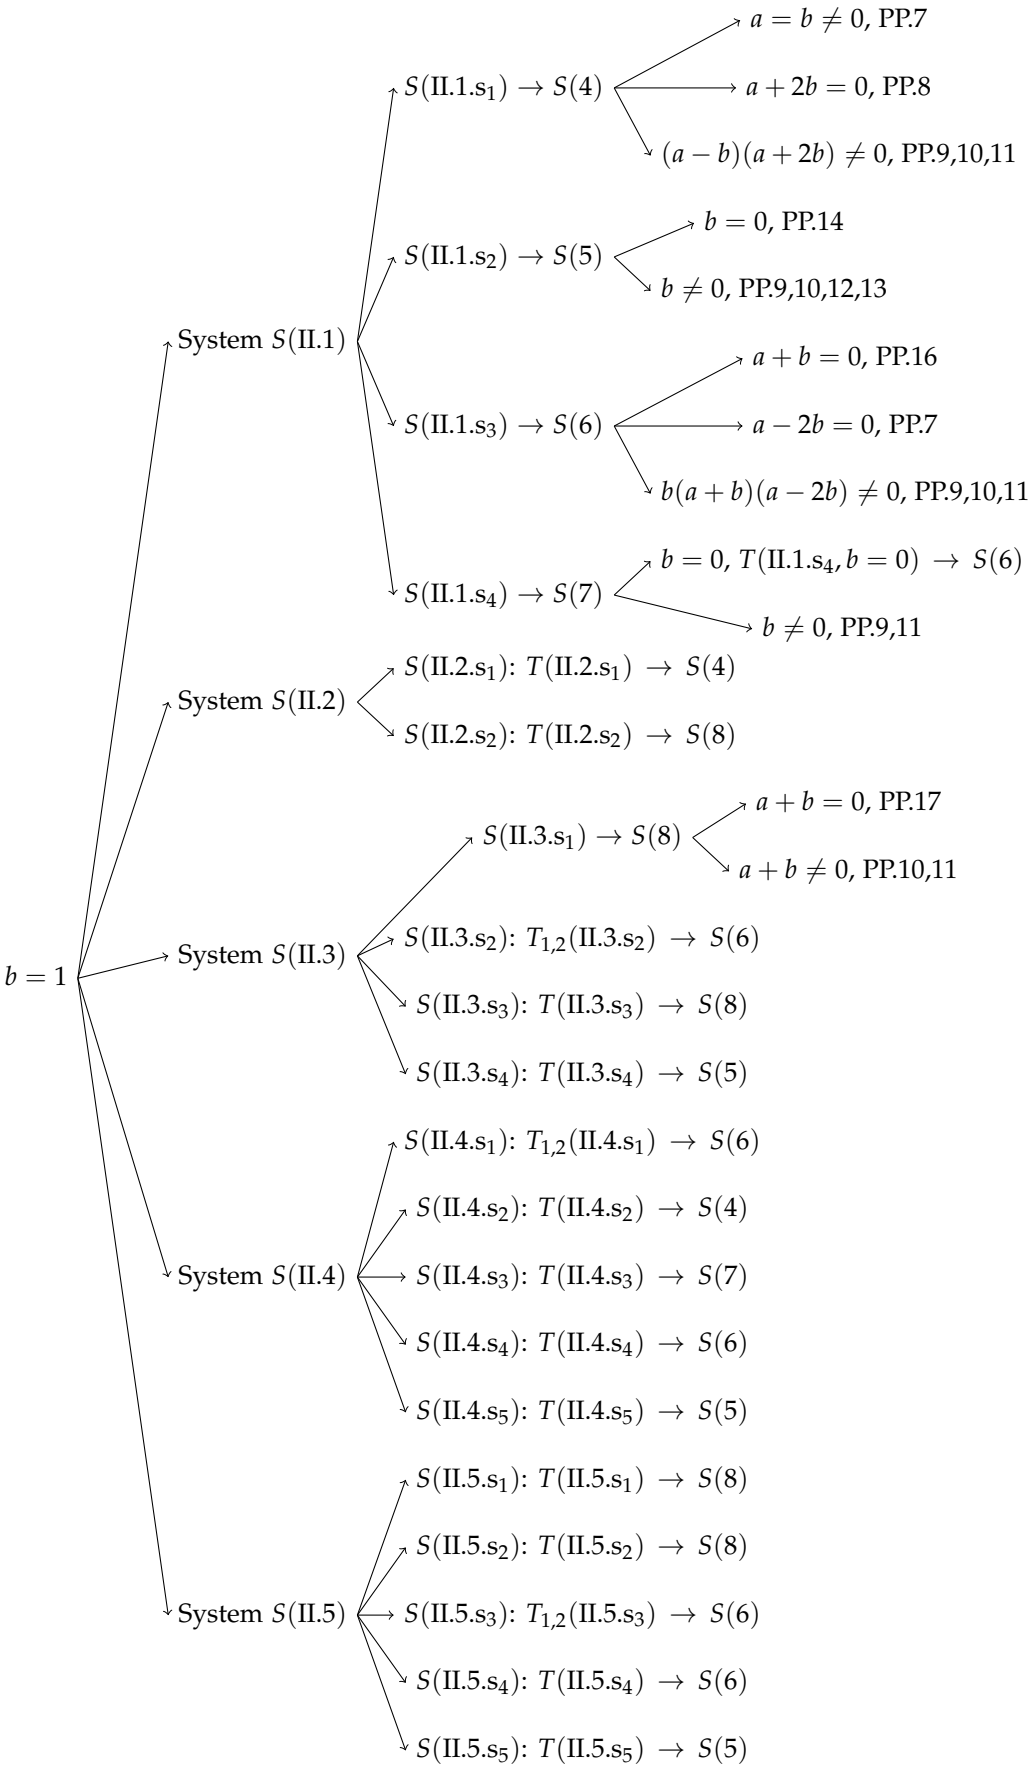

Figure 4.2: Structure of the proof of Theorem 3.1 when $b = 1$.

5 Proof of Theorem 3.1

Proof. Our objective is to determine the general forms of all systems in **QSR2P**. The proof begins with system (P) in Lemma 2.3, which admits an invariant parabola defined by $f_1 = y - x^2 = 0$.

The approach is first to force the existence of one additional invariant straight line $f_2 = 0$ in system (P). By applying the definition of invariant algebraic curve, we obtain all possible systems with one invariant straight line. After that, for each system, we force the existence of a second invariant straight line $f_3 = 0$. In this way, we obtain all systems that admit two invariant straight lines $f_2 = 0$ and $f_3 = 0$, and the invariant parabola $f_1 = 0$.

To facilitate the computations in the study of system (P) we consider the two distinct cases $b = 0$ and $b = 1$. Note that when $b \neq 0$, after rescaling the time, we can assume $b = 1$; the other parameters of the new system are divided by b, but we keep using the same letters to denote them.

Case I: $b = 0$. If $a = 0$, the existence of the invariant parabola requires $c \neq 0$. In this case, after performing the change of parameters $(p, q, r) \to (cp, cq, cr)$ together with the time rescaling $t \to \dfrac{t}{c}$, the system (P) simplifies to

$$\dot{x} = -qx - ry - p, \quad \dot{y} = (y - x^2) - 2x(qx + ry + p). \tag{P.1}$$

The existence of one invariant straight line $f_2 = 0$ in system (P.1) leads to two distinct subsystems, denoted by $S(\text{I}.k)$ for $k = 1, 2$.

If $a \neq 0$, after doing the change of parameters $(p, q, r, c) \to \left(\frac{ap}{2}, \frac{aq}{2}, \frac{ar}{2}, -\frac{ac}{2}\right)$ and the time rescaling $t \to \frac{-2t}{a}$ the system (P) reduces to

$$\dot{x} = y - x^2 + qx + ry + p, \quad \dot{y} = c(y - x^2) + 2x(qx + ry + p). \tag{P.2}$$

The existence of an invariant straight line $f_2 = 0$ in system (P.2) leads to five distinct subsystems, denoted by $S(\text{I}.k)$ for $k = 3, 4, 5, 6, 7$.

Case II: $b = 1$. The system (P) reduces to

$$\dot{x} = \frac{1}{2}xy - \frac{a}{2}(y - x^2) - (qx + ry + p), \quad \dot{y} = y^2 + c(y - x^2) - 2x(qx + ry + p). \tag{P.3}$$

Forcing the existence of the straight line $f_2 = 0$ produces five subsystems, denoted by $S(\text{II}.k)$ for $k = 1, 2, 3, 4, 5$.

Thus, we have obtained a total of twelve systems. To each of these systems we force the existence of a second invariant straight line $f_3 = 0$ in order to find all possible systems in the class **QSR2P**.

The proof is organised into the following fourteen steps:

- **Step 1**: Derivation of the systems $S(\text{I}.1)$ through $S(\text{I}.7)$,
- **Step 2**: Derivation of the systems $S(\text{II}.1)$ through $S(\text{II}.5)$,
- **Steps 3–14**: To each of the above twelve systems we force the existence of a second invariant straight line $f_3 = 0$ for generating all systems in **QSR2P**.

Step 1. Suppose that system (P.1) possesses an invariant straight line $f_2 = a_1x + a_2y + a_0 = 0$ with cofactor $K_2 = k_1x + k_2y + k_0$. Substituting f_2, K_2 and the system (P.1) into (2.1), we obtain

two solutions

$$\text{I.s}_1 = \left\{ \begin{array}{l} a_0 = \dfrac{a_1^2}{4a_2},\ k_0 = \dfrac{a_1k_1}{2a_2} + 1,\ k_2 = 0,\ p = -\dfrac{a_1(2a_2 + a_1k_1)}{8a_2^2}, \\ q = -\dfrac{a_2 + a_1k_1}{2a_2},\ r = -\dfrac{k_1}{2} \end{array} \right\},$$

$$\text{I.s}_2 = \left\{ a_2 = 0,\ k_1 = 0,\ k_2 = 0,\ p = -\frac{a_0k_0}{a_1},\ q = -k_0,\ r = 0 \right\}.$$

Since $a_2 \neq 0$ in solution (I.s$_1$), substituting it into the system (P.1), after doing the transformation $a_1 \to 2a_1a_2$ and the time rescaling $t \to 2t$, we obtain the system

$$\begin{array}{ll} S(\text{I.1}) & \dot{x} = (2a_1k_1 + 1)x + k_1y + a_1 + a_1^2k_1, \\ & \dot{y} = 4a_1k_1x^2 + 2k_1xy + (2a_1 + 2a_1^2k_1)x + 2y, \\ & f_2 = 2a_1x + y + a_1^2, \quad K_2 = 2k_1x + 2k_1a_1 + 2. \end{array}$$

For the solution (I.s$_2$), we have $a_1k_0 \neq 0$. Indeed, if $k_0 = 0$, then we must have $p = q = r = 0$, which implies $\dot{x} = 0$. Substituting (I.s$_2$) into the system (P.1), after doing the transformation $a_0 \to \frac{a_1a_0}{k_0}$, we obtain the system

$$\begin{array}{ll} S(\text{I.2}) & \dot{x} = k_0x + a_0, \quad \dot{y} = (2k_0 - 1)x^2 + 2a_0x + y, \\ & f_2 = k_0x + a_0, \quad K_2 = k_0. \end{array}$$

Suppose that the system (P.2) possesses an invariant straight line $f_2 = 0$ with cofactor K_2 as defined previously. To simplify the computations, we consider two cases for the parameter a_1 in f_2: $a_1 = 1$ and $a_1 = 0$. Of course, if $a_1 \neq 0$ by rescaling of the time we can set $a_1 = 1$.
Case 1. $a_1 = 1, f_2 = x + a_2y + a_0$. Substituting f_2, K_2, and the system (P.2) into (2.1), we obtain the following three solutions

$$\text{I.s}_3 = \left\{ a_0 = \frac{1}{4a_2},\ c = \frac{2a_2k_0 - k_1 - 2}{2a_2},\ k_2 = 0,\ p = \frac{k_0}{4a_2},\ q = \frac{2a_2k_0 + k_1}{4a_2},\ r = \frac{k_1}{2} \right\},$$

$$\text{I.s}_4 = \{ a_2 = 0,\ k_1 = -1,\ k_2 = 0,\ p = a_0k_0,\ q = k_0 - a_0,\ r = -1 \},$$

$$\text{I.s}_5 = \left\{ c = -\frac{1}{a_2},\ k_1 = 2a_2k_0,\ k_2 = 0,\ p = a_0k_0,\ q = k_0,\ r = a_2k_0 \right\}.$$

For the solution (I.s$_3$), we have $a_2 \neq 0$. Substituting (I.s$_3$) into the system (P.2), after doing the transformation $(x,\ y,\ t,\ k_0) \to \left(\frac{x}{a_2},\ \frac{y}{a_2^2},\ 4a_2t,\ \frac{k_0}{a_2}\right)$, we obtain the system

$$\begin{array}{ll} S(\text{I.3}) & \dot{x} = -4x^2 + (2k_0 + k_1)x + (2k_1 + 4)y + k_0, \\ & \dot{y} = (4k_1 + 4)x^2 + 2k_0x + 4k_1xy + (4k_0 - 2k_1 - 4)y, \\ & f_2 = 4x + 4y + 1, \quad K_2 = 4(k_1x + k_0). \end{array}$$

Substituting the solution (I.s$_4$) into system the (P.2), we obtain the system $*S(\text{I.4})$

$$\dot{x} = -x^2 + (k_0 - a_0)\,x + a_0k_0, \quad \dot{y} = (2k_0 - 2a_0 - c)\,x^2 + 2a_0k_0\,x - 2xy + cy.$$

Here we have $c + 2a_0 \neq 0$. Otherwise, if $c + 2a_0 = 0$, the system becomes

$$\dot{x} = -(x + a_0)(x - k_0), \quad \dot{y} = 2(x + a_0)(k_0x - y),$$

and can be reduced to a linear differential system.

Doing the transformation $(x,\ y,\ t,\ a_0,\ c,\ k_0) \to \left(c_1x,\ c_1^2y,\ \frac{t}{c_1},\ a_0c_1,\ c_1 - 2a_0,\ k_0c_1\right)$ with $c_1 \neq 0$ to system $*S(\text{I.4})$ we obtain

$$S(\text{I.4})\ \dot{x} = -x^2 + (k_0 - a_0)\,x + a_0k_0, \quad \dot{y} = (2k_0 - 1)\,x^2 + 2a_0k_0\,x - 2xy - (2a_0 - 1)\,y,$$
$$f_2 = x + a_0, \quad K_2 = k_0 - x.$$

For the solution (I.s_5), we have $a_2 \neq 0$. Substituting (I.s_5) into the system (P.2), after doing the transformation $(x,\ y,\ t,\ k_0,\ a_0) \to \left(\frac{x}{a_2},\ \frac{y}{a_2^2},\ a_2t,\ \frac{k_0}{a_2},\ \frac{a_0}{a_2}\right)$, we obtain the system

$$S(\text{I.5})\ \dot{x} = -x^2 + k_0x + (k_0 + 1)\,y + a_0k_0, \quad \dot{y} = (2k_0 + 1)\,x^2 + 2a_0k_0\,x + 2k_0xy - y,$$
$$f_2 = x + y + a_0, \quad K_2 = k_0(2x + 1).$$

Case 2. $a_1 = 0$, $f_2 = a_2y + a_0$. Substituting f_2, K_2, and the system (P.2) into (2.1), we obtain two solutions

$$\text{I.s}_6 = \left\{a_0 = 0,\ k_0 = c,\ k_2 = 0,\ p = 0,\ q = \frac{c}{2},\ r = \frac{k_1}{2}\right\},$$
$$\text{I.s}_7 = \left\{c = 0,\ k_0 = 0,\ k_2 = 0,\ p = \frac{a_0k_1}{2a_2},\ q = 0,\ r = \frac{k_1}{2}\right\}.$$

For the solution (I.s_6), we have $k_1 \neq 2$. Indeed, substituting (I.s_6) and $k_1 = 2$ into the system (P.2) we obtain a linear differential system. Taking (I.s_6) into (P.2), doing the parameter change $k_1 \to k_1 - 2$ and the time rescaling $t \to 2t$ we obtain

$$S(\text{I.6})\ \dot{x} = -2x^2 + cx + k_1y, \quad \dot{y} = (2k_1 - 4)\,xy + 2cy,$$
$$f_2 = y, \quad K_2 = (2k_1 - 4)\,x + 2c.$$

For the solution (I.s_7), we have $a_2 \neq 0$. Substituting (I.s_7) into the system (P.2), after doing the transformation $(x,\ y,\ t,\ a_0) \to \left(\frac{x}{a_2},\ \frac{y}{a_2^2},\ 2a_2t,\ \frac{a_0}{a_2k_1}\right)$, we obtain the system

$$S(\text{I.7})\ \dot{x} = -2x^2 + (k_1 + 2)\,y + a_0, \quad \dot{y} = 2k_1xy + 2a_0x,$$
$$f_2 = k_1y + a_0, \quad K_2 = 2k_1x.$$

Step 2. Suppose that system (P.3) possesses an invariant straight line $f_2 = 0$ with cofactor K_2 as defined previously. In order to simplify the computations, we consider two cases for the parameter a_1 in f_2: $a_1 = 1$ and $a_1 = 0$.

Case 1. $a_1 = 1$, $f_2 = x + a_2y + a_0$. Substituting f_2, K_2, and the system (P.3) into (2.1), we obtain three solutions

$$\text{II.s}_1 = \left\{\begin{array}{l} a = 2a_2c - 2a_2k_0 + k_1,\ a_0 = \dfrac{1}{4a_2},\ k_2 = 1,\ p = -\dfrac{k_0}{4a_2},\ q = -\dfrac{2a_2k_0 + k_1}{4a_2}, \\ r = -\dfrac{2a_2k_1 + 1}{4a_2} \end{array}\right\},$$
$$\text{II.s}_2 = \left\{a = 2k_1,\ a_2 = 0,\ k_2 = \frac{1}{2},\ p = -a_0k_0,\ q = -k_0 - a_0k_1,\ r = -\frac{a_0 + 2k_1}{2}\right\},$$
$$\text{II.s}_3 = \left\{\begin{array}{l} a = \dfrac{2a_2^2c - 2a_0a_2 + 1}{a_2},\ k_1 = \dfrac{4a_2^2k_0 + 1}{2a_2},\ k_2 = 1,\ p = -a_0k_0, \\ q = -\dfrac{a_0 + 2a_2k_0}{2a_2},\ r = -\dfrac{2a_2^2k_0 + 1}{2a_2} \end{array}\right\}.$$

For the solution (II.s_1), we have $a_2 \neq 0$. Substituting (II.s_1) into the system (P.3), after doing the transformation $(x, y, t, k_0, k_1, c) \to \left(\frac{x}{a_2},\ \frac{y}{a_2^2},\ 4a_2^2t,\ \frac{2k_0}{a_2^2},\ \frac{k_1}{a_2},\ \frac{c}{a_2^2}\right)$, we obtain the system

$$S(\text{II.1})\ \dot{x} = (4c - 8k_0 + 2k_1)\,x^2 + 2xy + (4k_0 + k_1)\,x + (8k_0 - 4c + 1)\,y + 2k_0,$$
$$\dot{y} = (8k_0 - 4c + 2k_1)\,x^2 + (2 + 4k_1)\,xy + 4y^2 + 4k_0x + 4cy,$$
$$f_2 = 4(x + y) + 1, \quad K_2 = 4(k_1x + y + 2k_0).$$

Substituting (II.s_2) into the system (P.3) and doing the time rescaling $t \to 2t$, it simplifies to system $*S(\text{II.2})$

$$\begin{aligned}\dot{x} &= 2k_1x^2 + xy + (2k_0 + 2a_0k_1)\,x + a_0y + 2a_0k_0,\\ \dot{y} &= (4a_0k_1 + 4k_0 - 2c)\,x^2 + (2a_0 + 4k_1)\,xy + 2y^2 + 4a_0k_0x + 2c\,y.\end{aligned}$$

Here we have $c - 2k_0 \neq 0$. If $c - 2k_0 = 0$, the system becomes

$$\dot{x} = (x + a_0)(2k_1x + y + 2k_0), \quad \dot{y} = 2(a_0x + y)(2k_1x + y + 2k_0),$$

and can be reduced to a linear differential system.

Doing the following transformation to system $*S(\text{II.2})$

$$(x, y, t, a_0, c, k_0, k_1) \to \left(\sqrt{c_1}\,x,\ c_1y,\ \frac{t}{c_1},\ \sqrt{c_1}\,a_0,\ c_1(2k_0 + 1),\ c_1k_0,\ \sqrt{c_1}\,k_1\right)$$

yields

$$\begin{aligned}S(\text{II.2})\ \ &\dot{x} = 2k_1x^2 + xy + a_0y + (2k_0 + 2a_0k_1)\,x + 2a_0k_0,\\ &\dot{y} = (4a_0k_1 - 2)\,x^2 + (2a_0 + 4k_1)\,xy + 2y^2 + 4a_0k_0x + (2 + 4k_0)\,y,\\ &f_2 = x + a_0, \quad K_2 = 2k_1x + y + 2k_0.\end{aligned}$$

For the solution (II.s_3), we have $a_2 \neq 0$. Substituting (II.s_3) into the system (P.3), after doing the transformation $(x, y, t, k_0, c, a_0) \to \left(\frac{x}{a_2},\ \frac{y}{a_2^2},\ 2a_2^2t,\ \frac{k_0}{a_2^2},\ \frac{c}{a_2^2},\ \frac{a_0}{a_2}\right)$, it reduces to

$$\begin{aligned}S(\text{II.3})\ \ &\dot{x} = (2c - 2a_0 + 1)\,x^2 + xy + (a_0 + 2k_0)\,x + (2a_0 - 2c + 2k_0)\,y + 2a_0k_0,\\ &\dot{y} = (2a_0 - 2c + 4k_0)\,x^2 + (4k_0 + 2)\,xy + 2y^2 + 4a_0k_0x + 2cy,\\ &f_2 = x + y + a_0, \quad K_2 = (4k_0 + 1)\,x + 2y + 2k_0.\end{aligned}$$

Case 2. $a_1 = 0$, $f_2 = a_2y + a_0$. Since $a_2 \neq 0$, we set $a_2 = 1$ and then $f_2 = y + a_0$. Substituting f_2, K_2, and the system (P.3) into (2.1), we obtain two solutions

$$\begin{aligned}\text{II.s}_4 &= \left\{a_0 = 0,\ k_0 = c,\ k_2 = 1,\ p = 0,\ q = -\frac{c}{2},\ r = -\frac{k_1}{2}\right\},\\ \text{II.s}_5 &= \left\{c = a_0,\ k_0 = 0,\ k_2 = 1,\ p = -\frac{a_0k_1}{2},\ q = -\frac{a_0}{2},\ r = -\frac{k_1}{2}\right\}.\end{aligned}$$

Substituting the solution (II.s_4) into the system (P.3) and doing the time rescaling $t \to 2t$ yields system $*S(\text{II.4})$

$$\dot{x} = ax^2 + xy + cx + (k_1 - a)\,y, \qquad \dot{y} = 2k_1xy + 2y^2 + 2cy.$$

Here we have $k_1 - a \neq 0$. If $k_1 - a = 0$, the system reduces to

$$\dot{x} = x(ax + y + c), \quad \dot{y} = 2y(ax + y + c),$$

and can be reduced to a linear differential system.

Applying the transformation $(x, y, t, a, c, k_1) \to \left(kx,\ k^2y,\ \frac{t}{k^2},\ ak,\ ck^2,\ k(a+1)\right)$ to the system $*S(\text{II.4})$ yields

$$\begin{aligned}S(\text{II.4})\ \ &\dot{x} = ax^2 + xy + cx + y, \quad \dot{y} = (2a + 2)\,xy + 2y^2 + 2cy,\\ &f_2 = y, \quad K_2 = 2(a + 1)\,x + 2y + 2c.\end{aligned}$$

Substituting the solution $(\mathrm{II.s}_5)$ into the system (P.3) and doing the time rescaling $t \to 2t$ yields system $*S(\mathrm{II.5})$

$$\dot{x} = ax^2 + xy + a_0x + (k_1 - a)\,y + a_0k_1, \qquad \dot{y} = 2k_1xy + 2y^2 + 2a_0k_1x + 2a_0y.$$

Here we have $a \neq 0$. If $a = 0$, the system becomes

$$\dot{x} = (x + k_1)(y + a_0), \quad \dot{y} = 2(y + a_0)(k_1x + y),$$

and it can be reduced to a linear differential system.

Applying the transformation $(x, y, t, a_0, k_1) \to \left(ax,\ a^2y,\ \frac{t}{a^2},\ a_0a^2,\ k_1a\right)$ to the system $*S(\mathrm{II.5})$ yields

$$\begin{aligned} S(\mathrm{II.5})\ \ & \dot{x} = x^2 + xy + a_0x + (k_1 - 1)\,y + a_0k_1, \quad \dot{y} = 2k_1xy + 2y^2 + 2a_0k_1x + 2a_0y, \\ & f_2 = y + a_0, \quad K_2 = 2(k_1x + y). \end{aligned}$$

Step 3. Suppose that system $S(\mathrm{I.1})$ possesses an invariant straight line $f_3 = b_1x + b_2y + b_0 = 0$ with cofactor $K_3 = l_1x + l_2y + l_0$. Substituting f_3, K_3, and the system $S(\mathrm{I.1})$ into (2.1), we obtain the following four solutions

$$\begin{aligned} \mathrm{I.1.s}_1 &= \left\{b_0 = a_1^2b_2,\ b_1 = 2a_1b_2,\ l_0 = 2a_1k_1 + 2,\ l_1 = 2k_1,\ l_2 = 0\right\}, \\ \mathrm{I.1.s}_2 &= \left\{b_0 = a_1b_1,\ b_2 = 0,\ k_1 = 0,\ l_0 = 1,\ l_1 = 0,\ l_2 = 0\right\}, \\ \mathrm{I.1.s}_3 &= \left\{b_0 = \frac{a_1b_1}{2},\ b_2 = \frac{b_1}{2a_1},\ k_1 = 0,\ l_0 = 2,\ l_1 = 0,\ l_2 = 0\right\}, \\ \mathrm{I.1.s}_4 &= \left\{a_1 = 0,\ b_0 = 0,\ b_2 = 0,\ k_1 = 0,\ l_0 = 1,\ l_1 = 0,\ l_2 = 0\right\}. \end{aligned}$$

Solutions $(\mathrm{I.1.s}_k), k = 2, 3, 4$ correspond to linear systems, so we discard them. Solution $(\mathrm{I.1.s}_1)$ corresponds to a system with a double invariant straight line. By requiring that f_2^2 be a factor of the extactic polynomial E_1 we obtain the following polynomial system

$$2a_1^3k_1^2 + 4a_1^2k_1 + a_1 = 0, \quad 6a_1^2k_1^2 + 8a_1k_1 + 1 = 0, \quad 6a_1k_1^2 + 4k_1 = 0,\ 2k_1^2 = 0.$$

However, there are no solutions for the above polynomial system.

Step 4. Imposing an invariant straight line $f_3 = 0$ with cofactor K_3 on $S(\mathrm{I.2})$, and substituting f_3, K_3, and $S(\mathrm{I.2})$ into (2.1), we obtain the following three solutions

$$\begin{aligned} \mathrm{I.2.s}_1 &= \left\{a_0 = \frac{b_0l_0}{b_1},\ b_2 = 0,\ k_0 = l_0,\ l_1 = 0,\ l_2 = 0\right\}, \\ \mathrm{I.2.s}_2 &= \left\{a_0 = \frac{b_1}{4b_2},\ b_0 = \frac{b_1^2}{4b_2},\ k_0 = \frac{1}{2},\ l_0 = 1,\ l_1 = 0,\ l_2 = 0\right\}, \\ \mathrm{I.2.s}_3 &= \left\{a_0 = 0,\ b_0 = 0,\ b_1 = 0,\ k_0 = \frac{1}{2},\ l_0 = 1,\ l_1 = 0,\ l_2 = 0\right\}. \end{aligned}$$

Solutions $(\mathrm{I.2.s}_2), (\mathrm{I.2.s}_3)$ correspond to linear systems. Solution $(\mathrm{I.2.s}_1)$ corresponds to a system with a double invariant straight line. By requiring that f_2^2 be a factor of the extactic polynomial E_1 we obtain the following polynomial equations

$$\frac{b_0^2l_0(l_0 - 1)}{a_1b_1^2} = 0, \quad \frac{l_0(1 - l_0)}{a_1} = 0,$$

and two solutions $l_0 = 0$ and $l_0 = 1$. If $l_0 = 0$, the system degenerates to

$$\dot{x} = 0, \quad \dot{y} = y - x^2.$$

If $l_0 = 1$, taking it into the solution (I.2.s_1) we obtain

$$\text{I.2.s}_{1.1} = \left\{ a_0 = \frac{b_0}{b_1},\ b_2 = 0,\ k_0 = 1,\ l_0 = 1,\ l_1 = 0,\ l_2 = 0 \right\}.$$

Substituting $(\text{I.2.s}_{1.1})$ into system $S(\text{I.2})$, we obtain the system $S(\text{I.2.s}_{1.1})$:

$$\dot{x} = x + \frac{b_0}{b_1}, \qquad \dot{y} = x^2 + \frac{2b_0 x}{b_1} + y.$$

If $b_0 \neq 0$, set $a \neq 0$. Doing the transformation $(x, y, b_0) \to (ax,\ a^2 y,\ a b_1)$, the system $S(\text{I.2.s}_{1.1})$ reduces to

$$\begin{aligned} S(1)\ \ & \dot{x} = x + 1, \quad \dot{y} = x^2 + 2x + y, \\ & f_1 = y - x^2, \quad K_1 = 1, \\ & f_2 = x + 1, \quad K_2 = 1, \quad H = \frac{f_1}{f_2}. \end{aligned}$$

Here and in what follows, H denotes a first integral.

If $b_0 = 0$, applying the translation $(x, y) \to (x + 1,\ y - 1)$ to the system $S(\text{I.2.s}_{1.1})$, it reduces to $S(1)$.

Step 5. We impose that $S(\text{I.3})$ possesses an invariant straight line $f_3 = 0$ with cofactor K_3. To simplify the computations, we consider the parameter b_1 in f_3 in two cases: $b_1 = 1$ and $b_1 = 0$.

Case 1. $b_1 = 1$, so that $f_3 = x + b_2 y + b_0$. Substituting f_3, K_3, and $S(\text{I.3})$ into (2.1), eliminating the solutions corresponding to linear systems, and treating the solutions corresponding to systems with a double invariant straight line as in $S(\text{I.1})$ and $S(\text{I.2})$, we eventually obtain two solutions

$$\begin{aligned} \text{I.3.s}_1 &= \left\{ b_0 = \frac{1}{2} - \frac{b_2}{4},\ k_0 = \frac{1}{2} - \frac{1}{b_2},\ k_1 = -1,\ l_0 = -\frac{2}{b_2},\ l_1 = -4,\ l_2 = 0 \right\}, \\ \text{I.3.s}_2 &= \left\{ b_0 = \frac{1}{4b_2},\ k_0 = -\frac{1}{2b_2},\ k_1 = -1,\ l_0 = -2,\ l_1 = -4,\ l_2 = 0 \right\}. \end{aligned}$$

Substituting (I.3.s_1) into $S(\text{I.3})$, we obtain the system $S(\text{I.3.s}_1)$:

$$\dot{x} = -4x^2 - \frac{2}{b_2} x + 2y - \frac{1}{b_2} + \frac{1}{2}, \qquad \dot{y} = -4xy - \left(\frac{2}{b_2} - 1 \right) x - \frac{4}{b_2} y.$$

Doing the transformation $b_2 \to \frac{1}{a}$, the system reduces to

$$\begin{aligned} S(2)\ \ & \dot{x} = -4x^2 - 2ax + 2y - a + \frac{1}{2}, \quad \dot{y} = -4xy + (1 - 2a)\, x - 4ay, \\ & f_1 = y - x^2, \quad K_1 = -4(2x + a), \\ & f_2 = 4x + 4y + 1, \quad K_2 = -4x - 4a + 2, \\ & f_3 = 4ax + 4y + 2a - 1, \quad K_3 = -2(2x + a), \quad H = \frac{f_1}{f_3^2}. \end{aligned}$$

Substituting (I.3.s_2) into $S(\text{I.3})$, we obtain the system $S(\text{I.3.s}_2)$:

$$\dot{x} = -4x^2 - \left(\frac{1}{b_2} + 1\right) x + 2y - \frac{1}{2b_2}, \qquad \dot{y} = -4xy - \frac{1}{b_2} x - \left(\frac{2}{b_2} + 2\right) y.$$

However, applying the parameter change $T(\text{I.3.s}_2) : a \to \frac{b_2+1}{2b_2}$ to system $S(2)$, the system reduces to $S(\text{I.3.s}_2)$.

Case 2. $b_1 = 0$, so that $f_3 = b_2 y + b_0$. Following the same process as in **Case 1**, we obtain two solutions

$$\text{I.3.s}_3 = \{b_0 = 0,\ k_0 = 0,\ k_1 = -1,\ l_0 = -2,\ l_1 = -4,\ l_2 = 0\},$$
$$\text{I.3.s}_4 = \left\{b_0 = -\frac{b_2}{4},\ k_0 = \frac{1}{2},\ k_1 = -1,\ l_0 = 0,\ l_1 = -4,\ l_2 = 0\right\}.$$

However, the system associated with solution (I.3.s_3) is the case $b_2 = 2$ of system $S(\text{I.3.s}_1)$, while the solution (I.3.s_4) arises when $b_2 = -1$ in system $S(\text{I.3.s}_2)$.

Step 6. Substituting f_3, K_3, and $S(\text{I.4})$ into (2.1), and following the same process as in $S(\text{I.3})$, we obtain a solution

$$\text{I.4.s}_1 = \{b_0 = -k_0,\ b_2 = 0,\ l_0 = -a_0,\ l_1 = -1,\ l_2 = 0\}.$$

Substituting (I.4.s_1) into $S(\text{I.4})$ yields system $S(\text{I.4.s}_1)$:

$$\dot{x} = -x^2 + (k_0 - a_0)\, x + a_0 k_0, \qquad \dot{y} = (2k_0 - 1)\, x^2 - 2xy + (1 - 2a_0)\, y + 2a_0 k_0 x.$$

Applying the parameter change $(a_0, k_0) \to (-a,\ b)$ to the above system yields

$$\begin{aligned} S(3)\ \ & \dot{x} = -x^2 + (a+b)\, x - ab, \quad \dot{y} = (2b-1)\, x^2 - 2xy + (2a+1)\, y - 2abx, \\ & f_1 = y - x^2, \quad K_1 = -2x + 2a + 1, \\ & f_2 = x - a, \quad K_2 = b - x, \\ & f_3 = x - b, \quad K_3 = a - x, \quad H = f_1^{a-b}\, f_2\, f_3^{2b-2a-1}. \end{aligned}$$

Here we have $2a - 2b + 1 \neq 0$. If $2a - 2b + 1 = 0$, the system becomes

$$\dot{x} = -\frac{1}{2}(2x - 2a - 1)(x - a), \quad \dot{y} = (2x - 2a - 1)(ax - y),$$

and can be reduced to a linear differential system.

Step 7. Substituting f_3, K_3, and $S(\text{I.5})$ into (2.1), we obtain two solutions

$$\text{I.5.s}_1 = \{a_0 = b_0 - b_0^2,\ b_2 = 0,\ k_0 = -1,\ l_0 = b_0 - 1,\ l_1 = -1,\ l_2 = 0\},$$
$$\text{I.5.s}_2 = \left\{a_0 = \frac{2b_2 - 1}{4b_2^2},\ b_0 = \frac{1}{4b_2},\ k_0 = -\frac{1}{2},\ l_0 = \frac{1 - 2b_2}{2b_2},\ l_1 = -1,\ l_2 = 0\right\}.$$

Substituting (I.5.s_1) and (I.5.s_2) into $S(\text{I.5})$, we obtain systems $S(\text{I.5.s}_1)$ and $S(\text{I.5.s}_2)$:

$$\dot{x} = -x^2 - x + b_0^2 - b_0, \qquad \dot{y} = -x^2 - 2xy + (2b_0^2 - 2b_0)\, x - y.$$

$$\dot{x} = -x^2 - \frac{1}{2}x + \frac{1}{2}y + \frac{1}{8b_2^2} - \frac{1}{4b_2}, \qquad \dot{y} = -xy + \left(\frac{1}{4b_2^2} - \frac{1}{2b_2}\right) x - y,$$

respectively. Applying the transformations $T(\text{I.5.s}_1)$ to system $S(3)$, it reduces to $S(\text{I.5.s}_1)$, where

$$T(\text{I.5.s}_1) : (x, y, t, a, b) \to \left(a + \frac{x + b_0}{2b_0 - 1},\ a^2 + \frac{b_0^2 + 2a(b_0 + x) - y}{2b_0 - 1},\ (2b_0 - 1)^2 t,\ a,\ a + 1\right).$$

For the system $S(\text{I.5.s}_2)$, if $2b_2-1\neq 0$, then applying the transformation $T_1(\text{I.5.s}_2)$ to system $S(2)$ yields $S(\text{I.5.s}_2)$ with $b_2\neq\frac{1}{2}$; if $2b_2-1=0$, then applying the transformation $T_2(\text{I.5.s}_2)$ to system $S(2)$ yields $S(\text{I.5.s}_2)$ with $b_2=\frac{1}{2}$, where

$$T_1(\text{I.5.s}_2):\quad (x,y,t,a)\to\left(\frac{b_2x}{2b_2-1},\ \frac{b_2^2y}{(2b_2-1)^2},\ \frac{(2b_2-1)t}{4b_2},\ \frac{b_2}{2b_2-1}\right).$$

$$T_2(\text{I.5.s}_2):\quad (x,y,t,a)\to\left(\frac{x}{2},\ \frac{y}{4},\ \frac{t}{2},\ \frac{1}{2}\right).$$

Step 8. Substituting f_3, K_3, and $S(\text{I.6})$ into (2.1), we obtain a solution

$$\text{I.6.s}_1=\{b_0=0,\ c=-b_2,\ k_1=1,\ l_0=-b_2,\ l_1=-2,\ l_2=0\}.$$

Substituting (I.6.s_1) into $S(\text{I.6})$, the system $S(\text{I.6})$ simplifies to $S(\text{I.6.s}_1)$:

$$\dot{x}=-2x^2-b_2x+y,\qquad \dot{y}=-2xy-2b_2y.$$

If $b_2\neq 0$, then applying the transformation $T_1(\text{I.6.s}_1)$ to $S(2)$ yields $S(\text{I.6.s}_1)$; if $b_2=0$, then applying the transformation $T_2(\text{I.6.s}_1)$ to $S(2)$ yields $S(\text{I.6.s}_1)$ with $b_2=0$, where

$$T_1(\text{I.6.s}_1):\quad (x,y,t,a)\to\left(\frac{x}{2b_2},\ \frac{y}{4b_2^2},\ b_2t,\ \frac{1}{2}\right).$$

$$T_2(\text{I.6.s}_1):\quad (x,y,t,a)\to\left(-x-\frac{1}{2},\ x+y+\frac{1}{4},\ -\frac{t}{2},\ 1\right).$$

Step 9. Substituting f_3, K_3, and $S(\text{I.7})$ into (2.1), we obtain two solutions

$$\text{I.7.s}_1=\left\{a_0=\frac{b_2^2}{4},\ b_0=\frac{b_2}{4},\ k_1=-1,\ l_0=b_2,\ l_1=-2,\ l_2=0\right\},$$
$$\text{I.7.s}_2=\{a_0=2b_0^2,\ b_2=0,\ k_1=-2,\ l_0=2b_0,\ l_1=-2,\ l_2=0\}.$$

Substituting (I.7.s_1) and (I.7.s_2) into $S(\text{I.7})$, we obtain the systems $S(\text{I.7.s}_1)$ and $S(\text{I.7.s}_2)$

$$\dot{x}=-2x^2+y+\frac{b_2^2}{4},\qquad \dot{y}=-2xy+\frac{b_2^2}{2}x,$$

$$\dot{x}=-2x^2+2b_0^2,\qquad \dot{y}=-4xy+4b_0^2x,$$

respectively. Applying the transformation $T(\text{I.7.s}_1)$ to system $S(2)$ yields $S(\text{I.7.s}_1)$, where

$$T(\text{I.7.s}_1):\quad (x,y,t,a)\to\left(-x+\frac{b_2}{2}-\frac{1}{2},\ (1-b_2)\,x+y+\frac{1}{4}(b_2-1)^2,\ -\frac{t}{2},\ 1-b_2\right).$$

Similarly, applying the transformation $T(\text{I.7.s}_2)$ to $S(3)$ yields $S(\text{I.7.s}_2)$, where

$$T(\text{I.7.s}_2):\quad (x,y,t,a,b)\to\left(a+\frac{x+b_0}{2b_0},\ a^2-b_0^2+\frac{(2a+1)(x+b_0)}{2b_0}+y,\ -4b_0t,\ a,\ a+1\right).$$

Step 10. Substituting f_3, K_3, and $S(\text{II.1})$ into (2.1), we obtain four solutions

$$\text{II.1.s}_1 = \left\{ b_2 = 0,\ c = b_0(l_0 - \frac{1}{2}) + \frac{1}{4},\ k_1 = b_0 + l_0,\ k_0 = \frac{l_0 b_0}{2},\ l_1 = 2l_0 + 1,\ l_2 = 2 \right\},$$

$$\text{II.1.s}_2 = \{ b_0 = 2k_0,\ b_2 = 1,\ k_1 = 1,\ l_0 = 1,\ l_1 = 4,\ l_2 = 4 \},$$

$$\text{II.1.s}_3 = \left\{ \begin{array}{l} b_0 = \dfrac{2 - b_2}{4},\ k_0 = \dfrac{(2 - b_2)(4c + 1)}{16},\ k_1 = \dfrac{4b_2^2 c + b_2^2 - 2b_2 + 4}{4b_2}, \\ l_0 = 2c + \dfrac{1}{2},\ l_1 = \dfrac{b_2^2 + 4b_2^2 c + 2}{b_2},\ l_2 = 4 \end{array} \right\},$$

$$\text{II.1.s}_4 = \left\{ \begin{array}{l} b_0 = \dfrac{1}{4b_2},\ c = \dfrac{8b_2k_0 + 8b_2^2k_0 - 1}{4b_2},\ k_1 = \dfrac{8b_2^2k_0 + 1}{2b_2},\ l_0 = 8b_2k_0, \\ l_1 = 16b_2k_0 + 2,\ l_2 = 4 \end{array} \right\}.$$

Substituting (II.1.k) into $S(\text{II.1})$, we obtain the systems $S(\text{II.1.k})$ for $k = \text{s}_1,\ \text{s}_2,\ \text{s}_3,\ \text{s}_4$.

$$\begin{aligned} \dot{x} &= (2l_0 + 1)\,x^2 + 2xy + (b_0 + l_0 + 2b_0l_0)\,x + 2b_0y + b_0l_0, \\ \dot{y} &= (4b_0 + 2l_0 - 1)\,x^2 + (4b_0 + 4l_0 + 2)\,xy + 4y^2 + 2b_0l_0x + (4b_0l_0 - 2b_0 + 1)\,y. \end{aligned} \tag{$S(\text{II.1.s}_1)$}$$

$$\begin{aligned} \dot{x} &= 2(2c - 4k_0 + 1)\,x^2 + 2xy + (4k_0 + 1)\,x + (8k_0 - 4c + 1)\,y + 2k_0, \\ \dot{y} &= 2(4k_0 - 2c + 1)\,x^2 + 6xy + 4y^2 + 4k_0x + 4cy. \end{aligned} \tag{$S(\text{II.1.s}_2)$}$$

$$\begin{aligned} \dot{x} &= \left(\frac{2}{b_2} + b_2 + 4b_2c - 2\right)x^2 + 2xy + \left(\frac{1}{b_2} + 2c\right)x - \left(\frac{b_2}{2} + 2b_2c - 2\right)y \\ &\quad + \left(c - \frac{b_2c}{2} - \frac{b_2}{8} + \frac{1}{4}\right), \\ \dot{y} &= \frac{2}{b_2}x^2 + \left(\frac{4}{b_2} + b_2 + 4b_2c\right)xy + \left(2c - \frac{b_2}{4} - b_2c + \frac{1}{2}\right)x + 4y^2 + 4cy. \end{aligned} \tag{$S(\text{II.1.s}_3)$}$$

$$\begin{aligned} \dot{x} &= 16b_2k_0\,x^2 + 2xy + \left(4k_0 + 4b_2k_0 + \frac{1}{2b_2}\right)x + \left(\frac{1}{b_2} - 8b_2k_0 + 1\right)y + 2k_0, \\ \dot{y} &= \frac{2}{b_2}x^2 + \left(\frac{2}{b_2} + 16b_2k_0 + 2\right)xy + 4y^2 + 4k_0x + \left(8k_0 + 8b_2k_0 - \frac{1}{b_2}\right)y. \end{aligned} \tag{$S(\text{II.1.s}_4)$}$$

Applying the parameter change $(b_0, l_0) \to \left(b + \frac{1}{2},\ a + \frac{1}{2}\right)$ and the time rescaling $t \to 4t$ to $S(\text{II.1.s}_1)$, we obtain

S(4) $\dot{x} = 8(a+1)\,x^2 + 8xy + 2(4ab + 4a + 4b + 3)\,x + 4(2b+1)\,y + (4ab + 2a + 2b + 1)$,
$\dot{y} = 8(a + 2b + 1)\,x^2 + 8(2a + 2b + 3)\,xy + 2(4ab + 2a + 2b + 1)\,x + 4(4ab + 2a + 1)\,y + 16y^2$,
$f_1 = y - x^2, \quad K_1 = 16(a+1)\,x + 16y + 4(4ab + 2a + 1)$,
$f_2 = 4x + 4y + 1, \quad K_2 = 16(a + b + 1)\,x + 16y + 4(4ab + 2a + 2b + 1)$,
$f_3 = 2x + 2b + 1, \quad K_3 = 8(a+1)\,x + 8y + 2(2a + 1)$,
$R = \dfrac{f_2^{(a-2b)/(2b)}}{f_1^{(a+b)/(2b)} f_3^2}$.

Here R is an integrating factor of the system and $ab \neq 0$. If $a = 0$, the system becomes

$$\dot{x} = (4x + 4y + 1)(2x + 2b + 1), \quad \dot{y} = 2(4x + 4y + 1)((2b + 1)x + 2y).$$

If $b = 0$, the system becomes

$$\dot{x} = (4(a+1)x + 4y + 2a + 1)(2x + 1), \quad \dot{y} = 2(4(a+1)x + 4y + 2a + 1)(x + 2y).$$

In both cases these systems can be reduced to linear differential systems.

Applying the parameter change $(c, k_0) \to \left(\frac{1+a}{4}, \frac{1+b}{8}\right)$ and the time rescaling $t \to 4t$ to $S(\text{II.1.s}_2)$, we obtain

S(5) $\dot{x} = 4(a-b+2)\,x^2 + 8xy + 2(b+3)\,x - 4(a-b-1)\,y + (b+1)$,
$\dot{y} = 4(2-a+b)\,x^2 + 24xy + 16y^2 + 2(b+1)\,x + 4(a+1)\,y$,
$f_1 = y - x^2, \quad K_1 = 8(a-b+2)\,x + 16y + 4(a+1)$,
$f_2 = 4x + 4y + 1, \quad K_2 = 4(4x + 4y + b + 1)$,
$f_3 = 4x + 4y + b + 1, \quad K_3 = 4(4x + 4y + 1)$,
$R = \dfrac{1}{f_1\sqrt{f_2}\,f_3}$.

Here we have $a - b \neq 0$. If $a - b = 0$, the system becomes

$$\dot{x} = (4x + 4y + b + 1)(2x + 1), \quad \dot{y} = 2(4x + 4y + b + 1)(x + 2y),$$

and the system can be reduced to a linear differential system.

Applying the parameter change $(c, b_2) \to \left(\frac{a+2}{(b+2)^2} - \frac{1}{4}, \frac{b+2}{2}\right)$ and the time rescaling $t \to 4(b+2)^2 t$ to $S(\text{II.1.s}_3)$, we obtain

S(6) $\dot{x} = 8(ab + 2a - b^2 + 4)\,x^2 + 8(b+2)^2\,xy - 2(b^2 - 4a - 12)\,x - 4(ab - 2b^2 - 6b + 2a - 4)\,y - (ab - 2a + 2b - 4)$,
$\dot{y} = 16(2+b)\,x^2 + 8(ab + 2a + 6b + 12)\,xy + 16(b+2)^2\,y^2 - 2(ab - 2a + 2b - 4)\,x - 4(b^2 - 4a + 4b - 4)\,y$,
$f_1 = y - x^2, \quad K_1 = 16(ab + 2a - b^2 + 4)\,x + 16(b+2)^2\,y - 4(b^2 - 4a + 4b - 4)$,
$f_2 = 4x + 4y + 1, \quad K_2 = 8(ab + 2a + 2b - b^2 + 8)\,x + 16(b+2)^2\,y - 4(ab - 2a + 2b - 4)$,
$f_3 = 8x + 4(b+2)\,y + (2-b), \quad K_3 = 8(a+4)(b+2)\,x + 16(b+2)^2\,y + 8(a+2)$,
$R = \dfrac{f_1^{(a-3b)/(2b-2a)} f_2^{b/(b-a)}}{f_3^2}$.

Here we have $(a-b)(b+2) \neq 0$. Indeed, if $a - b = 0$, the system becomes

$$\dot{x} = (a+2)(8x + 4(a+2)y - a + 2)(2x + 1), \quad \dot{y} = 2(a+2)(8x + 4(a+2)y - a + 2)(x + 2y).$$

If $b + 2 = 0$, the system becomes

$$\dot{x} = 4(a+2)(2x + 1), \quad \dot{y} = 8(a+2)(x + 2y).$$

Applying the parameter change $(k_0, b_2) \to \left(\frac{(b+1)(a+1)}{8}, \frac{1}{b+1}\right)$ and the time rescaling $t \to 4t$ to $S(\text{II.1.s}_4)$, we obtain

S(7) $\dot{x} = 8(a+1)\,x^2 + 8xy + 2(ab + 2a + 2b + 3)\,x - 4(a-b-1)\,y + (ab + a + b + 1)$,
$\dot{y} = 8(b+1)\,x^2 + 8(a + b + 3)\,xy + 16y^2 + (2ab + 2a + 2b + 2)\,x + 4(ab + 2a + 1)\,y$,
$f_1 = y - x^2, \quad K_1 = 16(a+1)\,x + 16y + 4(ab + 2a + 1)$,
$f_2 = 4x + 4y + 1, \quad K_2 = 8(a + b + 2)\,x + 16y + 4(ab + a + b + 1)$,
$f_3 = 4(b+1)\,x + 4y + (b+1)^2, \quad K_3 = 8(a+2)\,x + 16y + 4(a+1)$,
$R = \dfrac{1}{\sqrt{f_1}\,f_2\,f_3}$.

Here we have $a(a-b)\neq 0$. If $a=0$ the system becomes

$$\dot{x}=(4x+4y+1)(2x+b+1),\quad \dot{y}=2(4x+4y+1)((b+1)x+2y).$$

If $a-b=0$, the system becomes

$$\dot{x}=(4(a+1)x+4y+(a+1)^2)(2x+1),\quad \dot{y}=2(4(a+1)x+4y+(a+1)^2)(x+2y).$$

Step 11. Substituting f_3, K_3, and $S(\mathrm{II}.2)$ into (2.1), we obtain two solutions

$$\mathrm{II}.2.\mathrm{s}_1=\left\{\begin{array}{l} b_0=\dfrac{1}{4b_2},\ k_0=\dfrac{2a_0b_2+4b_2^2-1}{8b_2^2(2a_0b_2-1)},\ k_1=\dfrac{2b_2(a_0+b_2)-1}{2b_2(2a_0b_2-1)},\\ l_0=\dfrac{a_0(2a_0b_2+4b_2^2-1)}{b_2(2a_0b_2-1)},\ l_1=\dfrac{4(1+a_0^2)b_2^2-1}{b_2(2a_0b_2-1)},\ l_2=2 \end{array}\right\},$$

$$\mathrm{II}.2.\mathrm{s}_2=\left\{\begin{array}{l} b_0=a_0-a_0^2b_2,\ k_0=\dfrac{(a_0b_2-1)(a_0-2b_2-2a_0^2b_2)}{2b_2(2a_0b_2-1)},\ k_1=\dfrac{2b_2(a_0+b_2)-1}{2b_2(2a_0b_2-1)},\\ l_0=\dfrac{2b_2+2a_0^2b_2-a_0}{b_2(2a_0b_2-1)},\ l_1=\dfrac{4(a_0^2+1)b_2^2-1}{b_2(2a_0b_2-1)},\ l_2=2 \end{array}\right\}.$$

Substituting $(\mathrm{II}.2.k)$ into $S(\mathrm{II}.2)$, we obtain the systems $S(\mathrm{II}.2.k)$ for $k=\mathrm{s}_1,\ \mathrm{s}_2$.

$$\begin{aligned}\dot{x}=&\frac{1}{4b_2^2(2a_0b_2-1)}\left(4b_2(2a_0b_2+2b_2^2-1)\,x^2+4b_2^2(2a_0b_2-1)\,xy+4a_0b_2^2(2a_0b_2-1)\,y\right.\\&\left.+(8a_0^2b_2^2+8a_0b_2^3+4b_2^2-2a_0b_2-1)\,x+a_0(2a_0b_2+4b_2^2-1)\right),\\ \dot{y}=&\frac{1}{4b_2^2(2a_0b_2-1)}\left(8(2a_0^2b_2^2-a_0b_2+b_2^2)\,x^2+8b_2(2a_0^2b_2^2+a_0b_2+2b_2^2-1)\,xy\right.\\&\left.+8b_2^2(2a_0b_2-1)\,y^2+2a_0(2a_0b_2+4b_2^2-1)\,x+2(8a_0b_2^3+2a_0b_2-1)\,y\right).\end{aligned}\tag{$S(\mathrm{II}.2.\mathrm{s}_1)$}$$

$$\begin{aligned}\dot{x}=&\frac{1}{b_2(2a_0b_2-1)}\left((2a_0b_2+2b_2^2-1)\,x^2+b_2(2a_0b_2-1)\,xy+a_0b_2(2a_0b_2-1)\,y\right.\\&\left.-(2a_0^3b_2^2-5a_0^2b_2+2a_0-2b_2)\,x-(2a_0^4b_2^2-3a_0^3b_2+2a_0^2b_2^2+a_0^2-2a_0b_2)\right),\\ \dot{y}=&\frac{1}{b_2(2a_0b_2-1)}\left(2(2a_0^2b_2-a_0+b_2)\,x^2+(4a_0^2b_2^2+2a_0b_2+4b_2^2-2)\,xy\right.\\&+2(2a_0b_2^2-b_2)\,y^2-(4a_0^4b_2^2+4a_0^2b_2^2-6a_0^3b_2-4a_0b_2+2a_0^2)\,x\\&\left.-(4a_0^3b_2^2-6a_0^2b_2+2a_0-2b_2)\,y\right).\end{aligned}\tag{$S(\mathrm{II}.2.\mathrm{s}_2)$}$$

Doing the transformation $T(\mathrm{II}.2.\mathrm{s}_1)$ to system $S(4)$ yields $S(\mathrm{II}.2.\mathrm{s}_1)$, where

$$T(\mathrm{II}.2.\mathrm{s}_1):\quad (x,y,t,a,b)\to\left(b_2x,\ b_2^2y,\ \frac{t}{8b_2^2},\ \frac{2b_2^2}{2a_0b_2-1},\ a_0b_2-\frac{1}{2}\right).$$

Applying the transformation

$$T_1(\mathrm{II}.2.\mathrm{s}_2):\quad (x,y,a_0)\to\left(x-\frac{2ab_2+1}{2b_2},\ \frac{(b_2-1)\,x}{b_2}+y+\frac{(1+2ab_2)^2}{4b_2^2},\ \frac{2ab_2+1}{2b_2}\right),$$

to $S(\mathrm{II}.2.\mathrm{s}_2)$ we obtain the system $S(\mathrm{II}.2.\mathrm{s}_2.1)$.

$$\dot{x}=\frac{a+1}{a}\,x^2+xy-2x,\qquad \dot{y}=\frac{2a^2+a+1}{a}\,x^2+\frac{2a^2+3a+2}{a}\,xy+2y^2-2y.$$

In **Step 12** we will prove that this system is a special case of system $S(8)$.
Step 12. Substituting f_3, K_3, and $S(\text{II}.3)$ into (2.1), we obtain four solutions

$$\text{II}.3.\text{s}_1 = \left\{ \begin{array}{l} a_0 = (1-b_0)b_0,\ b_2 = 0,\ c = \dfrac{b_0}{2} - b_0^2 + k_0,\ l_0 = 2(1-b_0)k_0, \\ l_1 = 1 - b_0 + 2k_0,\ l_2 = 1 \end{array} \right\},$$

$$\text{II}.3.\text{s}_2 = \left\{ \begin{array}{l} a_0 = \dfrac{2b_2-1}{4b_2^2},\ b_0 = \dfrac{1}{4b_2},\ c = 2k_0 - \dfrac{1}{4b_2^2},\ l_0 = \left(4 - \dfrac{2}{b_2}\right) k_0, \\ l_1 = 4k_0 - \dfrac{1}{b_2} + 2,\ l_2 = 2 \end{array} \right\},$$

$$\text{II}.3.\text{s}_3 = \left\{ \begin{array}{l} a_0 = -\dfrac{(2b_2k_0-1)(2b_2k_0+b_2-1)}{b_2^2},\ b_0 = 2k_0(1-2b_2k_0), \\ c = \dfrac{b_2 + 8b_2k_0 - 8b_2^2k_0^2 - 2}{2b_2^2},\ l_0 = \dfrac{b_2 + 2b_2k_0 - 1}{b_2^2}, \\ l_1 = 4k_0 - \dfrac{1}{b_2} + 2,\ l_2 = 2 \end{array} \right\},$$

$$\text{II}.3.\text{s}_4 = \left\{ b_0 = \frac{1}{4},\ b_2 = 1,\ k_0 = \frac{1}{4},\ l_0 = 2a_0,\ l_1 = 2,\ l_2 = 2 \right\}.$$

Substituting $(\text{II}.3.k)$ into $S(\text{II}.3)$, we obtain the systems $S(\text{II}.3.k)$ for $k = \text{s}_1,\ \text{s}_2,\ \text{s}_3,\ \text{s}_4$.

$$\begin{aligned} \dot{x} &= (2k_0 - b_0 + 1)\,x^2 + xy + b_0 y - (b_0^2 - b_0 - 2k_0)\,x - 2b_0k_0(b_0 - 1), \\ \dot{y} &= (2k_0 + b_0)\,x^2 + (4k_0 + 2)\,xy + 2y^2 - 4b_0k_0(b_0 - 1)\,x - (2b_0^2 - b_0 - 2k_0)\,y. \end{aligned} \tag{$S(\text{II}.3.\text{s}_1)$}$$

$$\begin{aligned} \dot{x} &= \frac{1}{4b_2^2}\left(4b_2(4b_2k_0 + b_2 - 1)\,x^2 + 4b_2^2\,xy - 4b_2(2b_2k_0 - 1)\,y + (8b_2^2k_0 + 2b_2 - 1)\,x \right. \\ &\quad \left. +2k_0(2b_2 - 1)\right), \end{aligned} \tag{$S(\text{II}.3.\text{s}_2)$}$$

$$\dot{y} = \frac{1}{4b_2^2}\left(4b_2\,x^2 + 8b_2^2(2k_0 + 1)\,xy + 8b_2^2\,y^2 + 4k_0(2b_2 - 1)\,x + 2(8b_2^2k_0 - 1)\,y\right).$$

$$\begin{aligned} \dot{x} &= \frac{1}{b_2^2}\left(b_2(4b_2k_0 + b_2 - 1)\,x^2 + b_2^2\,xy - b_2(2b_2k_0 - 1)\,y - (4b_2^2k_0^2 - 4b_2k_0 - b_2 + 1)\,x \right. \\ &\quad \left. -8b_2^2k_0^3 - 4b_2^2k_0^2 + 8b_2k_0^2 + 2b_2k_0 - 2k_0\right), \\ \dot{y} &= \frac{1}{b_2^2}\left(b_2\,x^2 + 2b_2^2(2k_0 + 1)\,xy + 2b_2^2\,y^2 - 4k_0(4b_2^2k_0^2 + 2b_2^2k_0 - 4b_2k_0 - b_2 + 1)\,x \right. \\ &\quad \left. -(8b_2^2k_0^2 - 8b_2k_0 - b_2 + 2)\,y\right). \end{aligned} \tag{$S(\text{II}.3.\text{s}_3)$}$$

$$\begin{aligned} \dot{x} &= -(2a_0 - 2c - 1)\,x^2 + xy + \left(a_0 + \frac{1}{2}\right)x + \left(2a_0 - 2c + \frac{1}{2}\right)y + \frac{a_0}{2}, \\ \dot{y} &= (2a_0 - 2c + 1)\,x^2 + 3xy + 2y^2 + a_0 x + 2cy. \end{aligned} \tag{$S(\text{II}.3.\text{s}_4)$}$$

Applying the parameter change $(b_0, k_0) \to \left(b + \frac{1}{2},\ \frac{2a+1}{4}\right)$ and the time rescaling $t \to 8t$ to $S(\text{II}.3.\text{s}_1)$, we obtain

$$\begin{aligned} \text{S(8)}\quad & \dot{x} = 8(a - b + 1)\,x^2 + 8xy - 2(4b^2 - 4a - 3)\,x + 4(2b + 1)\,y - (2a + 1)(4b^2 - 1), \\ & \dot{y} = 8(a + b + 1)\,x^2 + 8(2a + 3)\,xy + 16y^2 - 2(8ab^2 + 4b^2 - 2a - 1)\,x - 4(4b^2 + 2b - 2a - 1)\,y, \\ & f_1 = y - x^2, \quad K_1 = 16(a - b + 1)\,x + 16y - 4(4b^2 + 2b - 2a - 1), \end{aligned}$$

$$f_2 = 4b^2 - 1 - 4x - 4y, \quad K_2 = 16(a+1)\,x + 16y + 4(2a+1),$$
$$f_3 = 2x + 2b + 1, \quad K_3 = 8(a-b+1)\,x + 8y - 2(4ab - 2a + 2b - 1),$$
$$R = f_1^{-(a+3b)/(2b)} f_2^{(a-3b)/(2b)} f_3.$$

Here we have $b(a-b) \neq 0$. If $b = 0$ the system becomes

$$\dot{x} = (4(a+1)x + 4y + 2a + 1)(2x+1), \quad \dot{y} = 2(4(a+1)x + 4y + 2a + 1)(x + 2y).$$

If $a - b = 0$, the system becomes

$$\dot{x} = (4x + 4y - 4a^2 + 1)(2x + 2a + 1), \quad \dot{y} = 2(4x + 4y - 4a^2 + 1)((2a+1)x + 2y).$$

Applying transformation $T_2(\text{II.2.s}_2)$ to $S(8)$ yields $S(\text{II.2.s}_2.1)$.

$$T_2(\text{II.2.s}_2): \quad (x, y, t, a, b) \to \left(x - a - \frac{1}{2},\ y + \frac{1}{4}(2a+1)^2,\ \frac{t}{8},\ \frac{1}{a} + a,\ a\right).$$

For solution (II.3.s_2), if $2b_2 - 1 \neq 0$, then applying the transformation $T_1(\text{II.3.s}_2)$ to $S(6)$ yields $S(\text{II.3.s}_2)$; if $2b_2 - 1 = 0$, then applying the transformation $T_2(\text{II.3.s}_2)$ to $S(6)$ yields $S(\text{II.3.s}_2)$ with $b_2 = \dfrac{1}{2}$, where

$$T_1(\text{II.3.s}_2): \quad (x, y, t, a, b) \to$$
$$\left(x + \frac{1-b_2}{2b_2},\ y + \frac{(b_2-1)(b_2 - 4b_2x - 1)}{4b_2^2},\ \frac{(2b_2-1)^2 t}{32b_2^2},\ \frac{2b_2(4k_0-1)}{2b_2-1},\ \frac{2(1-b_2)}{2b_2-1}\right).$$

$$T_2(\text{II.3.s}_2): \quad (x, y, t, a, b) \to \left(\frac{x}{2},\ \frac{y}{4},\ \frac{t}{32},\ 8k_0 - 2,\ 2\right).$$

Applying the transformation $T(\text{II.3.s}_3)$ to $S(8)$ yields $S(\text{II.3.s}_3)$, where

$$T(\text{II.3.s}_3): \quad (t, a, b) \to \left(\frac{t}{8},\ 2k_0 - \frac{1}{2},\ \frac{1 - 2b_2k_0}{b_2} - \frac{1}{2}\right).$$

For the solution (II.3.s_4) applying the transformation $T(\text{II.3.s}_4)$ to $S(5)$ yields $S(\text{II.3.s}_4)$, where

$$T(\text{II.3.s}_4): \quad (t, a, b) \to \left(\frac{t}{8},\ 4c - 1,\ 4a_0 - 1\right).$$

Step 13. Substituting f_3, K_3, and $S(\text{II.4})$ into (2.1), we obtain five solutions

$$\text{II.4.s}_1 = \left\{a = \frac{1}{b_2} - 2,\ b_0 = 0,\ c = -\frac{1}{b_2},\ l_0 = -\frac{1}{b_2},\ l_1 = \frac{1}{b_2} - 2,\ l_2 = 2\right\},$$
$$\text{II.4.s}_2 = \{a = l_1,\ b_0 = 1,\ b_2 = 0,\ c = l_1,\ l_0 = 0,\ l_2 = 1\},$$
$$\text{II.4.s}_3 = \left\{a = \frac{1}{b_2} - 2,\ b_0 = \frac{1}{4b_2},\ c = \frac{1-2b_2}{4b_2^2},\ l_0 = 0,\ l_1 = \frac{1}{b_2} - 2,\ l_2 = 2\right\},$$
$$\text{II.4.s}_4 = \{a = -2,\ b_0 = 0,\ c = 0,\ l_0 = 0,\ l_1 = -2,\ l_2 = 2\},$$
$$\text{II.4.s}_5 = \left\{a = -1,\ c = \frac{b_0}{b_2},\ l_0 = 0,\ l_1 = 0,\ l_2 = 2\right\}.$$

Substituting $(\text{II.4.}k)$ into $S(\text{II.4})$, we obtain the systems $S(\text{II.4.}k)$ for $k = \text{s}_1,\ \text{s}_2,\ \text{s}_3,\ \text{s}_4,\ \text{s}_5$. In system $S(\text{II.4.s}_5)$ we replace $\frac{b_0}{b_2}$ by c.

$$\dot{x} = -\frac{2b_2 - 1}{b_2}\,x^2 + xy - \frac{1}{b_2}x + y, \qquad \dot{y} = \frac{-2(b_2-1)}{b_2}\,xy + 2y^2 - \frac{2}{b_2}y. \qquad (S(\text{II.4.s}_1))$$

$$\dot{x} = (x+1)(l_1 x + y), \qquad \dot{y} = 2y\left((l_1+1)\,x + y + l_1\right). \tag{S(II.4.s$_2$)}$$

$$\dot{x} = -\frac{2b_2-1}{b_2}\,x^2 + xy - \frac{2b_2-1}{4b_2^2}\,x + y, \qquad \dot{y} = \frac{-2(b_2-1)}{b_2}\,xy + 2y^2 - \frac{2b_2-1}{2b_2^2}\,y. \tag{S(II.4.s$_3$)}$$

$$\dot{x} = -2x^2 + xy + y, \qquad \dot{y} = -2xy + 2y^2. \tag{S(II.4.s$_4$)}$$

$$\dot{x} = -x^2 + xy + cx + y, \qquad \dot{y} = 2y^2 + 2cy. \tag{S(II.4.s$_5$)}$$

Applying the following transformations T(II.4.s$_2$) to $S(4)$, T(II.4.s$_3$) to $S(7)$, T(II.4.s$_4$) to $S(6)$, and T(II.4.s$_5$) to $S(5)$ yields S(II.4.s$_2$), S(II.4.s$_3$), S(II.4.s$_4$), and S(II.4.s$_5$), respectively.

$$T(\text{II.4.s}_2): \quad (x,y,t,b,a) \to \left(-x-\frac{1}{2},\ x+y+\frac{1}{4},\ \frac{t}{8},\ -1,\ -l_1\right).$$

$$T(\text{II.4.s}_3): \quad (x,y,t,a,b) \to \left(\frac{1}{2}(x-1),\ -\frac{1}{4}(2x-y-1),\ \frac{t}{2},\ \frac{1}{2b_2}-1,\ \frac{1}{2b_2}\right).$$

$$T(\text{II.4.s}_4): \quad (x,y,t,a,b) \to \left(\frac{1}{2}(x-1),\ -\frac{1}{4}(2x-y-1),\ \frac{t}{8},\ -2,\ 0\right).$$

$$T(\text{II.4.s}_5): \quad (x,y,t,a,b) \to \left(\frac{1}{2}(x-1),\ -\frac{1}{4}(2x-y-1),\ \frac{t}{2},\ c-1,\ c\right).$$

For solution (II.4.s$_1$), if $2b_2+1 \neq 0$, then applying the transformation T_1(II.4.s$_1$) to system $S(6)$ yields S(II.4.s$_1$); if $2b_2+1=0$, then applying the transformation T_2(II.4.s$_1$) to $S(6)$ yields S(II.4.s$_1$) with $b_2=-\frac{1}{2}$, where

$$T_1(\text{II.4.s}_1): \quad (x,y,t,a,b) \to \left(\frac{1}{2}(x-1),\ -\frac{1}{4}(2x-y-1),\ \frac{(2b_2+1)^2 t}{32b_2^2},\ -2,\ -\frac{2}{2b_2+1}\right).$$

$$T_2(\text{II.4.s}_1): \quad (x,y,t,a,b) \to \left(-\frac{1}{2}(x+1),\ \frac{1}{4}(2x+y+1),\ \frac{t}{2},\ 0,\ -1\right).$$

Step 14. Substituting f_3, K_3, and S(II.5) into (2.1), we obtain five solutions

$$\text{II.5.s}_1 = \left\{a_0 = -b_0^2,\ b_2 = 0,\ k_1 = b_0+1,\ l_0 = -b_0(b_0+1),\ l_1 = 1,\ l_2 = 1\right\},$$

$$\text{II.5.s}_2 = \left\{a_0 = -\frac{(b_2-1)^2}{4b_2^2},\ b_0 = \frac{1-b_2^2}{4b_2},\ k_1 = \frac{b_2+1}{2b_2},\ l_0 = \frac{b_2-1}{2b_2^2},\ l_1 = 1,\ l_2 = 2\right\},$$

$$\text{II.5.s}_3 = \left\{a_0 = -\frac{1}{4b_2^2},\ b_0 = \frac{1}{4b_2},\ k_1 = \frac{b_2+1}{2b_2},\ l_0 = -\frac{b_2+1}{2b_2^2},\ l_1 = 1,\ l_2 = 2\right\},$$

$$\text{II.5.s}_4 = \left\{a_0 = 0,\ b_0 = 0,\ k_1 = \frac{1}{2},\ l_0 = 0,\ l_1 = 1,\ l_2 = 2\right\},$$

$$\text{II.5.s}_5 = \left\{b_0 = 0,\ k_1 = 0,\ l_0 = 2a_0,\ l_1 = 0,\ l_2 = 2\right\}.$$

Substituting (II.5.k) into S(II.5), we obtain systems S(II.5.k) for $k = \text{s}_1,\ \text{s}_2,\ \text{s}_3,\ \text{s}_4,\ \text{s}_5$.

$$\begin{aligned} \dot{x} &= x^2 + xy - b_0^2 x + b_0 y - b_0^2(b_0+1), \\ \dot{y} &= 2(b_0+1)\,xy + 2y^2 - 2b_0^2(b_0+1)\,x - 2b_0^2 y. \end{aligned} \tag{S(II.5.s$_1$)}$$

$$\begin{aligned} \dot{x} &= \frac{1}{8b_2^3}\left(8b_2^3x^2 + 8b_2^3xy - 2b_2(b_2-1)^2x - 4b_2^2(b_2-1)y - b_2^3 + b_2^2 + b_2 - 1\right), \\ \dot{y} &= \frac{1}{8b_2^3}\left(8b_2^2(b_2+1)\,xy + 16b_2^3y^2 - 2(b_2-1)^2(b_2+1)\,x - 4b_2(b_2-1)^2 y\right). \end{aligned} \tag{S(II.5.s$_2$)}$$

$$\begin{aligned}\dot{x} &= \frac{1}{8b_2^3}\left(8b_2^3x^2+8b_2^3xy-2b_2x-4b_2^2(b_2-1)\,y-(b_2+1)\right),\\ \dot{y} &= \frac{1}{8b_2^3}\left(8b_2^2(b_2+1)\,xy+16b_2^3y^2-2(b_2+1)\,x-4b_2y\right).\end{aligned} \tag{S(II.5.s$_3$)}$$

$$\dot{x} = x^2-\frac{1}{2}y+xy, \qquad \dot{y} = xy+2y^2. \tag{S(II.5.s$_4$)}$$

$$\dot{x} = x^2+xy+a_0x-y, \qquad \dot{y} = 2y^2+2a_0y. \tag{S(II.5.s$_5$)}$$

Applying the following transformations T(II.5.s$_1$) to $S(8)$, T(II.5.s$_2$) to $S(8)$, T(II.5.s$_4$) to $S(6)$, and T(II.5.s$_5$) to $S(5)$ yields S(II.5.s$_1$), S(II.5.s$_2$), S(II.5.s$_4$), and S(II.5.s$_5$), respectively.

$$T(\text{II.5.s}_1): \quad (x,y,t,a,b)\to\left(-x-\frac{1}{2},\ x+y+\frac{1}{4},\ \frac{t}{8},\ -b_0-1,\ -b_0\right).$$

$$T(\text{II.5.s}_2): \quad (x,y,t,a,b)\to \left(\frac{x}{2}+\frac{1-2b_2}{4b_2},\ \frac{1-2b_2}{4b_2}\,x+\frac{y}{4}+\frac{(2b_2-1)^2}{16b_2^2},\ \frac{t}{2},\ \frac{b_2-2}{4b_2},\ -\frac{1}{4}\right).$$

$$T(\text{II.5.s}_4): \quad (x,y,a,b)\to\left(-x-\frac{1}{2},\ x+y+\frac{1}{4},\ \frac{t}{32},\ -2,\ 0\right).$$

$$T(\text{II.5.s}_5): \quad (x,y,t,a,b)\to\left(-\frac{1}{2}(x+1),\ \frac{1}{4}(2x+y+1),\ \frac{t}{2},\ a_0-1,\ a_0\right).$$

For the solution (II.5.s$_3$), if $2b_2-1\neq 0$, then applying the transformation T_1(II.5.s$_3$) to system $S(6)$ yields S(II.5.s$_3$); if $2b_2-1=0$, then applying the transformation T_2(II.5.s$_3$) to $S(6)$ yields S(II.5.s$_3$) with $b_2=\dfrac{1}{2}$, where

$$T_1(\text{II.5.s}_3): \quad (x,y,t,a,b)\to \left(\frac{x}{2}-\frac{2b_2-1}{4b_2},\ \frac{1-2b_2}{4b_2}\,x+\frac{y}{4}+\frac{(2b_2-1)^2}{16b_2^2},\ \frac{(2b_2-1)^2t}{32b_2^2},\ \frac{2(b_2+1)}{2b_2-1},\ \frac{2}{2b_2-1}\right).$$

$$T_2(\text{II.5.s}_3): \quad (x,y,t,a,b)\to\left(-\frac{x}{2}-1,\ x+\frac{y}{4}+1,\ \frac{t}{2},\ -\frac{3}{2},\ -1\right).$$

This finishes the proof. □

6 Proof of Theorem 3.2

Proof. **System** $S(1)$**.** The system together with its invariant curves is

$$\dot{x}=x+1, \quad \dot{y}=x^2+2x+y.$$

$$f_1=y-x^2, \quad f_2=x+1.$$

It has only one finite equilibrium at $P_1=(-1,1)$ with eigenvalues $1,1$. In what follows, we use the notation $P_1=(-1,1):1,1$ to denote the equilibrium point and its corresponding eigenvalues.

The Poincaré compactification of this system in the chart U_1 (with coordinates (u,v)) is

$$\dot{u}=-uv^2+2v+1, \quad \dot{v}=-v^3-v^2.$$

Hence, there are no infinite equilibria in the chart U_1.

The Poincaré compactification of this system in the chart U_2 is

$$\dot{u} = -u^3 - 2u^2v + v^2, \quad \dot{v} = -u^2v - 2uv^2 - v^2.$$

The infinite equilibrium point O_2 at the origin of the local chart U_2 is linearly zero. Doing the vertical blow-up $(u, v) = (u_1, u_1v_1)$ and a rescaling of the time we eliminate the common factor u_1 between $\dot{u}_1$ and $\dot{v}_1$ obtaining the system

$$\dot{u}_1 = -2u_1^2v_1 + u_1v_1^2 - u_1^2, \qquad \dot{v}_1 = -v_1^3 - v_1^2.$$

It has two infinite equilibria on the straight line $u_1 = 0$:

$$(0, 0) : 0, 0; \quad (0, -1) : -1, 1.$$

However, the origin in the coordinates (u_1, v_1) is again a linearly zero equilibrium. Since $u_1 = 0$ is a characteristic direction of the equilibrium $(0, 0)$, we do the twist $(u_1, v_1) = (u_2 - v_2, v_2)$ in order to avoid the loss of information when we do a vertical blow-up, in this way we obtain the system

$$\dot{u}_2 = -4v_2^3 + 5u_2v_2^2 - 2u_2^2v_2 - u_2^2 + 2u_2v_2 - 2v_2^2, \qquad \dot{v}_2 = -v_2^3 - v_2^2.$$

Doing the vertical blow-up $(u_2, v_2) = (u_3, u_3v_3)$ and a rescaling of time we eliminate the common factor u_3 between $\dot{u}_3$ and $\dot{v}_3$, obtaining the system

$$\begin{aligned}\dot{u}_3 &= -4u_3^2v_3^3 + 5u_3^2v_3^2 - 2u_3^2v_3 - 2u_3v_3^2 + 2u_3v_3 - u_3,\\ \dot{v}_3 &= 4u_3v_3^4 - 6u_3v_3^3 + 2u_3v_3^2 + 2v_3^3 - 3v_3^2 + v_3.\end{aligned}$$

This system has three equilibria on the straight line $u_3 = 0$:

$$(0, 0) : -1, 1; \quad \left(0, \frac{1}{2}\right) : -\frac{1}{2}, -\frac{1}{2}; \quad (0, 1) : -1, 1.$$

Doing the blowing-down $B(\text{I.2.s}_1)$ (Figure 6.1) we obtain the local phase portrait of the infinite equilibrium O_2.

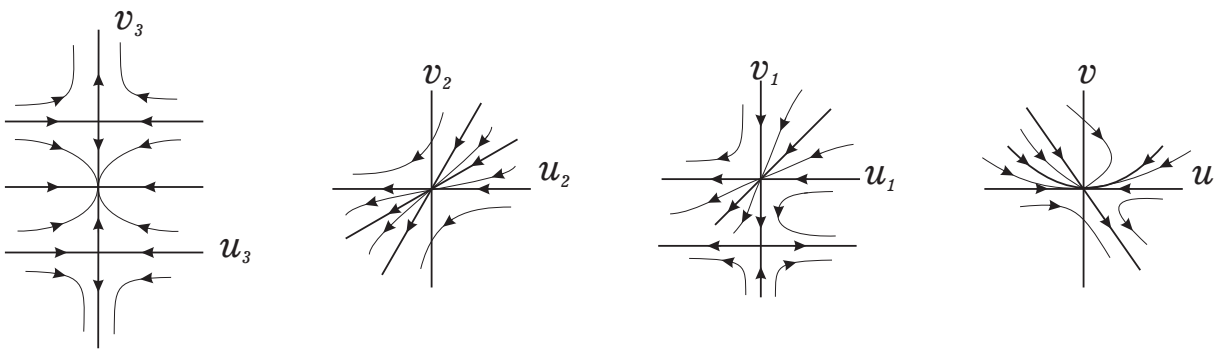

Figure 6.1: $B(\text{I.2.s}_1)$: Blowing-down at the origin O_2 of the chart U_2 for system $S(1)$.

Since $y - x^2 = 0$ and $x + 1 = 0$ are invariant algebraic curves of system $S(1)$, we obtain the configuration $C(\text{I.2.s}_1)$ (see Figure 6.2).

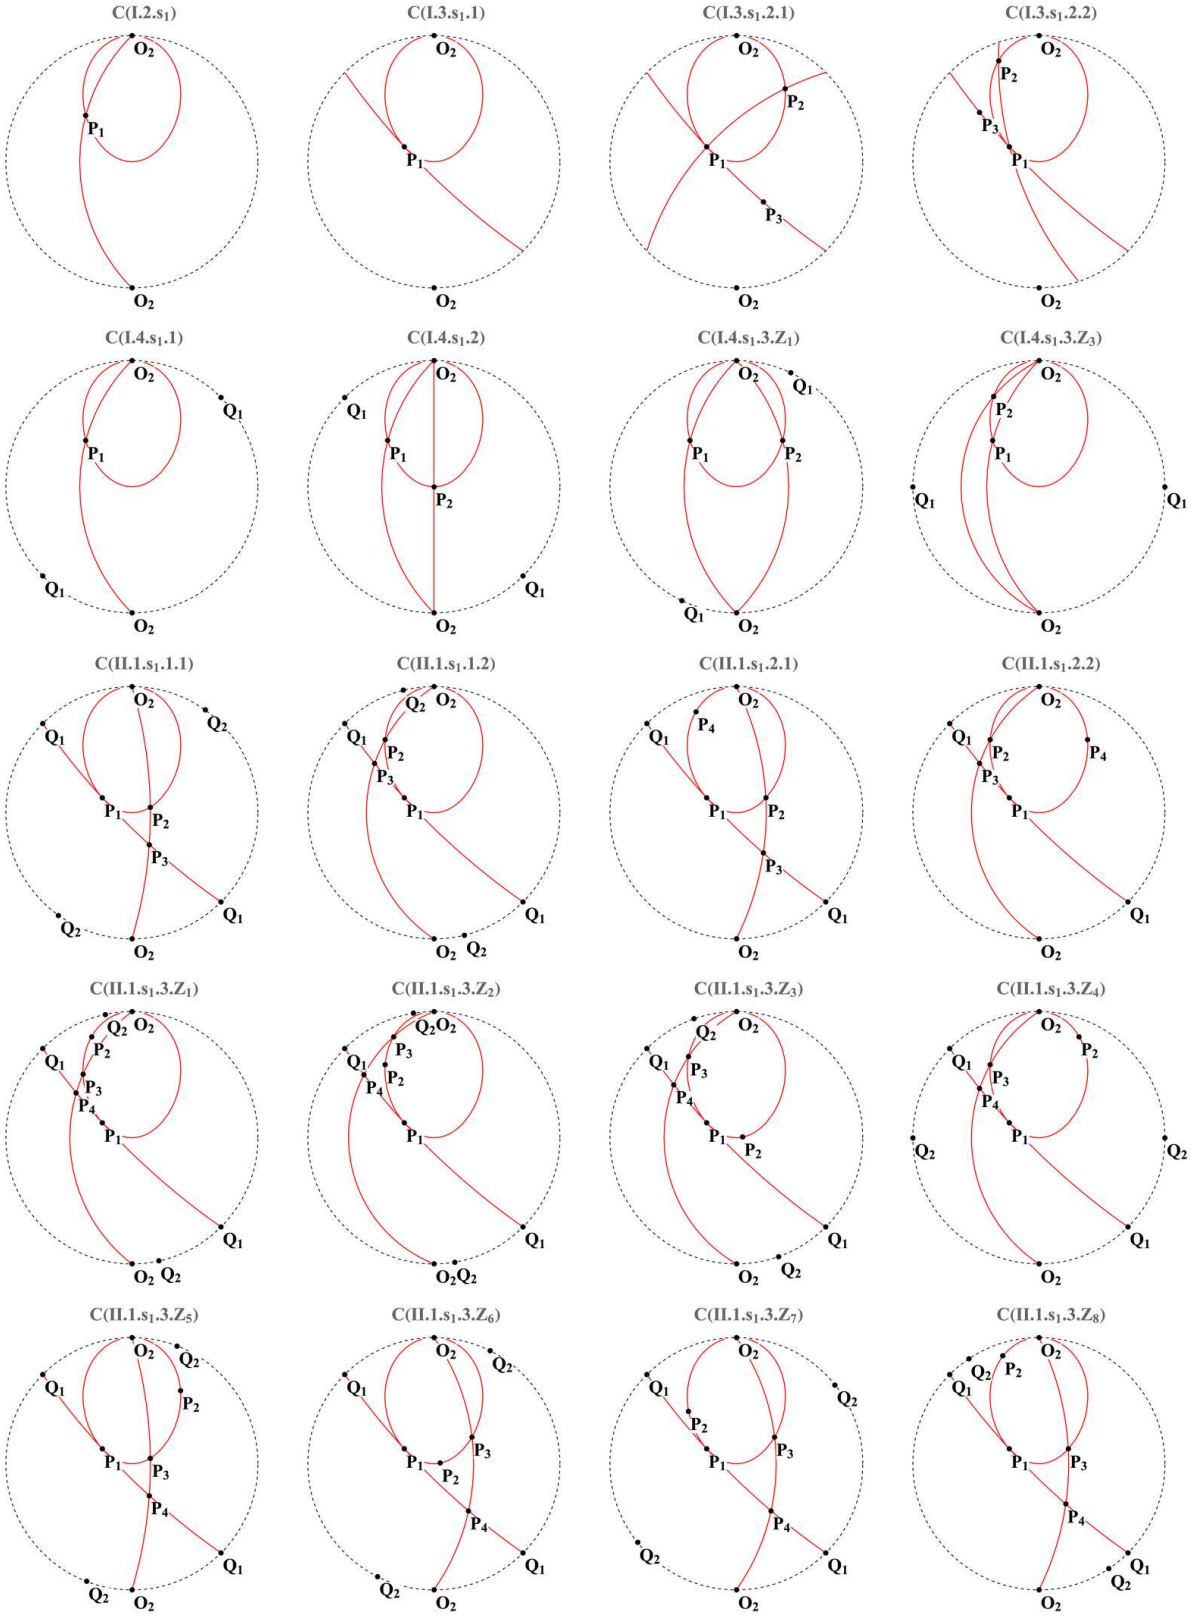

Figure 6.2: Configurations of the invariant algebraic curves of the systems of Theorem 3.1. Here P_i for $i = 1,2,3,4$ are equilibria in the plane $\mathbb{R}^2$, Q_i for $i = 1,2$ are equilibria in the chart U_1 and O_2 is the origin of the chart U_2.

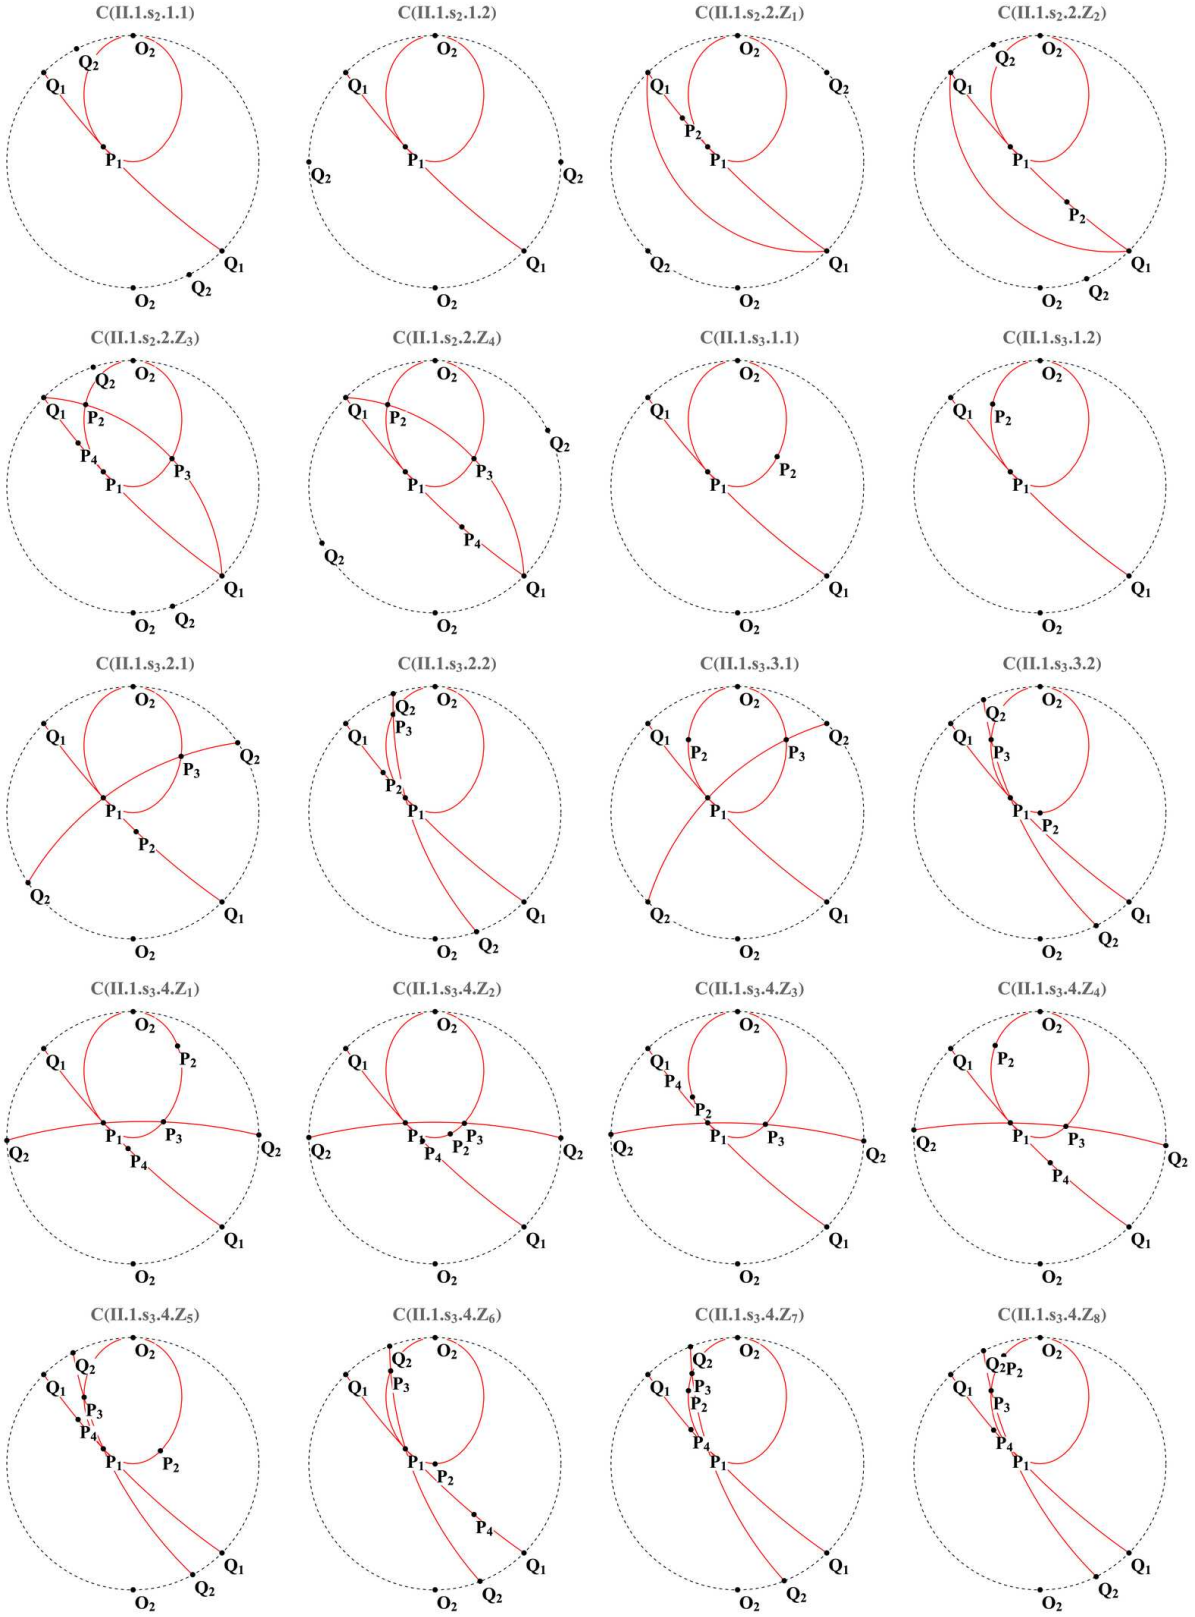

Figure 6.3: Configurations of the invariant algebraic curves of the systems of Theorem 3.1. Here P_i for $i = 1,2,3,4$ are equilibria in the plane $\mathbb{R}^2$, Q_i for $i = 1,2$ are equilibria in the chart U_1 and O_2 is the origin of the chart U_2.

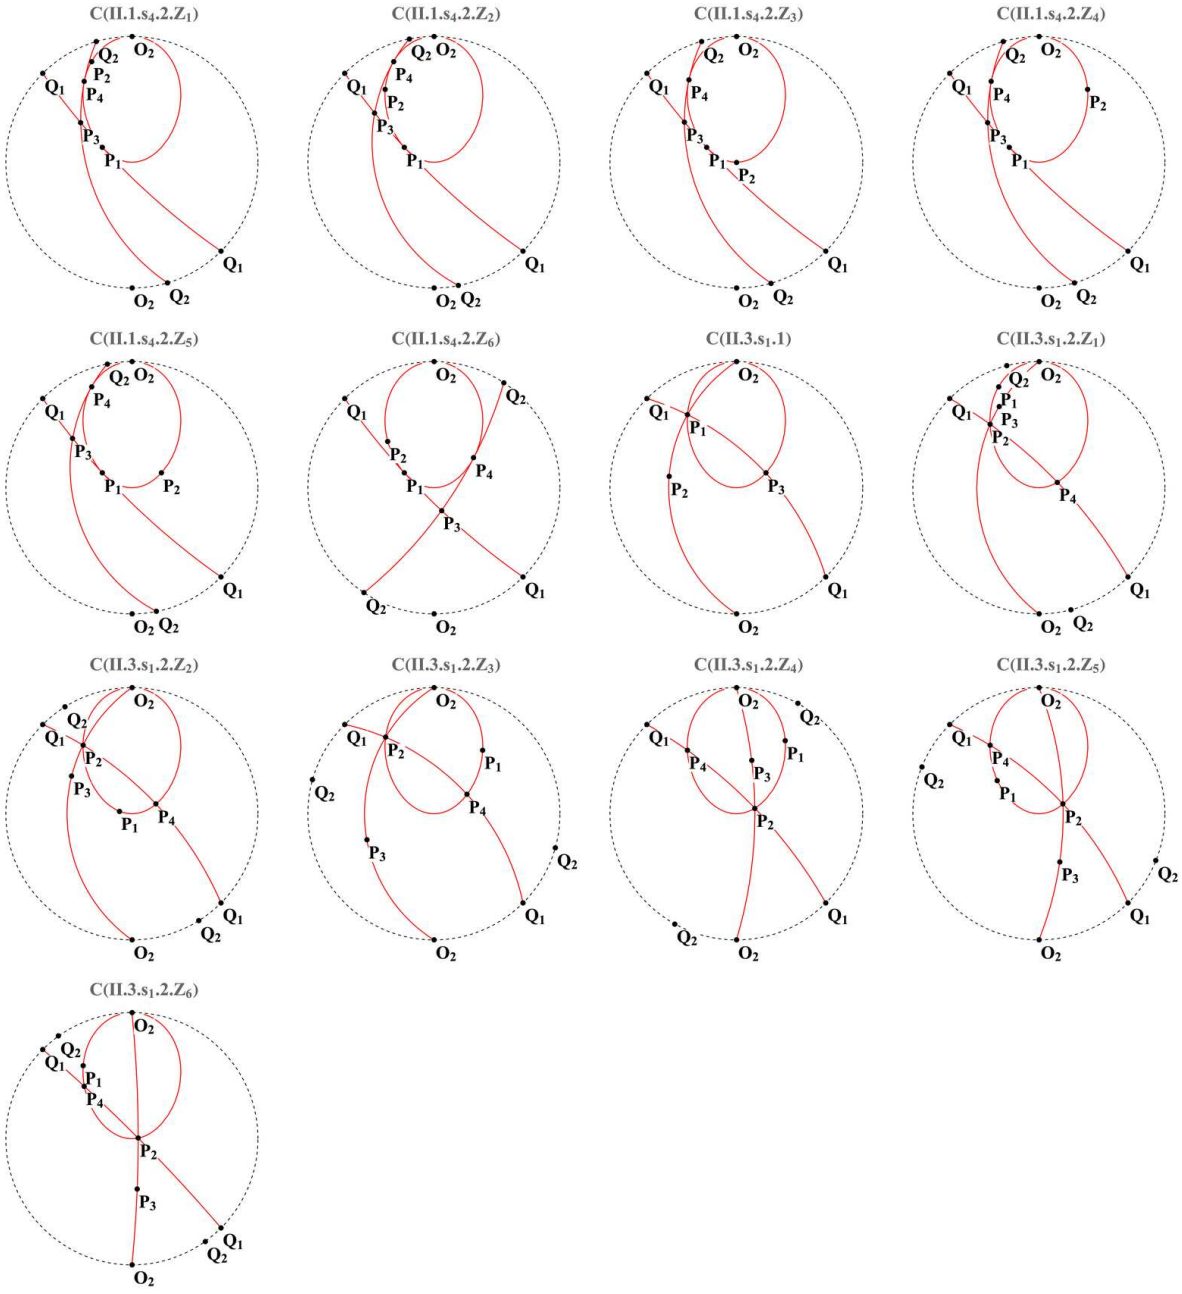

Figure 6.4: Configurations of the invariant algebraic curves of the systems of Theorem 3.1. Here P_i for $i = 1,2,3,4$ are equilibria in the plane $\mathbb{R}^2$, Q_i for $i = 1,2$ are equilibria in the chart U_1 and O_2 is the origin of the chart U_2.

Taking into account the blowing-down $B(\mathrm{I.2.s}_1)$ and the configuration $C(\mathrm{I.2.s}_1)$, we obtain the phase portrait PP.1 of Figure 3.1.

System $S(2)$**.** The system together with its invariant curves is

$$\dot{x} = -4x^2 - 2ax + 2y - a + \frac{1}{2}, \quad \dot{y} = -4xy + (1-2a)\,x - 4ay.$$

$$f_1 = y - x^2, \quad f_2 = 4x + 4y + 1, \quad f_3 = 4ax + 4y + 2a - 1.$$

We divide the study of the phase portraits of system $S(2)$ into two cases: $a = 1$ and $a \neq 1$.

Case 1. $a = 1$**.** Then system $S(2)$ reduces to the system

$$\dot{x} = -4x^2 - 2x + 2y - \frac{1}{2}, \qquad \dot{y} = -4xy - x - 4y.$$

This system has a finite equilibrium at $P_1 = \left(-\frac{1}{2}, \frac{1}{4}\right) : 0, 0$. It is a nilpotent equilibrium and satisfies condition (4.iii.iii2) of Theorem 3.5 in [11], then its phase portrait is formed by one hyperbolic and one elliptic sector.

The Poincaré compactification of this system in the chart U_1 is

$$\dot{u} = \frac{1}{2}uv^2 - 2u^2v - 2uv - v, \qquad \dot{v} = \frac{1}{2}v^3 - 2uv^2 + 2v^2 + 4v.$$

Every point at infinity is an equilibrium. Removing the common factor v between $\dot{u}$ and $\dot{v}$, we obtain the system

$$\dot{u} = -2u^2 + \frac{1}{2}uv - 2u - 1, \qquad \dot{v} = \frac{1}{2}v^2 - 2uv + 2v + 4.$$

It has no equilibria on $v = 0$.

The Poincaré compactification in the chart U_2 is

$$\dot{u} = u^2v + 2uv - \frac{1}{2}v^2 + 2v, \qquad \dot{v} = uv^2 + 4uv + 4v^2.$$

Removing the common factor v between $\dot{u}$ and $\dot{v}$, we obtain the system

$$\dot{u} = u^2 + 2u - \frac{1}{2}v + 2, \qquad \dot{v} = uv + 4u + 4v.$$

There is an orbit tangent to the line at infinity at the origin O_2.

Since $y - x^2 = 0$ and $4x + 4y + 1 = 0$ are invariant curves of this system, we obtain the configuration $C(\mathrm{I.3.s}_{1.1})$ shown in Figure 6.2. Based on this configuration and the local phase portrait of the equilibrium P_1, we obtain the phase portrait PP.2 of Figure 3.1.

Case 2. $a \neq 1$**.** System $S(2)$ has three finite equilibria and their corresponding eigenvalues are

$$P_1 = \left(-\frac{1}{2}, \frac{1}{4}\right) : -4(a-1), -2(a-1);$$
$$P_2 = \left(-\frac{1}{2}(2a-1), \frac{1}{4}(2a-1)^2\right) : 2(a-1), 4(a-1);$$
$$P_3 = \left(-\frac{a}{2}, \frac{1}{4}(2a-1)\right) : -2(a-1), 2(a-1).$$

The Poincaré compactification of this system in the chart U_1 is

$$\dot{u} = \frac{2a-1}{2}uv^2 - 2u^2v - 2auv + (1-2a)v, \qquad \dot{v} = -2uv^2 + 2av^2 + \frac{2a-1}{2}v^3 + 4v.$$

Every point at infinity is an equilibrium.

The Poincaré compactification of this system in the chart U_2 is

$$\dot{u} = (2a-1)u^2v + 2auv + \left(\frac{1}{2} - a\right)v^2 + 2v, \qquad \dot{v} = (2a-1)uv^2 + 4av^2 + 4uv.$$

Removing the common factor v, we find an orbit tangent to the line at infinity at the origin O_2. Since $y - x^2 = 0$, $4x + 4y + 1 = 0$ and $4ax + 4y + 2a - 1 = 0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{I.3.s}_{1.1})$ and $C(\text{I.3.s}_{1.2})$, as shown in Figure 6.2.

Table 6.1 shows the local phase portraits of the finite equilibria and the corresponding configurations and phase portraits in the Poincaré disc according to the parameter a.

Zone	P_1	P_2	P_3	Configuration	PP
$a > 1$	Ns	Nu	S	$C(\text{I.3.s}_1\text{.2.2})$	PP.3
$a < 1$	Nu	Ns	S	$C(\text{I.3.s}_1\text{.2.1})$	PP.3

Table 6.1: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 2 of the system $S(2)$. The abbreviations "Ns", "Nu", and "S" denote "stable node", "unstable node" and "saddle", respectively.

System $S(3)$**.** The system together with its invariant curves is

$$\dot{x} = -x^2 + (a+b)\,x - ab, \quad \dot{y} = (2b-1)\,x^2 - 2xy + (2a+1)\,y - 2abx,$$

$$f_1 = y - x^2, \quad f_2 = x - a, \quad f_3 = x - b,$$

where $(2a - 2b + 1) \neq 0$.

We consider the following four cases: 1. $a = b \neq 0$; 2. $a = b = 0$; 3. $ab = 0$ and $a^2 + b^2 \neq 0$; 4. $ab(a-b) \neq 0$.

Case 1. $a = b \neq 0$ and $(2a - 2b + 1) \neq 0$. Let $c \neq 0$. The transformation $(x,\ y,\ t,\ a,\ b) \to \left(-\frac{x}{c},\ \frac{y}{c^2},\ \frac{t}{c},\ \frac{1}{c},\ \frac{1}{c}\right)$ reduces the system to $S(\text{I.4.s}_{1.1})$:

$$\dot{x} = (x+1)^2, \quad \dot{y} = (2-c)x^2 + 2xy + 2x + (c+2)y, \quad f_1 = y - x^2, \quad f_2 = x + 1.$$

We now analyse the phase portraits of the system $S(\text{I.4.s}_{1.1})$. There is a finite equilibrium $P_1 = (-1,\ 1) : 0,\ c$. According to Theorem 2.19 of [11], the point is a saddle-node.

The Poincaré compactification of this system in the chart U_1 is

$$\dot{u} = -uv^2 + cuv + u + 2v - c + 2, \qquad \dot{v} = -v^3 - 2v^2 - v.$$

There is an equilibrium $Q_1 = (c+2,\ 0) : -1,\ 1$.

The Poincaré compactification of this system in the chart U_2 is

$$\dot{u} = (c-2)u^3 - 2u^2v - u^2 - cuv + v^2, \qquad \dot{v} = (c-2)u^2v - 2uv^2 - 2uv - (c+2)v^2.$$

The origin O_2 is linearly zero. Doing a vertical blow-up $(u, v) \to (u_1, u_1v_1)$ on the system, followed by a time rescaling $(\dot{u}_1, \dot{v}_1) \to \left(\frac{\dot{u}_1}{u_1}, \frac{\dot{v}_1}{u_1}\right)$, we obtain the system:

$$\dot{u}_1 = cu_1^2 - 2u_1^2v_1 + u_1v_1^2 - (c+2)u_1v_1 - u_1, \qquad \dot{v}_1 = -v_1^3 - 2v_1^2 - v_1.$$

There are two equilibria on $u_1 = 0$:

$$(0,-1) : 0,\ c; \quad (0,0) : -1,\ -1.$$

According to Theorem 2.19 of [11], $(0,-1)$ is a saddle-node.

By carrying out the blow-downs $B(\text{I.4.s}_{1.1}.k)$ for $k = 1, 2$, we obtain the local phase portrait of O_2.

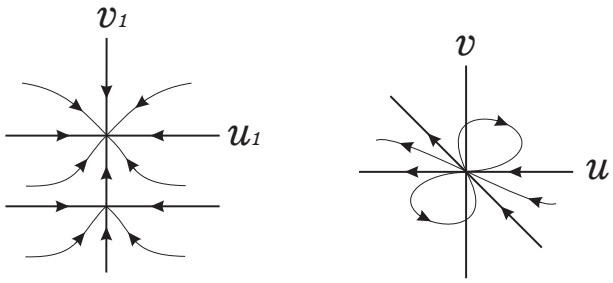

Figure 6.5: $B(\text{I.4.s}_1.1.1)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_{1.1})$ with $c < 0$.

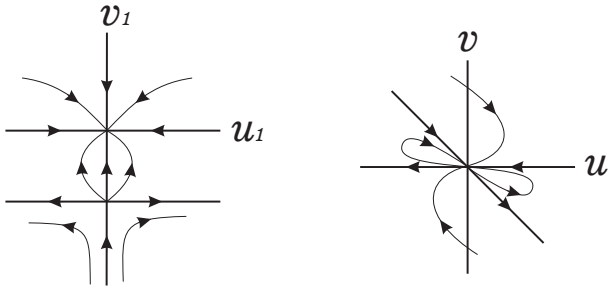

Figure 6.6: $B(\text{I.4.s}_1.1.2)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_{1.1})$ with $c > 0$.

Table 6.2 shows the local phase portraits of the finite and infinite equilibria. By analysing the local behaviour at O_2, we obtain the phase portraits in the Poincaré disc.

Zone	P_1	P_2	Q_1	O_2	Blow-up	Configuration	PP
$c < 0$	SN	S	S	LN	$B(\text{I.4.s}_1.1.1)$	$C(\text{I.4.s}_1.1)$	PP.4
$c > 0$	SN	S	S	LN	$B(\text{I.4.s}_1.1.2)$	$C(\text{I.4.s}_1.1)$	PP.4

Table 6.2: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 1 of the system $S(3)$. The abbreviations "SN" and "LN" denote "saddle-node" and "linearly zero equilibrium", respectively.

Case 2. $a = b = 0$ and $(4a - 2b + 1)(2a + 1) \neq 0$. Then system $S(3)$ simplifies to

$$\dot{x} = -x^2, \quad \dot{y} = -x^2 - 2xy + y.$$

Taking $c = -1$ in the system $S(\text{I.4.s}_1.1)$ and applying the transformation $(x, y) \to (x - 1, y - 2x + 1)$, we obtain the above system. Thus, it is a particular case of Case 1 with $a = b = -1$.

Case 3. $ab = 0$ and $(a^2 + b^2)(2a - 2b + 1) \neq 0$. If $b \neq 0$, then system $S(3)$ for $a = 0$ simplifies to $S(\text{I.4.s}_1.a = 0)$

$$\dot{x} = -x(x - b), \quad \dot{y} = (2b - 1)x^2 - 2xy + y.$$

Let $c \neq 0$, doing the transformation $(x, y, t, b) \to \left(-\frac{x}{c}, \frac{y}{c^2}, ct, \frac{1}{c}\right)$ to $S(\text{I.4.s}_1.a = 0)$ yields $S(\text{I.4.s}_1.2)$:

$$\dot{x} = x(x+1), \quad \dot{y} = (2-c)x^2 + 2xy + cy,$$
$$f_1 = y - x^2, \quad f_2 = x, \quad f_3 = x + 1.$$

Since $2a - 2b + 1 \neq 0$, $a = 0$ and $b = \dfrac{1}{c}$, here we have $c(c-2) \neq 0$.

If $b = 0$ then system $S(3)$ simplifies to $S(\text{I.4.s}_1.b = 0)$

$$\dot{x} = -x(x-a), \quad \dot{y} = -x^2 - 2xy + (2a+1)y.$$

Let $c - 2 \neq 0$, doing the transformation $(x, y, t, a) \to \left(\frac{-x}{c-2}, \frac{y}{(c-2)^2}, (c-2)t, \frac{1}{c-2}\right)$ to $S(\text{I.4.s}_1.b = 0)$ yields $S(\text{I.4.s}_1.2)$. Thus, we only have to consider system $S(\text{I.4.s}_1.2)$ in this case.

The system $S(\text{I.4.s}_1.2)$ has two finite equilibria

$$P_1 = (-1,\ 1) : -1,\ c-2; \quad P_2 = (0,\ 0) : 1,\ c.$$

The Poincaré compactification of this system in the chart U_1 is

$$\dot{u} = (c-1)uv + u - c + 2, \qquad \dot{v} = -v^2 - v.$$

Hence, there is an infinite equilibrium $Q_1 = (c-2, 0) : -1, 1$ in the chart U_1.

The Poincaré compactification of this system in the chart U_2 is

$$\dot{u} = (c-2)u^3 - u^2 + (1-c)uv, \qquad \dot{v} = (c-2)u^2v - 2uv - cv^2.$$

The origin O_2 is linearly zero. Since $u = 0$ is a characteristic direction of the equilibrium, we perform the twist $(u, v) \to (u_1 - v_1, v_1)$, and obtain the following system:

$$\dot{u}_1 = (c-2)u_1^3 + 2(2-c)u_1^2v_1 + (c-2)u_1v_1^2 - u_1^2 + (1-c)u_1v_1,$$
$$\dot{v}_1 = (c-2)u_1^2v_1 - 2(c-2)u_1v_1^2 + (c-2)v_1^3 - 2u_1v_1 + (2-c)v_1^2.$$

By doing the vertical blow-up $(u_1, v_1) \to (u_2, u_2v_2)$ and eliminating the common factor u_2 between $\dot{u}_2$ and $\dot{v}_2$ doing a time rescaling, we obtain the system

$$\dot{u}_2 = (c-2)u_2^2v_2^2 - 2(c-2)u_2^2v_2 + (1-c)u_2v_2 + (c-2)u_2^2 - u_2, \qquad \dot{v}_2 = v_2^2 - v_2.$$

This system has two equilibria on the straight line $u_2 = 0$

$$(0,\ 0) : -1,\ -1; \quad (0,\ 1) : 1,\ -c.$$

By doing the blow-downs $B(\text{I.4.s}_1.2.k)$ for $k = 1, 2, 3$, we obtain the local phase portrait of O_2.

Since $y - x^2 = 0$, $x = 0$, and $x + 1 = 0$ are invariant algebraic curves of the system, we obtain the configuration $C(\text{I.4.s}_1.2)$.

Table 6.3 shows the local phase portraits of the finite and infinite equilibria, the process of blowing-down at O_2, and the corresponding phase portraits in the Poincaré disc.

Case 4. $ab(a-b)(2a-2b+1) \neq 0$. Assume that $c(c-1)(d-2c) \neq 0$, doing the following transformation to system $S(3)$

$$(x, y, t, a, b) \to \left(\frac{-x}{d-2c}, \frac{y}{(d-2c)^2}, (d-2c)t, \frac{c}{d-2c}, \frac{1}{d-2c}\right),$$

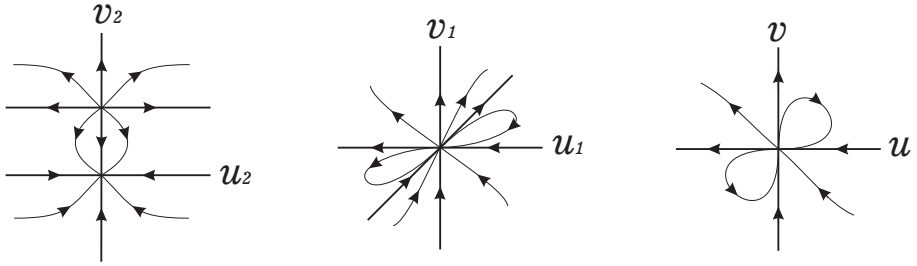

Figure 6.7: $B(\text{I.4.s}_1\text{.2.1})$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.2})$ with $c < 0$.

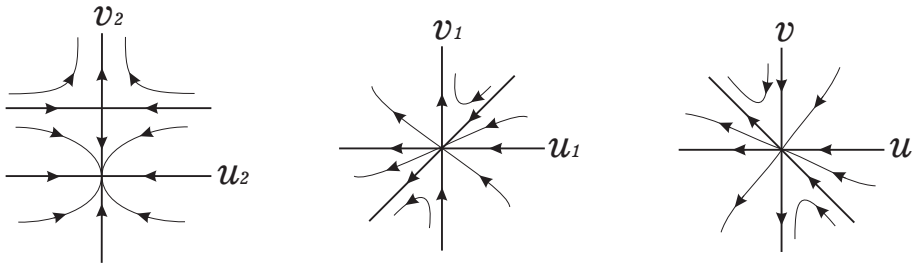

Figure 6.8: $B(\text{I.4.s}_1\text{.2.2})$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.2})$ with $0 < c < 2$.

we obtain the system $S(\text{I.4.s}_1\text{.3})$

$$\dot{x} = (x+1)(x+c), \quad \dot{y} = (2c-d+2)\,x^2 + 2xy + 2cx + dy,$$
$$f_1 = y - x^2, \quad f_2 = x + c, \quad f_3 = x + 1.$$

Since $(2a - 2b + 1) \neq 0$ in system $S(3)$, it follows that $(d-2) \neq 0$ in $S(\text{I.4.s}_1\text{.3})$. This further implies that the full parameter condition is $c(c-1)(d-2c)(d-2) \neq 0$.

The system has two finite equilibria

$$P_1 = (-1,\ 1) : c-1,\ d-2; \quad P_2 = (-c,\ c^2) : 1-c,\ d-2c.$$

The Poincaré compactification of this system in the chart U_1 is

$$\dot{u} = -cuv^2 - (c-d+1)uv + 2cv + u + 2c - d + 2, \qquad \dot{v} = -cv^3 - (c+1)v^2 - v.$$

Hence, there is an infinite equilibrium $Q_1 = (d-2c-2, 0) : (-1, 1)$ in the local chart U_1.

The Poincaré compactification of this system in the chart U_2 is

$$\dot{u} = (d-2c-2)u^3 - 2cu^2v - u^2 + (c-d+1)uv + cv^2,$$
$$\dot{v} = (d-2c-2)u^2v - 2cuv^2 - 2uv - dv^2.$$

The origin is linearly zero. By doing the vertical blow-up $(u, v) \to (u_1, u_1v_1)$ and eliminating the common factor u_1 between $\dot{u}_1$ and $\dot{v}_1$ doing a time rescaling, we obtain the system

$$\dot{u}_1 = (d-2c-2)u_1^2 - 2cu_1^2v_1 + cu_1v_1^2 + (c-d+1)u_1v_1 - u_1,$$
$$\dot{v}_1 = -cv_1^3 - (c+1)v_1^2 - v_1.$$

This system has three equilibria on the straight line $u_1 = 0$

$$(0,\ -1) : 1-c,\ d-2; \quad (0,\ 0) : -1,\ -1; \quad \left(0,\ -\frac{1}{c}\right) : \frac{c-1}{c},\ \frac{d-2c}{c}.$$

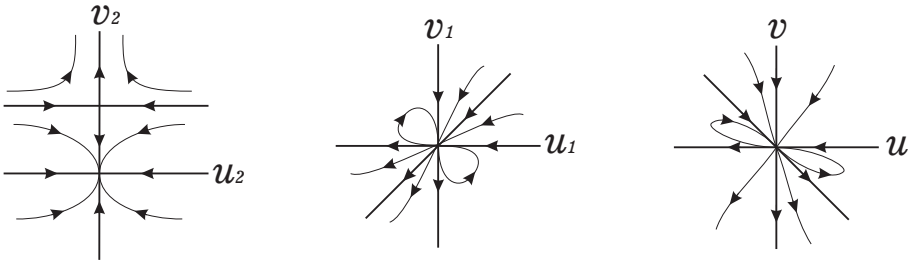

Figure 6.9: $B(\text{I.4.s}_1\text{.2.3})$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.2})$ with $c > 2$.

Zone	P_1	P_2	Q_1	O_2	Blow-up	Configuration	PP
$c < 0$	Ns	S	S	LN	$B(\text{I.4.s}_1\text{.2.1})$	$C(\text{I.4.s}_1\text{.2})$	PP.5

$c > 2$	S	Nu	S	LN	$B(\text{I.4.s}_1\text{.2.3})$	$C(\text{I.4.s}_1\text{.2})$	PP.5

Table 6.3: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 3 of the system $S(3)$.

According to the expressions of the eigenvalues, and under the condition $c(c-1)(2c-d)(d-2) \neq 0$, we divide the parameter space (c,d) into nine regions Z_k for $k = 1,2,\ldots,9$, as shown in Figure 6.10.

By doing the blow-downs $B(\text{I.4.s}_1\text{.3.}Z_k)$ for $k = 1,2,4,5,8,9$, we obtain the local phase portrait at O_2.

Since $y - x^2 = 0, x + c = 0$, and $x + 1 = 0$ are invariant curves of the system, we obtain the configurations $C(\text{I.4.s}_1\text{.3.}Z_1)$ and $C(\text{I.4.s}_1\text{.3.}Z_3)$.

Table 6.4 shows the types of finite and infinite equilibria, the process of blowing-down at O_2, and the corresponding global phase portraits in different regions.

Table 6.4: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 4 of system $S(3)$.

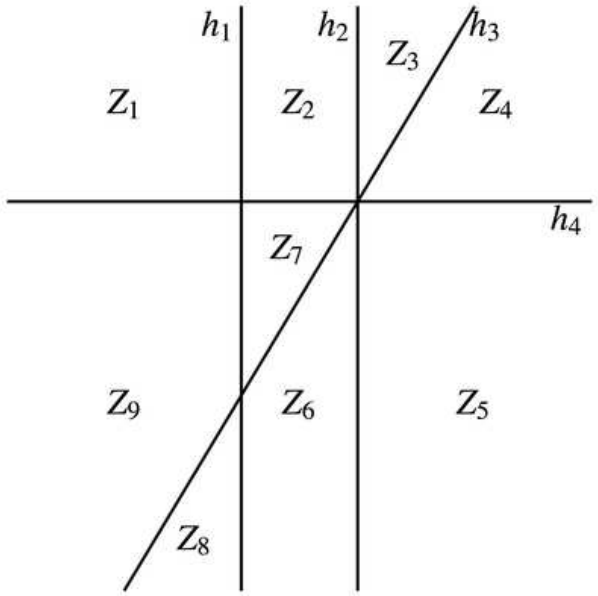

Figure 6.10: Zones of the parameter space (c, d), bounded by the straight lines $h_1 : c = 0$, $h_2 : c = 1$, $h_3 : d = 2c$, and $h_4 : d = 2$.

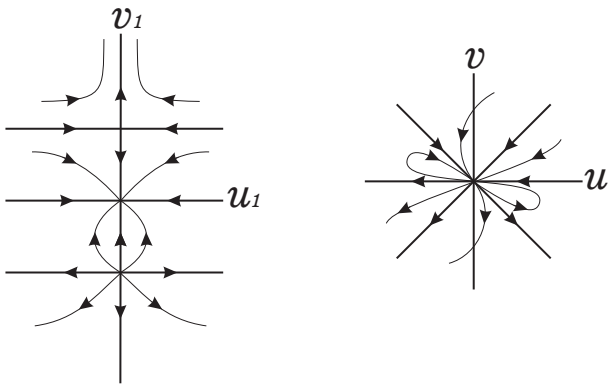

Figure 6.11: $B(\text{I.4.s}_1\text{.3.}Z_1)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.3})$ with (c, d) in Z_1.

System $S(4)$**.** The system together with its invariant curves is

$$\dot{x} = 8(a+1)\,x^2 + 8xy + 2(4ab+4a+4b+3)\,x + 4(2b+1)\,y + (4ab+2a+2b+1),$$
$$\dot{y} = 8(a+2b+1)\,x^2 + 8(2a+2b+3)\,xy + 2(4ab+2a+2b+1)\,x + 4(4ab+2a+1)\,y + 16y^2,$$

$$f_1 = y - x^2, \quad f_2 = 4x + 4y + 1, \quad f_3 = 2x + 2b + 1,$$

where $ab \neq 0$.

We consider the following three cases: 1. $a = b \neq 0$; 2. $a + 2b = 0$; 3. $(a - b)(a + 2b) \neq 0$.

Case 1. $a = b \neq 0$. The system simplifies to

$$\dot{x} = 8(b+1)x^2 + 8xy + 2(2b+1)(2b+3)x + 4(2b+1)y + (2b+1)^2,$$
$$\dot{y} = 8(3b+1)x^2 + 8(4b+3)xy + 2(2b+1)^2x + 4(4b^2+2b+1)y + 16y^2.$$

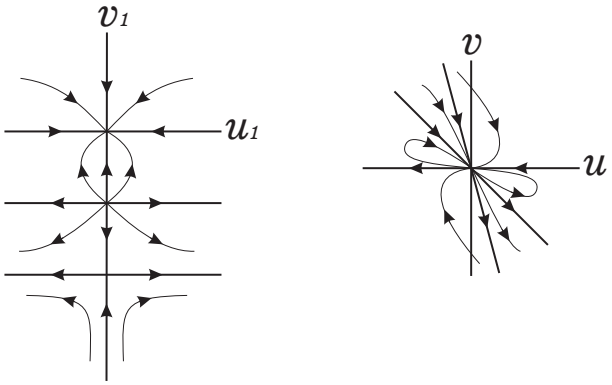

Figure 6.12: $B(\text{I.4.s}_1\text{.3}.Z_2)$: Blowing-down of the origin on chart U_2 for system $S(\text{I.4.s}_1\text{.3})$ with (c,d) in Z_2, Z_3.

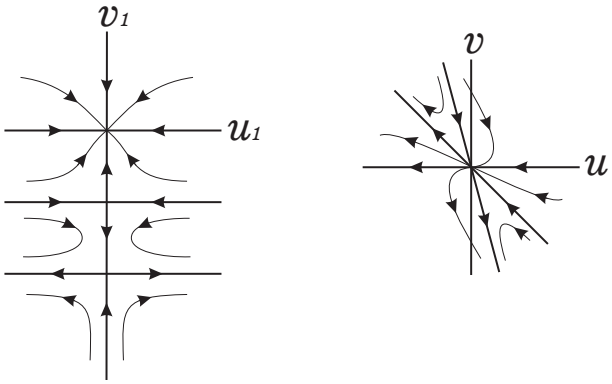

Figure 6.13: $B(\text{I.4.s}_1\text{.3}.Z_4)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.3})$ with (c,d) in Z_4, Z_7.

There are three equilibria

$$P_1 = \left(-\frac{1}{2},\ \frac{1}{4}\right) : 8b^2,\ 16b^2; \quad P_2 = \left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(2b+1)^2\right) : 0,\ 16b^2,$$
$$P_3 = \left(-b-\frac{1}{2},\ \frac{b}{4}\right) : -16b^2,\ -8b^2.$$

The Poincaré compactification in the chart U_1 is

$$\begin{aligned}\dot{u} &= 8u^2 - 4(2b+1)u^2v + 2(4b^2-4b-1)uv - (2b+1)^2uv^2 + 8(3b+2)u \\ &\quad + 2(2b+1)^2v + 8 + 24b, \\ \dot{v} &= -(2b+1)^2v^3 - 4(2b+1)uv^2 - 2(2b+1)(2b+3)v^2 - 8uv - 8(b+1)v.\end{aligned}$$

There are two equilibria:

$$Q_1 = (-1,\ 0) : -8b,\ 24b; \quad Q_2 = (-3b-1,\ 0) : -24b,\ 16b.$$

The Poincaré compactification in the chart U_2 is

$$\begin{aligned}\dot{u} &= -8(3b+1)u^3 - 2(2b+1)^2u^2v - 8(3b+2)u^2 - 2(4b^2-4b-1)uv - 8u \\ &\quad + (2b+1)^2v^2 + 4(2b+1)v, \\ \dot{v} &= -8(3b+1)u^2v - 2(2b+1)^2uv^2 - 8(4b+3)uv - 4(4b^2+2b+1)v^2 - 16v.\end{aligned}$$

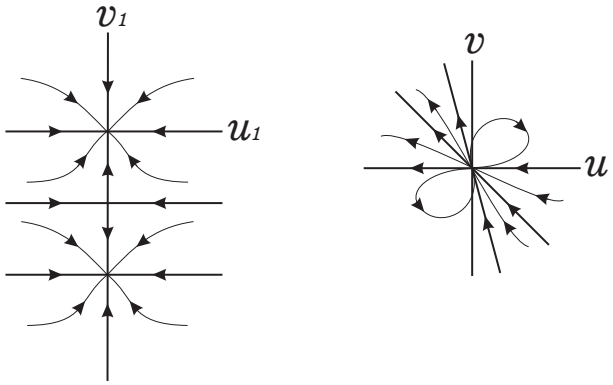

Figure 6.14: $B(\text{I.4.s}_1\text{.3.}Z_5)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.3})$ with (c, d) in Z_5, Z_6.

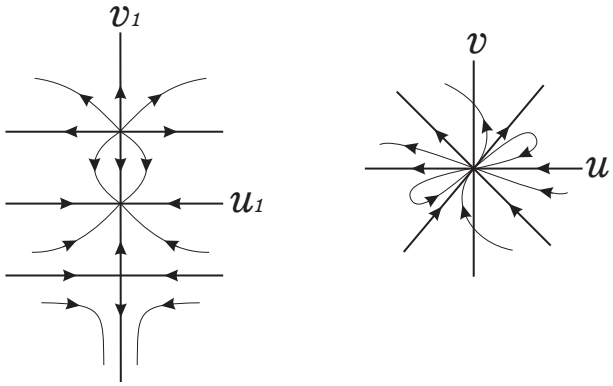

Figure 6.15: $B(\text{I.4.s}_1\text{.3.}Z_8)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.3})$ with (c, d) in Z_8.

The origin is an equilibrium with eigenvalues: $-16, -8$.

Since $y - x^2 = 0, 4x + 4y + 1 = 0$, and $2x + 2b + 1 = 0$ are invariant curves of the system, we obtain the configurations $C(\text{II.1.s}_1\text{.1.1})$ and $C(\text{II.1.s}_1\text{.1.2})$.

Table 6.5 shows the different types of finite and infinite equilibria, the corresponding configurations, and the associated global phase portraits.

Zone	P_1	P_2	P_3	Q_1	O_2	Configuration	PP
$a = b < 0$	Nu	SN	Ns	S	Ns	$C(\text{II.1.s}_1\text{.1.1})$	PP.7
$a = b > 0$	Nu	SN	Ns	S	Ns	$C(\text{II.1.s}_1\text{.1.2})$	PP.7

Table 6.5: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 1 of the system $S(4)$.

Case 2. $a + 2b = 0$ and $ab \neq 0$. The system simplifies to

$$\dot{x} = -8(2b-1)x^2 + 8xy - 2(8b^2 + 4b - 3)x + 4(2b+1)y - (2b+1)(4b-1),$$
$$\dot{y} = 8x^2 - 8(2b-3)xy - 2(2b+1)(4b-1)x - 4(8b^2 + 4b - 1)y + 16y^2.$$

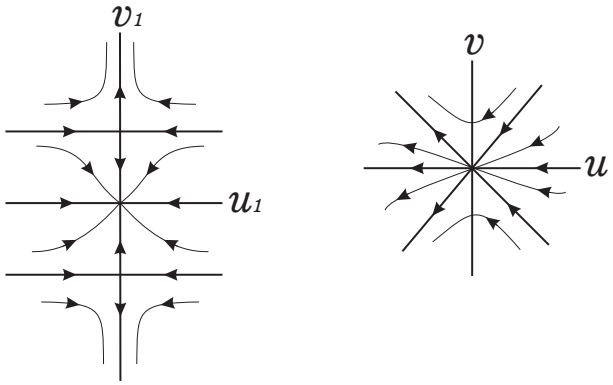

Figure 6.16: $B(\text{I.4.s}_1\text{.3.}Z_9)$: Blowing-down at O_2 of the system $S(\text{I.4.s}_1\text{.3})$ with (c,d) in Z_9.

This system has four equilibria

$$
\begin{aligned}
P_1 &= \left(-\frac{1}{2},\ \frac{1}{4}\right) : -32b^2,\ -16b^2;\\
P_2 &= \left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(2b+1)^2\right) : 16b^2,\ 24b^2;\\
P_3 &= \left(-b-\frac{1}{2},\ b+\frac{1}{4}\right) : -16b^2,\ 16b^2;\\
P_4 &= \left(-\frac{1}{2}(1-4b),\ \frac{1}{4}(1-4b)^2\right) : -32b^2,\ 48b^2.
\end{aligned}
$$

The Poincaré compactification in the chart U_1 is

$$
\begin{aligned}
\dot{u} &= -4(2b+1)u^2v + (2b+1)(4b-1)uv^2 - 2(8b^2+4b+1)uv + 8u^2 + 16u\\
&\quad -2(2b+1)(4b-1)v + 8,\\
\dot{v} &= (2b+1)(4b-1)v^3 - 4(2b+1)uv^2 + 2(8b^2+4b-3)v^2 - 8uv + 8(2b-1)v.
\end{aligned}
$$

There is an equilibrium $Q_1 = (-1,0) : 0, 16b$.

The Poincaré compactification in the chart U_2 is

$$
\begin{aligned}
\dot{u} &= -8u^3 + 2(2b+1)(4b-1)u^2v - 16u^2 + 2(8b^2+4b+1)uv - 8u\\
&\quad -(2b+1)(4b-1)v^2 + 4(2b+1)v,\\
\dot{v} &= -8u^2v + 8(2b-3)uv + 2(2b+1)(4b-1)uv^2 + 4(8b^2+4b-1)v^2 - 16v.
\end{aligned}
$$

The origin is an equilibrium with eigenvalues: $-16, -8$.

Since $y - x^2 = 0, 4x + 4y + 1 = 0$, and $2x + 2b + 1 = 0$ are invariant curves of the system, we obtain the configurations $C(\text{II.1.s}_1\text{.2.1})$ and $C(\text{II.1.s}_1\text{.2.2})$.

Table 6.6 shows the types of finite and infinite equilibria, the corresponding configurations, and the associated global phase portraits.

Zone	P_1	P_2	P_3	P_4	Q_1	O_2	Configuration	PP
$a=-2b>0$	Ns	Nu	S	S	SN	Ns	$C(\text{II.1.s}_1\text{.2.1})$	PP.8
$a=-2b<0$	Ns	Nu	S	S	SN	Ns	$C(\text{II.1.s}_1\text{.2.2})$	PP.8

Table 6.6: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 2 of the system $S(4)$.

Case 3. $ab(a-b)(a+2b)\neq 0$. Then system $S(4)$ has four finite equilibria

$$\begin{aligned}
P_1&=\left(-\frac{1}{2},\ \frac{1}{4}\right):8ab,\ 16ab;\\
P_2&=\left(-\frac{1}{2}(2a+1),\ \frac{1}{4}(2a+1)^2\right):16ab,\ 8a(a-b);\\
P_3&=\left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(2b+1)^2\right):8b(b-a),\ 16b^2;\\
P_4&=\left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(4b+1)\right):-8ab,\ -16b^2.
\end{aligned}$$

The Poincaré compactification in the chart U_1 is

$$\begin{aligned}
\dot u&=-4(2b+1)u^2v-(2a+1)(2b+1)uv^2+2(4ab-4b-1)uv+2(2a+1)(2b+1)v,\\
&\quad +8u^2+8(a+2b+2)u+8(a+2b+1)\\
\dot v&=-4(2b+1)uv^2-(2a+1)(2b+1)v^3-2(4ab+4a+4b+3)v^2-8uv-8(a+1)v.
\end{aligned}$$

The system in the chart U_1 has two infinite equilibria

$$Q_1=(-1,\ 0):-8a,\ 8(a+2b);\quad Q_2=(-a-2b-1,\ 0):-8(a+2b),\ 16b.$$

The Poincaré compactification in the chart U_2 is

$$\begin{aligned}
\dot u&=-8(a+2b+1)u^3-2(2a+1)(2b+1)u^2v-8(a+2b+2)u^2+2(4b+1-4ab)uv\\
&\quad -8u+(2a+1)(2b+1)v^2+4(2b+1)v,\\
\dot v&=-2(2a+1)(2b+1)uv^2-4(4ab+2a+1)v^2-8(a+2b+1)u^2v\\
&\quad -8(2a+2b+3)uv-16v.
\end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues $-16,-8$.

According to the expressions of the eigenvalues, and under the condition $ab(a-b)(a+2b)\neq 0$, we divide the parameter space (a,b) into eight regions Z_k for $k=1,\dots,8$, as shown in Figure 6.17.

Since $y-x^2=0$, $4x+4y+1=0$, and $2x+2b+1=0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{II.1.s}_1\text{.3.}Z_k)$ for $k=1,2,\dots,8$.

Table 6.7 shows the types of finite and infinite equilibria, the corresponding configurations, and the corresponding phase portraits in the Poincaré disc of Figure 3.1.

System $S(5)$**.** The system together with its invariant curves is

$$\begin{aligned}
\dot x&=4(a-b+2)\,x^2+8xy+2(b+3)\,x-4(a-b-1)\,y+(b+1),\\
\dot y&=4(2-a+b)\,x^2+24xy+16y^2+2(b+1)\,x+4(a+1)\,y,
\end{aligned}$$

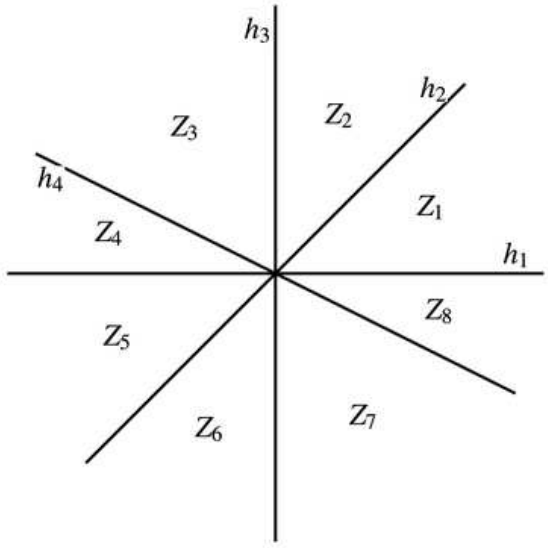

Figure 6.17: Zones of the parameter space (a, b), bounded by the straight lines $h_1 : b = 0$, $h_2 : a - b = 0$, $h_3 : a = 0$, and $h_4 : a + 2b = 0$.

$$f_1 = y - x^2, \quad f_2 = 4x + 4y + 1, \quad f_3 = 4x + 4y + b + 1,$$

where $a - b \neq 0$.

We consider two cases: 1. $b = 0$; 2. $b \neq 0$.

Case 1. $b = 0$ and $a - b \neq 0$. System $S(5)$ simplifies to

$$\begin{aligned} \dot{x} &= 4(a+2)x^2 + 8xy + 6x - 4(a-1)y + 1, \\ \dot{y} &= -4(a-2)x^2 + 24xy + 2x + 4(1+a)y + 16y^2. \end{aligned}$$

There is a finite equilibrium $P_1 = \left(-\frac{1}{2},\ \frac{1}{4}\right) : (0,\ 0)$. It satisfies condition (4.i.i2) in Theorem 3.5 of [11] and is therefore a saddle-node.

The Poincaré compactification in the chart U_1 is

$$\begin{aligned} \dot{u} &= 4(a-1)u^2v + 2(2a-1)uv - 4(a-4)u + 8u^2 - uv^2 + 2v - 4(a-2), \\ \dot{v} &= 4(a-1)uv^2 - 8uv - 4(a+2)v - 6v^2 - v^3. \end{aligned}$$

Hence, the system has two infinite equilibria in the chart U_1

$$P_1 = (-1,\ 0) : -4a,\ -4a; \quad P_2 = \left(\frac{1}{2}(a-2),\ 0\right) : -8a,\ 4a.$$

The Poincaré compactification in the chart U_2 is

$$\begin{aligned} \dot{u} &= 4(a-2)u^3 + 4(a-4)u^2 - 2u^2v - 2(2a-1)uv - 8u + v^2 - 4(a-1)v, \\ \dot{v} &= 4(a-2)u^2v - 2uv^2 - 24uv - 4(a+1)v^2 - 16v. \end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues: $-16, -8$.

Since $y - x^2 = 0$, $4x + 4y + 1 = 0$ are invariant curves of the system, we obtain the configurations $C(\text{II.1.s}_2\text{.1.1})$ and $C(\text{II.1.s}_2\text{.1.2})$.

Table 6.7: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 3 of the system $S(4)$.

Zone	P_1	Q_1	Q_2	O_2	Configuration	PP
$b=0, a<0$	Ni	Nu	S	Ns	$C(\text{II.1.s}_2\text{.1.1})$	PP.14
$b=0, a>0$	Ni	Ns	S	Ns	$C(\text{II.1.s}_2\text{.1.2})$	PP.14

Table 6.8: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 1 of the system $S(5)$. Here "Ni" stands for "nilpotent".

Table 6.8 shows the phase portraits of the finite and infinite equilibria, the corresponding configurations, and the associated global phase portraits in Figure 3.1.

Case 2. $b(a-b)\neq 0$. If $b<0$, then system $S(5)$ has four finite equilibria

$$
\begin{aligned}
P_1 &= \left(-\frac{1}{2},\ \frac{1}{4}\right) : 2b,\ 4b;\\
P_2 &= \left(-\frac{1}{2}\left(\sqrt{-b}+1\right),\ \frac{1}{4}\left(1+2\sqrt{-b}-b\right)\right) : -4(a-b)\sqrt{-b},\ -4b;\\
P_3 &= \left(\frac{1}{2}\left(\sqrt{-b}-1\right),\ \frac{1}{4}\left(1-2\sqrt{-b}-b\right)\right) : 4(a-b)\sqrt{-b},\ -4b;\\
P_4 &= \left(\frac{-a}{2(a-b)},\ \frac{a+b}{4(a-b)}\right) : -2b,\ 4b.
\end{aligned}
$$

If $b>0$, then the system $S(5)$ has only two finite equilibria P_1 and P_4.

The Poincaré compactification in the chart U_1 is

$$
\begin{aligned}
\dot{u} &= 4(a-b-1)u^2v-(b+1)uv^2+2(2a-b-1)uv+8u^2-4(a-b-4)u\\
&\quad +2(b+1)v-4(a-b-2),\\
\dot{v} &= 4(a-b-1)uv^2-8uv-(b+1)v^3-(2b+6)v^2-4(a-b+2)v.
\end{aligned}
$$

There are two equilibria

$$
P_1=(-1,\ 0) : 4(b-a),\ 4(b-a);\quad P_2=\left(\frac{a-b-2}{2},\ 0\right) : 8(b-a),\ 4(a-b).
$$

The Poincaré compactification in the chart U_2 is

$$\begin{aligned}\dot{u} &= 4(a-b-2)u^3 - 2(b+1)u^2v + 4(a-b-4)u^2 - 2(2a-b-1)uv - 8u \\ &\quad +(b+1)v^2 - 4(a-b-1)v, \\ \dot{v} &= 4(a-b-2)u^2v - 2(b+1)uv^2 - 24uv - 4(a+1)v^2 - 16v.\end{aligned}$$

The origin is an equilibrium with eigenvalues: $-16, -8$.

According to the expressions of the eigenvalues, and under the condition $b \neq 0$, we divide the parameter space (a, b) into four regions Z_k for $k = 1, 2, 3, 4$, as shown in Figure 6.18.

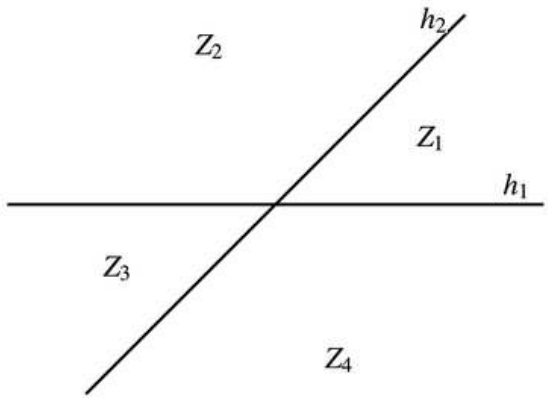

Figure 6.18: Zones of the parameter space (a, b), bounded by the straight lines $h_1 : b = 0$, $h_2 : a - b = 0$.

Since $y - x^2 = 0, 4x + 4y + 1 = 0$, and $4x + 4y + b + 1 = 0$ are invariant curves of the system, we obtain the configurations $C(\text{II.1.s}_2\text{.1.}Z_k)$ for $k = 1, 2, 3, 4$.

Table 6.9 shows the types of finite and infinite equilibria, the corresponding configurations, and the associated global phase portraits.

Zone	P_1	P_2	P_3	P_4	Q_1	Q_2	O_2	Configuration	PP
Z_1	Nu	–	–	S	Ns	S	Ns	$C(\text{II.1.s}_2\text{.2.}Z_1)$	PP.13
Z_2	Nu	–	–	S	Nu	S	Ns	$C(\text{II.1.s}_2\text{.2.}Z_2)$	PP.13
Z_3	Ns	Nu	S	S	Nu	S	Ns	$C(\text{II.1.s}_2\text{.2.}Z_3)$	PP.9,10,12
Z_4	Ns	S	Nu	S	Ns	S	Ns	$C(\text{II.1.s}_2\text{.2.}Z_4)$	PP.9,10,12

Table 6.9: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 2 of the system $S(5)$.

System $S(6)$**.** The system together with its invariant curves is

$$\begin{aligned}\dot{x} &= 8(ab+2a-b^2+4)\,x^2+8(b+2)^2\,xy-2(b^2-4a-12)\,x\\ &\quad -4(ab-2b^2-6b+2a-4)\,y-(ab-2a+2b-4),\\ \dot{y} &= 16(2+b)\,x^2+8(ab+2a+6b+12)\,xy+16(b+2)^2\,y^2-2(ab-2a+2b-4)\,x\\ &\quad -4(b^2-4a+4b-4)\,y,\end{aligned}$$

$$f_1 = y-x^2, \quad f_2 = 4x+4y+1, \quad f_3 = 8x+4(b+2)\,y+(2-b),$$

where $(a-b)(b+2)\neq 0$.

We distinguish four cases: $1.b=0$; $2.a+b=0$; $3.a-2b=0$; $4.b(a+b)(a-2b)\neq 0$.

Case 1. $b=0$ and $(a-b)(b+2)\neq 0$. System $S(6)$ simplifies to

$$\begin{aligned}\dot{x} &= 16(a+2)x^2+32xy+8(a+3)x+8(2-a)y+2a+4,\\ \dot{y} &= 32x^2+16(a+6)xy+4(a+2)x+16(a+1)y+64y^2.\end{aligned}$$

This system has two finite equilibria

$$P_1=\left(-\frac{1}{2},\,\frac{1}{4}\right):0,\;0; \quad P_2=\left(-\frac{1}{4}(a+2),\,\frac{1}{16}(a+2)^2\right):-4a^2,\;2a^2.$$

The point P_1 satisfies the condition (4.iii.iii2) in Theorem 3.5 of [11]. Therefore, its phase portrait is formed by one hyperbolic and one elliptic sector.

The Poincaré compactification of this system in the chart U_1 is

$$\begin{aligned}\dot{u} &= 8(a-2)u^2v-2(a+2)uv^2+8(a-1)uv+32u^2+64u+4(a+2)v+32,\\ \dot{v} &= -2(a+2)v^3+8(a-2)uv^2-8(a+3)v^2-32uv-16(a+2)v.\end{aligned}$$

Hence, there is an infinite equilibrium $Q_1=(-1,0):-16a,0$ in the chart U_1.

The Poincaré compactification of the system in the chart U_2 is

$$\begin{aligned}\dot{u} &= -32u^3-4(a+2)u^2v-64u^2-8(a-1)uv-32u+2(a+2)v^2-8(a-2)v,\\ \dot{v} &= -32u^2v-4(a+2)uv^2-16(a+6)uv-16(a+1)v^2-64v.\end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues $-64, -32$.

Since $y-x^2=0$, $4x+4y+1=0$ are invariant algebraic curves for this system, we obtain the configurations $C(\text{II.1.s}_3\text{.1.1})$ and $C(\text{II.1.s}_3\text{.1.2})$ and the phase portraits in the Poincaré disc indicated in Table 6.10.

Zone	P_1	P_2	Q_1	O_2	Configuration	PP
$b=0,\ a<0$	Ni	S	SN	Ns	$C(\text{II.1.s}_3\text{.1.1})$	PP.15
$b=0,\ a>0$	Ni	S	SN	Ns	$C(\text{II.1.s}_3\text{.1.2})$	PP.15

Table 6.10: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 1 of the system $S(6)$.

Case 2. $a+b=0$ and $b(a-b)(b+2)\neq 0$. System $S(6)$ simplifies to

$$\begin{aligned}\dot{x} &= -16(b-1)(b+2)x^2+8(b+2)^2xy-2(b-2)(b+6)x+4(b+2)(3b+2)y+(b-2)^2,\\ \dot{y} &= 16(b+2)x^2-8(b-6)(b+2)xy+2(b-2)^2x-4(b^2+8b-4)y+16(b+2)^2y^2.\end{aligned}$$

Since $b+2 \neq 0$, this system has three finite equilibria

$$P_1 = \left(-\frac{1}{2},\ \frac{1}{4}\right) : 8b^2,\ 16b^2; \quad P_2 = \left(-\frac{b+6}{6(b+2)},\ -\frac{b-6}{12(b+2)}\right) : -8b^2,\ \frac{16b^2}{3};$$
$$P_3 = \left(\frac{b-2}{2(b+2)},\ \frac{(b-2)^2}{4(b+2)^2}\right) : -16b^2,\ 0.$$

The Poincaré compactification of this system in the chart U_1 is

$$\begin{aligned}\dot{u} &= -4(3b+2)(b+2)u^2v - (b-2)^2uv^2 - 2(b^2+12b+4)uv + 8(b+2)^2u^2,\\ &\quad +8(b+2)(b+4)u + 2(b-2)^2v + 16(b+2)\\ \dot{v} &= -4(b+2)(3b+2)uv^2 - 8(b+2)^2uv - (b-2)^2v^3 + 2(b-2)(b+6)v^2\\ &\quad +16(b+2)(b-1)v.\end{aligned}$$

Since $b+2 \neq 0$, the system has two infinite equilibria in the chart U_1

$$Q_1 = (-1,\ 0) : 24b(b+2),\ -8b(b+2); \quad Q_2 = \left(\frac{-2}{b+2},\ 0\right) : 16b(b+2),\ 8b(b+2).$$

The Poincaré compactification of the system in the chart U_2 is

$$\begin{aligned}\dot{u} &= -16(b+2)u^3 - 2(b-2)^2u^2v - 8(b+2)(b+4)u^2 + 2(b^2+12b+4)uv\\ &\quad -8(b+2)^2u + (b-2)^2v^2 + 4(b+2)(3b+2)v,\\ \dot{v} &= -16(b+2)u^2v - 2(b-2)^2uv^2 + 8(b-6)(b+2)uv + 4(b^2+8b-4)v^2 - 16(b+2)^2v.\end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues: $-16(b+2)^2, -8(b+2)^2$.

Since $y - x^2 = 0$, $4x + 4y + 1 = 0$, and $8x + 8y + 4by - b + 2 = 0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{II.1.s}_3\text{.2.1})$ and $C(\text{II.1.s}_3\text{.2.2})$.

Table 6.11 shows the local phase portraits of the finite and infinite equilibria, the corresponding configurations and phase portraits in the Poincaré disc.

Table 6.12: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 3 of the system $S(6)$.

Case 4. $b(a-2b)(a+b)(a-b)(b+2) \neq 0$. Then system $S(6)$ has four finite equilibria

$$\begin{aligned}P_1 &= \left(-\frac{1}{2},\ \frac{1}{4}\right) : 8b(b-a),\ 4b(b-a);\\ P_2 &= \left(-\frac{a+2}{2(b+2)},\ \frac{(a+2)^2}{4(b+2)^2}\right) : -4(a-b)^2,\ 2(a-b)(a+b);\\ P_3 &= \left(\frac{b-2}{2(b+2)},\ \frac{(b-2)^2}{4(b+2)^2}\right) : 4b(a+b),\ 8(a-b)b;\\ P_4 &= \left(\frac{b(b+4)-2a}{2(a-2b)(b+2)},\ -\frac{a(b-2)+4b}{4(a-2b)(b+2)}\right) : -\frac{4(a-b)^2b}{a-2b},\ 4(a-b)b,\end{aligned}$$

The Poincaré compactification in the chart U_1 is

$$\begin{aligned}\dot{u} &= 4(a-2b-2)(b+2)u^2v + (a+2)(b-2)uv^2 - 2(b^2-4a+8b+4)uv\\ &\quad +8(b+2)^2u^2 + 8(b+2)(b+4)u - 2(a+2)(b-2)v + 16(b+2),\\ \dot{v} &= (a+2)(b-2)v^3 + 2(b^2-4a-12)v^2 + 4(a-2b-2)(b+2)uv^2\\ &\quad -8(a-b+2)(b+2)v - 8(b+2)^2uv.\end{aligned}$$

Since $b+2 \neq 0$, there are two equilibria

$$Q_1 = (-1,\ 0) : 8(2b-a)(b+2),\ -8b(b+2);$$
$$Q_2 = \left(-\frac{2}{b+2},\ 0\right) : 8(b-a)(b+2),\ 8b(b+2),$$

The Poincaré compactification in the chart U_2 is

$$\begin{aligned}
\dot{u} &= -8(b+2)^2u - 8(b+2)(b+4)u^2 - 16(b+2)u^3 - 4(a-2b-2)(b+2)v \\
&\quad +2(b^2-4a+8b+4)uv - (a+2)(b-2)v^2 + 2(a+2)(b-2)u^2v, \\
\dot{v} &= -16(b+2)u^2v - 8(a+6)(b+2)uv + 2(a+2)(b-2)uv^2 \\
&\quad +4(b^2-4a+4b-4)v^2 - 16(b+2)^2v.
\end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues: $-16(b+2)^2, -8(b+2)^2$.

According to the expressions of the eigenvalues, and under the condition $b(a+b)(a-b)(a+2b)(b+2) \neq 0$, we divide the parameter space (a,b) into twelve regions Z_k for $k = 1,2,\ldots,12$, as shown in Figure 6.19.

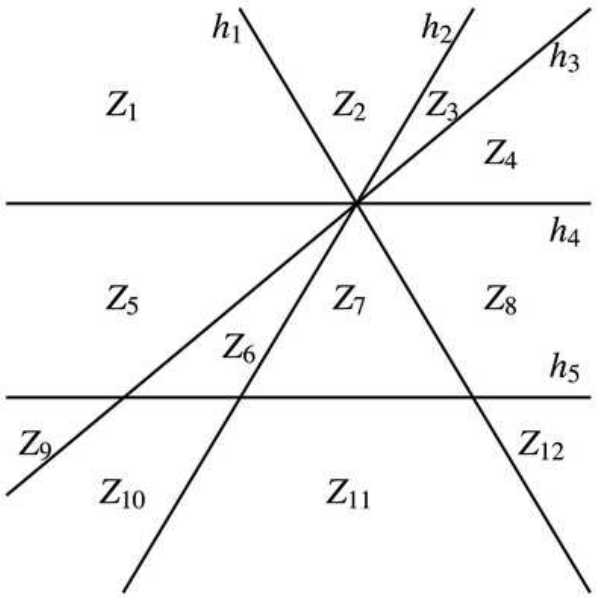

Figure 6.19: Zones of the parameter space (a,b), bounded by the straight lines $h_1 : a+b=0$, $h_2 : a-b=0$, $h_3 : a-2b=0$, $h_4 : b=0$, and $h_5 : b+2=0$.

Since $y-x^2=0$, $4x+4y+1=0$, and $8x+8y+4by-b+2=0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{II.1.s}_3\text{.4.}Z_k)$ for $k = 1,2,\ldots,8$.

Table 6.13 shows the local phase portraits of the finite and infinite equilibria, the corresponding configurations, and phase portraits in the Poincaré disc.

System $S(7)$**.** The system together with its invariant curves is

$$\begin{aligned}
\dot{x} &= 8(a+1)\,x^2 + 8xy + 2(ab+2a+2b+3)\,x - 4(a-b-1)\,y + (ab+a+b+1), \\
\dot{y} &= 8(b+1)\,x^2 + 8(a+b+3)\,xy + 16y^2 + (2ab+2a+2b+2)\,x + 4(ab+2a+1)\,y,
\end{aligned}$$

$$f_1 = y - x^2, \quad f_2 = 4x+4y+1, \quad f_3 = 4(b+1)\,x + 4y + (b+1)^2,$$

Table 6.13: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 4 of the system $S(6)$.

where $a(a-b) \neq 0$.

We divide the study of this system into two cases: $1.b = 0$; $\quad 2.b \neq 0$.

Case 1. $b = 0$ and $a(a-b) \neq 0$. System $S(7)$ simplifies to

$$\dot{x} = 8(a+1)x^2 + 8xy + 2(2a+3)x - 4(a-1)y + a + 1,$$
$$\dot{y} = 8x^2 + 8(a+3)xy + 2(a+1)x + 16y^2 + 4(2a+1)y.$$

Doing the transformation $(a, b, t) \to \left(2a,\ 0,\ \frac{t}{4}\right)$ on $S(6)$ we obtain the above system.

Case 2. $ab(a-b) \neq 0$. Then system $S(7)$ has four finite equilibria

$$P_1 = \left(-\frac{1}{2}, \frac{1}{4}\right) : 2ab,\ 4ab; \quad P_2 = \left(-\frac{1}{2}(a+1),\ \frac{1}{4}(a+1)^2\right) : -4a(a-b),\ 2a(a-b);$$
$$P_3 = \left(-\frac{1}{4}(b+2),\ \frac{b+1}{4}\right) : -2ab,\ 2(a-b)b;$$
$$P_4 = \left(-\frac{1}{2}(b+1),\ \frac{1}{4}(b+1)^2\right) : 4b(b-a),\ 2b(b-a),$$

The Poincaré compactification of system $S(7)$ in the chart U_1 is

$$\dot{u} = 4(a-b-1)u^2v - (a+1)(b+1)uv^2 + 2(ab+2a-2b-1)uv + 8u^2 + 8(b+2)u$$
$$+2(a+1)(b+1)v + 8(b+1),$$
$$\dot{v} = -(a+1)(b+1)v^3 + 4(a-b-1)uv^2 - 2(ab+2a+2b+3)v^2 - 8uv - 8(a+1)v,$$

Hence, there are two infinite equilibria in the chart U_1

$$Q_1 = (-1,\ 0) : -8a,\ 8b; \quad Q_2 = (-b-1,\ 0) : -8(a-b),\ -8b.$$

The Poincaré compactification of system $S(7)$ in the chart U_2 is

$$\dot{u} = -8(b+1)u^3 - 8(b+2)u^2 - 2(a+1)(b+1)u^2v - 2(ab+2a-2b-1)uv - 8u$$
$$+(a+1)(b+1)v^2 + 4(b-a+1)v,$$
$$\dot{v} = -8(b+1)u^2v - 2(a+1)(b+1)uv^2 - 8(a+b+3)uv - 4(ab+2a+1)v^2 - 16v.$$

The origin O_2 is an infinite equilibrium with eigenvalues: $-16, -8$.

According to the expressions of the eigenvalues, and under the condition $ab(a-b) \neq 0$, we divide the parameter space (a,b) into six regions Z_k for $k = 1, 2, \ldots, 6$, as shown in Figure 6.20.

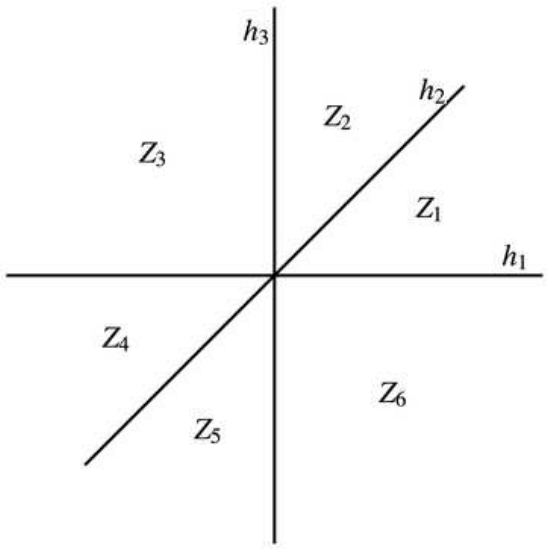

Figure 6.20: Zones of parameter space (a,b), bounded by the straight lines h_1 : $b = 0$, $h_2 : a - b = 0$, and $h_3 : a = 0$.

Since $y - x^2 = 0$, $4x + 4y + 1 = 0$, and $b^2 + 4x + 4bx + 4y + 2b + 1 = 0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{II.1.s}_4\text{.2.}Z_k)$ for $k = 1, \ldots, 6$.

Table 6.14 shows the local phase portraits of the finite and infinite equilibria, the corresponding configurations, and phase portraits in the Poincaré disc.

Zone	P_1	P_2	P_3	P_4	Q_1	Q_2	O_2	Configuration	PP

Table 6.14: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 2 of the system $S(7)$.

System $S(8)$**.** The system together with its invariant curves is

$$\begin{aligned}
\dot{x} &= 8(a-b+1)\,x^2 + 8xy - 2(4b^2 - 4a - 3)\,x + 4(2b+1)\,y - (2a+1)(4b^2-1),\\
\dot{y} &= 8(a+b+1)\,x^2 + 8(2a+3)\,xy + 16y^2 - 2(8ab^2 + 4b^2 - 2a - 1)\,x\\
&\quad -4(4b^2 + 2b - 2a - 1)\,y,
\end{aligned}$$

$$f_1 = y - x^2, \quad f_2 = 4x + 4y - 4b^2 + 1, \quad f_3 = 2x + 2b + 1,$$

where $b(a-b) \neq 0$.

For studying this system we consider the two cases: $1.a+b=0$; $\quad 2.a+b\neq 0$.

Case 1. $a+b=0$ and $b(a-b)\neq 0$. The system simplifies to:

$$\begin{aligned}\dot{x} &= -8(2b-1)\,x^2+8xy-2(2b-1)(2b+3)\,x+4(2b+1)\,y+(2b-1)^2(2b+1),\\ \dot{y} &= 8x^2-8(2b-3)\,xy+2(2b-1)^2(2b+1)\,x-4(4b^2+4b-1)\,y+16y^2.\end{aligned}$$

The system has three finite equilibria

$$\begin{aligned}P_1 &= \left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(2b+1)^2\right) : 32b^2,\ 32b^2;\\ P_2 &= \left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(1+4b-4b^2)\right) : -32b^2,\ 16b^2;\\ P_3 &= \left(\frac{1}{2}(2b-1),\ \frac{1}{4}(2b-1)^2\right) : -32b^2,\ 0,\end{aligned}$$

The Poincaré compactification of this system in the chart U_1 is

$$\begin{aligned}\dot{u} &= -4(2b+1)\,u^2v-(2b-1)^2(2b+1)\,uv^2-2(2b+1)^2\,uv+2(2b-1)^2(2b+1)\,v\\ &\quad +8u^2+16u+8,\\ \dot{v} &= -(2b-1)^2(2b+1)\,v^3-4(2b+1)\,uv^2+2(2b-1)(2b+3)\,v^2-8uv+8(2b-1)\,v.\end{aligned}$$

Hence, there is an infinite equilibrium $Q_1=(-1,0):0,16b$ in the local chart U_1. According to Theorem 2.19 of [11], this equilibrium is a saddle–node.

The Poincaré compactification of this system in the chart U_2 is

$$\begin{aligned}\dot{u} &= -8u^3-2(2b-1)^2(2b+1)\,u^2v+2(2b+1)^2\,uv+(2b-1)^2(2b+1)\,v^2-16u^2\\ &\quad -8u+4(2b+1)\,v,\\ \dot{v} &= -8u^2v-2(2b-1)^2(2b+1)\,uv^2+8(2b-3)\,uv+4(4b^2+4b-1)\,v^2-16v.\end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues: $-16,-8$.

Since $y-x^2=0$, $4x+4y-4b^2+1=0$, and $2x+2b+1=0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{II.3.s}_1.1)$.

Table 6.15 shows the local phase portraits of the finite and infinite equilibria, the corresponding configurations, and phase portraits in the Poincaré disc.

Zone	P_1	P_2	P_3	Q_1	O_2	Configuration	PP
$a+b=0$	Nu	S	SN	SN	Ns	$C(\text{II.3.s}_1.1)$	PP.17

Table 6.15: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 1 of the system $S(8)$.

Case 2. $b(a-b)(a+b)\neq 0$. Then system $S(8)$ has four finite equilibria

$$P_1=\left(-\frac{1}{2}(2a+1),\ \frac{1}{4}(2a+1)^2\right):16(a-b)b,\ 8(a-b)(a+b);$$
$$P_2=\left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(2b+1)^2\right):16b(b-a),\ 16b(b-a);$$
$$P_3=\left(-\frac{1}{2}(2b+1),\ \frac{1}{4}(4ab+4b+1)\right):-8b(a-b),\ 16b(a-b);$$
$$P_4=\left(\frac{1}{2}(2b-1),\ \frac{1}{4}(2b-1)^2\right):16(a-b)b,\ 16b(a+b).$$

The Poincaré compactification of this system in the chart U_1 is

$$\begin{aligned}\dot{u}&=-4(2b+1)\,u^2v+(4b^2-1)(2a+1)\,uv^2-2(2b+1)^2\,uv+8u^2+8(a+b+2)\,u\\&\quad-2(4b^2-1)(2a+1)\,v+8(a+b+1),\\\dot{v}&=(4b^2-1)(2a+1)\,v^3-4(2b+1)\,uv^2+2(4b^2-4a-3)\,v^2-8uv-8(a-b+1)\,v.\end{aligned}$$

Hence, there are two infinite equilibria in the local chart U_1

$$Q_1=(-1,\ 0):8(b-a),\ 8(a+b);\quad Q_2=(-a-b-1,\ 0):-8(a+b),\ 16b,$$

The Poincaré compactification of this system in the chart U_2 is

$$\begin{aligned}\dot{u}&=-8(a+b+1)\,u^3+2(2a+1)(4b^2-1)\,u^2v-8(a+b+2)\,u^2\\&\quad+2(2b+1)^2\,uv-8u-(4b^2-1)(2a+1)\,v^2+4(2b+1)\,v,\\\dot{v}&=-8(a+b+1)\,u^2v+2(2a+1)(4b^2-1)\,uv^2-8(2a+3)\,uv\\&\quad+4(4b^2-2a+2b-1)\,v^2-16v.\end{aligned}$$

The origin O_2 is an infinite equilibrium with eigenvalues: $-16,-8$.

According to the expressions of the eigenvalues, and under the condition $b(a+b)(a-b)\neq 0$, we divide the parameter space (a,b) into six regions Z_k for $k=1,2,\ldots,6$, as shown in Figure 6.21.

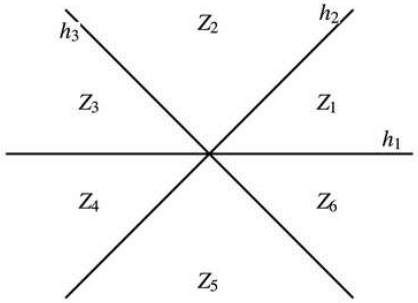

Figure 6.21: Zones of the parameter space (a,b), bounded by the straight lines $h_1:b=0$, $h_2:a-b=0$, and $h_3:a+b=0$.

Since $y - x^2 = 0$, $4x + 4y - 4b^2 + 1 = 0$, and $2x + 2b + 1 = 0$ are invariant algebraic curves of the system, we obtain the configurations $C(\text{II.3.s}_1\text{.2.}Z_k)$ for $k = 1, \ldots, 6$.

Table 6.16 shows the local phase portraits of the finite and infinite equilibria, the corresponding configurations, and phase portraits in the Poincaré disc.

Table 6.16: Types of the finite and infinite equilibria, together with their corresponding local phase portraits, configurations, and global phase portraits in the Poincaré disc for Case 2 of the system $S(8)$.

This completes the proof. □

7 Conclusion

This study systematically classifies the phase portraits in the Poincaré disc of the quadratic systems with one or two invariant real straight lines taking into account that their total multiplicity be two and an invariant parabola. The distinct phase portraits in the Poincaré disc of these class of quadratic systems are given in Theorem 3.2. The results contribute to a broader understanding of quadratic systems with algebraic invariant curves, offering new insights into their global dynamics and bifurcations.

As a natural extension of this work, future research will focus on the classification of phase portraits for quadratic systems with one or two invariant real straight lines taking into account that their total multiplicity be two and an invariant ellipse or hyperbola. This will ultimately lead to a complete classification of all planar quadratic differential systems possessing two invariant straight lines and an irreducible conic. This classification will provide a unified framework for analysing the global dynamics of this important class of quadratic systems.

8 Data and code availability

All symbolic computations supporting Theorems 3.1 and 3.2 are openly available at the following public repository:

- Llibre, J. & Ou, H. (2025). *Mathematica computations for the parabola paper (Theorems 3.1 and 3.2).* Repository: `https://github.com/Ovason/R2P` (accessed on December 4, 2025).

The repository contains the Mathematica notebooks ordered exactly as in the manuscript.

Acknowledgements

We gratefully thank the editor and the referee for their careful and constructive review of our paper, which has greatly improved the clarity and completeness of the manuscript.

Abstract. This paper is concerned with the existence and multiplicity of a ground state solution for a class of fractional (p,t)-type systems involving logarithmic nonlinearities with sign-changing coefficients, which are obtained by variational methods. More precisely, by combining Nehari manifold and fibering map method. The paper proves two results: The first one provides the existence of a ground-state solution for the proposed problem. Under a different set of hypotheses with respect to the first result, a second result is obtained, which provides the existence of at least two nontrivial ground state solutions.

Keywords: logarithmic nonlinearity, fibering map, Nehari manifold, (p,t) fractional operator, multiplicity, mountain pass theorem.

2020 Mathematics Subject Classification: 35K55, 35R11, 47G20.

1 Introduction and main results

The study of elliptic equations and systems involving fractional operators (see [14]), as well as, fractional (p,t) Laplacians has energized many applications in nonlinear mathematical and physical analysis. In recent years, much attention has been paid to research on very delicate readings about the existence and multiplicity of ground state solutions for such elliptic problems with different types of nonlinearities. This paper deals with nonhomogeneous systems of equations involving fractional operators of type (p,t) with logarithmic coupling terms with coefficients changing sign, specifically we study the following equation

$$\begin{cases} (-\Delta)_p^{s_1}u + (-\Delta)_t^{s_2}u = \lambda H_1(x)|u|^{\theta-2}u\ln|u| + \dfrac{q}{r+q}R_1(x)|v|^r|u|^{q-2}u & \text{in } \Omega, \\ (-\Delta)_p^{s_1}v + (-\Delta)_t^{s_2}v = \mu H_2(x)|v|^{\theta-2}v\ln|v| + \dfrac{r}{r+q}R_2(x)|u|^r|v|^{q-2}v & \text{in } \Omega, \\ u = v = 0, \qquad \mathbb{R}^N \setminus \Omega, \end{cases} \tag{P}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $s \in (0,1)$, $N > ps$, $\lambda, \mu > 0$, $0 < s_2 < s_1 < 1 < t < p < \theta < p^*_{s_1} = \frac{pN}{N-ps_1}$, $\lambda, \mu > 0$ are two parameters, $r > 1, q > 1$ satisfies $q + r < p^*_{s_1}$ and the additional weights $H_1, H_2, R_1, R_2 \in C(\bar{\Omega})$ are such that: $R_1(x), R_2(x)$ are positive functions and $H_1(x), H_2(x)$ are sign-changing functions. The operators $(-\Delta)^{s_1}_p$ and $(-\Delta)^{s_2}_t$ represents, both, fractional p-Laplacian operator, a generalization for the fractional Laplacian $(-\Delta)^s, 0 < s_i < 1$ for $p = 2$, defined in a integral way as

$$(-\Delta)^{s_i} u(x) := \frac{c(n,s_i)}{2} \int_{\mathbb{R}^N} \frac{2u(x) - (x+y) - u(x-y)}{|y|^{n+2s_i}} dy, \qquad x \in \mathbb{R}^N,$$

where $c(n,s)$ is a positive normalizing constant, and another fractional operator.

Specifically, the operators $(-\Delta)^i_{p_i}$ are defined, up to a normalization constant, by the formula

$$(-\Delta)^{s_i}_{p_i} u(x) := \lim_{\varepsilon \to 0^+} 2 \int_{\mathbb{R}^N \setminus B_\varepsilon(x)} \frac{|u(x) - u(y)|^{p_i - 2}(u(x) - u(y))}{|x-y|^{N+s_i p_i}} dy,$$

where $u \in u \in C^\infty_0(\mathbb{R}^N)$ and $B_\varepsilon(x)$ denotes ball in $\mathbb{R}^N$ with centre x and radius ε. When $s_1 = s_2$ the equation reduces to a (p,t)-type Laplacian problem which appears in a more general reaction-diffusion system

$$u_t = \nabla \cdot (f(u)\nabla u) + h(x,u) \tag{1.1}$$

where $f(u) = |\nabla u|^{p-2}\nabla u + |\nabla u|^{t-2}\nabla u$. Such problems have a wide range of applications in physics and related sciences such as biophysics, plasma physics, and chemical reaction design, etc. where u describes a concentration, and the first term on the right-hand side of (1.1) corresponds to a diffusion with a diffusion coefficient $f(u)$; the term $g(x,u)$ stands for the reaction, related to sources and energy-loss processes. On the other hand, since logarithmic nonlinearities play a significant role in depicting the mathematical and physical phenomena, they have received much attention in PDEs (see [19,20,22] and references therein).

In [19], the authors studied the existence and multiplicity of a class of fractional Laplacian systems with logarithmic nonlinearity in which three types of weights with certain regularity are involved.

$$\begin{cases} (-\Delta)^s u = \lambda g_1(x) u \ln(|u|) + \dfrac{p}{p+q} b(x)|v|^q |u|^{p-2}u & \text{in } \Omega, \\ (-\Delta)^t v = \mu g_2(x) v \ln(|v|) + \dfrac{r}{q+r} b(x)|u|^r |v|^{q-2}v & \text{in } \Omega, \\ u = v = 0, \quad \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.2}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $s, t \in (0,1)$, $N > \max\{2s, 2t\}$, $\lambda, \mu > 0$, $2 < q + p < \min\left\{\frac{2N}{N-2s}, \frac{2N}{N-2t}\right\}$, and the additional weights $g_1, g_2, b \in C(\overline{\Omega})$ are such that: $b(x)$ are positive functions and $g_1(x), g_2(x)$ are sign-changing functions.

In [20], the authors studied a class of systems of equations where they showed the existence and multiplicity of solutions for a mixed local-nonlocal system with logarithmic nonlinearities

$$\begin{cases} (-\Delta)^s u_j + u_j = \lambda_j a_j(x) u_j \ln|u_j| + \sum_{i \neq j} \beta_{ij} |u_j|^{q-2} u_j & \text{in } \Omega, \\ u = v = 0, \quad \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.3}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $s \in (0,1)$, $N > 4$, λ_j are parameters, $\beta_{ij} > 0$ for all $1 \leq i < j \leq k$, $\beta_{ij} = \beta_{ji}$ for all $i, j = 1, \ldots, k$, $a_j \in C(\overline{\Omega})$. When

$1 < 2q < 2 < 2^* = \frac{2N}{N-2}$ and a_j they are functions that change sign, they obtained two different solutions using Nehari Method. When $2 < q < 2 < 2^* = \frac{2N}{N-2}$ and a_j are positive constant functions, the existence of the ground state solution is obtained using the minimization method.

In [13], the authors studied a class of fractional Laplacian systems where they showed the existence of solutions using the Nehari method and multiplicity of solutions using the Lusternik–Schnirelmann category, with polynomial nonlinearity.

$$\begin{cases} (-\Delta)^s u = \lambda |u|^{p-2}u + \dfrac{2\alpha}{\alpha+\beta}|v|^{\beta}|u|^{\alpha-2}u & \text{in } \Omega, \\ (-\Delta)^s v = \mu |u|^{p-2}u + \dfrac{2\beta}{\alpha+\beta}|u|^{\alpha}|v|^{\beta-2}v & \text{in } \Omega, \\ u = v = 0, \quad \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.4}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $s \in (0,1)$, $N > 4s$, $\lambda, \mu > 0$ are parameters, $\alpha + \beta = \frac{2N}{N-2s}$ is the critical Sobolev exponent.

In [5], the authors showed the existence of solutions for the fractional critical system (p,q) Laplacian using variational method

$$\begin{cases} (-\Delta)_p^{s_1} u + (-\Delta)_q^{s_2} u = \lambda Q(x)|u|^{r-2}u + \dfrac{2\alpha}{\alpha+\beta}|v|^{\beta}|u|^{\alpha-2}u & \text{in } \Omega, \\ (-\Delta)_p^{s_1} v + (-\Delta)_q^{s_2} v = \mu Q(x)|u|^{r-2}u + \dfrac{2\beta}{\alpha+\beta}|u|^{\alpha}|v|^{\beta-2}v & \text{in } \Omega, \\ u = v = 0, \quad \text{in } \mathbb{R}^N \setminus \Omega \end{cases} \tag{1.5}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded domain, $0 < s_2 < s_1 < 1$, $1 < q < p < r < p_{s_1}^*$, $N > p_{s_1}$, $\lambda, \mu > 0$ are parameters and $\alpha > 1$ $\beta > 1$ satisfy $\alpha + \beta = p_{s_1}^*$ with $\frac{Np}{N-ps_1}$ is the critical Sobolev exponent, and $(-\Delta)_t^s$ is the fractional t-Laplacian operator.

In [22] was concerned with the existence and asymptotic behavior of normalized ground states solutions for the following coupled Schrödinger system with logarithmic terms:

$$\begin{cases} -\Delta u_1 + \omega_1 u_1 = \mu_1 u_1 \log u_1^2 + \dfrac{p}{p+q}|u_2|^q |u_1|^{p-2}u_1, & \text{in } \Omega, \\ -\Delta u_2 + \omega_2 u_2 = \mu_2 u_2 \log u_2^2 + \dfrac{q}{p+q}|u_1|^p |u_2|^{q-2}u_2, & \text{in } \Omega, \\ \int_\Omega |u_i|^2 dx = \rho_i, \qquad i = 1,2, \end{cases} \tag{1.6}$$

where $\Omega = \mathbb{R}^N$ or $\Omega \subset \mathbb{R}^N (N \geq 3)$ is a bounded smooth domain, $\omega_i \in \mathbb{R}, \mu_i, \rho_i > 0, i = 1,2$. Moreover, $p, q \geq 1, 2 \leq p + q \leq 2^*$ where $2^* := \frac{2N}{N-2}$.

In [11] the authors demonstrate existence of solutions for fractional (p,q) Laplacian systems

$$\begin{cases} (-\Delta)_p^{s_1} u + (-\Delta)_q^{s_2} u = \lambda |u|^{r-2} + \dfrac{\alpha\eta}{\eta+\nu}|u|^{\eta-2}|v|^{\nu}u & \text{in } \Omega, \\ (-\Delta)_p^{s_1} v + (-\Delta)_q^{s_2} v = \mu |v|^{r-2} + \dfrac{\alpha\nu}{\nu+\eta}|v|^{\nu-2}|u|^{\eta}v & \text{in } \Omega, \\ u = v = 0, \quad x \in \mathbb{R}^N \setminus \Omega, \end{cases} \tag{1.7}$$

where $\Omega \subset \mathbb{R}^N$ is a bounded smooth domain, $0 < s_2 < s_1 < 1 < q < r < p < p_{s_1}^* = \frac{pN}{N-ps_1}$, $\lambda, \mu > 0$ are two parameters, $r > 1, q > 1$ satisfies $q + r = p_{s_1}^*$.

In [21] the authors studied the existence of least energy solutions to the following fractional Kirchhoff problem with logarithmic nonlinearity

$$\begin{cases} M([u]_{s,t}^{p})(-\Delta)_{p}^{s}u = h(x)|u|^{\theta p-2}u\ln|u| + \lambda|u|^{q-2}u, & x \in \Omega \\ u = 0, \quad x \in \mathbb{R}^{N} \setminus \Omega, \end{cases} \tag{1.8}$$

where $s \in (0,1)$, $1 < p < Np$, $\Omega \subset \mathbb{R}^N$ is a bounded domain with Lipschitz boundary, $M([u]_{s,p}^{p}) = [u]_{s,p}^{(\theta-1)p}$, with $\theta \geq 1$ and $u, h \in C(\overline{\Omega})$ may change sign, $\lambda > 0$ and $q \in (1, p_{s_1}^{*})$.

On the other hand, parabolic and hyperbolic type equations with logarithmic nonlinearity have been studied extensively in recent years. Here we only refer some results involving fractional Laplacian. [2] considered the Cauchy problem of the following Schrödinger equation

$$iu_t - (-\Delta)^{s}u + u\log|u|^2 = 0, \qquad x \in \Omega,\ t > 0. \tag{1.9}$$

The existence of global solutions was obtained by using a compactness method. Moreover, the author obtained the existence of ground states by the Nehari manifold approach.

The main tool used in this paper is the so-called fibering method introduced by Pohozaev [15], [16] and [17], and applied to a single equation of p-Laplacian type by Drábek and Pohozaev in [12]. Bozhkov and Mitidieri [3] used this method to study the existence for multiple solution for a quasilinear system. Fibering method is very used to proof existence of multiple solution for a large class of equations. For example, Brown and Wu [4] used this method to show the existence of at least two positive solutions for the semilinear elliptic boundary-value problem. For more recent applying of fibering method we indicate [1], used to show existence of multiple solution for a class of Schrödinger equations involving indefinite weight functions, and other interesting work involving the fractional operator is [7].

Inspired by references [9, 10, 13, 19, 20, 22], in this article, we investigate the existence and multiplicity of ground state solutions for problem (P) in both subcritical and critical cases. One goal of this present work is to establish the existence of a nontrivial ground state solution using variational methods. We remark that there are several types of difficulty in deriving the existence results:

(1) Furthermore, we need to deal with essential difficulties due to the fact that the logarithmic term $f(u) = |u|^{\theta-2}u\ln|u|$ neither satisfies the monotonicity condition nor the Ambrosetti–Rabinowitz (A-R) condition, we manage to overcome these difficulties by combining the Brezis–Lieb lemma with some delicate estimates of this logarithmic term.

(2) Since the weights $H_1, H_2 \in C(\bar{\Omega})$ change sign, the study of this type of problem becomes difficult, to overcome this difficulty we use the fibers in the Nehari manifold.

(3) The operator $(-\Delta)_{p}^{s_1} + (-\Delta)_{t}^{s_2}$ does not have homogeneity properties, which makes it difficult to solve.

(4) This system is a broader class of the system studied in [9].

The main results of this paper is writing as follows:

Theorem 1.1. *Problem (P) has a nontrivial ground state solution in W for $0 < s_2 < s_1 < 1 < t < p < \theta < p_{s_1}^{*}$ and H_1, H_2 being positive functions in $C(\overline{\Omega})$.*

Theorem 1.2. *Problem (P) has a nontrivial ground state solution in W for $0 < s_2 < s_1 < 1 < t < p < \theta < p^*_{s_1}$ and H_1, H_2 two sign-changing functions in $C(\overline{\Omega})$.*

The paper is organized as follows. In Section 2 we study the variational framework. In Section 3 we study Nehari Manifold and fibering map analysis. In Section 4 we prove Theorem 1.1. In Section 5 we prove Theorem 1.2.

2 The variational framework

This paper starts with an introduction to the fractional Sobolev space, where the solutions for problem (P) lies. After this introduction, some technical results that will be use to proof the next results that will be shown in the others chapters.

For this, let Ω be a bounded domain in $\mathbb{R}^N$ with smooth boundary, for $p \in (1, +\infty)$, $s_1 \in (0,1)$ and $N > s_1 p$, we define the fractional Sobolev space.

$$W^{s_1,p}(\Omega) := \left\{ u \in L^p(\Omega) : \ \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps_1}} \in L^p(\Omega) \times L^p(\Omega) \right\}. \tag{2.1}$$

The space $W^{s_1,p}(\Omega)$ is an intermediate Banach space between $L^p(\Omega)$ and $W^{1,p}(\Omega)$, endowed with the natural norm

$$\|u\|_{W^{s_1,p}} = \left(\int_\Omega |u|^p dx \right)^{1/p} + [u]^p_{s_1},$$

where

$$[u]^p_{s_1,p} = \int_{\Omega\times\Omega} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps_1}} dxdy$$

is the so-called Gagliardo seminorm of u.

We set $\Omega^c = \mathbb{R}^N \setminus \Omega$ and $\mathcal{Q}^c = \mathbb{R}^N \setminus \Omega^c \times \Omega^c$. We define the following set

$$X^{s_1,p}(\Omega) := \left\{ u : \mathbb{R}^N \to \mathbb{R} \text{ is measurable, } u|_\Omega \in L^p(\Omega), \text{ and } \int_{\mathcal{Q}} \frac{|u(x)-u(y)|^p}{|x-y|^{N+s_1 p}} dxdy < +\infty \right\}.$$

The space $X^{s_1,p}(\Omega)$ is endowed with the norm defined by

$$\|u\|_{X^{s_1,p}(\Omega)} = \left(\int_\Omega |u|^p dx \right)^{1/p} + \left(\int_{\mathcal{Q}} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps_1}} dxdy \right)^{1/p}.$$

Also, we define the space

$$X_0^{s_1,p}(\Omega) := \{ u \in X^{s_1,p}(\Omega) : \ u = 0 \ a.e \text{ in } \Omega^c \},$$

or equivalently as $\overline{C_0^\infty(\Omega)}^{X^{s_1,p}(\Omega)}$. It is well-known that for $p > 1$, $X_0^{s_1,p}(\Omega)$ is a uniformly convex Banach space endowed with the norm

$$\|u\|_{s_1,p} = \left(\int_{\mathcal{Q}} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps_1}} dxdy \right)^{1/p}.$$

Since $u = 0$ in $\mathbb{R}^N \setminus \{0\}$, the above integral can be extended to all of $\mathbb{R}^N$.

The embedding $X_0^{s_1,p}(\Omega) \hookrightarrow L^\kappa(\Omega)$ is continuous for any $\kappa \in [0, p^*_{s_1}]$ and compact for $\kappa \in [1, p^*_{s_1})$.

Lemma 2.1 ([8]). *Let $1 \leq t \leq p$, $0 < s_2 < s_1 < 1$. Then, $W^{s_1,p}(\Omega) \subset W^{s_2,t}(\Omega)$.*

Lemma 2.2 ([8]). *Let $1 \leq t \leq p$, $0 < s_2 < s_1 < 1$ and and Ω be a smooth bounded domain in $\mathbb{R}^N$ where $N > s_1 p$. Then, $X_0^{s_1,p}(\Omega) \subset X_0^{s_2,t}(\Omega)$ and there exists $C = C(\Omega, t, p, s_1, s_2)$ such that*

$$\|u\|_{s_2,t} \leq C\|u\|_{s_1,p}, \qquad \forall u \in X_0^{s_1,p}(\Omega). \tag{2.2}$$

Let $W_p := X_0^{s_1,p}(\Omega) \times X_0^{s_1,p}(\Omega)$ and $W_t := X_0^{s_2,t}(\Omega) \times X_0^{s_2,t}(\Omega)$ be reflexive Banach spaces equipped, respectively, with the norms

$$\|(u,v)\|_{s_1,p} = \left(\|u\|_{s_1,p}^p + \|v\|_{s_1,p}^p\right)^{1/p}, \qquad \|(u,v)\|_{s_2,t} = \left(\|u\|_{s_2,t}^t + \|v\|_{s_2,t}^t\right)^{1/t}.$$

In this paper, we work over the space $W := W_p \bigcap W_t$ endowed the norm $\|(u,v)\| := \|(u,v)\|_{s_1,p} + \|(u,v)\|_{s_2,t}$.

The following lemma is very important.

Lemma 2.3 ([8, Theorem 6.7]). *W is continuously embedding on $L^{s_1,p}(\Omega) \times L^{s_2,t}(\Omega)$.*

Lemma 2.4. *Let $S_{s_1,p}$ the best fractional critical Sobolev constant of embedding $X_0^{s_1,p}(\Omega)$ to $L^{p_{s_1}^*}(\Omega)$*

$$S_{s_1,p} := \inf_{u \in X_0^{s,p}(\Omega)\setminus\{0\}} \left\{ \frac{\|u\|_{s_1,p}^p}{\left(\int_\Omega |u|^{p_s^*} dx\right)^{p/p_s^*}} \right\}. \tag{2.3}$$

and the definition of $S_{q,r}$ is as follows:

$$S_{q,r} := \inf_{(u,v)\in W\setminus\{0\}} \left\{ \frac{\|(u,v)\|_{s_1,p}^p}{\left(\int_\Omega |u|^q |v|^r dx\right)^{p/p_{s_1}^*}} \right\}, \tag{2.4}$$

Then,

$$S_{q,r} := \left[\left(\frac{q}{r}\right)^{r/(q+r)} + \left(\frac{r}{q}\right)^{q/(q+r)} \right] S_{s_1,p}.$$

Lemma 2.5. *Let $\xi, \eta \in \mathbb{R}^N$. Then,*

$$|\xi - \eta|^p \leq \begin{cases} 2^p(|\xi|^{p-2}\xi + |\eta|^{p-2}\eta)(\xi - \eta), & \text{for } p \geq 2, \\ \dfrac{1}{(p-1)} \dfrac{\left[(|\xi|^{p-2}\xi + |\eta|^{p-2}\eta)(\xi - \eta)\right]^{p/2}}{(|\xi|^p + |\eta|^p)^{(p-2)/p}} & \text{for } 1 < p < 2. \end{cases} \tag{2.5}$$

The proof of this lemma can be found in [18, Lemma 6].

Now we will use some technical results that involve the logarithmic term. This result represents an important part of the continuation of this paper

Lemma 2.6 ([10, Lemma 2.6]). *Let ρ be a positive real number. Then we have the following inequalities*

$$t^p \ln t \leq \frac{t^{p+\rho}}{e\rho} \quad \text{for all } 1 \leq t \tag{2.6}$$

and

$$|t^p \ln t| \leq \frac{1}{e\rho} \quad \text{for all } 0 < t < 1, \tag{2.7}$$

where e is Euler logarithm basis.

Proceeding with the introduction, we will now make some definitions about the variational framework.

Definition 2.7. We say that $(u,v) \in W$ is a weak solution of problem (P) if

$$\begin{aligned}
&\int_{\Omega\times\Omega} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps_1}}dxdy \\
&\quad + \int_{\Omega\times\Omega} \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps_1}}dxdy \\
&\quad + \int_{\Omega\times\Omega} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\phi(x)-\phi(y))}{|x-y|^{N+ts_2}}dxdy \\
&\quad + \int_{\Omega\times\Omega} \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\phi(x)-\phi(y))}{|x-y|^{N+ts_2}}dxdy \\
&= \lambda\int_\Omega H_1(x)|u|^{\theta-2}u\ln|u|\varphi dx + \mu\int_\Omega H_2(x)|v|^{\theta-2}v\ln|v|\phi dx \\
&\quad + \frac{q}{q+r}\int_\Omega R_1(x)|v|^r|u|^{q-2}u\varphi dx + \frac{r}{q+r}\int_\Omega R_2(x)|u|^q|v|^{r-2}v\phi dx,
\end{aligned}$$

for any $(\varphi,\phi) \in W$.

Because of the above definition, we consider the energy functional for problem (P), $E : W \to \mathbb{R}$ defined by

$$\begin{aligned}
E(u,v) = \frac{1}{p}\|(u,v)\|^p_{s_1,p} + \frac{1}{t}\|(u,v)\|^t_{s_2,t} - \frac{\lambda}{\theta}\int_\Omega H_1(x)|u|^\theta\ln|u|dx + \frac{\lambda}{\theta^2}\int_\Omega H_1(x)|u|^\theta dx \\
- \frac{\mu}{\theta}\int_\Omega H_2(x)|v|^\theta\ln|v|dx + \frac{\mu}{\theta^2}\int_\Omega H_2(x)|v|^\theta dx - \frac{2}{q+r}\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx.
\end{aligned}$$

We also consider the auxiliary functional

$$\begin{aligned}
I(u,v) = \|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} - \lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx \\
- \mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx - \int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx.
\end{aligned}$$

As a consequence of embedding on Remark 2.3 and Lemma 2.4, we obtain that the functional I is well-defined and $E, I \in C^1(W,\mathbb{R})$. Furthermore, we have that the derivatives I' and E' in the Fréchet sense are given as

$$\begin{aligned}
E'(u,v)(\varphi,\phi) = &\int_{\Omega\times\Omega} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps_1}}dxdy \\
&+ \int_{\Omega\times\Omega} \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps_1}}dxdy \\
&+ \int_{\Omega\times\Omega} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\phi(x)-\phi(y))}{|x-y|^{N+ts_2}}dxdy \\
&+ \int_{\Omega\times\Omega} \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\phi(x)-\phi(y))}{|x-y|^{N+ts_2}}dxdy \\
&- \lambda\int_\Omega H_1(x)|u|^{\theta-2}u\ln|u|\varphi dx - \mu\int_\Omega H_2(x)|v|^{\theta-2}v\ln|v|\phi dx \\
&- \frac{q}{q+r}\int_\Omega R_1(x)|v|^r|u|^{q-2}u\varphi dx - \frac{r}{q+r}\int_\Omega R_2(x)|u|^q|v|^{r-2}v\phi dx
\end{aligned}$$

and

$$\begin{aligned}
I'(u,v)(\varphi,\phi) = {} & p\int_{\Omega\times\Omega}\frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps_1}}dxdy \\
& + p\int_{\Omega\times\Omega}\frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps_1}}dxdy \\
& + t\int_{\Omega\times\Omega}\frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\phi(x)-\phi(y))}{|x-y|^{N+t_2}}dxdy \\
& + t\int_{\Omega\times\Omega}\frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\phi(x)-\phi(y))}{|x-y|^{N+ts_2}}dxdy \\
& - \lambda\theta\int_\Omega H_1(x)|u|^{\theta-2}u\varphi\ln|u|dx - \lambda\int_\Omega H_1(x)|u|^{\theta-2}u\varphi dx \\
& - \mu\theta\int_\Omega H_2(x)|v|^{\theta-2}v\phi\ln|v|dx - \mu\int_\Omega H_2(x)|v|^{\theta-2}v\phi dx \\
& - (q+r)\Big[\int_\Omega R_1(x)|v|^r|u|^{q-2}u\varphi dx + \int_\Omega R_2(x)|u|^q|v|^{r-2}v\phi\Big]dx
\end{aligned}$$

for all $(\varphi,\phi)\in W$.

We now prove the Lebesgue dominated convergence theorem for the logarithm function.

Lemma 2.8 ([9, Lemma 2.6]). *Assume that (u_n,v_n) is bounded in W such that u_n converges to u a.e. and v_n converges to v in Ω . Then*

$$\lim_{n\to\infty}\int_\Omega H_1(x)|u_n|^\theta\ln|u_n|dx = \int_\Omega H_1(x)|u|^\theta\ln|u|\,dx, \quad \text{for } \theta\in(2,p_{s_1}^*),$$

and

$$\lim_{n\to\infty}\int_\Omega H_2(x)|v_n|^\theta\ln|v_n|dx = \int_\Omega H_2(x)|v|^\theta\ln|v|\,dx, \quad \text{for } \theta\in(2,p_{s_1}^*).$$

Lemma 2.9 ([6, Lemma 3.2]). *Let the sequences (u_n) and (v_n) be in $W_0^{s_1,p}(\Omega)$ such that $u_n\rightharpoonup u$, $v_n\rightharpoonup v$ in $W_0^{s_1,p}(\Omega)$ and $u_n(x)\to u(x)$, $v_n(x)\to v(x)$ a.e. in Ω. Then,*

$$\lim_{n\to\infty}\int_\Omega\left(|u_n|^q|v_n|^r - |u_n-u|^q|v_n-v|^r\right)dx = \int_\Omega|u|^q|v|^r\,dx.$$

Lemma 2.10. *Let $(u,v)\in W\setminus\{(0,0)\}$. Then*

$$\begin{aligned}
&\int_\Omega(\lambda H_1(x)|u|^\theta\ln|u| + \mu H_2(x)|v|^\theta\ln|v|)\,dx \\
&\quad\le(\lambda C_{H_1}+\mu C_{H_2})L\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) \\
&\qquad + \ln\|(u,v)\|\int_\Omega(\lambda H_1(x)|u|^\theta + \mu H_2(x)|v|^\theta)\,dx
\end{aligned}$$

where

$$L := \frac{|\Omega|}{e\theta} + \frac{1}{e(p_{s_1}^*-\theta)}S_{p_{s_1}^*}^{\frac{p_{p_{s_1}^*}}{}}, \qquad C_{H_1} := \max_{x\in\overline{\Omega}}|H_1(x)|, \qquad C_{H_2} := \max_{x\in\overline{\Omega}}|H_2(x)|$$

and $S>0$ denote the best constants of embeddings from $W_0^{s_1,p}(\Omega)$ to $L^{p_{s_1}^*}(\Omega)$.

Proof. Let us consider $\Omega = \Omega_1 \cup \Omega_2$, using integration properties over Ω, where $\Omega_1 = \{x \in \Omega : |u(x)| \leq \|(u,v)\|\}$ and $\Omega_2 = \{x \in \Omega : |u(x)| > \|(u,v)\|\}$. Then

$$\int_\Omega H_1(x)|u|^\theta \ln \frac{|u(x)|}{\|(u,v)\|}dx = \int_{\Omega_1} H_1(x)|u|^\theta \ln \frac{|u(x)|}{\|(u,v)\|}dx + \int_{\Omega_2} H_1(x)|u|^\theta \ln \frac{|u(x)|}{\|(u,v)\|}dx.$$

Using (2.7) by direct calculation gives that

$$\int_{\Omega_1} H_1(x)|u|^\theta \ln \frac{|u(x)|}{\|(u,v)\|}dx \quad \leq \quad C_{H_1}\|(u,v)\|^\theta \int_\Omega \frac{1}{e\theta}dx = C_{H_1}\|(u,v)\|^\theta |\Omega|\frac{1}{e\theta}.$$

By Lemma 2.6 for $\rho = p^*_{s_1} - \theta > 0$ and direct calculation

$$\begin{aligned}
\int_{\Omega_2} H_1(x)|u|^\theta \ln \frac{|u(x)|}{\|(u,v)\|}dx &\leq \frac{C_{H_1}}{e(p^*_{s_1}-\theta)} \int_\Omega |u|^\theta \left[\frac{|u(x)|}{\|(u,v)\|}\right]^{p^*_{s_1}-\theta} dx \\
&\leq \frac{C_{H_1}}{e(p^*_{s_1}-\theta)} \frac{1}{\|(u,v)\|^{p^*_{s_1}-\theta}} \int_\Omega |u|^{p^*_{s_1}} dx \\
&\leq \frac{C_{H_1}}{e(p^*_{s_1}-\theta)} \frac{1}{\|(u,v)\|^{p^*_{s_1}-\theta}} S^{p^*_{s_1}}_{p^*_{s_1}} \|u\|^{p^*_{s_1}}_{p^*_{s_1}} \\
&\leq \frac{C_{H_1}}{e(p^*_{s_1}-\theta)} S^{p^*_{s_1}}_{p^*_{s_1}} \|(u,v)\|^\theta.
\end{aligned}$$

Consequently, we get

$$\int_\Omega |u|^\theta \ln \left[\frac{|u(x)|}{\|(u,v)\|}\right]dx \leq C_{H_1}\left[\frac{|\Omega|}{e\theta} + \frac{S^{p^*_{s_1}}_{p^*_{s_1}}}{e(p^*_{s_1}-\theta)}\right]\|(u,v)\|^\theta.$$

On the other hand,

$$\begin{aligned}
&\lambda \int_\Omega H_1(x)|u|^\theta \ln|u|dx \\
&\quad = \lambda \int_\Omega H_1(x)|u|^\theta \ln\left[\frac{|u(x)|}{\|(u,v)\|}\right]dx + \ln(\|(u,v)\|)\int_\Omega \lambda H_1(x)|u|^\theta dx \\
&\quad \leq \lambda C_{H_1}\left[\frac{|\Omega|}{e\theta} + \frac{S^{p^*_{s_1}}}{e(p^*_{s_1}-\theta)}\right]\|(u,v)\|^\theta + C_{H_1}\ln(\|(u,v)\|)\int_\Omega \lambda|u|^\theta dx. \qquad (2.8)
\end{aligned}$$

Similarly,

$$\mu\int_\Omega H_2(x)|v|^\theta \ln|v|dx \leq \mu C_{H_2}\left[\frac{|\Omega|}{e\theta} + \frac{S^{p^*_{s_1}}}{e(p^*_t-\theta)}\right]\|(u,v)\|^\theta + C_{H_2}\ln(\|(u,v)\|)\int_\Omega \mu|v|^\theta dx. \quad (2.9)$$

Combining (2.8) and (2.9) follows the result. □

3 Nehari manifold and fibering map analysis

Continuing with the paper, for The main tool used in this paper is the so-called fibering method, introduced by Pohozaev [15], [16] and [17]. In this section, we assume $\lambda, \mu > 0$, and the functions $H_1, H_2, R_1, R_2 \in C(\overline{\Omega})$.

We define the Nehari Manifolds as:

$$\mathcal{N} := \{(u,v) \in W \setminus \{(0,0)\} \ \mid \ I(u,v) = 0\}.$$

For all $(u,v) \in \mathcal{N}$, we have $(u,v) \neq 0$ and

$$\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} = \lambda \int_\Omega H_1(x)|u|^\theta \ln|u|dx + \mu \int_\Omega H_2(x)|v|^\theta \ln|v|dx + \int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx.$$

Now we define the fibering map $\Phi_{(u,v)} : (0,\infty) \to \mathbb{R}$, given by $\Phi_{(u,v)}(k) := E(k(u,v))$, $k > 0$, it is

$$\begin{aligned}\Phi_{(u,v)}(k) = {} & \frac{k^p}{p}\|(u,v)\|^p_{s_1,p} + \frac{k^t}{t}\|(u,v)\|^t_{s_2,t} - \frac{\lambda k^\theta}{\theta}\ln|k|\int_\Omega H_1(x)|u|^\theta dx - \frac{\lambda k^\theta}{\theta}\int_\Omega H_1(x)|u|^\theta \ln|u|dx \\ & + \frac{\lambda k^\theta}{\theta^2}\int_\Omega H_1(x)|u|^\theta dx - \frac{\mu k^\theta}{\theta}\ln|k|\int_\Omega H_2(x)|v|^\theta dx - \frac{\mu k^\theta}{\theta}\int_\Omega H_2(x)|v|^\theta \ln|v|dx \\ & + \frac{\mu k^\theta}{\theta^2}\int_\Omega H_2(x)|v|^\theta dx - \frac{k^{p^*_{s_1}}}{p^*_{s_1}}\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx. \end{aligned} \tag{3.1}$$

Differentiating (3.1) with respect to t, we have

$$\begin{aligned}\Phi'_{(u,v)}(k) = {} & k^{p-1}\|(u,v)\|^p_{s_1,p} + k^{t-1}\|(u,v)\|^t_{s_2,t} - \lambda k^{\theta-1}\int_\Omega H_1(x)|u|^\theta \ln|ku|dx \\ & - \mu k^{\theta-1}\int_\Omega H_2(x)|v|^\theta \ln|kv|dx - k^{p^*_{s_1}-1}\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx. \end{aligned} \tag{3.2}$$

Again, differentiating (3.2) with respect to t, we get

$$\begin{aligned}\Phi''_{(u,v)}(k) = {} & (p-1)k^{p-2}\|(u,v)\|^p_{s_1,p} + (t-1)k^{t-2}\|(u,v)\|^t_{s_2,t} - (\theta-1)k^{\theta-2}\lambda\int_\Omega H_1(x)|u|^\theta \ln|ku|dx \\ & - (\theta-1)k^{\theta-2}\mu\int_\Omega H_2(x)|v|^\theta \ln|kv|dx - \lambda k^{\theta-2}\int_\Omega H_1(x)|u|^\theta dx \\ & - \mu k^{\theta-2}\int_\Omega H_2(x)|v|^\theta dx - (p^*_{s_1}-1)k^{p^*_{s_1}-2}\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx. \end{aligned}$$

Thus, one can easily verify that for all $(u,v) \in \mathcal{N}$, $\Phi'_{(u,v)}(1) = 0$ and

$$\begin{aligned}\Phi''_{(u,v)}(1) = {} & (p-1)\|(u,v)\|^p_{s_1,p} + (t-1)\|(u,v)\|^t_{s_2,t} - \lambda(\theta-1)\int_\Omega H_1(x)|u|^\theta \ln|u|dx \\ & - \mu(\theta-1)\int_\Omega H_2(x)|v|^\theta \ln|v|dx - \lambda\int_\Omega H_1(x)|u|^\theta dx - \mu\int_\Omega H_2(x)|v|^\theta dx \\ & - (p^*_{s_1}-1)\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx, \end{aligned}$$

which implies that

$$\begin{aligned}\Phi''_{(u,v)}(1) = {} & (p-p^*_{s_1})\|(u,v)\|^p_{s_1,p} + (t-p^*_{s_1})\|(u,v)\|^t_{s_2,t} - (\theta-p^*_{s_1})\lambda\int_\Omega H_1(x)|u|^\theta \ln|u|dx \\ & - (\theta-p^*_{s_1})\mu\int_\Omega H_2(x)|v|^\theta \ln|v|dx - \lambda\int_\Omega H_1(x)|u|^\theta dx - \mu\int_\Omega H_2(x)|v|^\theta dx. \end{aligned}$$

As a consequence of the previously calculus, it's make possible to rewrite the Nehari manifold $\mathcal{N}$ as

$$\mathcal{N} = \mathcal{N}^+ \cup \mathcal{N}^0 \cup \mathcal{N}^-, \tag{3.3}$$

where

$$\mathcal{N}^+ = \Big\{(u,v)\in\mathcal{N} \;\mid\; \Phi''_{(u,v)}(1)>0\Big\} = \Big\{(tu,tv)\in W\setminus(0,0) \;\mid\; \Phi'_{(u,v)}(t)=0,\ \Phi''_{(u,v)}(t)>0\Big\};$$
$$\mathcal{N}^0 = \Big\{(u,v)\in\mathcal{N} \;\mid\; \Phi''_{(u,v)}(1)=0\Big\} = \Big\{(tu,tv)\in W\setminus(0,0) \;\mid\; \Phi'_{(u,v)}(t)=0,\ \Phi''_{(u,v)}(t)=0\Big\};$$
$$\mathcal{N}^- = \Big\{(u,v)\in\mathcal{N} \;\mid\; \Phi''_{(u,v)}(1)<0\Big\} = \Big\{(tu,tv)\in W\setminus(0,0) \;\mid\; \Phi'_{(u,v)}(t)=0,\ \Phi''_{(u,v)}(t)<0\Big\}.$$

Lemma 3.1. *Assume $(u,v)\in W\setminus\{(0,0)\}$ and $k>0$. Then $(ku,kv)\in\mathcal{N}$ if, and only if, $\Phi'_{(u,v)}(k)=0$.*

Proof. If $k(u,v)\in\mathcal{N}$, for $k>0$ we have $I(ku,kv)=0$. Then, we get

$$0 = k^p\|(u,v)\|^p_{s_1,p} + k^t\|(u,v)\|^t_{s_2,t} - \lambda k^\theta\int_\Omega H_1(x)|u|^\theta\ln|ku|dx - \mu k^{p^*_{s_1}}\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx.$$

Dividing the above equation for $k>0$, we have

$$\begin{aligned}0 = {} & k^{p-1}\|(u,v)\|^p_{s_1,p} + k^{t-1}\|(u,v)\|^t_{s_2,t} - \lambda k^{\theta-1}\int_\Omega H_1(x)|u|^\theta\ln|ku|dx\\ & - \mu k^{\theta-1}\int_\Omega H_2(x)|u|^\theta\ln|kv|dx - k^{p^*_{s_1}-1}\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx = \Phi'(k).\end{aligned}$$

This completes the proof. □

Lemma 3.2. *If (u,v) is a local minimizer for the functional E on $\mathcal{N}$, with $(u,v)\notin\mathcal{N}^0$. Then, $E'(u,v)=0$.*

Proof. By the assumption for $u\in\mathcal{N}$, applying Lagrange's multipliers, there exists $\gamma\in\mathbb{R}$ such that

$$E'(u,v)(u,v) = \gamma I'(u,v)(u,v). \tag{3.4}$$

But because of $(u,v)\in\mathcal{N}$, we get

$$\begin{aligned}E'(u,v)(u,v) = {} & \|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} - \lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx - \mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\\ & - \int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx = 0.\end{aligned}$$

Thus, $\gamma I'(u,v)(u,v)=0$. Now since $(u,v)\in\mathcal{N}^0$, we get

$$\begin{aligned}I'(u,v)(u,v) = {} & (p-p^*_{s_1})\|(u,v)\|^p_{s_1,p} + (t-p^*_{s_1})\|(u,v)\|^t_{s_2,t}\\ & - (\theta-p^*_{s_1})\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx - (\theta-p^*_{s_1})\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\\ & - \lambda\int_\Omega H_1(x)|u|^\theta dx - \mu\int_\Omega H_2(x)|v|^\theta dx = \Phi''_{(u,v)}(1).\end{aligned}$$

Thus, $\gamma\neq 0$, and $E'(u,v)=0$. □

Lemma 3.3. *Let $0<\lambda C_{H_1}+\mu C_{H_2}<\frac{1}{L}$ and $2<q+r<p^*_{s_1}$. If $R_1,R_2\in L^\infty(\Omega)$ are non-negative functions satisfying $C_B<K$, where $C_B:=\max_{x\in\overline{\Omega}}|R_1(x)+R_2(x)|$ then, for any $(u,v)\in W\setminus\{(0,0)\}$, we get*

1) *If $\lambda\int_\Omega H_1(x)|u|^\theta+\mu\int_\Omega H_2(x)|v|^\theta dx\geq 0$, then there exists a unique $k_{(u,v)}>0$ such that $\Phi'_{(u,v)}(k_{(u,v)})=0$ and $k_{(u,v)}(u,v)\in\mathcal{N}^-$. Moreover,*

$$E(k_{(u,v)}u,k_{(u,v)}v) = \sup_{k>0}E(ku,kv).$$

2) *If* $\lambda \int_\Omega H_1(x)|u|^\theta + \mu \int_\Omega H_2(x)|v|^\theta dx < 0$, *then there exists* $k_1, k_2 > 0$ *such that* $0 < k_1 < k_{\max} < k_2 < \infty$ *where* $\Phi'_{(u,v)}(k_1) = 0 = \Phi'_{(u,v)}(k_2)$ *witch* $(k_1u, k_1v) \in \mathcal{N}^+$ *and* $(k_2u, k_2v) \in \mathcal{N}^-$. *Moreover,*

$$E(k_1u, k_1v) = \inf_{0<k<k_{\max}} E(ku, kv) \quad \text{and} \quad E(k_2u, k_2v) = \sup_{k>0} E(ku, kv).$$

Proof. For $k > 0$, we defined a function $f : \mathbb{R} \to W$ given by

$$f(k) = k^{p-p^*_{s_1}} \Big[\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} - \lambda \ln|k| \int_\Omega H_1(x)|u|^\theta dx - \lambda \int_\Omega H_1(x)|u|^\theta \ln|u| dx$$
$$- \mu \ln|k| \int_\Omega H_2(x)|v|^\theta dx - \mu \int_\Omega H_2(x)|v|^\theta \ln|v| dx \Big].$$

We can rewrite $f(k)$, for $k > 0$, as

$$f(k) = k^{p-p^*_{s_1}} \left(\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} \right) - k^{p-p^*_{s_1}} \ln|k| \lambda \int_\Omega H_1(x)|u|^\theta dx$$
$$- k^{p-p^*_{s_1}} \lambda \int_\Omega H_1(x)|u|^\theta \ln|u| dx - k^{p-p^*_{s_1}} \ln|k| \lambda \int_\Omega H_2(x)|v|^\theta dx$$
$$- k^{p-p^*_{s_1}} \lambda \int_\Omega H_2(x)|v|^\theta \ln|v| dx.$$

A direct computation shows that

$$f'(k) = k^{p-p^*_{s_1}-1} \Big[(p - p^*_{s_1}) \left(\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} \right) - \lambda (p - p^*_{s_1}) \int_\Omega H_1(x)|u|^\theta dx$$
$$- \lambda (p - p^*_{s_1}) \int_\Omega H_1(x)|u|^\theta \ln|u| dx$$
$$- \mu \int_\Omega H_2(x)|v|^\theta dx - \mu (p - p^*_{s_1}) \int_\Omega H_2(x)|v|^\theta \ln|v| dx$$
$$- (p - p^*_{s_1}) \ln|k| \Big(\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx \Big) \Big]$$

Now we analyze all the possibilities:

i) If $\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx > 0$, then $f \in C(0,\infty)$ and because $p^*_{s_1} > p > t$, we have

$$\lim_{k\to 0^+} f(k) = +\infty \quad \text{and} \quad \lim_{k\to\infty} f(k) = 0.$$

Then there exists a unique minimum point $k_{\min} > 0$ such that $f'(k_{\min}) = 0$. Because $k_{\min} > 0$,

$$(p - p^*_{s_1}) \ln|k_{\min}| \Big[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx \Big]$$
$$= (p - p^*_{s_1}) \left[\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} \right]$$
$$- \lambda \int_\Omega H_1(x)|u|^\theta dx - \lambda (p - p^*_{s_1}) \int_\Omega H_1(x)|u|^\theta \ln|u| dx$$
$$- \mu \int_\Omega H_2(x)|u|^\theta dx - \mu (p - p^*_{s_1}) \int_\Omega H_2(x)|v|^\theta \ln|v| dx.$$

This implies that

$$k_{\min} = \exp\left[\frac{\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} - \int_\Omega [\lambda H_1(x)|u|^\theta \ln|u| + \mu H_2(x)|v|^\theta \ln|v|] dx}{\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx} - \frac{1}{p - p^*_{s_1}} \right]. \tag{3.5}$$

Obviously, f is decreasing on $(0,k_{\min})$ and increasing on $(k_{\min},\infty)$. Then, because of equation (3.5), the fact that $k_{\min}>0$ and that

$$\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx>0,$$

we get

$$\begin{aligned}f(k_{\min})=k_{\min}^{p-p^*_{s_1}}\Bigg[&\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\\&-\ln|k_{\min}|\left(\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right)\\&-\left(\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\right)\Bigg]\\=k_{\min}^{p-p^*_{s_1}}&\left[\frac{1}{p-p^*_{s_1}}\left(\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right)\right]<0.\end{aligned}$$

Since we have

$$\int_\Omega(R_1+R_2)(x)|u|^q|v|^r dx>0,\quad\text{and}\quad\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx>0,$$

and because

$$\begin{aligned}\Phi'_{(u,v)}(k)=k^{p^*_{s_1}+\theta-p-1}\Big[&f(k)-k^{2p-p^*_{s_1}-\theta}\|(u,v)\|^p_{s_1,p}+k^{2t-p^*_{s_1}-\theta}\|(u,v)\|^t_{s_1,t}\\&-k^{p-p^*_{s_1}}\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)-k^{p-\theta}\int_\Omega(R_1+R_2)(x)|u|^q|v|^r dx\Big],\end{aligned}$$

there exists a unique $k_{(u,v)}$ such that $0<k_{(u,v)}<k_{\min}$ such that

$$\begin{aligned}f(k_{(u,v)})=k_{(u,v)}^{p-p^*_{s_1}}\Big[&\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}-\lambda\ln|k_{(u,v)}|\int_\Omega H_1(x)|u|^\theta dx\\&-\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx-\mu\ln|k_{(u,v)}|\int_\Omega H_2(x)|v|^\theta dx\\&-\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\Big]\end{aligned}$$

and $f'(k_{(u,v)})<0$, we get $k_{(u,v)}(u,v)\in\mathcal{N}^-$. Moreover, it follows from $f(k)<f(k_{(u,v)})$, for all $k>k_{(u,v)}$ and $f(k)>f(k_{(u,v)})$, for all $k<k_{(u,v)}$, that

$$E(k_{(u,v)}(u,v))=\sup_{k>0}E(ku,kv).$$

ii) If $\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx=0$, it follow from Lemma 2.10 there exists a unique $k_{(u,v)}>0$ such that $k_{(u,v)}(u,v)\in\mathcal{N}^-$, and

$$E(k_{(u,v)})=\sup_{k>0}E(ku,kv).$$

iii) If $\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx < 0$, then $f \in C(0,\infty)$, $\lim_{k\to 0^+} f(k) = -\infty$ and $\lim_{k\to\infty} f(k) = 0$. Then f has a unique maximum point $k_{\max} > 0$ which is given by

$$k_{\max} = \exp\left[\frac{\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} - \int_\Omega [\lambda H_1(x)|u|^\theta \ln|u| + \mu H_2(x)|v|^\theta \ln|v|]dx}{\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx} - \frac{1}{p - p^*_{s_1}}\right].$$

Moreover, f is increasing on $(0, k_{\max})$ and decreasing on $(k_{\max}, \infty)$. By Lemma 2.10, we get

$$k_{\max} \geq \exp\left[\frac{(1 - (\lambda C_{H_1} + \mu C_{H_2})L)\left(\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t}\right)}{\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx} - \ln\|(u,v)\| - \frac{1}{p - p^*_{s_1}}\right].$$

So,

$$k^{p-p^*_{s_1}}_{\max} \geq \exp\left[(p - p^*_{s_1})\frac{(1 - (\lambda C_{H_1} + \mu C_{H_2})L)\left(\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t}\right)}{\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx} - 1\right] \|(u,v)\|^{p^*_{s_1}}.$$

It's known that the following inequality holds:

$$\exp(k-1) \geq k, \qquad \forall\, k \geq 0.$$

Then

$$k^{p-p^*_{s_1}}_{\max} \geq (p - p^*_{s_1})\frac{1 - (\lambda C_{H_1} + \mu C_{H_2})L}{\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx}\|(u,v)\|^{p^*_{s_1}}.$$

Therefore

$$\begin{aligned} f(k_{\max}) &= k^{p-p^*_{s_1}}_{\max}\frac{\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx}{p - p^*_{s_1}} \\ &\geq (1 - (\lambda C_{H_1} + \mu C_{H_2})L)\|(u,v)\|^{p^*_{s_1}}. \end{aligned}$$

Because $\left(k^{2p-p^*_{s_1}-\theta}_{(u,v)} + k^{p-p^*_{s_1}}_{(u,v)}\right)\left(\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t}\right) + k^{p-\theta}_{(u,v)} \int_\Omega (R_1 + R_2)(x)|u|^q|v|^r dx > 0$, by Hölder's inequality,

$$\int_\Omega (R_1 + R_2)(x)|u|^p|v|^r dx \leq C_B S^{\frac{p}{p^*_{s_1}}}_{q,r}\|(u,v)\|^{p^*_{s_1}},$$

for all $(u,v) \in W$, where $C_B = \max_{x\in\overline{\Omega}} |R_1(x) + R_2(x)|$.

Then

$$(1 - (\lambda C_{H_1} + \mu C_{H_2})L)S^{\frac{p}{p^*_{s_1}}}_{q,r} > C_B,$$

it implies that

$$\begin{aligned} f(k_{\max}) &> k^{2p-p^*_{s_1}-\theta}_{(u,v)}\|(u,v)\|^p_{s_1,p} + k^{2t-p^*_{s_1}-\theta}_{(u,v)}\|(u,v)\|^t_{s_2,t} + k^{p-\theta}_{(u,v)}\int_\Omega (R_1 + R_2)(x)|u|^q|v|^r dx \\ &> 0 = \lim_{k\to\infty} f(k), \end{aligned}$$

and it shows us that there exists k_1, k_2 for which

$$0 < k_1 < k_{\max} < k_2 < \infty,$$

such that

$$f(k_1) = k_{(u,v)}^{2p-p_{s_1}^*-\theta}\|(u,v)\|_{s_1,p}^p + k_{(u,v)}^{2t-p_{s_1}^*-\theta}\|(u,v)\|_{s_2,t}^t + k_{(u,v)}^{p-\theta}\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx$$
$$> 0 = \lim_{k\to\infty} f(k) = f(k_2).$$

It shows us that $\Phi'_{(u,v)}(k_1) = 0 = \Phi'_{(u,v)}(k_2)$. Moreover, f is increasing on $(0, k_{\max})$ and decreasing on $(k_{\max}, \infty)$. So

$$k_1(u,v) \in \mathcal{N}^+ \quad \text{and} \quad k_2(u,v) \in \mathcal{N}^-.$$

Furthermore, we have for all $k \in [k_1, k_2]$, that

$$f(k) \geq k_{(u,v)}^{2p-p_{s_1}^*-\theta}\|(u,v)\|_{s_1,p}^p + k_{(u,v)}^{2t-p_{s_1}^*-\theta}\|(u,v)\|_{s_2,t}^t + k_{(u,v)}^{p-\theta}\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx$$
$$> 0 = \lim_{k\to\infty} f(k),$$

and

$$f(k) < k_{(u,v)}^{2p-p_{s_1}^*-\theta}\|(u,v)\|_{s_1,p}^p + k_{(u,v)}^{2t-p_{s_1}^*-\theta}\|(u,v)\|_{s_2,t}^t + k_{(u,v)}^{p-\theta}\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx,$$

for all $k \in \mathbb{R}_+^* \setminus [k_1, k_2]$.

Thus

$$E(k_1(u,v)) = \inf_{0<k\leq k_{\max}} E(k(u,v)) \qquad \text{and,} \qquad E(k_2(u,v)) = \sup_{k>0} E(k(u,v)).$$

The proof is complete. □

The next remark will help in understanding the next results.

Remark 3.4. In what follows, we define

$$M := \frac{|\Omega| S_{q,r}^{\frac{p_{s_1}^*}{p}}}{p_{s_1}^* - p}, \quad \text{and} \quad K := \frac{1-(\lambda C_{H_1} + \mu C_{H_2})(L+M)}{S_{q,r}^{\frac{p_{s_1}^*}{p}}}.$$

Lemma 3.5. *If $0 < \lambda C_{H_1} + \mu C_{H_2} < \frac{1}{L+M}$ and $C_B < K$, then $\mathcal{N}^0 = \emptyset$.*

Proof. Arguing by contradiction, let $(u,v) \in \mathcal{N}^0$. Then $I(u,v) = 0$, and

$$\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) - \lambda\int_\Omega H_1(x)|u|^\theta dx - \mu\int_\Omega H_2(x)|v|^\theta dx$$
$$= \int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx \quad (3.6)$$

and

$$0 = (p-p_{s_1}^*)\|(u,v)\|_{s_1,p}^p + (t-p_{s_1}^*)\|(u,v)\|_{s_2,t}^t - (\theta-p_{s_1}^*)\lambda\int_\Omega H_1(x)|u|^\theta \ln|u| dx$$
$$- (\theta-p_{s_1}^*)\mu\int_\Omega H_2(x)|v|^\theta \ln|v| dx - \lambda\int_\Omega H_1(x)|u|^\theta dx - \mu\int_\Omega H_2(x)|v|^\theta dx. \quad (3.7)$$

From equations (3.6) and (3.7), and Lemma 2.10, we get

$$\begin{aligned}
&\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) - \int_\Omega (R_1+R_2)(x)|u|^\theta dx \\
&\quad \leq (\lambda C_{H_1} + \mu C_{H_2}) L \left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) \\
&\qquad + \ln\|(u,v)\| \left(\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right). \qquad (3.8)
\end{aligned}$$

Then, again by (3.7)

$$\begin{aligned}
&(1-(\lambda C_{H_1}+\mu C_{H_2})L)\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) \\
&\quad \leq \ln\|(u,v)\| \left[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right] + \int_\Omega (R_1+R_2)(x)|v|^q|v|^r dx \\
&\quad \leq \ln\|(u,v)\| \left[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right] \\
&\qquad + \frac{1}{p-p_{s_1}^*}\left[-\lambda(p-\theta)\int_\Omega H_1(x)|u|^\theta \ln|u| dx\right. \\
&\qquad \left. -\mu(p-\theta)\int_\Omega H_2(x)|v|^\theta \ln|v| dx + \lambda\int_\Omega H_1(x)|u|^\theta dx + \mu\int_\Omega H_2(x)|v|^\theta dx\right].
\end{aligned}$$

That is,

$$\begin{aligned}
&(1-(\lambda C_{H_1}+\mu C_{H_2})L)\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) \\
&\quad \leq \ln\|(u,v)\| \left(\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right) \\
&\qquad + \frac{1}{p-p_{s_1}^*}\left[-\lambda(p-\theta)\int_\Omega H_1(x)|u|^\theta \ln|u| dx - \mu(p-\theta)\int_\Omega H_2(x)|v|^\theta \ln|v| dx\right] \\
&\qquad + \frac{\lambda C_{H_1}+\mu C_{H_2}}{p_{s_1}^*-p}\left[|\Omega|^{p_s^*} S_{q,r}^{\frac{p_{s_1}^*}{p}}\right]\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right), \qquad (3.9)
\end{aligned}$$

which means that

$$\begin{aligned}
&\left[1-(\lambda C_{H_1}+\mu C_{H_2})L - \frac{\lambda C_{H_1}+\mu C_{H_2}}{p_{s_1}^*-p}\left[|\Omega|^{p_s^*} S_{q,r}^{\frac{p_{s_1}^*}{p}}\right]\right]\left(\|(u,v)\|_{s_1,p}^p + \|(u,v)\|_{s_2,t}^t\right) \\
&\quad \leq \ln\|(u,v)\| \left[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right] \\
&\qquad + \frac{1}{p-p_{s_1}^*}\left(-\lambda(p-\theta)\int_\Omega H_1(x)|u|^\theta \ln|u| dx - \mu(p-\theta)\int_\Omega H_2(x)|v|^\theta \ln|v| dx\right).
\end{aligned}$$

Using again equation (3.7), in view of $p < p_{s_1}^*$, we have

$$\begin{aligned}
0 > &\ln\|(u,v)\| \left(\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right) \\
&+ \frac{1}{p-p_{s_1}^*}\left(-\lambda(p-\theta)\int_\Omega H_1(x)|u|^\theta \ln|u| dx - \mu(p-\theta)\int_\Omega H_2(x)|v|^\theta \ln|v| dx\right).
\end{aligned}$$

Thus, it follows from $\lambda C_{H_1} + \mu C_{H_2} < \frac{1}{L+M}$ that $\|(u,v)\| \leq 1$, where, here we consider M as in Remark 3.4.

Otherwise, using (3.9), and one more time (3.6) and (3.7),

$$\begin{aligned}
&\left[1-(\lambda C_{H_1}+\mu C_{H_2})L\right]\left(\|(u,v)\|_{s_1,p}^{p}+\|(u,v)\|_{s_2,t}^{t}\right)\\
&\quad\leq \ln\|(u,v)\|\Big(\lambda\int_\Omega H_1(x)|u|^{\theta}dx+\mu\int_\Omega H_2(x)|v|^{\theta}dx\Big)+\int_\Omega (R_1+R_2)(x)|u|^{q}|v|^{r}dx\\
&\quad\leq (p-p_{s_1}^{*})\ln\|(u,v)\|\int_\Omega (R_1+R_2)(x)|u|^{q}|v|^{r}dx\\
&\qquad+(\lambda C_{H_1}+\mu C_{H_2})M\left(\|(u,v)\|_{s_1,p}^{p}+\|(u,v)\|_{s_2,t}^{t}\right).
\end{aligned}\tag{3.10}$$

Now, we can note that

$$\int_\Omega (R_1+R_2)(x)|u|^{q}|v|^{r}dx\leq C_B S_{q,r}^{\frac{p_{s_1}^{*}}{p}}\|(u,v)\|^{p_{s_1}^{*}},\tag{3.11}$$

thus

$$\left[1-(\lambda C_{H_1}+\mu C_{H_2})(L+M)-C_B S_{q,r}^{\frac{p_{s_1}^{*}}{p}}\right]\left(\|(u,v)\|_{s_1,p}^{p}+\|(u,v)\|_{s_2,t}^{t}\right)\leq 0.$$

Since $(\lambda C_{H_1}+\mu C_{H_2})<\frac{1}{L+M}$, and

$$C_B<K:=\frac{1-(\lambda C_{H_1}+\mu C_{H_2})(L+M)}{S_{q,r}^{\frac{p_{s_1}^{*}}{p}}},$$

it follows that $\|(u,v)\|=0$. Then $(u,v)=(0,0)$, which is a contradiction. Therefore $\mathcal{N}^0=\emptyset$. □

For the next result, we consider

$$\Lambda_{\lambda,\mu}:=\min\left\{1,\left(\frac{1-(\lambda C_{H_1}+\mu C_{H_2})L-C_B S_{q,r}^{\frac{p_{s_1}^{*}}{p}}}{C_B S_{q,r}^{\frac{p_{s_1}^{*}}{p}}}\right)^{\frac{1}{p_{s_1}^{*}-p}}\right\}.$$

Lemma 3.6. *If $0<\lambda C_{H_1}+\mu C_{H_2}<\frac{1}{L+M}$ and $C_B<K$, then $\|(U,V)\|\geq\Lambda_{\lambda,\mu}$, for all $(U,V)\in\mathcal{N}^{-}$ and $\|(u,v)\|\leq 1$, for all $(u,v)\in\mathcal{N}^{+}$.*

Proof. Let $(U,V)\in\mathcal{N}^{-}$. Then

$$\begin{aligned}
&\int_\Omega (R_1+R_2)(x)|U|^{q}|V|^{r}dx\\
&\quad=\left(\|(u,v)\|_{s_1,p}^{p}+\|(u,v)\|_{s_2,t}^{t}\right)-\lambda\int_\Omega H_1(x)|U|^{\theta}\ln|U|dx-\mu\int_\Omega H_2(x)|V|^{\theta}\ln|V|dx,
\end{aligned}\tag{3.12}$$

and

$$\begin{aligned}
&(p-p_{s_1}^{*})\|(U,V)\|_{s_1,p}^{p}+(t-p_{s_1}^{*})\|(U,V)\|_{s_2,t}^{t}\\
&\quad<\lambda\int_\Omega H_1(x)|U|^{\theta}dx+\mu\int_\Omega H_2(x)|V|^{\theta}dx\\
&\qquad-(p_{s_1}^{*}-\theta)\Big(\lambda\int_\Omega H_1(x)|U|^{\theta}\ln|U|dx+\mu\int_\Omega H_2(x)|V|^{\theta}\ln|V|dx\Big).
\end{aligned}\tag{3.13}$$

Similarly to equation (3.10) in Lemma 3.5, we have

$$\begin{aligned}
&\left[1-(\lambda C_{H_1}+\mu C_{H_2})L\right]\|(u,v)\left(\|_{s_1,p}^{p}+\|(u,v)\|_{s_2,t}^{t}\right)\\
&\quad\leq\ln\|(U,V)\|\left(\lambda\int_\Omega H_1(x)|U|^{\theta}dx+\mu\int_\Omega H_2(x)|V|^{\theta}dx\right)+C_B S_{p_{s_1}^{*}}^{q}S_{p_{s_1}^{*}}^{r}\|(U,V)\|^{p_{s_1}^{*}}.
\end{aligned}\tag{3.14}$$

We consider two cases:

i) If $\lambda \int_\Omega H_1(x)|U|^\theta dx + \mu \int_\Omega H_2(x)|V|^\theta dx > 0$, then $\|(U,V)\| \geq 1$, because otherwise, being $\|(U,V)\| < 1$, we have

$$[1-(\lambda C_{H_1}+\mu C_{H_2})L]\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right) < C_B S^q_{p^*_{s_1}} S^r_{p^*_{s_1}} \|(U,V)\|^{p^*_{s_1}},$$

and together with $C_B < K$, we get

$$\|(U,V)\| > \left(\frac{1-(\lambda C_{H_1}+\mu C_{H_2})L}{C_B S^q_{p^*_{s_1}} S^r_{p^*_{s_1}}}\right)^{\frac{1}{p^*_{s_1}-p}} > 1, \tag{3.15}$$

which is a contradiction. Thus $\|(U,V)\| \geq 1$.

ii) If $\lambda \int_\Omega H_1(x)|U|^\theta dx + \mu \int_\Omega H_2(x)|V|^\theta dx < 0$, we have two more cases to analyse:

2.1) If $\|(U,V)\| > 1$, similar to case i) above, we get the same equation (3.15).

2.2) If $\|(U,V)\| < 1$, we have by equations (3.12) and (3.13),

$$\begin{aligned}
&[1-(\lambda C_{H_1}+\mu C_{H_2})L]\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)\\
&\quad < C_B S^q_{p^*_{s_1}} S^r_{p^*_{s_1}} \|(U,V)\|^p\\
&\qquad + (p-\theta)\left(\lambda \int_\Omega H_1(x)|U|^\theta \ln|U| dx + \mu \int_\Omega H_2(x)|V|^\theta \ln|V| dx\right)\\
&\qquad + C_B S^q_{p^*_{s_1}} S^r_{p^*_{s_1}} \|(U,V)\|^{p^*_{s_1}}.
\end{aligned}$$

So, because $p \leq \theta$,

$$\|(U,V)\| > \left(\frac{1-(\lambda C_{H_1}+\mu C_{H_2})L - C_B S^q_{p^*_{s_1}} S^r_{p^*_{s_1}}}{C_B S^q_{p^*_{s_1}} S^r_{p^*_{s_1}}}\right)^{\frac{1}{p^*_{s_1}-p}} > 1.$$

Thus, $\|(U,V)\| \geq \Lambda_{\lambda,\mu}$, for all $(U,V) \in \mathcal{N}^-$.

Now, if $(u,v) \in \mathcal{N}^+$, a similar discussion shows us that $\|(u,v)\| \leq 1$. □

Lemma 3.7. *If $0 < \lambda C_{H_1} + \mu C_{H_2} < \frac{1}{L+M}$ and $C_B < K$, then $\mathcal{N}^-$ is a closed subset o W.*

Proof. The proof follows directly from Lemmas 3.5 and 3.6. □

Lemma 3.8. *If $0 < \lambda C_{H_1} + \mu C_{H_2} < \frac{1}{L+M}$. Then the functional E is bounded from below on $\mathcal{N}$.*

Proof. Because of the relationship between the functionals E and I, for $(u,v) \in \mathcal{N}$, we have

$$\begin{aligned}
E(u,v) = &\left(\frac{1}{p}-\frac{1}{\theta}\right)\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right) + \frac{1}{\theta^2}\left(\lambda\int_\Omega H_1(x)|u|^\theta dx + \mu\int_\Omega H_2(x)|v|^\theta dx\right)\\
&- \left(\frac{1}{p^*_{s_1}}-\frac{1}{\theta}\right)\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx.
\end{aligned}$$

Because $(u,v) \in \mathcal{N}$, we have also

$$\begin{aligned}
&\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx\\
&\quad = \left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right) - \lambda\int_\Omega H_1(x)|u|^\theta \ln|u| dx - \mu\int_\Omega H_2(x)|v|^\theta \ln|v| dx.
\end{aligned}$$

So

$$\begin{aligned}E(u,v) = &\left(\frac{1}{p}-\frac{1}{p^*_{s_1}}\right)\|(u,v)\|^p_{s_1,p}+\left(\frac{1}{t}-\frac{1}{p^*_{s_1}}\right)\|(u,v)\|^t_{s_2,t}\\&+\frac{1}{\theta^2}\Big(\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\Big)\\&+\left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\left(\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\right).\end{aligned}$$

Now, concerning to exposed above, we consider two cases:

i) If $\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx>0$, because $0<t<p<\theta<p^*_{s_1}$, it follows that

$$E(u,v)>\left(\frac{1}{p}-\frac{1}{p^*_{s_1}}\right)\|(u,v)\|^p_{s_1,p}+\left(\frac{1}{t}-\frac{1}{p^*_{s_1}}\right)\|(u,v)\|^t_{s_2,t}\geq 0.$$

ii) If $\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\leq 0$, it follows from Lemma 2.10 that

$$\begin{aligned}E(u,v) = &\left(\frac{1}{p}-\frac{1}{p^*_{s_1}}\right)[1-(\lambda C_{H_1}+\mu C_{H_2})L]\|(u,v)\left(\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)\\&+\left[\frac{1}{\theta^2}-\left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\ln\|(u,v)\|\right]\left(\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right).\end{aligned}$$

Now, if $\frac{1}{\theta^2}-\left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\ln\|(u,v)\|\geq 0$, then $E(u,v)\geq 0$.

Otherwise, if $\frac{1}{\theta^2}-\left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\ln\|(u,v)\|<0$, there exists a constant $C>0$ such that

$$\begin{aligned}E(u,v)&\geq\left(\frac{1}{p}-\frac{1}{p^*_{s_1}}\right)[1-(\lambda C_{H_1}+\mu C_{H_2})L]\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)\\&\quad+\left[\frac{1}{\theta^2}-\left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\ln\|(u,v)\|\right]\left(\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right)\\&\geq\left(\frac{1}{p}-\frac{1}{p^*_{s_1}}\right)[1-(\lambda C_{H_1}+\mu C_{H_2})L]\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)\\&\quad-C\left[\frac{1}{\theta^2}-\left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\ln\|(u,v)\|\right]\geq -C.\end{aligned}$$

Thus, E is bounded from below on $\mathcal{N}$. □

4 Ground state solution for positive weight function

After the introductory part, in the two following sections we establish the existence of a ground state solution for problem (P). Specifically in this section, we carry on with the weights functions $H_1, H_2 > 0$, it is H_1, H_2 being non sign-changing functions. For this, we use the Mountain Pass theorem to show the existence of a level $c_* \in W$, where the functional E satisfy the $(PS)_{c_*}$ condition.

The version of Mountain Pass Theorem used in this paper is given in the below lemma.

Lemma 4.1. *Let $H_1, H_2 \in C(\overline{\Omega})$ and $H_1(x), H_2(x) > 0$ for all $x \in \Omega$. Then there exist $\eta, \zeta > 0$, such that*

(*i*) $E(u,v) \geq \eta > 0$ *for all* $\|(u,v)\| = \zeta$,

(*ii*) *there exists* $(u,v) \in W$ *such that* $E(u,v) < 0$ *if* $\|(u,v)\| > \zeta$.

Proof. Because of the definition of E and inequality (3.11) and $1 < q < p < p + r = p^*_{s_1}$, we have

$$\begin{aligned} E(u,v) \geq & \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right] \|(u,v)\|^p_{s_1,p} + \left[\frac{1}{t} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right] \|(u,v)\|^t_{s_2,t} \\ & - \frac{1}{\theta}\Big(\ln\|(u,v)\| - \frac{1}{\theta}\Big)\left[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right] - C_B S_{q,r}^{\frac{p^*_s}{p}} \|(u,v)\|^{p^*_{s_1}} \\ \geq & \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right] \|(u,v)\|^p_{s_1,p} \\ & - \frac{1}{\theta}\Big(\ln\|(u,v)\| - \frac{1}{\theta}\Big)\left[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right] - C_B S_{q,r}^{\frac{p^*_s}{p}} \|(u,v)\|^{p^*_{s_1}}, \end{aligned}$$

which implies that, for all $(u,v) \in W$ with $0 < \|(u,v)\| \leq 1$, we have

$$E(u,v) \geq \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right] \|(u,v)\|^p_{s_1,p} - C_B S_{q,r}^{\frac{p^*_{s_1}}{p}} \|(u,v)\|^{p^*_{s_1}}.$$

Choosing $\zeta \in (0,1]$ small enough, such that

$$\left(\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right) - C_B S_{q,r}^{\frac{p^*_{s_1}}{p}} \|(u,v)\|^{p^*_{s_1}} \zeta^{p^*_{s_1}} > 0,$$

we have

$$E(u,v) \geq \left[\left(\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right) - C_B S_{q,r}^{\frac{p^*_{s_1}}{p}} \|(u,v)\|^{p^*_{s_1}} \zeta^{p^*_{s_1}}\right] \zeta^p > 0,$$

for all $(u,v) \in W$, with $\|(u,v)\| = \zeta$. Thus (i) holds.

Otherwise, for all $(u,v) \in W \setminus \{0,0\}$ and $k > 0$, we have

$$\begin{aligned} E(ku,kv) = k^{p^*_{s_1}} \Bigg[& \frac{k^{p-p^*_{s_1}}}{p} \|(u,v)\|^p_{s_1,p} + \frac{k^{t-p^*_{s_1}}}{t} \|(u,v)\|^t_{s_2,t} - \frac{k^{\theta-p^*_{s_1}} \ln|k|}{\theta} \int_\Omega H_1(x)|u|^\theta dx \\ & - \frac{k^{\theta-p^*_{s_1}}}{\theta} \lambda \int_\Omega H_1(x)|u|^\theta \ln|u| dx + \frac{k^{\theta-p^*_{s_1}}}{\theta^2} \lambda \int_\Omega H_1(x)|u|^\theta dx \\ & - \frac{k^{\theta-p^*_{s_1}} \ln|k|}{\theta} \int_\Omega H_2(x)|v|^\theta dx - \frac{k^{\theta-p^*_{s_1}}}{\theta} \mu \int_\Omega H_2(x)|v|^\theta \ln|v| dx \\ & + \frac{k^{\theta-p^*_{s_1}}}{\theta^2} \mu \int_\Omega H_2(x)|v|^\theta dx - \frac{1}{p^*_{s_1}} \int_\Omega (R_1 + R_2)(x)|u|^q|v|^r dx \Bigg], \end{aligned}$$

and because $1 < \theta < q < p < p^*_{s_1}$ it implies that there exists $k_0 > 0$ large enough such that $\|(k_0u, k_0v)\| > \zeta$ and $E(k_0u, k_0v) < 0$. So, taking $(u,v) = (k_0u, k_0v)$, item (ii) holds □

Lemma 4.2. *Let* (u_n, v_n) *be a* $(PS)_{c_*}$ *sequence of the functional* E. *Then, a sequence* (u_n, v_n) *is bounded in* W.

Proof. For $c_* \in \mathbb{R}$, we assume that $\{(u_n, v_n)\}_n \subset W$ with $\|(u_n, v_n)\| > 1$ is a $(PS)_{c_*}$ sequence with, it is $E(u_n, v_n) \to c_*$ and $E'(u_n, v_n)(u_n, v_n) \to 0$, as $n \to \infty$. On the other hand, since that (u_n, v_n) is a $(PS)_{c_*}$ sequence for functional E, we have

$$\begin{aligned} c_* + o_n(1) &\geq E(u_n, v_n) - \frac{1}{p} E'(u_n, v_n)(u_n, v_n) \\ &= \left(\frac{1}{t} - \frac{1}{p}\right) \|(u, v)\|^t_{s_2,p} \\ &\quad + \left(\frac{1}{p} - \frac{1}{\theta}\right) \left[\lambda \int_\Omega H_1(x)|u|^\theta \ln|u| dx + \mu \int_\Omega H_2(x)|v|^\theta \ln|v| dx\right] \\ &\quad + \frac{1}{\theta^2} \left[\lambda \int_\Omega H_1(x)|u|^\theta dx + \mu \int_\Omega H_2(x)|v|^\theta dx\right] \\ &\geq \frac{1}{\theta^2} \left[\lambda \int_\Omega H_1(x)|u_n|^\theta dx + \mu \int_\Omega H_2(x)|v_n|^\theta dx\right]. \end{aligned} \tag{4.1}$$

We have also

$$\begin{aligned} c_* + o_n(1) &\geq E(u_n, v_n) - \frac{1}{p^*_{s_1}} E'(u_n, v_n)(u_n, v_n) \\ &= \left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right) \|(u_n, v_n)\|^p_{s_1,p} + \left(\frac{1}{t} - \frac{1}{p^*_{s_1}}\right) \|(u_n, v_n)\|^t_{s_2,t} \\ &\quad + \frac{1}{\theta^2} \left[\lambda \int_\Omega H_1(x)|u_n|^\theta dx + \mu \int_\Omega H_2(x)|v_n|^\theta dx\right] \\ &\quad - \left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right) \left[\lambda \int_\Omega H_1(x)|u_n|^\theta \ln u_n dx + \mu \int_\Omega H_2(x)|v_n|^\theta \ln v_n dx\right] \\ &\geq \left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right) \|(u_n, v_n)\|^p_{s_1,p} \\ &\quad - \left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right) \left[\lambda \int_\Omega H_1(x)|u_n|^\theta \ln u_n + \mu \int_\Omega H_2(x)|v_n|^\theta \ln v_n\right]. \end{aligned} \tag{4.2}$$

Combining equations (4.1) and (4.2), Lemma 2.6 and Lemma 2.10, we have

$$\begin{aligned} \left[\left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right) [1 - (\lambda C_{H_1} + \mu C_{H_2}) L]\right] \|(u, v)\| &\leq \left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right) \frac{\theta^2 [(u_n, v_n)]^\sigma}{e\sigma} [c_* + o(1)] \\ &\leq C \left(1 + \|(u_n, v_n)\|^{1+\sigma}\right) + o(1), \end{aligned}$$

where $\sigma \in (0, p-1)$. Thus $\{(u_n, v_n)\}_n$ is bounded in W. □

Lemma 4.3. *Let (u_n, v_n) be a $(PS)_{c_*}$ sequence of the functional E. Then, functional E satisfies the $(PS)_{c_*}$ condition at any level c_*.*

Proof. By Lemmas 2.8 and 2.9, we get

$$\lim_{n\to\infty} \int_\Omega H_1(x) u |u_n|^{\theta-1} \ln|u| dx = \int_\Omega H_1(x)|u|^\theta \ln|u| dx, \tag{4.3}$$

$$\lim_{n\to\infty} \int_\Omega H_2(x) v |v_n|^{\theta-1} \ln|v| dx = \int_\Omega H_2(x)|v|^\theta \ln|v| dx, \tag{4.4}$$

$$\lim_{n\to\infty}\int_\Omega (R_1+R_2)(x)|u_n|^{q-2}u_n|v_n|^r(u_n-u)dx=0, \tag{4.5}$$

$$\lim_{n\to\infty}\int_\Omega (R_1+R_2)(x)|v_n|^{r-2}v_n|u_n|^\theta(v_n-v)dx=0. \tag{4.6}$$

Note that

$$\begin{aligned}\|(u_n-u,v_n-v)\|^p &= (E'(u_n,v_n)-E'(u,v))(u_n-u,v_n-v)\\ &+\lambda\int_\Omega H_1(x)\left(|u_n|^{\theta-1}\ln|u_n|-|u|^{\theta-1}\ln|u|\right)(u_n-u)dx\\ &+\mu\int_\Omega H_2(x)\left(|v_n|^{\theta-1}\ln|v_n|-|v|^{\theta-1}\ln|v|\right)(v_n-v)dx\\ &+\frac{q}{p^*_{s_1}}\int_\Omega (R_1+R_2)(x)\left(|v_n|^r u_n^{q-2}u_n-|v|^r|u|^{q-2}u\right)(u_n-u)dx\\ &+\frac{r}{p^*_{s_1}}\int_\Omega (R_1+R_2)(x)\left(|u_n|^q v_n^{r-2}v_n-|u|^q|v|^{r-2}v^{r-2}v\right)(v_n-v)dx.\end{aligned}$$

Since $(E'(u_n,v_n)-E'(u,v))(u_n-u,v_n-v)\to 0$ as $n\to\infty$, it follow from equations (4.3), (4.4), (4.5), (4.6) and Lemma 2.5, that $(u_n,v_n)\to(u,v)$ in W. This yields the proof. □

Now we can prove the first of the main results in the paper. More precisely, in what follows, we prove Theorem 1.1.

4.1 Proof of Theorem 1.1

Define $\mathfrak{N}:=\{(u,v)\in W\setminus\{0,0\}\mid E'(u,v)(u,v)=0\}$. By the previous lemmas, $\mathfrak{N}$ is nonempty. Let $(u,v)\in\mathfrak{N}$, from Lemma 2.10, we have

$$\begin{aligned}0&=\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}-\left(\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\right)\\ &\quad-\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx\\ &\geq (1-(\lambda C_{H_1}+\mu C_{H_2})L)\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)\\ &\quad-\ln\|(u,v)\|\left(\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx+\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\right)\\ &\quad-\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx.\end{aligned} \tag{4.7}$$

If $\|(u,v)\|\leq 1$, it follows from the above equation (4.7) that

$$[1-(\lambda C_{H_1}+\mu C_{H_2})]\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)\leq\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx\leq C_B S_{q,r}^{\frac{p^*_{s_1}}{p}}.$$

Then,

$$\|(u,v)\|\geq\left[\frac{1-(\lambda C_{H_1}+\mu C_{H_2})L}{C_B S_{q,r}^{\frac{p^*_{s_1}}{p}}}\right]^{\frac{1}{p^*_{s_1}-p}},$$

which implies that

$$\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx \geq [1-(\lambda C_{H_1}+\mu C_{H_2})L]\left(\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}\right)$$
$$\geq \left[\frac{[1-(\lambda C_{H_1}+\mu C_{H_2})L]^{p^*_{s_1}}}{\left(C_B S_{q,r}^{\frac{p^*_{s_1}}{p}}\right)^p}\right]^{\frac{1}{p^*_{s_1}-p}}. \tag{4.8}$$

Define

$$\tilde{C} := \left[\frac{[1-(\lambda C_{H_1}+\mu C_{H_2})L]^{p^*_{s_1}}}{\left(C_B S_{q,r}^{\frac{p^*_{s_1}}{p}}\right)^p}\right]^{\frac{1}{p^*_{s_1}-p}},$$

and

$$\mathfrak{C} := \inf\{E(u,v) \mid (\tilde{U}_n,\tilde{V}_n)\in\mathfrak{N}\},$$

then $\mathfrak{C}>0$, because otherwise, there exists $\{(\tilde{U}_n,\tilde{V}_n)\}_n\subset\mathfrak{N}$ such that $E'(\tilde{U}_n,\tilde{V}_n)\to 0$.

It follows from

$$E(u,v) = \left(\frac{1}{p}-\frac{1}{\theta}\right)\|(u,v)\|^p_{s_1,p}+\left(\frac{1}{t}-\frac{1}{\theta}\right)\|(u,v)\|^t_{s_2,t}+\frac{1}{\theta}I(u,v)$$
$$+\frac{1}{\theta^2}\left(\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right)$$
$$-\left(\frac{1}{p^*_{s_1}}-\frac{1}{\theta}\right)\int_\Omega (R_1+R_2)(x)|u|^q|v|^r dx,$$

that

$$\frac{1}{\theta^2}\left(\lambda\int_\Omega H_1(x)|\tilde{U}_n|^\theta dx+\mu\int_\Omega H_2(x)|\tilde{V}_n|^\theta dx\right)-\left(\frac{1}{p^*_{s_1}}-\frac{1}{p}\right)\int_\Omega (R_1+R_2)(x)|\tilde{U}_n|^q|\tilde{V}_n|^r dx\to 0,$$

when $n\to\infty$, and by Lemma 4.2. But, from equation (4.8) it follows that

$$\int_\Omega (R_1+R_2)(x)|\tilde{U}_n|^q|\tilde{V}_n|^r dx\geq\tilde{C}>0,$$

and it implies that $0\geq\tilde{C}>0$, which is a contradiction. Thus, $\mathfrak{C}>0$.

Finally, let $\{(u_n,v_n)\}_n\subset\mathfrak{N}$ be a minimizing sequence. Then $E'(u_n,v_n)(u_n,v_n)=0$ and $\lim_{n\to\infty}E(u_n,v_n)=\mathfrak{C}>0$. Again by Lemma 4.2, there exists $(u_0,v_0)\in W\setminus\{0,0\}$ such that

$$(u_n,v_n)\to(u_0,v_0)$$

in W. Hence $E(u_0,v_0)=\mathfrak{C}$ and $E'(u_0,v_0)=0$, and it means that (u_0,v_0) is a nontrivial ground state solution of problem (P).

5 Nontrivial solutions for sign-changing weight functions

To conclude this paper, we now proceed with the proof of the existence of solutions to the problem (P), but now for the cases in which the weight functions H_1, H_2 are sign-changing functions.

Lemma 5.1. *E has a nontrivial and nonnegative minimizer on $\mathcal{N}^+$.*

Proof. The proof of this lemma will be shown in two steps.

Step 1. The strong convergence of minimizing sequence. By Lemma 3.8, we get

$$c^+ = \inf_{(u,v)\in\mathcal{N}^+} E(u,v).$$

Claim: $c^+ < 0$. Indeed, for each $(u,v) \in \mathcal{N}^+$, we get

$$\begin{aligned}\|(u,v)\|^p_{s_1,p} + \|(u,v)\|^t_{s_2,t} &= \lambda\int_\Omega H_1(x)|u|^\theta \ln|u|dx + \mu\int_\Omega H_2(x)|v|^\theta \ln|v|dx \\ &\quad + \int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx \end{aligned} \tag{5.1}$$

and there holds

$$\begin{aligned}E(u,v) &= \frac{1}{p}\|(u,v)\|^p_{s_1,p} + \frac{1}{t}\|(u,v)\|^t_{s_2,t} - \frac{\lambda}{\theta}\int_\Omega H_1(x)|u|^\theta\ln|u|dx + \frac{\lambda}{\theta^2}\int_\Omega H_1(x)|u|^\theta dx \\ &\quad - \frac{\mu}{\theta}\int_\Omega H_2(x)|v|^\theta\ln|v|dx + \frac{\mu}{\theta^2}\int_\Omega H_2(x)|v|^\theta dx - \frac{1}{p^*_{s_1}}\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx \\ &= \frac{1}{p}\left[\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx + \mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx + \int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx\right] \\ &\quad - \frac{\lambda}{\theta}\int_\Omega H_1(x)|u|^\theta\ln|u|dx + \frac{\lambda}{\theta^2}\int_\Omega H_1(x)|u|^\theta dx - \frac{\mu}{\theta}\int_\Omega H_2(x)|v|^\theta\ln|v|dx \\ &\quad + \frac{\mu}{\theta^2}\int_\Omega H_2(x)|v|^\theta dx - \frac{1}{p^*_{s_1}}\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx \\ &= \left(\frac{1}{p}-\frac{1}{\theta}\right)\left[\lambda\int_\Omega H_1(x)|u|^\theta\ln|u|dx + \mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\right] \\ &\quad + \frac{1}{\theta^2}\left[\lambda\int_\Omega H_1(x)|u|^\theta dx + \mu\int_\Omega H_2(x)|v|^\theta dx\right] \\ &\quad + \left(\frac{1}{\theta}-\frac{1}{p^*_{s_1}}\right)\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx.\end{aligned}$$

Using the following inequality

$$\begin{aligned}&(p-\theta)\left[\lambda\int_\Omega H_1(x)|u_n|^\theta\ln|u|dx + \mu\int_\Omega H_2(x)|v_n|^\theta\ln|v|dx\right] \\ &\quad > (p^*_{s_1}-p)\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx + \lambda\int_\Omega H_1(x)|u|^\theta dx + \mu\int_\Omega H_2(x)|v|^\theta dx\end{aligned}$$

and $p < \theta$ we have

$$\begin{aligned}&\lambda\int_\Omega H_1(x)|u_n|^\theta\ln|u|dx + \mu\int_\Omega H_2(x)|v_n|^\theta\ln|v|dx \\ &\quad < -\frac{p^*_{s_1}-p}{\theta-p}\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx \\ &\qquad - \frac{1}{\theta-p}\left[\lambda\int_\Omega H_1(x)|u|^\theta dx + \mu\int_\Omega H_2(x)|v|^\theta dx\right].\end{aligned} \tag{5.2}$$

Using (5.2) implies that

$$\begin{aligned}
E(u,v) &= \left(\frac{1}{p}-\frac{1}{\theta}\right)\left[\lambda\int_\Omega H_1(x)|u|^\theta \ln|u|dx+\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\right]\\
&\quad+\frac{1}{\theta^2}\left[\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right]\\
&\quad+\left(\frac{1}{p}-\frac{1}{p^*_{s_1}}\right)\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx\\
&< (p-p^*_{s_1})\left(\frac{1}{\theta-p}-\frac{1}{p(p^*_{s_1})}\right)\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx\\
&\quad+\left(\frac{1}{\theta^2}-\frac{1}{\theta-p}\right)\left[\lambda\int_\Omega H_1(x)|u|^\theta dx+\mu\int_\Omega H_2(x)|v|^\theta dx\right]\\
&< 0.
\end{aligned}$$

Let $\{(u_n,v_n)\}\subset\mathcal{N}^+$ be a minimizing sequence. Then,

$$\begin{aligned}
\|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t} &= \lambda\int_\Omega H_1(x)|u_n|^\theta\ln|u|dx+\mu\int_\Omega H_2(x)|v_n|^\theta\ln|v|dx\\
&\quad+\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx, \qquad (5.3)
\end{aligned}$$

and using $\Phi''_{(u_n,v_n)}(1)>0$,

$$\begin{aligned}
\Phi''_{(u_n,v_n)}(1) &= \|(u,v)\|^p_{s_1,p}+\|(u,v)\|^t_{s_2,t}-\lambda\int_\Omega H_1(x)|u_n|^\theta\ln|u_n|dx-\mu\int_\Omega H_2(x)|v|^\theta\ln|v|dx\\
&\quad-\int_\Omega (R_1+R_2)(x)|u_n|^q|v_n|^r dx-\lambda\int_\Omega H_1(x)|u_n|^\theta dx\\
&\quad-\mu\int_\Omega H_2(x)|v_n|^\theta dx+(p-p^*_{s_1})\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx\\
&> 0. \qquad (5.4)
\end{aligned}$$

This implies

$$-\lambda\int_\Omega H_1(x)|u_n|^\theta dx-\mu\int_\Omega H_2(x)|v_n|^\theta dx+(p-p^*_{s_1})\int_\Omega (R_1(x)+R_2(x))|u|^q|v|^r dx>0. \qquad (5.5)$$

Since $\mathcal{N}^+$ is bounded by Lemma 3.7, up to subsequence we assume that

$$\begin{cases}
(u_n,v_n)\rightharpoonup(u^+,v^+) & \text{in } W;\\
u_n\to u^+,\ v_n\to v^+ & \text{strongly in } L^t(\Omega),\ \text{for } 1\le t<p^*_s\\
u_n(x)\to u^+(x),\ v_n(x)\to v^+(x) & \text{a.e in } \Omega.
\end{cases} \qquad (5.6)$$

Similarly to Lemma 4.3, we get

$$\lim_{n\to\infty}\int_\Omega H_1(x)u_n|u_n|^\theta\ln|u_n|dx=\int_\Omega H_1(x)|u^+|^\theta\ln|u^+|dx, \qquad (5.7)$$

$$\lim_{n\to\infty}\int_\Omega H_2(x)v_n|v_n|^\theta\ln|v_n|dx=\int_\Omega H_2(x)|v^+|^\theta\ln|v^+|dx, \qquad (5.8)$$

$$\lim_{n\to\infty}\int_\Omega R_1(x)|u_n|^q|v_n|^r dx=\int_\Omega R_2(x)|u^+|^q|v^+|^r dx, \qquad (5.9)$$

$$\lim_{n\to\infty}\int_\Omega R_2(x)|u_n|^q|v_n|^r dx=\int_\Omega R_2(x)|u^+|^q|v^+|^r dx. \qquad (5.10)$$

If $(u_n, v_n) \rightharpoonup (u^+, v^+)$ in W, then

$$\|(u^+, v^+)\|^2 \leq \liminf_{n\to+\infty} \|(u_n, v_n)\|^2. \tag{5.11}$$

This implies that

$$\begin{aligned}
&\|(u^+, v^+)\|^p_{s_1,p} + \|(u^+, v^+)\|^t_{s_2,t} - \lambda \int_\Omega H_1(x)|u^+|^\theta \ln|u^+|dx - \mu \int_\Omega H_1(x)|v^+|^\theta \ln|v^+|dx \\
&\quad - \int_\Omega R_1(x)|u^+|^q|v^+|^r dx - \int_\Omega R_2(x)|u^+|^q|v^+|^r dx \\
&< \liminf_{n\to+\infty} \left[\|(u_n, v_n)\|^2 - \lambda \int_\Omega H_1(x)|u_n|^\theta \ln|u_n|dx - \mu \int_\Omega H_1(x)|v_n|^\theta \ln|v_n|dx \right. \\
&\quad \left. - \int_\Omega R_1(x)|u_n|^q|v_n|^r dx - \int_\Omega R_2(x)|u_n|^q|v_n|^r dx \right] = 0.
\end{aligned} \tag{5.12}$$

Now we prove that for (u^+, v^+) there exists $0 < t_{(u^+,v^+)} \neq 1$ such that

$$t_{(u^+,v^+)}(u^+, v^+) \in \mathcal{N}^+.$$

Since $c^+ < 0$, we can show that $(u^+, v^+) \neq (0, 0)$. By (5.5), we deduce that

$$\lambda \int_\Omega R_1(x)|u^+|^q dx + \mu \int_\Omega R_2(x)|v^+|^r dx < 0,$$

then by Lemma 3.3 there exists $t_{(u^+,v^+)} > 0$ such that

$$t_{(u^+,v^+)}(u^+, v^+) \in \mathcal{N}^+ \quad \text{and} \quad \Psi'_{(u^+,v^+)}(t_{(u^+,v^+)}) = 0$$

By (5.12), $\Psi'_{(u^+,v^+)}(1)) < 0$. Thus, $t_{(u^+,v^+)} \neq 1$. Note that $t_{(u^+,v^+)}(u^+, v^+)$ is minimizer of $g(t) = E(\tau(u^+, \tau v^+)$. Thus,

$$E(t_{(u^+,v^+)}u^+, t_{(u^+,v^+)}v^+) < E(u^+, v^+)) \leq \lim_{n\to+\infty} E(u_n, v_n) = \inf_{(u,v)\in\mathcal{N}^+} E(u, v),$$

which is absurd. Therefore, we obtain $(u_n, v_n) \to (u^+, v^+)$ in W.

Step 2. Existence of nonnegative minimizers. From $(u_n, v_n) \to (u^+, v^+)$ in W and Lemma 3.8, we get

$$-\lambda \int_\Omega H_1(x)|u^+|^\theta dx - \mu \int_\Omega H_2(x)|v^+|^\theta dx + (p - p^*_{s_1}) \int_\Omega (R_1 + R_2)(x)|u^+|^q|v^+|^r dx > 0. \tag{5.13}$$

Thus, we obtain that $(u^+, v^+) \in \mathcal{N}^+$. This gives that (u^+, v^+) is a minimizer of E on $\mathcal{N}^+$. We can prove that $(|u^+|, |v^+|)$ is also a minimizer in $\mathcal{N}^+$. Since

$$E(|u^+|, |v^+|) \leq E(u^+, v^+)$$

and because (5.13) holds for $(|u^+|, |v^+|)$, one can show that

$$\begin{aligned}
&\|(u^+, v^+)\|^p_{s_1,p} + \|(u^+, v^+)\|^t_{s_2,t} - \lambda \int_\Omega H_1(x)|u^+|^\theta \ln|u^+|dx - \mu \int_\Omega H_1(x)|v^+|^\theta \ln|v^+|dx \\
&= \int_\Omega R_1(x)|u^+|^q|v^+|^r dx + \int_\Omega R_2(x)|u^+|^q|v^+|^r dx.
\end{aligned} \tag{5.14}$$

Using $[|u^+|]_s^p \leq [u^+]_s^p$, we obtain

$$\|(u^+,v^+)\|_{s_1,p}^p + \|(u^+,v^+)\|_{s_2,t}^t - \lambda\int_\Omega H_1(x)|u^+|^\theta \ln|u^+|dx - \mu\int_\Omega H_1(x)|v^+|^\theta \ln|v^+|dx$$
$$\leq \int_\Omega R_1(x)|u^+|^q|v^+|^r dx + \int_\Omega R_2(x)|u^+|^q|v^+|^r dx. \tag{5.15}$$

If

$$\|(u^+,v^+)\|_{s_1,p}^p + \|(u^+,v^+)\|_{s_2,t}^t - \lambda\int_\Omega H_1(x)|u^+|^\theta \ln|u^+|dx - \mu\int_\Omega H_1(x)|v^+|^\theta \ln|v^+|dx$$
$$< \int_\Omega R_1(x)|u^+|^q|v^+|^r dx + \int_\Omega R_2(x)|u^+|^q|v^+|^r dx, \tag{5.16}$$

then $\Psi'_{(|u^+|,|v^+|)}(1)) < 0$. For $(|u^+|,|v^+|)$, by Lemma 3.3 there exist $t_{(|u^+|,|v^+|)} \in \mathcal{N}^+$ and $\Psi'_{(|u^+|,|v^+|)}t_{(|u^+|,|v^+|)} = 0$. Thus, $t_{(|u^+|,|v^+|)} \neq 1$. For other hand $t_{(|u^+|,|v^+|)}$ is a minimizer of

$$\xi(t) := E(u^+,v^+).$$

Thus,

$$E(t_{(|u^+|,|v^+|)}|u^+|, t_{(|u^+|,|v^+|)}|v^+| \leq E(|u^+|,|v^+|) \leq E(u^+,v^+) = \inf_{(u,v)\in\mathcal{N}^+} E(u,v),$$

which is absurd. Thus, $(|u^+|,|v^+|) \in \mathcal{N}^+$ and

$$E(|u^+|,|v^+|) = \inf_{(u,v)\in\mathcal{N}^+} E(u,v).$$

In conclusion, we get nonnegative minimizer E on $\mathcal{N}^+$. □

Lemma 5.2. *E has a nontrivial and nonnegative minimizer on $\mathcal{N}^-$.*

Proof. By Lemma 3.8, we know $c^- := \inf_{(u,v)\in\mathcal{N}^-} E(u,v)$ is attained. Let $\{(u_n,v_n)\}_n \subset \mathcal{N}^-$ be a minimizing sequence such that $E(u_n,v_n) \to c^-$. Then

$$\|(u_n,v_n)\|_{s_1,p}^p + \|(u_n,v_n)\|_{s_2,t}^t - \lambda\int_\Omega H_1(x)|u_n|^\theta dx - \mu\int_\Omega H_2(x)|v_n|^\theta dx$$
$$= \int_\Omega (R_1+R_2)(x)|u_n|^q|v_n|^r dx, \tag{5.17}$$

and,

$$0 > \lambda(p-\theta)\int_\Omega H_1(x)|u_n|^\theta \ln|u_n|dx + \mu(p-\theta)\int_\Omega H_2(x)|v_n|^\theta \ln|v_n|dx$$
$$- \lambda(p-\theta)\int_\Omega H_1(x)|u_n|^\theta dx - \mu(p-\theta)\int_\Omega H_2(x)|v_n|^\theta dx$$
$$- (p_{s_1}^* - p)\int_\Omega (R_1+R_2)(x)|u_n|^q|v_n|^r dx. \tag{5.18}$$

We claim that $\{(u_n,v_n)\}_n$ is bounded in $\mathcal{N}^-$.

Without loss of generality, we assume that $\|(u_n,v_n)\| \geq 1$. Then

$$c^- + o_n(1) = E(u_n,v_n) - \frac{1}{p}E'(u_n,v_n)(u_n,v_n)$$
$$= \frac{1}{\theta^2}\left(\lambda\int_\Omega H_1(x)|u_n|^\theta dx + \mu\int_\Omega H_2(x)|v_n|^\theta dx\right)$$
$$+ \left(\frac{1}{p} - \frac{1}{p_{s_1}^*}\right)\int_\Omega (R_1+R_2)(x)|u_n|^q|v_n|^r dx. \tag{5.19}$$

So

$$c^- + o_n(1) \geq \frac{1}{\theta^2}\left(\lambda \int_\Omega H_1(x)|u_n|^\theta dx + \mu \int_\Omega H_2(x)|v_n|^\theta dx\right). \tag{5.20}$$

If $\lambda \int_\Omega H_1(x)|u_n|^\theta dx + \mu \int_\Omega H_2(x)|v_n|^\theta dx \geq 0$, then from equations (5.19), (5.20), we have

$$\|(u,v)\| \leq \left(\frac{1}{\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L}\right)^{\frac{1}{p-2}}.$$

If, $\lambda \int_\Omega H_1(x)|u_n|^\theta dx + \mu \int_\Omega H_2(x)|v_n|^\theta dx < 0$, from equation (5.20), we have

$$\begin{aligned} c^- + o_n(1) &= E(u_n, v_n) \\ &\geq \left[\frac{1}{p} - \frac{1}{\theta}(\lambda C_{H_1} + \mu C_{H_2})L\right]\left(\|(u_n,v_n)\|^p_{s_1,p} + \|(u_n,v_n)\|^t_{s_2,t}\right) \\ &\quad + \left[\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{p^*_{s_1}}\right)\ln\|(u_n,v_n)\|\right]\left(\lambda \int_\Omega H_1(x)|u_n|^\theta dx + \mu \int_\Omega H_2(x)|v_n|^\theta dx\right). \end{aligned}$$

We have two cases to analyze:

i) If $\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{p^*_{s_1}}\right)\ln\|(u_n,v_n)\| \leq 0$, we have $c^- + o_n(1) = \left(\frac{1}{p} - \frac{1}{p^*_{s_1}}\right)[1 - (\lambda C_{H_1} + \mu C_{H_2})L]$ $\left(\|(u_n,v_n)\|^p_{s_1,p} + \|(u_n,v_n)\|^t_{s_2,t}\right)$, which implies that

$$\|(u_n,v_n)\| \leq \left[\frac{p(p^*_{s_1})(c^- + o_n(1))}{(p^*_{s_1} - p)[1 - (\lambda C_{H_1} + \mu C_{H_2})L]}\right]^{\frac{1}{p}}.$$

ii) If $\frac{1}{\theta^2} - \left(\frac{1}{\theta} - \frac{1}{p^*_{s_1}}\right)\ln\|(u_n,v_n)\| > 0$, then $\|(u_n,v_n)\| < \exp\left(\frac{p^*_{s_1} - \theta}{\theta^3(p^*_{s_1})}\right)$. So there exists $C > 0$ such that $\|(u_n,v_n)\| < C$.

Thus, every minimizer sequence of E on $\mathcal{N}^-$ is bounded.
Now, since $\{(u_n,v_n)\}$ is bounded in $\mathcal{N}^-$, up to a subsequence, we may assume that

$$\begin{aligned} &(u_n,v_n) \rightharpoonup (u_-,v_-) && \text{weakly in } W; \\ &(u_n,v_n) \to (u_-,v_-) && \text{strongly in } L^\nu(\Omega) \times L^\tau(\Omega); \\ &(u_n,v_n) \to (u_+,v_+) && \text{a.e in } \Omega, \end{aligned}$$

where $1 < \nu, \tau < \min\{p^*_{s_1}, p^*_{s_1}\}$. It implies that

$$\begin{aligned} \lim_{n\to\infty}\int_\Omega H_1(x)|u_n|^\theta \ln|u_n|dx &= \int_\Omega H_1(x)|u_-|^\theta \ln|u_-|dx; \\ \lim_{n\to\infty}\int_\Omega H_2(x)|v_n|^\theta \ln|v_n|dx &= \int_\Omega H_2(x)|v_-|^\theta \ln|v_-|dx; \\ \lim_{n\to\infty}\int_\Omega H_1(x)|u_n|^\theta dx &= \int_\Omega H_1(x)|u_-|^\theta dx; \\ \lim_{n\to\infty}\int_\Omega H_1(x)|v_n|^\theta dx &= \int_\Omega H_2(x)|v_-|^\theta dx. \end{aligned}$$

An easy computation, combined to equation (5.18), shows that

$$I(u_-,v_-) \leq \liminf_{n\to\infty} I(u_n,v_n) = 0.$$

It means that $(u_-, v_-) \in \mathcal{N}^-$. Now, by Lemma 3.3, item $[i]$, there exists $k_{(u,v)} > 0$ such that $I'_{(u_-,v_-)}k_{(u_-,v_-)} = 0$ and $k_{(u_-,v_-)} \neq 1$. Since $(u_n, v_n) \not\to (u_-, v_-)$, we get

$$k_{(u_-,v_-)}(u_n, v_n) \not\to k_{(u_-,v_-)}(u_-, v_-)$$

in W. Another easy computation shows that

$$E(k_{(u_-,v_-)}u_-, k_{(u_-,v_-)}v_-) \leq E(k_{(u_-,v_-)}u_n, k_{(u_-,v_-)}v_n).$$

Now, observe that the function $z(k) := E(ku_n, kv_n)$ attains its maximum at $k = k_{(u_-,v_-)}$. So

$$\begin{aligned} E(k_{(u_-,v_-)}u_-, k_{(u_-,v_-)}v_-) &< \liminf_{n\to\infty} E(k_{(u_-,v_-)}u_n, k_{(u_-,v_-)}v_n) \\ &\leq \lim_{n\to\infty} E(u_n, v_n) = \inf_{(u,v)\in\mathcal{N}^-} E(u,v), \end{aligned}$$

which is a contradiction. Thus $(u_n, v_n) \to (u_-, v_-)$ in W.

Because $(u_-, v_-) \in \mathcal{N}^-$, then (u_-, v_-) is a minimizer of E on $\mathcal{N}^-$. Moreover, a similar discussion as Theorem 5.1 – *Step* 2 – one can show that $(|u_-|, |v_-|)$ is a minimizer of E on $\mathcal{N}^-$. This yields the proof. □

Now is possible to proof Theorem 1.2.

5.1 Proof of Theorem 1.2

From Lemmas 5.1 and 5.2, E has two non-negative minimizers $(u_+, v_+) \in \mathcal{N}^+$ and $(u_-, v_-) \in \mathcal{N}^-$. Then, from Lemma 3.2, E has two non-negative critical points on W, which is non-trivial and non-negative local least energy solution of problem (P). This two solution are distinct, because is obviously that $\mathcal{N}^- \cap \mathcal{N}^+ = \emptyset$.

We claim that (u_+, v_+) and (u_-, v_-) are not semi-trivial solution.

Supposing, otherwise, $v_+ = 0$ in (u_+, v_+), we get that u_+ is a non-trivial solution of the problem

$$\begin{cases} (-\Delta)_p^{s_1}u + (-\Delta)_t^{s_2}u = \lambda H_1(x)|u|^{\theta-2}u\ln|u| \quad \text{in } \Omega, \\ (u,v) \in W_0^{s_1,p}(\Omega) \times W_0^{s_2,t}(\Omega). \end{cases} \tag{P'}$$

Then $[u_+]_{s_1,p}^p + [u_+]_{s_2,t}^t = \lambda \int_\Omega H_1(x)|u_+|^\theta \ln|u_+|dx$, and because $(u_+, 0) \in \mathcal{N}^+$ and $\Phi''_{(u,v)}(1) > 0$, we get

$$\lambda(p-\theta)\int_\Omega H_1(x)|u_+|^\theta dx < \lambda \int_\Omega H_1(x)|u_+|^\theta dx.$$

Because $p < \theta$, we have $\int_\Omega H_1(x)|u_+|^\theta dx < 0$.

Now we choose $w \in W_0^{t,p}(\Omega) \setminus \{0\}$ such that $\int_\Omega H_1(x)|w|^\theta dx < 0$.

For (u_+, w), by Lemma 3.3, there exists a unique $k_1 > 0$ such that $k_1(u_+, w) \in \mathcal{N}^+$. Moreover, we have

$$k_{\max} = \exp\left[\frac{\|u_+\|_{s_1,p}^p + \|u_+\|_{s_2,t}^t - \left[\int_\Omega \lambda H_1(x)|u_+|^\theta \ln|u_+|^\theta + \mu H_2(x)|w|^\theta \ln|w|^\theta\right]dx}{\lambda\int_\Omega H_1(x)^\theta dx + \mu\int_\Omega H_2(x)|w|^\theta dx} - \frac{1}{p - p^*_{s_1}}\right],$$

and

$$E(k_1u_+, k_1w) = \inf_{0<k<k_{\max}} E(ku_+, kw).$$

It follows that

$$c^+ \leq E(k_1 u_+, k_1 w) < E(u_+, w) < E(u_+, 0) = c^+,$$

which is a contradiction. Thus (u_+, v_+) is not a semi-trivial solution for problem (P).

Otherwise, (u_-, v_-) is not a semi-trivial solution for problem (P), by using the same above argument, but this time assuming $v_- = 0$. In this case $(u_-, 0)$ is a nontrivial solution for problem (P') and $\int_\Omega H_1(x)|u_-|^\theta dx > 0$ and $w \in W_0^{t,p}(\Omega) \setminus \{0\}$ is taking such that $\lambda \int_\Omega H_1(x)|u_-|^\theta dx + \mu \int_\Omega H_2(x)|w|^\theta dx < 0$.

Abstract. This paper establishes the existence and nonexistence of positive solutions for a class of Dirichlet problems involving singular nonlinearities and gradient-dependent terms. The nonlinearities considered are subcritical in the Sobolev sense. Our approach is based on an approximation scheme.

Keywords: quasilinear elliptic equation, positive solution, singular nonlinearity, dependence on the gradient, convection term.

2020 Mathematics Subject Classification: 35J92, 35B09, 35B33, 35J25, 35J62.

1 Introduction

Let $\Omega \subset \mathbb{R}^N$ be a bounded domain with a C^2-boundary, $N \geq 2$, and $0 < \alpha < 1$. In this paper, we investigate the existence of at least one positive solution to the following singular elliptic equation with Dirichlet boundary conditions, driven by the p-Laplacian operator $-\Delta_p u = -\operatorname{div}\left(|\nabla u|^{p-2}\nabla u\right)$, with $1 < p < \infty$:

$$\begin{cases} -\Delta_p u = \lambda\left(\dfrac{1}{u^\alpha} + |\nabla u|^{r_2}\right) + f(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $0 < \lambda < \lambda^*$ is a parameter, r_2 is a constant such that $0 < r_2 < p-1$, and f is a continuous nonlinearity satisfying

$$0 \leq f(x,t) \leq a_2|t|^{r_1}, \tag{1.2}$$

with constants $a_2 > 0$ and $r_1 \in (0, p-1) \cup (p-1, p^*-1)$.

✉Corresponding author. Email: anderson.araujo@ufv.br

We denote by p^* the critical Sobolev exponent, that is, $p^* = \frac{Np}{N-p}$ if $1 < p < N$, and $p^* \in (p, \infty)$ if $p = N$.

In recent years, singular elliptic equations have posed considerable analytical challenges. A vast body of literature has been devoted to such problems, particularly from a theoretical standpoint. For example, the following problem has been extensively investigated:

$$\begin{cases} -\Delta_p u = \eta(x) u^{-\alpha} & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

where $\eta(x) \geq 0$ in Ω and $0 < \alpha < 1$. Canino, Sciunzi, and Trombetta [6] established the existence and uniqueness of solutions to (1.3) for $p \neq 2$ under various configurations. For the particular case $p = 2$, see, for instance, [14,20,27].

Giacomoni, Schindler, and Takáč [13] studied the existence and multiplicity of weak solutions for the following p-Laplacian equation:

$$\begin{cases} -\Delta_p u = \lambda u^{-\delta} + u^q & \text{in } \Omega, \\ u > 0 & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $1 < p < \infty$, $p - 1 < q \leq p^* - 1$, $\lambda > 0$, and $0 < \delta < 1$.

Further results concerning singular problems without convection terms can be found in [3, 5,12,25] and the references therein.

Elliptic problems involving convection terms have also attracted substantial attention, as they introduce additional analytical difficulties. For instance, Francesca and Puglisi [11], employing the subsolution–supersolution method, truncation techniques, nonlinear regularity theory, the Leray–Schauder alternative principle, and tools from set-valued analysis, proved the existence of a positive solution for the problem,

$$\begin{cases} -\Delta u = f(x, u(x), \nabla u(x)) + g(x, u(x)) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases}$$

where $f : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ satisfies an appropriate growth condition, and the semilinear function $g : \Omega \times (0, \infty) \to \mathbb{R}$ is singular at $s = 0$, that is,

$$\lim_{s \to 0^+} g(x, s) = +\infty.$$

It is worth noting that condition (1.2) in the present paper is considerably less restrictive than the assumptions imposed on f in [11] (see also [23] and the references therein).

Faria, Miyagaki, and Motreanu [10] established the existence of a positive solution for the following quasilinear elliptic problem involving the (p, q)-Laplacian and a convection term, by means of the Galerkin method and a Schauder basis:

$$\begin{cases} -\Delta_p u - \mu \Delta_q u = f(x, u, \nabla u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases}$$

Additional works concerning problems with convection terms can be found in [4,26,31] and the references therein.

Beyond the study of variational and nonvariational elliptic problems, the analytical framework of this paper is also connected to broader developments in partial differential equations with irregular coefficients and singular terms. Ragusa [30] proved existence and regularity results for elliptic boundary value problems under vanishing mean oscillation (VMO) assumptions on the coefficients, highlighting how solvability can be preserved even in the absence of smoothness. Polidoro and Ragusa [28] extended these ideas to degenerate ultraparabolic equations with singular lower-order terms, establishing a Harnack inequality and proving the existence of a Green's function for hypoelliptic operators. Kozhanov and Shipina [18] examined loaded elliptic equations and linear inverse problems, where source terms must be simultaneously recovered with the solution itself. Guariglia [15] developed a fractional-calculus framework for the Lerch zeta function, contributing to the analytic study of operators with nonlocal and fractional structures. The work of Guariglia and Silvestrov [16] successfully bridges harmonic analysis with fractional differential operators in complex domains. They achieved this by introducing a new fractional-wavelet analysis tailored for the spaces of positive definite distributions ($\mathcal{D}'(\mathbb{C})$). These contributions collectively advance the analytic study of nonlocal, fractional, and singular operators relevant to modern elliptic theory.

Unlike the cited works, which only address singular nonlinearities without gradient dependence or equations with regular lower-order terms, our study is unique because it simultaneously incorporates a singular term of the form $u^{-\alpha}$ and a convection term involving $|\nabla u|^{r_2}$. This interaction destroys the problem's variational structure and introduces substantial analytical challenges, in obtaining uniform estimates and ensuring the positivity of weak solutions. To address these difficulties, we develop an approximation scheme based on Galerkin approximations using a Schauder basis and non-variational *a priori* bounds, and pass to the limit to obtain existence results. This strategy not only circumvents the lack of a variational framework but also extends the existing theory to a broader class of nonlinear singular elliptic problems. A key contribution of this study is the proof of existence for an equation with a singular nonlinearity where the exponent r_1 of $|u|$ satisfies $r_1 < p^* - 1$.

We now state the main results of the paper.

Theorem 1.1. *Assume that f is a continuous function satisfying (1.2). Then there exists a constant $\lambda^* > 0$ such that, for every $\lambda \in (0, \lambda^*)$, problem (1.1) admits at least one positive solution $u_\lambda \in W_0^{1,p}(\Omega)$.*

Proposition 1.2. *Assume that $f(t) = |t|^{r_1}$, where $r_1 \in (p-1, p^*-1)$, and define*

$$\lambda^* = \sup\{\lambda > 0 : (1.1) \text{ admits a solution } u_\lambda \text{ in } W_0^{1,p}(\Omega)\}.$$

Then $\lambda^* < \infty$.

The paper is organized as follows. In Section 2, we introduce an auxiliary problem and apply the Galerkin method to prove the existence of λ^* such that the approximate problem admits at least one positive solution for each $\lambda \in (0, \lambda^*)$ (see Lemma 2.2). In Section 3, we prove Theorem 1.1. Using the *a priori* estimate obtained in Lemma 2.2, we demonstrate that the sequence of solutions to problem (2.1) converges, in an appropriate sense, to the solution of problem (1.1). To establish the positivity of the solution, we employ a comparison principle together with the solution to problem (3.2).

2 Approximation problem

For any $\varepsilon > 0$, we consider the auxiliary problem

$$\begin{cases} -\Delta_p u = \lambda \left(\dfrac{1}{(|u| + \varepsilon)^{\alpha}} + |\nabla u|^{r_2} \right) + f(x,u) & \text{in } \Omega, \\ \quad u > 0 & \text{in } \Omega, \\ \quad u = 0 & \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

We begin by proving the existence of a positive solution to problem (2.1) using the Galerkin method. This result will later be used in the proof of Theorem 1.1.

Let $\mathcal{B} = \{e_1, \ldots, e_m, \ldots\}$ be a Schauder basis of $W_0^{1,p}(\Omega)$. For each $m \in \mathbb{N}$, define

$$V_m := [e_1, \ldots, e_m]$$

as the m-dimensional subspace of $W_0^{1,p}(\Omega)$ generated by $\{e_1, \ldots, e_m\}$, equipped with the norm of $W_0^{1,p}(\Omega)$. Let $\xi = (\xi_1, \ldots, \xi_m) \in \mathbb{R}^m$ and observe that

$$|\xi|_m := \left\| \sum_{j=1}^{m} \xi_j e_j \right\|_{W_0^{1,p}(\Omega)}$$

defines a norm; see [2] for details. We denote by $\mathbb{R}^m$ the m-dimensional space $\mathbb{R}^m$ endowed with this norm. As a consequence of the isometric linear transformation

$$u = \sum_{j=1}^{m} \xi_j e_j \in W_0^{1,p}(\Omega) \mapsto \xi = (\xi_1, \ldots, \xi_m) \in \mathbb{R}^m,$$

the spaces V_m and $(\mathbb{R}^m, |\cdot|_m)$ can be identified.

The following result is a simple consequence of Brouwer's fixed point theorem; see [1] for its proof. We denote by $|x| = \sqrt{\langle x, x \rangle}$ the usual Euclidean norm in $\mathbb{R}^m$ induced by the inner product $\langle \cdot, \cdot \rangle$.

Lemma 2.1. *Let $F : (\mathbb{R}^m, |\cdot|_m) \to (\mathbb{R}^m, |\cdot|_m)$ be a continuous function such that $\langle F(\xi), \xi \rangle \geq 0$ for every $\xi \in \mathbb{R}^m$ with $|\xi| = R$, for some $R > 0$. Then there exists z_0 in the closed ball $\overline{B}_R^m(0)$ such that $F(z_0) = 0$.*

We now establish the existence of a solution to the auxiliary problem (2.1).

Lemma 2.2. *For any $\varepsilon > 0$, there exists $\lambda^* > 0$ such that (2.1) admits a weak positive solution $u_\varepsilon \in W_0^{1,p}(\Omega) \cap C^{1,\sigma}(\overline{\Omega})$ for some $0 < \sigma < 1$, for every $\lambda \in (0, \lambda^*)$.*

Proof. Define the function

$$F : \mathbb{R}^m \to \mathbb{R}^m, \qquad F(\xi) = (F_1(\xi), F_2(\xi), \ldots, F_m(\xi)),$$

where, for $j = 1, 2, \ldots, m$,

$$F_j(\xi) = \int_\Omega |\nabla u|^{p-2} \nabla u \nabla e_j - \lambda \left(\int_\Omega \frac{e_j}{(\varepsilon + |u|)^{\alpha}} + \int_\Omega |\nabla u|^{r_2} e_j \right) - \int_\Omega f(x,u) e_j.$$

It is straightforward to verify that F is continuous.

Since the embedding $W_0^{1,p}(\Omega) \hookrightarrow L^q(\Omega)$ is continuous for $1 \leq q \leq p^*$, it follows from hypothesis (1.2) and Hölder's inequality that

$$\langle F(\xi), \xi \rangle \geq \|u\|^p_{W_0^{1,p}(\Omega)} - \lambda \left(c_1 \|u\|^{1-\alpha}_{W_0^{1,p}(\Omega)} + c_2 \|u\|^{r_2+1}_{W_0^{1,p}(\Omega)} \right) - c_3 \|u\|^{r_1+1}_{W_0^{1,p}(\Omega)},$$

where c_1, c_2, and c_3 are positive constants independent of m and u.

If $r_1 \in (0, p-1)$, since $r_2 \in (0, p-1)$ and $1-\alpha < p$, we have that $\langle F(\xi), \xi \rangle$ is coercive; that is, for each $\lambda > 0$, there exists $R = R(\lambda) > 0$ sufficiently large such that $|\xi|_m = \|u\|_{W_0^{1,p}(\Omega)} = R$ implies $\langle F(\xi), \xi \rangle \geq 0$.

If $r_1 \in (p-1, p^*-1)$, assume that $\|u\|_{W_0^{1,p}(\Omega)} = R$ for some $R > 0$ and choose R such that

$$R^p - c_3 R^{r_1+1} \geq \frac{R^p}{2},$$

that is,

$$R \leq \left(\frac{1}{2c_3} \right)^{\frac{1}{r_1+1-p}}.$$

Therefore,

$$\langle F(\xi), \xi \rangle \geq \frac{R^p}{2} - \lambda (c_1 R^{1-\alpha} + c_2 R^{r_2+1}) \geq 0 \quad \Longleftrightarrow \quad \lambda \leq \frac{R^p}{2(c_1 R^{1-\alpha} + c_2 R^{r_2+1})}.$$

Now, taking $\lambda^* := \frac{R^p}{2(c_1 R^{1-\alpha} + c_2 R^{r_2+1})}$, it follows that $\langle F(\xi), \xi \rangle \geq 0$ for every $\lambda \in (0, \lambda^*)$.

By Lemma 2.1, for every $m \in \mathbb{N}$ there exists $y \in \mathbb{R}^m$, with $|y|_m \leq R$, such that $F(y) = 0$. Therefore, there exists $u_m \in V_m$ satisfying

$$\|u_m\|_{W_0^{1,p}(\Omega)} \leq R, \quad \text{for every } m \in \mathbb{N},$$

such that, for any $v \in V_m$,

$$\int_\Omega |\nabla u_m|^{p-2} \nabla u_m \nabla v = \lambda \left(\int_\Omega \frac{v}{(\varepsilon + |u_m|)^\alpha} + \int_\Omega |\nabla u_m|^{r_2} v \right) + \int_\Omega f(x, u_m) v. \tag{2.2}$$

Since R does not depend on m, the sequence (u_m) is bounded in $W_0^{1,p}(\Omega)$, and for some subsequence, there exists $u \in W_0^{1,p}(\Omega)$ such that

$$\begin{aligned} &u_m \rightharpoonup u && \text{weakly in } W_0^{1,p}(\Omega), \\ &u_m \to u && \text{strongly in } L^q(\Omega),\ 1 \leq q < p^*, \\ &u_m \to u && \text{a.e. in } \Omega, \end{aligned} \tag{2.3}$$

since the embedding $W_0^{1,p}(\Omega) \hookrightarrow L^q(\Omega)$ is compact. Moreover,

$$\|u\|_{W_0^{1,p}(\Omega)} \leq \liminf_{m \to \infty} \|u_m\|_{W_0^{1,p}(\Omega)} \leq R. \tag{2.4}$$

We claim that

$$u_m \to u \quad \text{in } W_0^{1,p}(\Omega). \tag{2.5}$$

Since $\mathcal{B}$ is a Schauder basis of $W_0^{1,p}(\Omega)$, for every $u \in W_0^{1,p}(\Omega)$ there exists a unique sequence $(\alpha_n)_{n \geq 1}$ in $\mathbb{R}$ such that $u = \sum_{j=1}^\infty \alpha_j e_j$. Hence,

$$\phi_m := \sum_{j=1}^m \alpha_j e_j \to u \quad \text{in } W_0^{1,p}(\Omega) \text{ as } m \to \infty. \tag{2.6}$$

It follows from (1.2) that

$$\int_\Omega |f(x,u_m)|^{\frac{r_1+1}{r_1}} \leq a_2^{\frac{r_1+1}{r_1}} \int_\Omega |u_m|^{r_1+1} \leq C, \quad \forall m \in \mathbb{N}, \tag{2.7}$$

which shows that $(f(x,u_m))_{m\in\mathbb{N}}$ is bounded in $L^{\frac{r_1+1}{r_1}}(\Omega)$.

Taking the test function $(u_m - \phi_m) \in V_m$ in (2.2), and using (1.2), Hölder's inequality, the boundedness of $\|u_m\|_{W_0^{1,p}(\Omega)}$, (2.3), and (2.6), we obtain

$$\begin{aligned}
&\int_\Omega |\nabla u_m|^{p-2}\nabla u_m \nabla(u_m-\phi_m) \\
&\quad = \lambda\left(\int_\Omega \frac{(u_m-\phi_m)}{(\varepsilon+|u_m|)^\alpha} + \int_\Omega |\nabla u_m|^{r_2}(u_m-\phi_m)\right) + \int_\Omega f(x,u_m)(u_m-\phi_m) \\
&\quad \leq \frac{\lambda}{\varepsilon^\alpha}\|u_m-\phi_m\|_{L^1(\Omega)} + \lambda\tilde{c}_1\|u_m\|^{r_2}_{W_0^{1,p}(\Omega)}\|u_m-\phi_m\|_{L^{r_2+1}(\Omega)} \\
&\qquad + \|f(\cdot,u_m)\|_{L^{\frac{r_1+1}{r_1}}(\Omega)}\|u_m-\phi_m\|_{L^{r_1+1}(\Omega)} \to 0 \quad \text{as } m\to\infty,
\end{aligned}$$

because $r_1 + 1 < p^*$. Thus, we obtain

$$\lim_{m\to\infty}\int_\Omega |\nabla u_m|^{p-2}\nabla u_m\nabla(u_m-u) = 0.$$

Now, it suffices to apply the (S_+) property of $-\Delta_p$ (see [24, Proposition 3.5]) to deduce (2.5).

Let $k \in \mathbb{N}$. Then, for every $m \geq k$ and every $v_k \in V_k$, we have

$$\int_\Omega |\nabla u_m|^{p-2}\nabla u_m\nabla v_k = \lambda\left(\int_\Omega \frac{v_k}{(\varepsilon+|u_m|)^\alpha} + \int_\Omega |\nabla u_m|^{r_2}v_k\right) + \int_\Omega f(x,u_m)v_k.$$

Note that for $x, y \in \mathbb{R}^N$ there exists a positive constant C_p, depending only on p, such that

$$\left|\, |x|^{p-2}x - |y|^{p-2}y \,\right| \leq C_p\left(|x|+|y|\right)^{p-2}|x-y|, \tag{2.8}$$

see [9, Lemma 2.1].

Thus, Hölder's inequality and (2.8) yield

$$\begin{aligned}
&\left|\int_\Omega (|\nabla u_m|^{p-2}\nabla u_m - |\nabla u|^{p-2}\nabla u)\nabla v_k\right| \\
&\quad \leq \int_\Omega \left||\nabla u_m|^{p-2}\nabla u_m - |\nabla u|^{p-2}\nabla u\right||\nabla v_k| \\
&\quad \leq C_p\int_\Omega (|\nabla u_m|+|\nabla u|)^{p-2}|\nabla(u_m-u)||\nabla v_k| \\
&\quad \leq C_p\left(\|\nabla u_m\|_{L^p(\Omega)} + \|\nabla u\|_{L^p(\Omega)}\right)^{p-2}\|\nabla(u_m-u)\|_{L^p(\Omega)}\|\nabla v_k\|_{L^p(\Omega)} \\
&\quad \to 0 \quad \text{as } m\to\infty.
\end{aligned}$$

Therefore,

$$\int_\Omega |\nabla u_m|^{p-2}\nabla u_m\nabla v_k \to \int_\Omega |\nabla u|^{p-2}\nabla u\nabla v_k. \tag{2.9}$$

Analogously, we have

$$\int_\Omega |\nabla u_m|^{r_2} v_k \to \int_\Omega |\nabla u|^{r_2} v_k. \tag{2.10}$$

Since (2.7) implies that $(f(x,u_m))_{m\in\mathbb{N}}$ is bounded in $L^{\frac{r_1+1}{r_1}}(\Omega)$, and since $u_m \to u$ a.e. in Ω, we obtain $f(x,u_m) \to f(x,u)$ a.e. in Ω. Therefore, by [17, Theorem 13.44], we have

$$f(x,u_m) \rightharpoonup f(x,u) \text{ in } L^{\frac{r_1+1}{r_1}}(\Omega).$$

Hence, for all $v_k \in V_k \subset W_0^{1,p}(\Omega)$, it follows that

$$\int_\Omega f(x,u_m) v_k \to \int_\Omega f(x,u) v_k. \tag{2.11}$$

Thus, (2.5), (2.9), (2.10), and (2.11) imply that for every $v_k \in V_k$ it holds that

$$\int_\Omega |\nabla u|^{p-2}\nabla u \nabla v_k = \lambda \left(\int_\Omega \frac{v_k}{(\varepsilon + |u|)^\alpha} + \int_\Omega |\nabla u|^{r_2} v_k \right) + \int_\Omega f(x,u) v_k.$$

By the density of $[V_k]_{k\in\mathbb{N}}$ in $W_0^{1,p}(\Omega)$, we conclude that for all $v \in W_0^{1,p}(\Omega)$,

$$\int_\Omega |\nabla u|^{p-2}\nabla u \nabla v = \lambda \left(\int_\Omega \frac{v}{(\varepsilon + |u|)^\alpha} + \int_\Omega |\nabla u|^{r_2} v \right) + \int_\Omega f(x,u) v.$$

Furthermore, since $u^- \in W_0^{1,p}(\Omega)$, we conclude that

$$\int_\Omega |\nabla u|^{p-2}\nabla u \nabla u^- = \lambda \left(\int_\Omega \frac{u^-}{(\varepsilon + |u|)^\alpha} + \int_\Omega |\nabla u|^{r_2} u^- \right) + \int_\Omega f(x,u) u^-,$$

which implies that

$$-\|u^-\|_{W_0^{1,p}(\Omega)} = \lambda \left(\int_{\Omega/\{u(x)>0\}} \frac{u^-}{(\varepsilon + |u|)^\alpha} + \int_{\Omega/\{u(x)>0\}} |\nabla u|^{r_2} u^- \right) \geq 0,$$

and we obtain that $u^- \equiv 0$ a.e. in Ω. Therefore, for every $v \in W_0^{1,p}(\Omega)$, it holds that

$$\int_\Omega |\nabla u|^{p-2}\nabla u \nabla v = \lambda \left(\int_\Omega \frac{v}{(\varepsilon + u)^\alpha} + \int_\Omega |\nabla u|^{r_2} v \right) + \int_\Omega f(x,u) v.$$

The equation in (2.1) ensures that $u \not\equiv 0$. By [19, Theorem 7.1], we infer that $u \in L^\infty(\Omega)$. Moreover, the regularity result up to the boundary in [21, Theorem 1] guarantees that $u \in C^{1,\sigma}(\overline{\Omega})$ for some $\sigma \in (0,1)$. By applying the strong maximum principle [29, Theorem 5.4.1], we conclude that $u > 0$ in Ω, thereby proving that u is a positive solution of problem (2.1). □

3 The main results

In order to prove Theorem 1.1, we recall the following results.

Lemma 3.1. *Let f be a non-negative continuous function such that $f(u)$ is nonincreasing for $u \in (0,\infty)$, where $1 < p$. Assume that $u, v \in W^{1,p}(\Omega)$ are weak solutions such that $u \geq v$ in $\partial\Omega$ and*

$$\begin{cases} -\Delta_p u \geq f(u), & u > 0 \text{ in } \Omega, \\ -\Delta_p v \leq f(v), & v > 0 \text{ in } \Omega. \end{cases}$$

Then $u \geq v$ in Ω.

The proof of Lemma 3.1 can be found in [8, Proposition 2.3].

Let $d_\Omega : \Omega \to \mathbb{R}_+$ be the distance function to the boundary defined by

$$d_\Omega(x) = \inf_{y \in \partial\Omega} |x - y|.$$

The next result can be found in [20, Lemma 1].

Lemma 3.2. *Suppose that $\Omega \subset \mathbb{R}^N$ is a domain of class C^k for some $k \geq 1$. Then*

$$\int_\Omega d_\Omega(x)^{-\sigma} < \infty \text{ for all } 0 < \sigma < 1.$$

We denote by λ_1 and ϕ_1 the first eigenpair of the p-Laplacian, that is,

$$\begin{cases} -\Delta_p \phi_1 = \lambda_1 \phi_1^{p-1} & \text{in } \Omega \\ \phi_1 = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.1}$$

with $\phi_1 > 0$ satisfying $\|\phi_1\|_\infty = 1$. Note that the strong maximum and boundary point principles (see [32, Theorem 5]) guarantee that $\phi_1 > 0$ in Ω and $\frac{\partial \phi_1}{\partial \nu} < 0$ on $\partial\Omega$, respectively. Hence, since $\phi_1 \in C^1(\bar{\Omega})$, there are constants ℓ and $L, 0 < \ell < L$, such that

$$\ell d_\Omega(x) \leq \phi_1(x) \leq L d_\Omega(x)$$

for all $x \in \Omega$.

Let us consider $u_0 \in W_0^{1,p}(\Omega) \cap C^{1,\beta}(\bar{\Omega})$ (where $0 < \beta < 1$), the only solution to the p-Laplacian equation

$$\begin{cases} -\Delta_p u_0 = u_0^{-\alpha} & \text{in } \Omega \\ u_0 > 0 & \text{in } \Omega \\ u_0 = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.2}$$

where $0 < \alpha < 1$. A more complete study of problem (3.2) can be found in [6, Theorem 1.3].

The solution of problem (3.2) combined with Lemma 3.1 will guarantee the positivity of the solution to problem (1.1).

3.1 Proof of Theorem 1.1.

Lemma 2.2 guarantees that for each $\lambda \in (0, \lambda^*)$ and $n \in \mathbb{N}$, we obtain a solution $u_n \in C^{1,\sigma}(\bar{\Omega})$ of the p-Laplacian equation

$$\begin{cases} -\Delta_p u_n = \lambda \left(\dfrac{1}{(u_n + \frac{1}{n})^\alpha} + |\nabla u_n|^{r_2} \right) + f(x, u_n) & \text{in } \Omega, \\ u_n > 0 & \text{in } \Omega, \\ u_n = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.3}$$

That is, for all $v \in W_0^{1,p}(\Omega)$ we have

$$\int_\Omega |\nabla u_n|^{p-2} \nabla u_n \nabla v = \lambda \left(\int_\Omega \frac{v}{(\frac{1}{n} + u_n)^\alpha} + \int_\Omega |\nabla u_n|^{r_2} v \right) + \int_\Omega f(x, u_n) v. \tag{3.4}$$

In particular, equality (3.4) holds for all $v \in C_0^1(\Omega)$.

It follows from (2.4) that (u_n) is a bounded sequence. Thus, by the arguments used to obtain (2.5), we can extract a subsequence, still denoted by (u_n), such that

$$u_n \to u \quad \text{in } W_0^{1,p}(\Omega). \tag{3.5}$$

We have that u_n satisfies

$$\begin{aligned} &-\Delta_p\left(u_n + \frac{1}{n}\right) = -\Delta_p u_n \geq \frac{\lambda}{\left(u_n + \frac{1}{n}\right)^{\alpha}}, \\ &\left(u_n + \frac{1}{n}\right)\Big|_{\partial\Omega} > 0. \end{aligned}$$

Let $w = \lambda^{\frac{1}{p-1-\alpha}} u_0$, where u_0 is the unique solution of (3.2). Then w satisfies the p-Laplacian equation

$$\begin{cases} -\Delta_p w = \dfrac{\lambda}{w^{\alpha}} & \text{in } \Omega, \\ w > 0 & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega. \end{cases} \tag{3.6}$$

It follows that $u_n + \frac{1}{n}$ is a supersolution of (3.6). By Lemma 3.1, we obtain

$$u_n + \frac{1}{n} \geq w.$$

Let ϕ_1 be the solution of (3.1). For each $\beta \in \left(0, \lambda_1^{-\frac{1}{p-1-\alpha}}\right)$, we have that $\beta\phi_1$ satisfies

$$\begin{cases} -\Delta_p(\beta\phi_1) \leq \dfrac{1}{(\beta\phi_1)^{\alpha}} & \text{in } \Omega, \\ \beta\phi_1 > 0 & \text{in } \Omega, \\ \beta\phi_1 = 0 & \text{on } \partial\Omega. \end{cases}$$

In particular, $\beta\phi_1$ is a subsolution of (3.2). By Lemma 3.1, we have $u_0 \geq \beta\phi_1$. Since there exists a constant $\ell > 0$ such that $\ell\, d_\Omega \leq \phi_1$, we obtain

$$u_0 \geq k\, d_\Omega, \tag{3.7}$$

where $k = \ell\beta$. Therefore, from (3.7) we obtain

$$w = \lambda^{\frac{1}{p-1-\alpha}} u_0 \geq k_1\, d_\Omega, \tag{3.8}$$

where $k_1 = k\lambda^{\frac{1}{p-1-\alpha}}$. Since (3.8) implies that

$$u_n + \frac{1}{n} \geq w \geq k_1 d_\Omega,$$

it follows that

$$\frac{|v|}{\left(u_n + \frac{1}{n}\right)^{\alpha}} \leq \frac{|v|}{(k_1 d_\Omega)^{\alpha}}, \quad \forall\, v \in C_0^1(\Omega). \tag{3.9}$$

Thus, by Lemma 3.2, we conclude that $\frac{v}{(k_1 d_\Omega)^\alpha}$ is integrable.

Since $u_n + \frac{1}{n} \to u$ a.e. in Ω and

$$\frac{v}{(\frac{1}{n} + u_n)^\alpha} \to \frac{v}{u^\alpha} \quad \text{a.e. in } \Omega \text{ as } n \to +\infty,$$

the Lebesgue dominated convergence theorem yields

$$\int_\Omega \frac{v}{(\frac{1}{n} + u_n)^\alpha} \to \int_\Omega \frac{v}{u^\alpha} \quad \text{as } n \to +\infty. \tag{3.10}$$

From (3.5), (3.10), and the fact that u_n satisfies (3.4), together with the density of $C_0^1(\Omega)$ in $W_0^{1,p}(\Omega)$, letting $n \to +\infty$ we conclude that

$$\int_\Omega |\nabla u|^{p-2}\nabla u \nabla v = \lambda \left(\int_\Omega \frac{v}{u^\alpha} + \int_\Omega |\nabla u|^{r_2} v \right) + \int_\Omega f(x,u)v, \quad \forall\, v \in W_0^{1,p}(\Omega).$$

Finally, to conclude the proof, we observe that (3.9) and $u_n + \frac{1}{n} \to u$ imply

$$u \geq k_1 d_\Omega > 0 \quad \text{a.e. in } \Omega.$$

□

3.2 Proof of Proposition 1.2

In this proof, we adopt some ideas from [7]. For the sake of contradiction, suppose that $\lambda^* = \infty$. Thus, there exists a sequence $\lambda_n \to \infty$ and corresponding solutions $u_{\lambda_n} > 0$ in Ω, given by Theorem 1.1. Define

$$P_1(t) = \lambda t^{-\alpha} + t^{r_1}.$$

We claim that there exists a constant $C_\lambda > 0$ such that

$$P_1(t) \geq C_\lambda t^{p-1} \quad \text{for every } t > 0.$$

Indeed, define the function $Q(t) = P_1(t)\, t^{-(p-1)}$. Since $p - 1 < r_1$, we have $Q(t) \to \infty$ as $t \to 0^+$ and as $t \to \infty$. The minimum value is $Q(t_1) = C_\lambda$, where $t_1 > 0$ is the unique solution of

$$Q'(t) = 0,$$

that is,

$$t_1 = \left[\frac{\lambda(p - 1 - \alpha)}{r_1 - (p-1)} \right]^{\frac{1}{r_1 + \alpha}}.$$

Consequently, by the argument above, $t_1 > 0$ is the unique minimizer of Q, with $Q(t_1) = C_\lambda$.

Let $\sigma_1 > 0$ and $\varphi_1 > 0$ denote, respectively, the principal eigenvalue and the corresponding eigenfunction of the eigenvalue problem

$$\begin{cases} -\Delta_p \varphi_1 = \sigma_1 |\varphi_1|^{p-2}\varphi_1 & \text{in } \Omega, \\ \varphi_1 = 0 & \text{on } \partial\Omega. \end{cases}$$

Since C_λ increases as λ_n increases (because $r_1 > p - 1$), for $\delta > 0$ small enough, there exists λ_0 in this sequence such that the corresponding constant satisfies $C_{\lambda_0} \geq \sigma_1 + \delta$. Hence, the solution u_{λ_0} of (1.1) associated with λ_0 satisfies $u_{\lambda_0} > 0$ in Ω and

$$\begin{cases} -\Delta_p u_{\lambda_0} \geq C_{\lambda_0} |u_{\lambda_0}|^{p-2} u_{\lambda_0} \geq (\sigma_1 + \delta)|u_{\lambda_0}|^{p-2}u_{\lambda_0} & \text{in } \Omega, \\ u_{\lambda_0} \geq 0 & \text{on } \partial\Omega. \end{cases}$$

Otherwise, taking $\varepsilon > 0$ small enough, we obtain $\varepsilon\varphi_1 < u_{\lambda_0}$ in Ω and

$$\begin{cases} -\Delta_p(\varepsilon\varphi_1) = \sigma_1|\varepsilon\varphi_1|^{p-2}(\varepsilon\varphi_1) \leq (\sigma_1+\delta)|\varepsilon\varphi_1|^{p-2}(\varepsilon\varphi_1) & \text{in } \Omega, \\ \varphi_1 = 0 & \text{on } \partial\Omega. \end{cases}$$

By the subsolution and supersolution method (see [7, Theorem 2.1]), there exists a solution $\varepsilon\varphi_1 \leq \omega \leq u_{\lambda_0}$ in Ω of

$$\begin{cases} -\Delta_p\omega = (\sigma_1+\delta)|\omega|^{p-2}\omega & \text{in } \Omega, \\ \omega = 0 & \text{on } \partial\Omega. \end{cases}$$

Hence, we reach a contradiction to the fact that σ_1 is isolated (see [22]). Therefore, $\lambda^* < \infty$.

Abstract. This paper investigates the nonexistence and existence of global weak solutions to semilinear differential inequalities in the exterior domain of the unit ball within the Heisenberg group $\mathbb{H}^N$. We establish a critical Fujita exponent $p^* = \frac{Q}{Q-2}$, where $Q = 2N + 2$ represents the homogeneous dimension of $\mathbb{H}^N$. In the subcritical case $1 < p \leq p^*$, we prove that no global positive solutions exist, while in the supercritical regime $p > p^*$, we construct explicit stationary solutions. Our approach combines the test function method with a detailed analysis of the Heisenberg group's geometric structure.

Keywords: Heisenberg group, global solution, blow-up.

2020 Mathematics Subject Classification: 35B44, 35A01, 35D30, 35G25.

1 Introduction

The study of nonlinear differential inequalities in non-Euclidean settings has attracted growing attention due to its relevance in geometric analysis, subelliptic PDEs, and mathematical physics. Among such structures, the Heisenberg group $\mathbb{H}^N$ plays a fundamental role as the simplest nontrivial example of a Carnot group, where the interplay between geometry and analysis reveals distinctive features absent in the Euclidean framework.

A central question in the theory of nonlinear PDEs is the dichotomy between the existence and nonexistence of positive global solutions, particularly in the presence of singularities and in unbounded or exterior domains. This dichotomy is often governed by critical exponents of Fujita type, which separate the regions of blow-up from those admitting global solutions.

The problem was first investigated in the Euclidean setting by Pohozaev and Véron [13], who demonstrated nonexistence results for singular inequalities. Later developments extended these results to the Heisenberg group and related structures, where the noncommutative geometry introduces additional analytical difficulties.

The problem of nonexistence of positive solutions for singular differential inequalities in exterior domains has been extensively studied by numerous authors; see, for instance, [1,9,10]

and the references therein. The investigation of singular differential equations was initiated by Pohozaev and Veron [13], followed by significant contributions from Georgiev and Palmieri [6], Jleli et al. [7], and Borikhanov et al. [3]. It has been established that in the subcritical case, i.e., for $1 < p \leq p^* = \frac{N+2}{N+1}$, the system admits no global positive solutions (see [1,7,13]), whereas in the supercritical case, where $p > p^*$, global positive solutions do exist (see [6]).

Important contributions in this direction include the works of D'Ambrosio [1], Garofalo and Lanconelli [5], Georgiev and Palmieri [6], and Jleli et al. [7,9].

In the subcritical regime, it has been established that global positive solutions cannot exist, while in the supercritical case, global solutions do exist [3]. The critical threshold is described by the Fujita exponent, which for the Heisenberg group is given by

$$p^* = \frac{Q}{Q-2},$$

where $Q = 2N + 2$ is the homogeneous dimension of $\mathbb{H}^N$.

In this paper, we contribute to this ongoing line of research by studying singular higher-order differential inequalities in the exterior domain of the unit ball in $\mathbb{H}^N$. While recent studies (e.g., [11]) focused on bounded domains, our objective is to establish sharp conditions for the existence and nonexistence of positive global weak solutions in the unbounded setting. The analysis is based on the test function method [12], a powerful approach that yields nonexistence results via integral inequalities, and also allows us to construct explicit stationary global solutions in the supercritical case.

Our main theorem (Theorem 2.2) shows that if $p < p^*$, then no nontrivial global weak solutions exist in the exterior domain of the unit ball within $\mathbb{H}^N$, whereas for $p > p^*$, stationary global solutions can be explicitly constructed. This result provides a complete characterization of the Fujita phenomenon in this non-Euclidean, singular, exterior-domain framework.

The critical case $p = p^*$ requires a more in-depth analysis and represents an interesting direction for future research.

2 Notations and principal results

2.1 Heisenberg group background

In this section, we recall some preliminary notions regarding the Heisenberg group. For further details and proofs, we refer to [2,4,5,14,15].

Let $\mathbb{H}^N$ denote the $(2N+1)$-dimensional Heisenberg group with coordinates $(x, y, \tau) \in \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}$, equipped with the group operation:

$$\xi \star \xi' = \left(x + x',\, y + y',\, \tau + \tau' + 2\left(\langle x, y'\rangle - \langle x', y\rangle\right)\right),$$

where $\langle \cdot, \cdot \rangle$ denotes the Euclidean inner product on $\mathbb{R}^N$, and $\xi = (x, y, \tau)$, $\xi' = (x', y', \tau')$.

The inverse of ξ is given by $\xi^{-1} = -\xi$. The Heisenberg norm is defined as:

$$\|\xi\|_{\mathbb{H}^N} = \left(r^4 + \tau^2\right)^{\frac{1}{4}}, \quad \text{where } r = \sqrt{\sum_{i=1}^{N}\left(x_i^2 + y_i^2\right)}.$$

The Heisenberg distance between two points ξ and ξ' is then:

$$d(\xi, \xi') = \|\xi^{-1} \star \xi'\|_{\mathbb{H}^N} = \left(\left(\|x - x'\|^2 + \|y - y'\|^2\right)^2 + \left(\tau - \tau' + 2\left(\langle x, y'\rangle - \langle x', y\rangle\right)\right)^2\right)^{\frac{1}{4}}.$$

A function $f\colon \mathbb{H}^N \to \mathbb{R}$ is said to be Heisenberg-homogeneous of degree $k \in \mathbb{Z}$ if, for all $\lambda > 0$,

$$f(\delta_\lambda(\xi)) = \lambda^k f(\xi),$$

where the dilation δ_λ is defined by:

$$\delta_\lambda(x, y, \tau) = (\lambda x, \lambda y, \lambda^2 \tau).$$

The open ball of radius R centered at ξ in the Heisenberg metric is:

$$B_{\mathbb{H}^N}(\xi, R) = \left\{ \xi' \in \mathbb{H}^N : d_{\mathbb{H}^N}(\xi, \xi') < R \right\}.$$

If $B(0, R)$ denotes the Euclidean open ball in $\mathbb{R}^{2N+1}$, then for $R > 1$,

$$B(0, R) \subset B_{\mathbb{H}^N}(0, R) \subset B(0, R^2).$$

Let $\Omega = B_{\mathbb{H}^N}(0, R_2) \setminus \overline{B_{\mathbb{H}^N}(0, R_1)}$, where $0 \leq R_1 < R_2 \leq +\infty$, and let $u \in L^1(\Omega)$ be a cylindrical function. Using the transformation Φ:

$$\begin{aligned}
x_1 &= \rho\ (\sin\theta)^{\frac{1}{2}} \cos\theta_1, \\
y_1 &= \rho\ (\sin\theta)^{\frac{1}{2}} \sin\theta_1 \cos\theta_2, \\
&\vdots \\
x_N &= \rho\ (\sin\theta)^{\frac{1}{2}} \sin\theta_1 \sin\theta_2 \ldots \cos\theta_{2N-1}, \\
y_N &= \rho\ (\sin\theta)^{\frac{1}{2}} \sin\theta_1 \sin\theta_2 \ldots \sin\theta_{2N-1}, \\
\tau &= \rho^2\ \cos\theta,
\end{aligned}$$

where $R_1 < \rho < R_2$, $\theta \in (0, \pi)$, and $\theta_i \in (0, \pi)$ for $i = 1, \ldots, 2N-2$, and $\theta_{2N-1} \in (0, 2\pi)$. We compute the determinant of the Jacobian matrix $J(\Phi)$:

$$\det J(\Phi) = \rho^{2N+1} \sin^{N-1}\theta \prod_{i=1}^{2N-2} \sin^{2N-i-1}\theta_i.$$

Thus, the integral of u over Ω can be expressed as:

$$\iint_\Omega u(r, \tau)\, d\lambda(\xi) = \omega_N \int_0^\pi d\theta \int_{R_1}^{R_2} \rho^{2N+1} \sin^{N-1}\theta\, u(\rho^2 \sin\theta, \rho^2 \cos\theta)\, d\rho, \tag{2.1}$$

where ω_N is the Lebesgue measure of the unit Euclidean sphere in $\mathbb{R}^{2N}$.

If u has the form

$$u(\xi) = \tilde{\psi}(\xi) v(\|\xi\|_{\mathbb{H}^N}),$$

then we obtain

$$\iint_\Omega v(\|\xi\|_{\mathbb{H}^N}) \tilde{\psi}(\xi)\, d\lambda(\xi) = s_N \int_{R_1}^{R_2} \rho^{2N+1} v(\rho)\, d\rho, \tag{2.2}$$

where

$$\tilde{\psi}(\xi) := \frac{r^2}{\|\xi\|^2_{\mathbb{H}^N}},$$

and

$$s_N = \omega_N \int_0^\pi \sin^N\theta\, d\theta.$$

If λ_N is the Lebesgue measure on $\mathbb{R}^N$, then from (2.1), we obtain

$$\lambda_{2N+1}(B_{\mathbb{H}^N}(\xi,R)) = \lambda_{2N+1}(B_{\mathbb{H}^N}(0,R)) = \lambda_{2N+1}(B_{\mathbb{H}^N}(0,1))R^{2N+2}.$$

The number $Q = 2N+2$ is called the homogeneous dimension of the group $\mathbb{H}^N$.

For $i = 1,\dots,N$, we introduce the vector fields

$$X_i := \frac{\partial}{\partial x_i} + 2y_i\frac{\partial}{\partial \tau}, \quad Y_i := \frac{\partial}{\partial y_i} - 2x_i\frac{\partial}{\partial \tau},$$

and define the associated Heisenberg gradient as

$$\nabla_{\mathbb{H}^N} = (X_1,\dots,X_N,Y_1,\dots,Y_N).$$

The Kohn–Laplacian $\Delta_{\mathbb{H}^N}$ is then given by

$$\Delta_{\mathbb{H}^N} := \sum_{i=1}^{N}\left(X_i^2 + Y_i^2\right).$$

The vector fields X_i and Y_i are 1-homogeneous under the dilation δ_λ:

$$X_i(\delta_\lambda) = \lambda\delta_\lambda(X_i), \quad Y_i(\delta_\lambda) = \lambda\delta_\lambda(Y_i),$$

which implies that $\Delta_{\mathbb{H}^N}$ is 2-homogeneous under the dilation δ_λ:

$$\Delta_{\mathbb{H}^N}(\delta_\lambda) = \lambda^2\delta_\lambda(\Delta_{\mathbb{H}^N}).$$

If $u \in \mathscr{C}^2(\Omega)$ is radial, then it follows that

$$|\nabla_{\mathbb{H}^N}u|^2 = \tilde{\psi}\left|u'\right|^2,$$

and

$$\Delta_{\mathbb{H}^N}u = \tilde{\psi}\left(u'' + \frac{2N+1}{\rho}u'\right). \tag{2.3}$$

Therefore,

$$|\nabla_{\mathbb{H}^N}\rho|^2 = \tilde{\psi}.$$

In the following, we denote $\mathbb{B}^c = \mathbb{H}^N \setminus B_{\mathbb{H}^N}(0,1)$. From (2.3), it follows that the function

$$H(\xi) = 1 - \frac{1}{\rho^{2N}}$$

is harmonic on $\mathbb{B}_N^c$ and radial, where $\rho(\xi) = \|\xi\|_{\mathbb{H}^N}$.

To define the weak solution, it is convenient to represent $\Delta_{\mathbb{H}^N}$ as a divergence form operator:

$$\Delta_{\mathbb{H}^N} = \operatorname{div}\big(A(x,y)\nabla\big), \tag{2.4}$$

where $A(x,y)$ is the matrix in $\mathscr{M}_{2N+1}$ given by

$$A(x,y) = \begin{pmatrix} 1 & & & & & & 2y_1 \\ & \ddots & & & & & \vdots \\ & & \ddots & & & & 2y_N \\ & & & \ddots & & & -2x_1 \\ & & & & \ddots & & \vdots \\ & & & & & 1 & -2x_N \\ 2y_1 & \dots & 2y_N & -2x_1 & \dots & -2x_N & 4r^2 \end{pmatrix},$$

where $r^2 = \sum_{j=1}^{N}(x_j^2 + y_j^2)$ and

$$\nabla = \left(\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_N}, \frac{\partial}{\partial y_1}, \dots, \frac{\partial}{\partial y_N}, \frac{\partial}{\partial \tau}\right).$$

Since

$$\nabla\rho(\xi) = \frac{1}{\rho^3(\xi)}\left(xr^2, yr^2, \frac{1}{2}\tau\right),$$

it follows that

$$A(x,y)\nabla\rho(\xi) = \frac{1}{\rho^3(\xi)}\left(xr^2 + y\tau, yr^2 - x\tau, 2r^2\tau\right).$$

Furthermore,

$$(A(x,y)\nabla\rho(\xi)) \cdot \nabla\rho(\xi) = \frac{r^2}{\rho^2(\xi)} = \tilde{\psi}(\xi).$$

For any $u \in \mathscr{C}^\infty(\mathbb{B}^c)$ and $v \in \mathscr{C}^\infty(\mathbb{H}^N)$ with compact support, we obtain from (2.4) and the divergence theorem

$$\begin{aligned}\int_{\mathbb{B}^c} \Delta_{\mathbb{H}^N} u(\xi) v(\xi)\, d\lambda(\xi) = &\int_{\mathbb{B}^c} u(\xi)\Delta_{\mathbb{H}^N} v(\xi)\, d\lambda(\xi) \\ &- \int_{\mathbb{S}} \left(u(\xi)(A(x,y)\nabla v(\xi)) \cdot \overrightarrow{n} - v(\xi)(A(x,y)\nabla u(\xi)) \cdot \overrightarrow{n}\right) dH_{2N},\end{aligned}$$

where

$$\overrightarrow{n} = -\frac{\nabla\rho(\xi)}{\|\nabla\rho(\xi)\|},$$

on $\mathbb{S}$, and dH_{2N} denotes the $2N$-dimensional Hausdorff measure in $\mathbb{R}^{2N+1}$.

2.2 Principal results

In this paper, we consider the following differential inequalities in the exterior of the unit ball in the Heisenberg group $\mathbb{H}^N$:

$$\begin{cases} \partial_t^k u(t,\xi) - \frac{1}{\tilde{\psi}}\Delta_{\mathbb{H}^N} u(t,\xi) \geq |u(t,\xi)|^p, & \text{on } (0,+\infty)\times\mathbb{B}^c, \\ u(t,\xi) = f(\xi), & \text{on } [0,+\infty)\times\mathbb{S}, \\ \partial_t^j u(0,\xi) = u_j(\xi), & 0 \leq j \leq k-1, \quad \text{on } \mathbb{B}^c, \\ f \geq 0, & f \in L^1(\mathbb{S}) \end{cases} \tag{2.5}$$

where $k \in \mathbb{N}$, $p > 1$, and $\mathbb{B}^c$ denotes the complement of the unit ball in the Heisenberg group. Here, $\Delta_{\mathbb{H}^N}$ represents the Kohn–Laplacian, and $\mathbb{S}$ is the boundary of the unit ball, referred to as the unit sphere. The function $\tilde{\psi}$ will be defined later.

Definition 2.1. A function $u \in L^p_{\text{loc}}([0,+\infty)\times\mathbb{B}^c)$ is called a local weak solution of (2.5) if

there exists $0 < T < +\infty$ such that

$$\begin{aligned}
&\int_{[0,T)\times\mathbb{B}^c} |u(t,\xi)|^p \tilde{\psi}(\xi)\psi(t,\xi)\,dt\,d\lambda(\xi) \\
&\quad\le \sum_{j=0}^{k-1}(-1)^{j+1}\int_{\mathbb{B}^c} u_{k-j-1}(\xi)\tilde{\psi}(\xi)\partial_t^{(j)}\psi(0,\xi)\,d\lambda(\xi) \\
&\quad\quad -(-1)^{k+1}\int_{[0,T)\times\mathbb{B}^c} u(t,\xi)\tilde{\psi}(\xi)\partial_t^{(k)}\psi(t,\xi)\,dt\,d\lambda(\xi) \\
&\quad\quad -\int_{[0,T)\times\mathbb{B}^c} u(t,\xi)\Delta_{\mathbb{H}^N}\psi(t,\xi)\,dt\,d\lambda(\xi) \\
&\quad\quad +\int_{[0,T]}\int_{\mathrm{S}} f(\xi)(A(x,y)\nabla\psi(t,\xi))\cdot\mathbf{n}\,dH_{2N}(\xi)\,dt,
\end{aligned} \tag{2.6}$$

for any test function $\psi \in C^k([0,T)\times\overline{\mathbb{B}^c})$ satisfying:

- $\psi_{|\mathrm{S}} = 0$;
- $\exists R > 1$ such that $\psi(t,x) = 0$ for $d_{\mathbb{B}_N}(0,x) > R$;
- $\frac{\partial\psi}{\partial n^+} \in C([0,T)\times\mathrm{S})$.

The solution u is called global if $T = +\infty$.

The principal result of this paper is stated in the following theorem.

Theorem 2.2. *Let k be a positive integer, and suppose that*

$$p < p^* = \frac{N+1}{N} = \frac{Q}{Q-2}.$$

Then, there exists no global weak solution to the system (2.5) with initial data $u_0,\dots,u_{k-1} \in L^1(\mathbb{B}^c)$. Here, $Q = 2N+2$ is the homogeneous dimension of $\mathbb{H}^N$.

Conversely, if $p > p^*$, then there exists a stationary global solution (2.5) for some function $f \ge 0$. The number p^* is referred to as the critical Fujita exponent.

The paper is organized as follows. In Section 2, we present the necessary preliminaries on the Heisenberg group, introduce the problem under consideration, and state our main result (Theorem 2.2). Section 3 is devoted to the proof of Theorem 2.2, where we construct suitable test functions, derive the key integral estimates, and establish both the nonexistence and existence results.

3 Proof of Theorem 2.2

3.1 Admissible test functions

Consider a local weak solution u of the system (2.5) such that $u(t,\xi) \in L^p_{\mathrm{loc}}(\mathbb{B}^c)$ for all $t \in [0,T]$, where $0 < T < \infty$.

Define the admissible test functions as follows:

$$\psi(t,\xi) = \psi_1(t)H(\xi)\psi_2(\xi), \quad (t,\xi) \in [0,T]\times\mathbb{B}^c,$$

where

$$\psi_1(t) = \Psi\left(\frac{t}{T}\right), \quad \psi_2(\xi) = \varphi^\ell\left(\frac{\|\xi\|_{\mathbb{H}^N}^4}{T^s}\right), \quad s > 0, \quad \ell \gg 1, \quad \xi \in \mathbb{B}^c.$$

The functions Ψ and φ satisfy

$$0 \le \varphi \le 1, \quad \varphi(r) = \begin{cases} 1 & \text{if } 0 \le r \le 1, \\ 0 & \text{if } r \ge 2, \end{cases}$$

and

$$0 \le \Psi \le 1, \quad \operatorname{supp}(\Psi) \subset (0,1), \quad \Psi \in \mathscr{C}^k((0,1)).$$

Using this choice of test functions, if u is a weak solution, then

$$\begin{aligned} &\int_{[0,T)\times\mathbb{B}^c} |u(t,\xi)|^p \tilde{\psi}(\xi)\psi(t,\xi)\,dt\,d\lambda(\xi) - \int_{[0,T]}\int_S f(\xi)\psi_1(t)\psi_2'(\|\xi\|_{\mathbb{H}^N})\tilde{\psi}(\xi)\,dH_{2N}(\xi)\,dt \qquad (3.1)\\ &\quad \le -\int_{[0,T)\times\mathbb{B}^c} u(t,\xi)\Delta_{\mathbb{H}^N}\psi(t,\xi)\,dt\,d\lambda(\xi) + (-1)^k\int_{[0,T)\times\mathbb{B}^c} u(t,\xi)\tilde{\psi}(\xi)\partial_t^{(k)}\psi(t,\xi)\,dt\,d\lambda(\xi). \end{aligned}$$

Remark 3.1. In the definition 2.1 and under the same conditions, if $\psi(t,\xi) = \psi_1(t)\psi_2(\|\xi\|_{\mathbb{H}^N})$, then

$$(A(x,y)\nabla\psi(t,\xi))\cdot\overrightarrow{n} = -\frac{1}{\|\nabla\rho(\xi)\|}\psi_1(t)\psi_2'(\|\xi\|_{\mathbb{H}^N})\tilde{\psi}(\xi).$$

Thus, condition (2.6) simplifies to

$$\begin{aligned} &\int_{[0,T)\times\mathbb{B}^c} |u(t,\xi)|^p\tilde{\psi}(\xi)\psi(t,\xi)\,dt\,d\lambda(\xi)\\ &\quad\le \sum_{j=0}^{k-1}(-1)^{j+1}\int_{\mathbb{B}^c} u_{k-j-1}(\xi)\tilde{\psi}(\xi)\partial_t^{(j)}\psi(0,\xi)\,d\lambda(\xi)\\ &\qquad -(-1)^{k+1}\int_{[0,T)\times\mathbb{B}^c} u(t,\xi)\tilde{\psi}(\xi)\partial_t^{(k)}\psi(t,\xi)\,dt\,d\lambda(\xi)\\ &\quad= -\int_{[0,T)\times\mathbb{B}^c} u(t,\xi)\Delta_{\mathbb{H}^N}\psi(t,\xi)\,dt\,d\lambda(\xi)\\ &\qquad -\int_{[0,T]}\int_S f(\xi)\frac{1}{\|\nabla\rho(\xi)\|}\psi_1(t)\psi_2'(\|\xi\|_{\mathbb{H}^N})\tilde{\psi}(\xi)\,dH_{2N}(\xi)\,dt. \end{aligned}$$

3.2 Preliminary estimates

Using the identity (2.2), we obtain the following estimate after simple computations:

$$\begin{aligned} \Delta_{\mathbb{H}^N}(H\psi_2) = \tilde{\psi}(\xi)\Bigg(&\frac{16N\ell\rho^2(\xi)}{T^s}\varphi'\varphi^{\ell-1} - \frac{8(N-2)\ell\rho^2(\xi)}{T^s}H\varphi'\varphi^{\ell-1}\\ &+\frac{16\ell(\ell-1)\rho^6(\xi)}{T^{2s}}H(\varphi')^2\varphi^{\ell-2} + \frac{16\ell\rho^6(\xi)}{T^{2s}}H\varphi''\varphi^{\ell-1}\Bigg), \end{aligned}$$

where $\rho(\xi) = \|\xi\|_{\mathbb{H}^N}$, $r^2 = \|x\|^2 + \|y\|^2$, and $H = 1 - \rho^{-2N}(\xi)$.

For notational simplicity, we write $\|\xi\|$ instead of $\|\xi\|_{\mathbb{H}^N}$ and C a generic positive constant, which may vary from line to line.

For the proof of Theorem 2.2, we require the following estimates.

Lemma 3.2. *Let*

$$I_T = \int_{[0,T)\times\mathbb{B}^c} |u(t,\xi)|^p \, \tilde{\psi}(\xi)\psi(t,\xi)\, dt\, d\lambda(\xi).$$

Then, the following estimates hold:

$$\frac{1}{T^s}\left|\int_{R_T} u(t,\xi)\tilde{\psi}(\xi)\psi_1(t)\|\xi\|^2\varphi'\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-1}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \le CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}};$$

$$\frac{1}{T^s}\left|\int_{R_T} u(t,\xi)\psi_1(t)\|\xi\|^2\tilde{\psi}(\xi)H(\xi)\varphi'\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-1}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \le CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}};$$

$$\frac{1}{T^{2s}}\left|\int_{R_T} u(t,\xi)\psi_1(t)\|\xi\|^6\tilde{\psi}(\xi)H(\xi)(\varphi')^2\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-2}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \le CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}};$$

$$\frac{1}{T^{2s}}\left|\int_{R_T} u(t,\xi)\psi_1(t)\|\xi\|^6\tilde{\psi}(\xi)H(\xi)\varphi''\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-1}\left(\frac{\|\xi\|^4}{T^s}\right)dtd\lambda(\xi)\right| \le CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}};$$

$$\left|\int_{R_T} u(t,\xi)\tilde{\psi}(\xi)\psi_1^{(k)}(t)H(\xi)\varphi^{\ell}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \le CI_T^{\frac{1}{p}}T^{((N+1)s-2k)\frac{p-1}{p}}.$$

Proof. Using the identity (2.2) and Hölder's inequality, we derive the estimates systematically. The detailed computations involve:

$$\begin{aligned}
&\frac{1}{T^s}\left|\int_{R_T} u(t,\xi)\tilde{\psi}(\xi)\psi_1(t)\|\xi\|^2\varphi'\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-1}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \\
&\quad\le \frac{C}{T^s}I_T^{\frac{1}{p}}\left(\int_{R_T} H^{-\frac{q}{p}}(\xi)\tilde{\psi}(\xi)\psi_1(t)\|\xi\|^{2q}\left|\varphi'\right|^q|\varphi|^{\ell-q}\,dt\,d\lambda(\xi)\right)^{\frac{1}{q}} \\
&\quad\le CI_T^{\frac{1}{p}}T^{\frac{(N+1-q)s}{2q}+\frac{1}{q}} = CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}},
\end{aligned}$$

$$\begin{aligned}
&\frac{1}{T^s}\left|\int_{R_T} u(t,\xi)\psi_1(t)\|\xi\|^2\tilde{\psi}(\xi)H(\xi)\varphi'\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-1}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \\
&\quad\le \frac{C}{T^s}I_T^{\frac{1}{p}}\left(\int_{R_T} H(\xi)\tilde{\psi}(\xi)\psi_1(t)\|\xi\|^{2q}\left|\varphi'\right|^q|\varphi|^{\ell-q}\,dt\,d\lambda(\xi)\right)^{\frac{1}{q}} \\
&\quad\le CI_T^{\frac{1}{p}}T^{\frac{(N+1-q)s}{2q}+\frac{1}{q}} = CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}},
\end{aligned}$$

$$\begin{aligned}
&\frac{1}{T^{2s}}\left|\int_{R_T} u(t,\xi)\psi_1(t)\|\xi\|^6\tilde{\psi}(\xi)H(\xi)(\varphi')^2\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-2}\left(\frac{\|\xi\|^4}{T^s}\right)dt\,d\lambda(\xi)\right| \\
&\quad\le \frac{C}{T^{2s}}I_T^{\frac{1}{p}}\left(\int_{R_T} H(\xi)\tilde{\psi}(\xi)\psi_1(t)\|\xi\|^{6q}\left|\varphi'\right|^q|\varphi|^{\ell-2q}\,dt\,d\lambda(\xi)\right)^{\frac{1}{q}} \\
&\quad\le CI_T^{\frac{1}{p}}T^{\frac{(N+1-q)s}{2q}+\frac{1}{q}} = CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}},
\end{aligned}$$

$$\begin{aligned}
&\frac{1}{T^{2s}}\left|\int_{R_T} u(t,\xi)\psi_1(t)\|\xi\|^6\tilde{\psi}(\xi)H(\xi)\varphi''\left(\frac{\|\xi\|^4}{T^s}\right)\varphi^{\ell-1}\left(\frac{\|\xi\|^4}{T^s}\right)\,dt\,d\lambda(\xi)\right|\\
&\quad\le \frac{C}{T^{2s}}I_T^{\frac{1}{p}}\left(\int_{R_T} H(\xi)\tilde{\psi}(\xi)\psi_1(t)\|\xi\|^{6q}\left|\varphi'\right|^q|\varphi|^{\ell-q}\,dt\,d\lambda(\xi)\right)^{\frac{1}{q}}\\
&\quad\le CI_T^{\frac{1}{p}}T^{\frac{(N+1-q)s}{2q}+\frac{1}{q}} = CI_T^{\frac{1}{p}}T^{(p-\frac{N+1}{N})\frac{Ns}{2p}+\frac{p-1}{p}},
\end{aligned}$$

$$\begin{aligned}
&\left|\int_{R_T} u(t,\xi)\psi_1^{(k)}(t)\tilde{\psi}(\xi)H(\xi)\varphi^{\ell}\left(\frac{\|\xi\|^4}{T^s}\right)dtd\lambda(\xi)\right|\\
&\quad\le I_T^{\frac{1}{p}}\left(\int_{R_T}\psi_1^{-\frac{q}{p}}(t)(\psi_1^{(k)})^q(t)\tilde{\psi}(\xi)H(\xi)\varphi^{\ell}\left(\frac{\|\xi\|^4}{T^s}\right)dtd\lambda(\xi)\right)^{\frac{1}{q}}\\
&\quad\le CI_T^{\frac{1}{p}}T^{\frac{(N+1)s}{2q}-\frac{k}{q}} = CI_T^{\frac{1}{p}}T^{((N+1)s-2k)\frac{p-1}{p}}.
\end{aligned}$$

□

3.3 Proof of Theorem 2.2

Using definition 2.1, the identity (3.1), and the properties of the test functions ψ_1 and ψ_2, for suitable values of s, there exists a constant $C>0$ such that

$$\begin{aligned}
I_T-\int_{[0,T]}\int_{\mathbb{S}^N} f(\xi)\psi_1(t)\psi_2'(\|\xi\|)\tilde{\psi}(\xi)\,dH_{2N}(\xi)\,dt &= I_T+C_1T\\
&\le CI_T^{\frac{1}{p}}T^{\frac{(N+1-q)s}{2q}+\frac{1}{q}}\\
&= CI_T^{\frac{1}{p}}T^{\left(p-\frac{N+1}{N}\right)\frac{Ns}{2p}+\frac{p-1}{p}}.
\end{aligned}$$

We deduce that

$$I_T+C_1T\le CI_T^{\frac{1}{p}}T^{\left(p-\frac{N+1}{N}\right)\frac{Ns}{2p}+\frac{p-1}{p}}. \tag{3.2}$$

If $p<\frac{N+1}{N}$, there exists $s>0$ such that

$$0<\left(p-\frac{N+1}{N}\right)\frac{Ns}{2p}+\frac{p-1}{p}.$$

Setting

$$a=\left(p-\frac{N+1}{N}\right)\frac{Ns}{2p}+\frac{p-1}{p}<1.$$

From (3.2), we get

$$CT\le CI_T^{\frac{1}{p}}T^a,$$

which implies

$$I_T\ge C^{-p}T^{p(1-a)}.$$

By iteration, we derive

$$\begin{aligned}
I_T &\ge C^{-(p+p^2+\cdots+p^n)}T^{p^n-a(p+p^2+\cdots+p^n)}\\
&= C^{-\frac{p^{n+1}}{p-1}}C^{-\frac{1}{p-1}}T^{p^n\left(1-\frac{ap}{p-1}\right)}T^{\frac{a}{p-1}}\\
&= \left(C^{-\frac{p}{p-1}}T^{\left(1-\frac{ap}{p-1}\right)}\right)^{p^n}C^{-\frac{1}{p-1}}T^{\frac{a}{p-1}}.
\end{aligned}$$

Since $1-\frac{ap}{p-1}>0$, there exists T_0 such that

$$C^{-\frac{p}{p-1}}T^{\left(1-\frac{ap}{p-1}\right)}>1.$$

Hence, $I_T=+\infty$ for $T\geq T_0$.

Supercritical case: $p>p^*=\frac{N+1}{N}$

In the supercritical case $p>p^*$, we claim to prove the existence of a global solution.

Assume that $p=\frac{s+N}{N}>\frac{N+1}{N}$, with $s>1$. For $\varepsilon>0$, consider the function

$$u=\varepsilon\|\xi\|^{-\frac{2N}{s}}.$$

From (2.3), we obtain

$$\frac{1}{\tilde{\psi}(\xi)}\Delta_{\mathbb{H}^N}u=u''+\frac{2N+1}{\rho(\xi)}u'=-\frac{4N^2(s-1)}{s^2}\varepsilon\|\xi\|^{-\frac{2N}{s}-2}.$$

If we choose

$$\varepsilon\leq\left(\frac{4N^2(s-1)}{s^2}\right)^{\frac{1}{p-1}},$$

it follows that

$$-\frac{1}{\tilde{\psi}(\xi)}\Delta_{\mathbb{H}^N}u\geq|u|^p=\varepsilon^p\|\xi\|^{-\frac{2N}{s}-2}.$$

Thus, the function

$$u=\varepsilon\|\xi\|^{-\frac{2N}{s}}$$

is a stationary solution of the system (2.5).

4 Conclusion

In this paper, we have established a complete characterization of the existence and nonexistence of global weak solutions to the semilinear differential inequality

$$\partial_t^k u(t,\xi)-\frac{1}{\tilde{\psi}(\xi)}\Delta_{\mathbb{H}_N}u(t,\xi)\geq|u(t,\xi)|^p$$

in the exterior domain $\mathbb{B}^c$ of the Heisenberg group $\mathbb{H}^N$.

Our main result, Theorem 2.2, demonstrates that the critical exponent governing blow-up phenomena is given by

$$p^*=\frac{Q}{Q-2}=\frac{N+1}{N},$$

where $Q=2N+2$ is the homogeneous dimension of $\mathbb{H}^N$. This result reveals several important aspects of the problem:

• The subcritical Case ($1<p\leq p^*$): We have proven that no global weak solution exists for the system (2.5) with any initial data $u_0,\ldots,u_{k-1}\in L^1(\mathbb{B}^c)$. This extends the classical Fujita phenomenon to the setting of the Heisenberg group and demonstrates how the geometric structure influences the critical threshold.

• The supercritical Case ($p > p^*$): We have constructed explicit stationary solutions of the form

$$u(\xi) = \varepsilon \|\xi\|^{-\frac{2N}{s}} \quad \text{with} \quad s = N(p-1),$$

thereby establishing the existence of global solutions in this regime. This construction provides a sharp contrast to the subcritical case and completes the picture of the solution behavior.
• Geometric Interpretation: The emergence of the homogeneous dimension $Q = 2N + 2$ in the critical exponent highlights the profound influence of the Heisenberg group's non-Euclidean geometry on the blow-up behavior. The exponential volume growth and the sub-Riemannian structure fundamentally alter the critical threshold compared to the Euclidean case.

This work contributes to the growing literature on nonlinear partial differential equations in sub-Riemannian settings, demonstrating how the unique geometric features of the Heisenberg group influence the qualitative behavior of solutions to semilinear problems. The techniques developed here, particularly the careful construction of test functions adapted to the Heisenberg geometry, may find applications in other problems involving nonlinear differential operators on Carnot groups.

Abstract. In this paper, we consider the following nonlinear Schrödinger–Poisson–Boltzmann (SPB) system under an L^2-norm constraint

$$\begin{cases} -\Delta u + \lambda u + \phi u = |u|^{p-2}u & \text{in } \mathbb{R}^3, \\ -\Delta \phi + \kappa^2 \phi = 4\pi u^2 & \text{in } \mathbb{R}^3, \\ \|u\|_2 = a, \end{cases}$$

where $p \in \left(2, \frac{10}{3}\right) \setminus \{3\}$, $\lambda \in \mathbb{R}$, $a > 0$ is a prescribed constant and $\kappa > 0$ is a parameter. We prove that the above system admits a positive ground state normalized solution with the Lagrange multiplier $\lambda > 0$ when either $2 < p < 3$ and $a > 0$ is sufficiently small, or $3 < p < \frac{10}{3}$ and $a > 0$ is large enough. Moreover, we prove that when $2 < p < 3$, $\kappa > 0$ and $a > 0$ is small enough, the ground state normalized solutions are radially symmetric up to translation, and as $\kappa \to 0$, they converge to a radially symmetric ground state normalized solution of the Schrödinger–Poisson–Slater system under the same L^2-norm constraint.

Keywords: Schrödinger–Poisson–Boltzmann system, ground state, constrained minimization, radial symmetry, limit behavior.

where $a > 0$ is a prescribed constant, $\kappa > 0$ is a parameter, $\lambda \in \mathbb{R}$ and $p \in \left(2, \frac{10}{3}\right) \setminus \{3\}$. System (1.1) arises from seeking the standing wave solutions $\Psi(x,t) = e^{i\lambda t}u(x)$ to the following system

$$\begin{cases} i\partial_t \Psi + \Delta_x \Psi - \phi\Psi + |\Psi|^{p-2}\Psi = 0 & \text{in } \mathbb{R}^3, \\ -\Delta\phi + \kappa^2\phi = 4\pi|\Psi|^2 & \text{in } \mathbb{R}^3, \end{cases} \tag{1.2}$$

where $\Psi : \mathbb{R}^3 \times [0,\infty) \to \mathbb{C}$ represents the wave function and $\phi : \mathbb{R}^3 \to \mathbb{R}$ denotes the electrostatic potential in the Poisson–Boltzmann equation. Therefore, system (1.2) describes a self-consistent quantum-electrostatic system, in which the wave function Ψ and the electrostatic potential ϕ mutually influence each other through nonlinear term and source term, collectively determining the dynamical behavior of this system.

The Poisson–Boltzmann (PB) equation describes an electric double layer model developed independently by Gouy [16] and Chapman [10], which explains the interaction between the ions in the solution and the charged layer. Subsequently, Andelman [1] proposed the Poisson–Boltzmann theory, in which the Poisson–Boltzmann equation is employed to depict the distribution of electrostatic potential within electrolyte solutions. Blossey [4] made further improvements to this theory. Since the electrolyte solutions formed after the dissolution of 1:1 salts (such as NaCl) play a crucial role in many biochemical reactions and physical processes, according to the Boltzmann distribution and Gauss's law, we obtain the following Poisson–Boltzmann equation for 1:1 salts

$$\Delta\phi = \kappa^2 \sinh\phi,$$

where ϕ denotes the electrostatic potential, Δ is the Laplace operator, κ is the inverse of Debye-Hückel screening length λ_D which satisfies

$$\kappa^2 = \frac{2n_0e^2}{\varepsilon k_B T},$$

where ε stands for the dielectric constant, k_B denotes the Boltzmann constant, T represents the absolute temperature, e is the elementary charge, and n_0 corresponds to the ionic concentration in a neutral electrolyte solution of (1:1) salt (see [4, Section 1.2]). In many physical situations, when the value of the electrostatic potential ϕ is relatively small, the above equation can be linearized into the following equation

$$\Delta\phi = \kappa^2\phi,$$

which not only demonstrates its convenience in the process of mathematical solving, but also has extensive and significant applications in fields such as biophysics, electrochemistry, and colloid chemistry. Moreover, the above linearized Poisson–Boltzmann equation is a classic example of the homogeneous modified Helmholtz equation, where the Laplacian of a function is directly proportional to the function itself (see [4, Section 1.3]). For more physical details, one can refer to the papers [1,4,9,21] and the references therein.

1.2 Problems and main results

In order to explore the existence of solutions to the SPB system (1.1), we would like to recall two distinct approaches in terms of the frequency λ. The first one is to fix $\lambda \in \mathbb{R}$ and search for the coupled solution (u,ϕ) of system (1.1), which is referred to the fixed frequency problem.

In this situation, any solution to system (1.1) can be identified as a critical point of the action functional $F_\lambda(u,\phi)$ on $H^1(\mathbb{R}^3)$, where

$$F_\lambda(u,\phi) := \frac{1}{2}\|\nabla u\|_2^2 + \frac{\lambda}{2}\|u\|_2^2 + \frac{1}{2}\int_{\mathbb{R}^3}\phi u^2 \mathrm{d}x - \frac{1}{16\pi}\|\nabla\phi\|_2^2 - \frac{\kappa^2}{16\pi}\|\phi\|_2^2 - \frac{1}{p}\|u\|_p^p,$$

and the potential ϕ is given by

$$\phi(x) := \left(\frac{e^{-\kappa|\cdot|}}{|\cdot|} * u^2\right)(x) = \int_{\mathbb{R}^3}\frac{e^{-\kappa|x-y|}}{|x-y|}u^2(y)\mathrm{d}y.$$

Due to the presence of ϕu, system (1.1) is classified as a nonlocal problem. A typical example of such nonlocal problems is the Schrödinger–Poisson–Slater system, and a substantial body of literature has investigated various properties of solutions to this system over the past decades. For further related results, we refer to [31,32,38] and the references therein.

Moreover, Han, Huh and Seok [18] studied the following Schrödinger equation coupled with a neutral scalar field N

$$\begin{cases} -\frac{1}{2m}\Delta u + \frac{q}{4m^2}|u|^2 u + (1+\frac{\kappa q}{2m})Nu + \omega u = 0 & \text{in } \mathbb{R}^2, \\ \left(-\Delta + \kappa^2 q^2\right)N + q(1+\frac{\kappa q}{2m})u^2 = 0 & \text{in } \mathbb{R}^2, \end{cases} \tag{1.3}$$

where $m, \kappa, q > 0$ respectively represent the mass of the particle, the Chern–Simons coupling constant and the Maxwell coupling constant. Since $N := -q\left(1+\frac{\kappa q}{2m}\right)\left(G^{\kappa q} * u^2\right)$, where $G^{\kappa q}$ is the Yukawa potential in two dimension (see [26, Theorem 6.23]), (1.3) is also a nonlocal problem. They proved the existence of standing wave solutions for system (1.3) in the radially symmetric space $H_r^1(\mathbb{R}^2)$ by applying Mountain-Pass theorem. Inspired by [18], Kang, Liu and Tang [23] considered the problem (1.3) in non-radial symmetric space $H^1(\mathbb{R}^2)$. By combining the Nehari manifold, Moser iteration and some analytical skills, they got a positive ground state solution to (1.3), which is classical and spherically symmetric.

D'Avenia and Siciliano [11] explored the following nonlinear Schrödinger–Bopp–Podolsky system

$$\begin{cases} -\Delta u + \omega u + q^2\tilde{\phi}u = |u|^{p-2}u & \text{in } \mathbb{R}^3, \\ -\Delta\tilde{\phi} + a^2\Delta^2\tilde{\phi} = 4\pi u^2 & \text{in } \mathbb{R}^3, \end{cases}$$

where $u, \tilde{\phi} : \mathbb{R}^3 \to \mathbb{R}$, a, $\omega > 0$, $p > 0$ and $q \neq 0$. Depending on the two parameters q and p, the authors established both existence and nonexistence results using variational methods. Moreover, they demonstrated that these solutions converge to those of the classical Schrödinger–Poisson–Slater system as $a \to 0$ in the radial case. However, as far as we know, there is scarcely any literature dedicated to studying the existence of solutions for the SPB system (1.1).

Alternatively, it is of great interest to study solutions to system (1.1) having prescribed L^2-norm. Namely, for any given mass $a > 0$, we consider solutions to system (1.1) under the L^2-norm constraint

$$S_a := \left\{u \in H^1(\mathbb{R}^3) : \|u\|_2 = a\right\}, \tag{1.4}$$

which is called the fixed mass problem. Such solutions are often referred to as the normalized solutions for the following system which is given by

$$\begin{cases} -\Delta u + \lambda u + \phi u = |u|^{p-2}u & \text{in } \mathbb{R}^3, \\ -\Delta\phi + \kappa^2\phi = 4\pi u^2 & \text{in } \mathbb{R}^3, \\ \|u\|_2 = a, \end{cases} \tag{1.5}$$

and the frequency $\lambda \in \mathbb{R}$ cannot be fixed any longer and appears as a Lagrange multiplier.

For the sake of simplicity, by applying the reduction argument introduced in [11,23], we simplify the system (1.5) to the following nonlocal equation with the constraint S_a

$$-\Delta u + \lambda u + \phi_u u = |u|^{p-2} u \quad \text{in } \mathbb{R}^3, \tag{1.6}$$

where $\phi_u := \phi \in H^1(\mathbb{R}^3)$ uniquely solves

$$-\Delta \phi + \kappa^2 \phi = 4\pi u^2 \quad \text{in } \mathbb{R}^3$$

(see Section 2.3). Therefore, for given $a > 0$, to search for the coupled solution (u, ϕ, λ) of system (1.5) is equivalent to find the solution pair (u, λ) of (1.6) under the constraint S_a, where $\|u\|_2 = a$ and $\phi_u = \phi$ in (1.6). In this case, the normalized solution u of (1.6) can be obtained as a critical point of the constrained functional $I|_{S_a}$, which is given by

$$\begin{aligned} I(u) &:= \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3} \phi_u u^2 \mathrm{d}x - \frac{1}{p}\|u\|_p^p \\ &= \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{e^{-\kappa|x-y|}}{|x-y|} u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{1}{p}\|u\|_p^p, \end{aligned} \tag{1.7}$$

and λ is the corresponding Lagrange multiplier.

We deduce that $\bar{p} := \frac{10}{3}$ is the mass critical exponent and $2^* = 6$ is the Sobolev critical exponent for $I|_{S_a}$ by scaling argument and the Gagliardo–Nirenberg inequality (see Lemma 2.1). For further clarification, we agree that the mass subcritical case, mass critical case and mass supercritical case mean that $2 < p < \frac{10}{3}$, $p = \bar{p} = \frac{10}{3}$ and $\frac{10}{3} < p < 6$, respectively.

When $2 < p < \frac{10}{3}$, namely, the mass subcritical case, it holds that the constrained functional $I|_{S_a}$ is coercive and bounded from below (see Lemma 2.10). This leads to the following global minimization problem

$$I_{a^2} := \inf_{u \in S_a} I(u). \tag{1.8}$$

In particular, if $(u, \phi, \lambda) \in S_a \times H^1(\mathbb{R}^3) \times \mathbb{R}$ is a coupled solution to system (1.5) such that $I(u) = I_{a^2}$, then $u \in S_a$ is the ground state normalized solution of (1.5).

The first study on normalized solutions to the Schrödinger–Poisson–Slater system was conducted by Sánchez and Soler [33], who established the foundational framework for this problem. Specifically, they studied the following system in $\mathbb{R}^3$

$$\begin{cases} -\frac{1}{2}\Delta u + Vu - C_S |u|^{\frac{2}{3}} u = \beta u \qquad \lim_{|x|\to\infty} u(x) = 0, \\ -\Delta V = u^2 \qquad \lim_{|x|\to\infty} V(x) = 0, \\ \|u\|_2 = M > 0, \end{cases}$$

where $V := \frac{1}{4\pi|x|} * u^2 \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ and C_S denotes the Slater constant. The corresponding energy functional is

$$E(u) := \frac{1}{2}\|\nabla u\|_2^2 + \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{1}{8\pi|x-y|} u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{3C_S}{4}\|u\|_{\frac{8}{3}}^{\frac{8}{3}}.$$

By applying the concentration-compactness argument in [28,29] and nonzero weak convergence after translations in [26], they proved that when $M > 0$ is sufficiently small, all the minimizing sequences for I_M are compact, where

$$I_M := \inf\left\{E(u) : u \in H^1(\mathbb{R}^3), \|u\|_2 = M\right\}.$$

Kikuchi [24] proved that if C_S is sufficiently large, then the infimum of the minimization problem $I(\mu) := \inf\left\{\mathcal{E}(v) : v \in H^1(\mathbb{R}^3), \|u\|_2^2 = \mu\right\}$ is achieved for any $\mu > 0$, where

$$\mathcal{E}(v) := \frac{1}{2}\|\nabla v\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}v^2(x)v^2(y)\mathrm{d}x\mathrm{d}y - \frac{C_S}{3}\|v\|_3^3.$$

More generally, Bellazzini and Siciliano [6, 7] explored the following Schrödinger–Poisson equation

$$-\Delta u + \varphi u - |u|^{p-2}u = \omega u \quad \text{in } \mathbb{R}^3, \tag{1.9}$$

where $\omega \in \mathbb{R}$, $p \in \left(2, \frac{10}{3}\right)\setminus\{3\}$ and $\varphi := \frac{1}{|x|} * u^2$ satisfying $-\Delta\varphi = 4\pi u^2$. They considered the following minimization problem

$$\mathcal{I}_\rho := \inf_{u\in B_\rho}\mathcal{I}(u), \tag{1.10}$$

where

$$\mathcal{I}(u) := \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{1}{p}\|u\|_p^p$$

and

$$B_\rho := \left\{u \in H^1(\mathbb{R}^3) : \|u\|_2 = \rho\right\},$$

and they proved that $\mathcal{I}_\rho$ admits a minimizer when either $3 < p < \frac{10}{3}$ and $\rho > 0$ is large enough, or $2 < p < 3$ and $\rho > 0$ is sufficiently small. Subsequently, Georgiev, Prinari and Visciglia [13] studied the radial symmetry of the minimizers of problem (1.10) up to translation provided that $2 < p < 3$ and $\rho > 0$ is sufficiently small. When $p \in [3, \frac{10}{3}]$, Jeanjean and Luo [22] specified a threshold value of $\rho > 0$ that separates the existence and nonexistence of minimizers for the minimization problem (1.10).

Based on the above research results, by applying minimizing method, He, Li and Chen [17] considered the following nonlinear Schrödinger–Bopp–Podolsky system with prescribed mass

$$\begin{cases} -\Delta u + \omega u + \tilde{\phi}u = |u|^{p-2}u & \text{in } \mathbb{R}^3, \\ -\Delta\tilde{\phi} + a^2\Delta^2\tilde{\phi} = 4\pi u^2 & \text{in } \mathbb{R}^3, \\ \|u\|_2 = \rho > 0, \end{cases} \tag{1.11}$$

where $\omega > 0$, $a > 0$, $p \in (2, \frac{10}{3})$ and $\tilde{\phi} := \frac{1-e^{-|x|/a}}{|x|} * u^2$. When $a = 1$, they respectively proved the existence of positive normalized solutions of system (1.11) when $2 < p < 3$ and ρ is sufficiently small, as well as when $3 < p < \frac{10}{3}$ and $\rho > 0$ is sufficiently large. Applying critical point theory, minimization method and some ideas borrowed from [6, 7, 13], de Paula Ramos and Siciliano [12] proved that when $p \in (2, \frac{10}{3})\setminus\{3\}$ and $a > 0$ is a parameter, system (1.11) has a ground state normalized solution. Meanwhile, under the assumptions that $p \in (2, \frac{14}{5})$ and $\rho > 0$ is sufficiently small, they demonstrated that the ground state normalized solution is radially symmetric up to translation, and these solutions converge to a ground state normalized solution of the Schrödinger–Poisson–Slater system as $a \to 0$.

In the light of [11] and [12], Hernandez and Siciliano [20] studied the existence and multiplicity of solutions for the following Schrödinger–Bopp–Podolsky system under an L^2-norm constraint

$$\begin{cases} -\Delta u + \tilde{\phi}u = \omega u & \text{in } \Omega, \\ -\Delta\tilde{\phi} + a^2\Delta^2\tilde{\phi} = u^2 & \text{in } \Omega, \\ u = \tilde{\phi} = \Delta\tilde{\phi} = 0 & \text{on } \partial\Omega, \\ \int_\Omega u^2\mathrm{d}x = 1, \end{cases}$$

where Ω is an open bounded and smooth domain in $\mathbb{R}^3$, and $a > 0$ is the Bopp–Podolsky parameter. The unknowns are $u, \tilde{\phi} : \Omega \to \mathbb{R}$ and $\omega \in \mathbb{R}$. By applying variational methods and topological invariants from Ljusternik–Schnirelmann theory in the critical point theory, they established that for any $a > 0$, there exist infinitely many nontrivial solutions with diverging energy and norm-divergent behavior. Moreover, they also showed that the ground state solutions of the above system converge to a ground state solution of the corresponding Schrödinger–Poisson system under the same L^2-norm constraint as $a \to 0$.

Motivated by [17] and [12], Li and Zhang [25] proved the existence, asymptotic behavior and the multiplicity of normalized solutions for the following Schrödinger–Bopp–Podolsky system with a critical term

$$\begin{cases} -\Delta u + \tilde{\phi} u = \lambda u + \mu |u|^{p-2} u + u^5 & \text{in } \mathbb{R}^3, \\ -\Delta \tilde{\phi} + \Delta^2 \tilde{\phi} = 4\pi u^2 & \text{in } \mathbb{R}^3, \\ \|u\|_2^2 = m^2 > 0, \end{cases} \tag{1.12}$$

where $\lambda \in \mathbb{R}$, $2 < p < 6$ and $\mu > 0$ is a parameter. For $p \in (\frac{10}{3}, 6)$, by applying Lagrange multipliers argument and Mountain-Pass theorem, they obtained the existence and asymptotic behavior of positive normalized ground state solutions for (1.12). For $p \in (2, \frac{10}{3}]$, they proved the existence of a normalized ground state solution to (1.12) by combining Mountain-Pass theorem with Lebesgue dominated convergence theorem. Moreover, they also verified the multiplicity of normalized solutions to (1.12).

When $\frac{10}{3} < p < 6$, that is, the mass supercritical case, and the minimizing method becomes inapplicable since the constrained functional $I|_{S_a}$ is unbounded from below, that is, $I_{a^2} = -\infty$. Therefore, by applying a Mountain-Pass argument, Bellazzini, Jeanjean and Luo [8] proved that for any $\rho > 0$ sufficiently small, there exist critical points of the constrained functional $\mathcal{I}|_{B_\rho}$ of the Schrödinger–Poisson equation (1.9).

However, when $p = \frac{10}{3}$, that is, the mass critical case, it becomes delicate to say that $I_{a^2} > -\infty$ or $I_{a^2} = -\infty$ since it depends on the range of value of $a > 0$.

Therefore, the purpose of this paper is to consider the existence and limit behavior of the ground state normalized solutions for system (1.5). As far as we know, no relevant results can be found in the existing literature. Next, we state our main results as follows.

Theorem 1.1. *Suppose that $p \in (2, 3)$ and $a, \kappa > 0$. Then there exists $a_0 > 0$, such that for any $a \in (0, a_0)$, system (1.5) admits a ground state normalized solution $(u, \phi_u, \lambda) \in H^1(\mathbb{R}^3) \times H^1(\mathbb{R}^3) \times (0, \infty)$ with $u > 0$ in $\mathbb{R}^3$.*

Theorem 1.2. *Suppose that $p \in (3, \frac{10}{3})$ and $a, \kappa > 0$. Then there exists $a_1 > 0$, such that for any $a \in (a_1, \infty)$, system (1.5) admits a ground state normalized solution $(u, \phi_u, \lambda) \in H^1(\mathbb{R}^3) \times H^1(\mathbb{R}^3) \times (0, \infty)$ with $u > 0$ in $\mathbb{R}^3$.*

Let $S_a^r := S_a \cap H_r^1(\mathbb{R}^3)$. Then, the following theorem reveals the radial symmetry of the ground state normalized solutions for system (1.5) when $p \in (2, 3)$ and $a > 0$ is sufficiently small.

Theorem 1.3. *Suppose that $p \in (2, 3)$, $\kappa > 0$ and $a_0 > 0$ is obtained in Theorem 1.1. Let $(u, \phi_u, \lambda) \in S_a \times H^1(\mathbb{R}^3) \times (0, \infty)$ be a ground state normalized solution to system (1.5) with $u > 0$. Then there exists $a_2 \in (0, a_0]$ such that up to translation, $(u, \phi_u, \lambda) \in S_a^r \times H_r^1(\mathbb{R}^3) \times (0, \infty)$ for any $a \in (0, a_2)$.*

Our final result concerns the limit behavior of the ground state normalized solutions $(u_\kappa, \phi_\kappa, \lambda_\kappa)$ to system (1.5) as $\kappa \to 0$. For this purpose, we introduce the following Schrödinger–Poisson–Slater system

$$\begin{cases} -\Delta u + \lambda u + \varphi u = |u|^{p-2}u & \text{in } \mathbb{R}^3, \\ -\Delta \varphi = 4\pi u^2 & \text{in } \mathbb{R}^3, \\ \|u\|_2 = a, \end{cases} \tag{1.13}$$

where $\varphi := \frac{1}{|x|} * u^2 \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ and the corresponding energy functional is

$$\mathcal{J}_0(u) := \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{1}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{1}{p}\|u\|_p^p. \tag{1.14}$$

Theorem 1.4. *Suppose that $p \in (2,3)$, $\kappa > 0$ and $a_2 > 0$ is obtained in Theorem 1.3. Let $\{(u_\kappa, \phi_\kappa, \lambda_\kappa)\} \subset S_a \times H^1(\mathbb{R}^3) \times (0,\infty)$ be a set of ground state normalized solutions to system (1.5) with $u_\kappa > 0$. Then when $a \in (0, a_2)$ is small enough, the Schrödinger–Poisson–Slater system (1.13) admits a ground state normalized solution $(u_0, \varphi_0, \lambda_0) \in S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times (0,\infty)$ such that, up to a subsequence and up to translation, the following holds*

$$(u_\kappa, \phi_\kappa, \lambda_\kappa) \to (u_0, \varphi_0, \lambda_0) \quad \text{in } S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times (0,\infty) \quad \text{as } \kappa \to 0. \tag{1.15}$$

1.3 Comments on the Theorems 1.1–1.4

- The proofs of Theorems 1.1 and 1.2 adopt the following approach: if we could prove that the minimizing sequences for the constrained functional $I|_{S_a}$ are precompact, then we conclude that the infimum $I_{a^2} := \inf_{u\in S_a} I(u)$ is achieved. For this end, we apply the abstract framework for constrained minimization problems developed by Bellazzini and Siciliano [6,7]. Furthermore, since it is known that $\varphi := \frac{1}{|x|} * u^2 \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ uniquely solves $-\Delta\varphi = 4\pi u^2$ and $\tilde{\phi} := \frac{1-e^{-|x|/a}}{|x|} * u^2 \in \{\phi \in \mathcal{D}^{1,2}(\mathbb{R}^3) : \Delta\phi \in L^2(\mathbb{R}^3)\}$ uniquely solves $-\Delta\tilde{\phi} + a^2\Delta^2\tilde{\phi} = 4\pi u^2$ for any $u \in H^1(\mathbb{R}^3)$, through a detailed study of operator $-\Delta + \kappa^2$ in the second equation of the SPB system (1.5), we conclude that for any $u \in H^1(\mathbb{R}^3)$, there exists a unique $\phi_u := \frac{e^{-\kappa|x|}}{|x|} * u^2 \in H^1(\mathbb{R}^3)$ satisfying $-\Delta\phi + \kappa^2\phi = 4\pi u^2$. Notably, according to Sections 2.4 and 2.5, by applying the regularity of solutions and the Pohožaev identity of system (1.5) which is obviously different from that of the Schrödinger–Poisson–Slater system (1.13), we further deduce that the ground state normalized solution u and the corresponding Lagrange multiplier λ of system (1.5) are positive, which is a novelty compared with [6,7,12].

- The proof of Theorem 1.3 follows from making small adjustments to the implicit function argument proposed by Georgiev, Prinari and Visciglia [13]. We remark that the argument rests on the study of the behavior of ground state normalized solutions under an appropriate scaling (see Section 3.3). To some extent, this scaling permits one to explore the asymptotic behavior of ground state normalized solutions to Schrödinger–Poisson–Slater system (1.13) as $a \to 0$ by means of solutions to the following semilinear partial differential equation

$$-\Delta u + \omega_0 u = |u|^{p-2}u \quad \text{in } \mathbb{R}^3,$$

where $\omega_0 > 0$ is a certain constant. Through further calculations in this paper, we demonstrate that the range of p can be extended from $(2, \frac{14}{5})$ to $(2,3)$. Therefore, when

$2 < p < 3$ and $a > 0$ is small enough, by applying the above argument, we obtain the radial symmetry of the ground state normalized solutions to system (1.5), which extends the result in [12, Theorem C].

- The proof of Theorem 1.4 is inspired by the results presented in [11, Theorem 1.3], [12, Theorem D] and [20, Theorem 1.3]. Based on Theorem 1.3 and the Sobolev embedding $H_r^1(\mathbb{R}^3) \hookrightarrow \mathcal{D}_r^{1,2}(\mathbb{R}^3)$, we conclude that the set of ground state normalized solutions $\{(u_\kappa, \phi_\kappa, \lambda_\kappa)\}$ is a subset of $S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times (0,\infty)$. Moreover, by applying Lemmas 3.6, 3.7, Proposition 3.8 and the Sobolev embedding $H_r^1(\mathbb{R}^3) \hookrightarrow\hookrightarrow L^p(\mathbb{R}^3)$ with $p \in (2,6)$, we get the limit behavior of radially symmetric ground state normalized solutions to system (1.5) as $\kappa \to 0$. In conclusion, our findings supplement and extend the results presented in [6,7,12,20].

This paper is organized as follows. In Section 1, we state the main results and make some comments on the proofs of Theorems 1.1–1.4. In section 2, we introduce some preliminary results, which are crucial to our subsequent arguments. Specifically, in Section 2.2, we establish some properties of operator $-\Delta + \kappa^2$, which play a crucial role in our subsequent analysis. Sections 2.3, 2.4 and 2.5 aim at exploring the energy functional, the regularity of solutions, and the Pohožaev identity respectively. Moreover, in Section 2.6, we present some lemmas and propositions for the constrained minimization problem (1.8) developed by Bellazzini and Siciliano [6,7]. Finally, Sections 3.1–3.4 are dedicated to proving Theorems 1.1–1.4 respectively.

We now introduce some notations which will be used in the sequel. Let $H^1(\mathbb{R}^3)$ be the usual Sobolev space endowed with the standard inner product and norm $\|\cdot\|_{H^1}$. $H_r^1(\mathbb{R}^3)$ denotes the usual radially symmetric space. $L^p(\mathbb{R}^3)$ denotes the usual Lebesgue space with the norm $\|\cdot\|_p$ for $1 \le p \le \infty$. $\mathcal{D}^{1,2}(\mathbb{R}^3)$ denotes the Sobolev space defined as the completion of $C_c^\infty(\mathbb{R}^3)$ with respect to the norm $\|\cdot\|_{\mathcal{D}^{1,2}} := \|\nabla \cdot\|_2$. For any $\rho > 0$ and $x \in \mathbb{R}^3$, $B_\rho(x)$ denotes the ball of radius ρ centered at x. As usual, C and C_i $(i = 1,2,3\dots)$ denote various positive constants that may change from line to line but are not essential for the analysis of the problem.

2 Preliminaries

2.1 Some important inequalities

Lemma 2.1 ([35]). *Let $2^* := \frac{2N}{N-2}$, for any $N \ge 3$ and $p \in [2, 2^*)$, there exists a constant $C_{N,p}$ depending on N, p such that the following well-known Gagliardo–Nirenberg inequality holds*

$$\|u\|_{L^p(\mathbb{R}^N)}^p \le C_{N,p}^p \|\nabla u\|_{L^2(\mathbb{R}^N)}^{p\gamma_p} \|u\|_{L^2(\mathbb{R}^N)}^{p-p\gamma_p} \quad \forall u \in H^1(\mathbb{R}^N),$$

where $\gamma_p := \frac{N(p-2)}{2p}$. In particular, when $p = 2^*$, the following Sobolev inequality holds

$$\mathcal{S} \|u\|_{L^{2^*}(\mathbb{R}^N)}^2 \le \|\nabla u\|_{L^2(\mathbb{R}^N)}^2 \quad \forall u \in \mathcal{D}^{1,2}(\mathbb{R}^N),\ N \ge 3,$$

where the constant $\mathcal{S}$ is called the best Sobolev constant.

Lemma 2.2 (Hardy–Littlewood–Sobolev inequality [26]). *Let $p, r > 1$ and $0 < \lambda < N$ with $\frac{1}{p} + \frac{\lambda}{N} + \frac{1}{r} = 2$, and for any $f \in L^p(\mathbb{R}^N)$ and $g \in L^r(\mathbb{R}^N)$, there exists a sharp constant $C_{N,\lambda,p,r}$ such that*

$$\left| \int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{f(x)g(y)}{|x-y|^\lambda} dxdy \right| \le C_{N,\lambda,p,r} \|f\|_p \|g\|_r .$$

Lemma 2.3 ([19,37]). *Let $\alpha \in (0, N)$, the Riesz potential operator J_α of order α (also referred to as the fractional integral operator) is defined by*

$$J_\alpha(f)(x) := \int_{\mathbb{R}^N} \frac{f(y)}{|x-y|^{N-\alpha}} \mathrm{d}y, \qquad x \in \mathbb{R}^N.$$

When $1 < p < \frac{N}{\alpha}$ and $\frac{1}{q} = \frac{1}{p} - \frac{\alpha}{N}$, there exists a constant $C_{N,\alpha}$ such that $\|J_\alpha(f)\|_q \le C_{N,\alpha} \|f\|_p$ for any $f \in L^p(\mathbb{R}^N)$.

2.2 The operator $-\Delta + \kappa^2$

In the field of electrostatics, by the Gauss's law (or Poisson equation), for a given charge-density distribution ρ in $\mathbb{R}^3$, the electrostatic potential ϕ satisfies $-\Delta\phi = \rho$. If $\rho = 4\pi\delta_y$ with $y \in \mathbb{R}^3$, where δ_y denotes Dirac's delta measure at y, then it is known that the fundamental solution of $-\Delta\phi = 4\pi\delta_y$ (or Green's function for $-\Delta$) is $G(x-y)$, where $G(x) := \frac{1}{|x|}$ (see [26, Theorem 6.20]). Particularly, for the following Poisson–Boltzmann equation

$$-\Delta\phi + \kappa^2 \sinh(\phi) = \rho \quad \text{in } \mathbb{R}^3, \tag{2.1}$$

where ϕ, κ and ρ are consistent with those in the previous text. According to Section 1.1, when the surface potential ϕ is small enough, (2.1) can be linearized by the following equation

$$-\Delta\phi + \kappa^2\phi = \rho \quad \text{in } \mathbb{R}^3.$$

In particular, when $\kappa > 0$ and $\rho = 4\pi\delta_y$, we find that $G^\kappa(x-y)$ is the fundamental solution of the following equation

$$-\Delta\phi + \kappa^2\phi = 4\pi\delta_y \quad \text{in } \mathbb{R}^3,$$

where

$$G^\kappa(x) := \frac{e^{-\kappa|x|}}{|x|}. \tag{2.2}$$

Namely, G^κ is the Green's function for $-\Delta + \kappa^2$ (see [2, Table 10.1]), which is also referred to as the Yukawa potential in three dimension (see [26, Theorem 6.23]).

Lemma 2.4. *For any $\kappa > 0$, we have $G^\kappa \in L^p(\mathbb{R}^3)$ with $1 \le p < 3$, and $\nabla G^\kappa \in L^1(\mathbb{R}^3)$. Moreover, in the sense of distributions, there holds*

$$-\Delta G^\kappa(x-y) + \kappa^2 G^\kappa(x-y) = 4\pi\delta_y, \tag{2.3}$$

where δ_y denotes Dirac's delta measure at y (often written as $\delta(x-y)$).

Proof. By applying spherical coordinate transformation and variable substitution, we deduce from (2.2) that

$$\begin{aligned}\|G^\kappa\|_p^p &= \int_{\mathbb{R}^3} \frac{e^{-\kappa p|x|}}{|x|^p} \mathrm{d}x = 4\pi \int_0^\infty r^{2-p} e^{-\kappa p r} \mathrm{d}r = \frac{4\pi}{(\kappa p)^{3-p}} \int_0^\infty y^{(3-p)-1} e^{-y} \mathrm{d}y \\ &= \frac{4\pi}{(\kappa p)^{3-p}} \Gamma(3-p),\end{aligned}$$

where $\Gamma(s)$ represents the Gamma function and thus we obtain that $1 \le p < 3$. Since

$$\frac{\partial G^\kappa}{\partial x_i} = -\left(\frac{\kappa x_i}{|x|^2} + \frac{x_i}{|x|^3}\right) e^{-\kappa|x|},\ i = 1,2,3 \quad \text{and} \quad \nabla G^\kappa = -\left(\frac{\kappa x}{|x|^2} + \frac{x}{|x|^3}\right) e^{-\kappa|x|}, \tag{2.4}$$

it follows from spherical coordinate transformation and integration by parts that

$$\int_{\mathbb{R}^3} |\nabla G^\kappa| \, \mathrm{d}x = \int_{\mathbb{R}^3} \left| -\left(\frac{\kappa x}{|x|^2} + \frac{x}{|x|^3} \right) \right| e^{-\kappa|x|} \mathrm{d}x \leq \int_{\mathbb{R}^3} \frac{\kappa e^{-\kappa|x|}}{|x|} \mathrm{d}x + \int_{\mathbb{R}^3} \frac{e^{-\kappa|x|}}{|x|^2} \mathrm{d}x = \frac{8\pi}{\kappa} < \infty.$$

To sum up, for any $\kappa > 0$, $G^\kappa \in L^p(\mathbb{R}^3)$ with $1 \leq p < 3$ and $\nabla G^\kappa \in L^1(\mathbb{R}^3)$.

Next, from [26, Theorem 6.20] or [11, Lemma 3.3], in order to prove (2.3), let $y = 0$ and then we need to show that for any $\psi \in C_c^\infty(\mathbb{R}^3)$, it holds that

$$-\int_{\mathbb{R}^3} G^\kappa(x-0)\Delta\psi \mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} G^\kappa(x-0)\psi \mathrm{d}x = 4\pi\psi(0). \tag{2.5}$$

Since $G^\kappa \in L^1_{\mathrm{loc}}(\mathbb{R}^3)$, it suffices to show that

$$\lim_{r\to 0^+} I(r) = 4\pi\psi(0), \tag{2.6}$$

where

$$I(r) := -\int_{|x|>r} G^\kappa(x-0)\Delta\psi \, \mathrm{d}x + \kappa^2 \int_{|x|>r} G^\kappa(x-0)\psi \, \mathrm{d}x.$$

Since ψ has compact support, we consider the annulus $A := \{x \in \mathbb{R}^3 : r < |x| < R\}$ for R large enough. Since $-\Delta G^\kappa + \kappa^2 G^\kappa = 0$ in A, by applying a standard integration by parts, we have

$$\begin{aligned}
I(r) &= -\int_A G^\kappa \Delta\psi \, \mathrm{d}x + \kappa^2 \int_A G^\kappa \psi \, \mathrm{d}x \\
&= \int_A \nabla G^\kappa \nabla\psi \, \mathrm{d}x - \int_{|x|=r} G^\kappa \nabla\psi \cdot \nu \, \mathrm{d}\mathbf{S} + \kappa^2 \int_A G^\kappa \psi \, \mathrm{d}x \\
&= -\int_A \psi \Delta G^\kappa \, \mathrm{d}x + \int_{|x|=r} \psi \nabla G^\kappa \cdot \nu \, \mathrm{d}\mathbf{S} - \int_{|x|=r} G^\kappa \nabla\psi \cdot \nu \, \mathrm{d}\mathbf{S} + \kappa^2 \int_A G^\kappa \psi \, \mathrm{d}x \\
&= \int_A \psi \left(-\Delta G^\kappa + \kappa^2 G^\kappa \right) \mathrm{d}x + \int_{|x|=r} \psi \nabla G^\kappa \cdot \nu \, \mathrm{d}\mathbf{S} - \int_{|x|=r} G^\kappa \nabla\psi \cdot \nu \, \mathrm{d}\mathbf{S} \\
&= \int_{|x|=r} \psi \nabla G^\kappa \cdot \nu \, \mathrm{d}\mathbf{S} - \int_{|x|=r} G^\kappa \nabla\psi \cdot \nu \, \mathrm{d}\mathbf{S} := I_1(r) - I_2(r),
\end{aligned}$$

where ν is the unit outward normal to A and $\mathbf{S}$ is the unit sphere in $\mathbb{R}^3$. When considering $I_1(r)$ on the sphere $|x| = r$, it follows from (2.4) that $\nabla G^\kappa \cdot \nu = \frac{\kappa r+1}{r^2} e^{-\kappa r}$. Since ψ is continuous, we get

$$I_1(r) = \int_{|x|=r} \psi \nabla G^\kappa \cdot \nu \, \mathrm{d}\mathbf{S} = \int_{\mathbf{S}_1} \psi(r\sigma)(\kappa r + 1) e^{-\kappa r} \, \mathrm{d}\sigma \to 4\pi\psi(0) \quad \text{as } r \to 0^+,$$

where σ represents a unit vector on the unit sphere surface $\mathbf{S}_1$.

As for $I_2(r)$, since ψ has compact support, there exists some constant $C_1 > 0$ such that $|\nabla\psi \cdot \nu| \leq C_1$. Moreover, $\left| |x|^2 G^\kappa \right| < |x|^{\frac{1}{2}}$ when $|x|$ is small enough. Thus,

$$|I_2(r)| = \left| \int_{|x|=r} G^\kappa \nabla\psi \cdot \nu \, \mathrm{d}\mathbf{S} \right| \leq \int_{|x|=r} |G^\kappa| \, |\nabla\psi \cdot \nu| \, \mathrm{d}\mathbf{S} \leq 4\pi C_1 r^{\frac{1}{2}} \to 0 \quad \text{as } r \to 0^+.$$

Namely, (2.6) has been verified and then (2.3) holds. □

Lemma 2.5. *For any $\kappa > 0$, if $G^\kappa, \nabla G^\kappa \in L^1(\mathbb{R}^3)$ and $f \in L^p(\mathbb{R}^3)$ with $1 \leq p \leq \infty$, the following conclusions hold:*

(i) The function $y \mapsto G^\kappa(x-y)f(y)$ is integrable on $\mathbb{R}^3$. Moreover, let

$$\phi(x) := (G^\kappa * f)(x) = \int_{\mathbb{R}^3} \frac{e^{-\kappa|x-y|}}{|x-y|} f(y)\,\mathrm{d}y. \tag{2.7}$$

Then for any $1 \le p \le \infty$, there holds

$$\phi \in L^p(\mathbb{R}^3) \quad \text{and} \quad \|\phi\|_p = \|G^\kappa * f\|_p \le \|G^\kappa\|_1 \|f\|_p.$$

(ii) In the sense of distributions, ϕ solves

$$-\Delta\phi + \kappa^2\phi = 4\pi f \qquad \text{in } \mathcal{D}'(\mathbb{R}^3), \tag{2.8}$$

where $\mathcal{D}'(\mathbb{R}^3)$ denotes the dual space of $C_c^\infty(\mathbb{R}^3)$. Moreover, ϕ has a distributional derivative, which is given by

$$\partial_i\phi(x) = \int_{\mathbb{R}^3} \frac{\partial G^\kappa(x-y)}{\partial x_i} f(y)\,\mathrm{d}y, \quad i = 1,2,3, \tag{2.9}$$

and $\nabla\phi = \int_{\mathbb{R}^3} \nabla G^\kappa(x-y)f(y)\,\mathrm{d}y \in L^p(\mathbb{R}^3)$ with $1 \le p \le \infty$.

Proof. (i) For any $\kappa > 0$, it follows from Lemma 2.4 that $G^\kappa \in L^1(\mathbb{R}^3)$. Therefore, from [3, Theorem 4.15], it follows that (2.7) is well defined for almost everywhere $x \in \mathbb{R}^3$. Moreover, $\phi \in L^p(\mathbb{R}^3)$ and $\|\phi\|_p = \|G^\kappa * f\|_p \le \|G^\kappa\|_1 \|f\|_p$ with $1 \le p \le \infty$.

(ii) To verify (2.8), we need to show that for any $\psi \in C_c^\infty(\mathbb{R}^3)$, it holds that

$$-\int_{\mathbb{R}^3} \phi\Delta\psi\,\mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} \phi\psi\,\mathrm{d}x = 4\pi \int_{\mathbb{R}^3} f\psi\,\mathrm{d}x. \tag{2.10}$$

First, let $F(x,y) := G^\kappa(x-y)f(y)\Delta\psi(x)$. Since $G^\kappa \in L^1(\mathbb{R}^3)$, $f \in L^p(\mathbb{R}^3)$ with $1 \le p \le \infty$, and $\psi \in C_c^\infty(\mathbb{R}^3)$, we deduce that $F \in L^1\left(\mathbb{R}^3 \times \mathbb{R}^3\right)$. Next, by substituting (2.7) into the first integral of (2.10) and applying Fubini's theorem, we deduce that

$$-\int_{\mathbb{R}^3} \phi\Delta\psi\,\mathrm{d}x = \int_{\mathbb{R}^3} f(y) \left(-\int_{\mathbb{R}^3} G^\kappa(x-y)\Delta\psi(x)\,\mathrm{d}x \right) \mathrm{d}y. \tag{2.11}$$

It follows from (2.5) that

$$-\int_{\mathbb{R}^3} G^\kappa(x-y)\Delta\psi(x)\,\mathrm{d}x = -\kappa^2 \int_{\mathbb{R}^3} G^\kappa(x-y)\psi(x)\,\mathrm{d}x + 4\pi\psi(y). \tag{2.12}$$

By substituting (2.12) into (2.11), it follows that

$$-\int_{\mathbb{R}^3} \phi\Delta\psi\,\mathrm{d}x = -\kappa^2 \int_{\mathbb{R}^3} f(y) \left(\int_{\mathbb{R}^3} G^\kappa(x-y)\psi(x)\,\mathrm{d}x \right) \mathrm{d}y + 4\pi \int_{\mathbb{R}^3} f(y)\psi(y)\,\mathrm{d}y. \tag{2.13}$$

Next, substituting (2.7) into the second integral of (2.10) and applying Fubini's theorem once again, we have

$$\kappa^2 \int_{\mathbb{R}^3} \phi\psi\,\mathrm{d}x = \kappa^2 \int_{\mathbb{R}^3} f(y) \left(\int_{\mathbb{R}^3} G^\kappa(x-y)\psi(x)\,\mathrm{d}x \right) \mathrm{d}y. \tag{2.14}$$

Combining (2.13) and (2.14), we have

$$-\int_{\mathbb{R}^3} \phi\Delta\psi\,\mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} \phi\psi\,\mathrm{d}x = 4\pi \int_{\mathbb{R}^3} f(y)\psi(y)\,\mathrm{d}y = 4\pi \int_{\mathbb{R}^3} f\psi\,\mathrm{d}x,$$

thus, (2.10) holds, namely, (2.8) holds true.

To prove (2.9), we start from the definition of distributional derivative. For any test function $\psi \in C_c^\infty(\mathbb{R}^3)$, we have that the distributional derivative $\partial_i\phi(x)$ satisfies

$$\int_{\mathbb{R}^3} \partial_i\phi(x)\psi(x)\,\mathrm{d}x = -\int_{\mathbb{R}^3} \phi(x)\partial_i\psi(x)\,\mathrm{d}x, \qquad i = 1,2,3. \tag{2.15}$$

Since $G^\kappa \in L^1(\mathbb{R}^3)$ and $f \in L^p(\mathbb{R}^3)$ with $1 \le p \le \infty$, by substituting (2.7) into the right side of (2.15) and applying Fubini's theorem, it follows that

$$-\int_{\mathbb{R}^3} \phi(x)\partial_i\psi(x)\,\mathrm{d}x = -\int_{\mathbb{R}^3} f(y)\left(\int_{\mathbb{R}^3} G^\kappa(x-y)\partial_i\psi(x)\,\mathrm{d}x\right)\mathrm{d}y. \tag{2.16}$$

Thus, according to (2.16), by applying integration by parts to $\int_{\mathbb{R}^3} G^\kappa(x-y)\partial_i\psi(x)\,\mathrm{d}x$ and the fact that $G^\kappa(x-y)\psi(x)$ vanishes as x goes to infinity due to the compact support of ψ, we infer that

$$\int_{\mathbb{R}^3} G^\kappa(x-y)\partial_i\psi(x)\,\mathrm{d}x = -\int_{\mathbb{R}^3} \psi(x)\frac{\partial G^\kappa(x-y)}{\partial x_i}\,\mathrm{d}x,$$

and

$$-\int_{\mathbb{R}^3} \phi(x)\partial_i\psi(x)\,\mathrm{d}x = \int_{\mathbb{R}^3} f(y)\left(\int_{\mathbb{R}^3} \psi(x)\frac{\partial G^\kappa(x-y)}{\partial x_i}\,\mathrm{d}x\right)\mathrm{d}y.$$

Since $\nabla G^\kappa \in L^1(\mathbb{R}^3)$, we have $\frac{\partial G^\kappa(x-y)}{\partial x_i} \in L^1(\mathbb{R}^3)$. Then, it follows from Fubini's theorem and (2.15) that

$$\int_{\mathbb{R}^3} \partial_i\phi(x)\psi(x)\,\mathrm{d}x = -\int_{\mathbb{R}^3} \phi(x)\partial_i\psi(x)\,\mathrm{d}x = \int_{\mathbb{R}^3}\left(\int_{\mathbb{R}^3} \frac{\partial G^\kappa(x-y)}{\partial x_i} f(y)\,\mathrm{d}y\right)\psi(x)\mathrm{d}x,$$

which shows that

$$\partial_i\phi(x) = \int_{\mathbb{R}^3} \frac{\partial G^\kappa(x-y)}{\partial x_i} f(y)\,\mathrm{d}y,$$

namely, (2.9) holds true and this completes the proof. □

Lemma 2.6. *For any $u \in H^1(\mathbb{R}^3)$ and $\kappa > 0$, the following conclusions hold:*

(i) There exists a unique $\phi_u \in H^1(\mathbb{R}^3)$ solving the following equation

$$-\Delta\phi + \kappa^2\phi = 4\pi u^2 \tag{2.17}$$

in the weak sense. Moreover, there exists some constant $C > 0$ such that $\|\phi_u\|_{H^1} \le C\|u\|_{H^1}^2$.

(ii) Let $\Phi : H^1(\mathbb{R}^3) \to H^1(\mathbb{R}^3)$ be the mapping defined by $\Phi(u) := \phi_u$. Then Φ maps bounded sets into bounded sets. Moreover, Φ is continuous.

(iii) When $1 \le p \le 3$, it holds that

$$\phi_u := \left(G^\kappa * u^2\right)(x) = \int_{\mathbb{R}^3} \frac{e^{-\kappa|x-y|}}{|x-y|} u^2(y)\mathrm{d}y \in L^p(\mathbb{R}^3)$$

and

$$\nabla\phi_u := \left(\nabla G^\kappa * u^2\right)(x) = \int_{\mathbb{R}^3} \nabla G^\kappa(x-y)u^2(y)\mathrm{d}y \in L^p(\mathbb{R}^3).$$

Moreover, $\|\phi_u\|_2 \le C\|u\|_4^2$ and $\int_{\mathbb{R}^3} \phi_u u^2 \mathrm{d}x \le C\|u\|_4^4$.

(iv) *If $u \in H_r^1(\mathbb{R}^3)$, then $\phi_u \in H_r^1(\mathbb{R}^3)$. For any $\theta > 0$, $\phi_{\theta u} = \theta^2 \phi_u$ and $\phi_{u(\cdot+z)}(x) = \phi_u(x+z)$.*

(v) *If $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$ and $u_n \rightharpoonup u$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$, then, there exists a unique $\phi_u \in H^1(\mathbb{R}^3)$ solving (2.17) in the weak sense such that, up to a subsequence, $\phi_{u_n} \rightharpoonup \phi_u$ in $H^1(\mathbb{R}^3)$,*

$$\|\phi_{u_n}\|_2^2 = \|\phi_{u_n} - \phi_u\|_2^2 + \|\phi_u\|_2^2 + o_n(1)$$

and

$$\|\nabla\phi_{u_n}\|_2^2 = \|\nabla\phi_{u_n} - \nabla\phi_u\|_2^2 + \|\nabla\phi_u\|_2^2 + o_n(1).$$

Furthermore, for any $\psi \in H^1(\mathbb{R}^3)$, the following holds

$$\lim_{n\to\infty} \int_{\mathbb{R}^3} \phi_{u_n} u_n \psi \, \mathrm{d}x = \int_{\mathbb{R}^3} \phi_u u \psi \, \mathrm{d}x. \tag{2.18}$$

Proof. (i) For any given $u \in H^1(\mathbb{R}^3)$, define a linear functional $L_u(v) : H^1(\mathbb{R}^3) \to \mathbb{R}$ by

$$L_u(v) := 4\pi \int_{\mathbb{R}^3} u^2 v \, \mathrm{d}x.$$

Then, from the continuous Sobolev embedding $H^1(\mathbb{R}^3) \hookrightarrow L^4(\mathbb{R}^3)$, we have

$$|L_u(v)| = 4\pi \left| \int_{\mathbb{R}^3} u^2 v \, \mathrm{d}x \right| \le C \|u\|_4^2 \|v\|_2 \le C \|u\|_{H^1}^2 \|v\|_{H^1} < \infty.$$

Hence, $L_u(v)$ is continuous in $H^1(\mathbb{R}^3)$. Now we define the following inner product $\langle u, v\rangle$ on $H^1(\mathbb{R}^3)$

$$\langle u, v\rangle := \int_{\mathbb{R}^3} \nabla u \nabla v \, \mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} uv \, \mathrm{d}x.$$

Then, from Lemma 2.5 and the Riesz representation theorem, for every $v \in H^1(\mathbb{R}^3)$, there exists a unique $\phi_u \in H^1(\mathbb{R}^3)$ satisfying

$$\int_{\mathbb{R}^3} \nabla\phi_u \nabla v \, \mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} \phi_u v \, \mathrm{d}x = 4\pi \int_{\mathbb{R}^3} u^2 v \, \mathrm{d}x,$$

which exactly means that ϕ_u solves (2.17) in the weak sense. In particular, let $v = \phi_u$ in the above equation, from Hölder's inequality, Lemma 2.5-(i) and Sobolev embedding theorem, we have that

$$\|\nabla\phi_u\|_2^2 + \kappa^2 \|\phi_u\|_2^2 = 4\pi \int_{\mathbb{R}^3} \phi_u u^2 \, \mathrm{d}x \le 4\pi \|\phi_u\|_2 \left\|u^2\right\|_2 \le 4\pi \|G^\kappa\|_1 \|u\|_4^4 \le C \|u\|_{H^1}^4,$$

which implies that there exists some constant $C > 0$ such that $\|\phi_u\|_{H^1} \le C \|u\|_{H^1}^2$.

(ii) Let $\{u_n\}$ be any bounded sequence in $H^1(\mathbb{R}^3)$. Then there exists $M > 0$ such that for all $n \in \mathbb{N}^+$, it holds that $\|u_n\|_{H^1} \le M$. Thus, according to (i), we have $\|\Phi(u_n)\|_{H^1} = \|\phi_{u_n}\|_{H^1} \le CM^2$, namely, $\Phi : H^1(\mathbb{R}^3) \to H^1(\mathbb{R}^3)$ maps bounded sets into bounded sets.

Next, we claim that if $u_n \to u$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$, then $\Phi(u_n) \to \Phi(u)$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$. Indeed, according to (i), we conclude that both $\Phi(u_n) = \phi_{u_n} \in H^1(\mathbb{R}^3)$ and $\Phi(u) = \phi_u \in H^1(\mathbb{R}^3)$ solve (2.17) in the weak sense. Therefore, for any $v \in H^1(\mathbb{R}^3)$, it holds that

$$\int_{\mathbb{R}^3} \nabla\Phi(u_n) \nabla v \, \mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} \Phi(u_n) v \, \mathrm{d}x = 4\pi \int_{\mathbb{R}^3} u_n^2 v \, \mathrm{d}x$$

and

$$\int_{\mathbb{R}^3} \nabla\Phi(u) \nabla v \, \mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} \Phi(u) v \, \mathrm{d}x = 4\pi \int_{\mathbb{R}^3} u^2 v \, \mathrm{d}x.$$

Subtracting the above two equations, we deduce that

$$\int_{\mathbb{R}^3} (\nabla\Phi(u_n) - \nabla\Phi(u)) \nabla v \,\mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} (\Phi(u_n) - \Phi(u)) v \,\mathrm{d}x = 4\pi \int_{\mathbb{R}^3} \left(u_n^2 - u^2\right) v \,\mathrm{d}x.$$

Let $v = \Phi(u_n) - \Phi(u)$. Then we have

$$\begin{aligned} C \left\|\Phi(u_n) - \Phi(u)\right\|_{H^1}^2 &\leq \left\|\nabla \left(\Phi(u_n) - \Phi(u)\right)\right\|_2^2 + \kappa^2 \left\|\Phi(u_n) - \Phi(u)\right\|_2^2 \\ &= 4\pi \int_{\mathbb{R}^3} \left(u_n^2 - u^2\right) \left(\Phi(u_n) - \Phi(u)\right) \mathrm{d}x. \end{aligned}$$

Since $u_n \to u$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$ and $\Phi(u_n), \Phi(u) \in H^1(\mathbb{R}^3)$, from Hölder's inequality and Sobolev's embedding theorem, we infer that

$$\begin{aligned} &\left| \int_{\mathbb{R}^3} \left(u_n^2 - u^2\right) \left(\Phi(u_n) - \Phi(u)\right) \mathrm{d}x \right| \\ &\leq \int_{\mathbb{R}^3} |u_n + u| \, |u_n - u| \, |\Phi(u_n)| \,\mathrm{d}x + \int_{\mathbb{R}^3} |u_n + u| \, |u_n - u| \, |\Phi(u)| \,\mathrm{d}x \\ &\leq C \left\|u_n + u\right\|_4 \left\|u_n - u\right\|_4 \left\|\Phi(u_n)\right\|_2 + C \left\|u_n + u\right\|_4 \left\|u_n - u\right\|_4 \left\|\Phi(u)\right\|_2 \\ &\leq C \left\|u_n + u\right\|_4 \left\|u_n - u\right\|_{H^1} \left\|\Phi(u_n)\right\|_2 + C \left\|u_n + u\right\|_4 \left\|u_n - u\right\|_{H^1} \left\|\Phi(u)\right\|_2 \to 0 \end{aligned}$$

as $n \to \infty$. Then $\left\|\Phi(u_n) - \Phi(u)\right\|_{H^1}^2 \to 0$, namely, $\Phi(u_n) \to \Phi(u)$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$.

(iii) Fix $u \in H^1(\mathbb{R}^3)$, from Lemma 2.5 and conclusion (i), we have that $\phi_u, \nabla\phi_u \in L^p(\mathbb{R}^3)$ with $1 \leq p \leq 3$. Moreover, from Lemma 2.5-(i) and the fact that $\left\|G^\kappa\right\|_1 = \frac{4\pi}{\kappa^2}$, we deduce that

$$\left\|\phi_u\right\|_2 \leq \left\|G^\kappa\right\|_1 \left\|u^2\right\|_2 = \frac{4\pi}{\kappa^2} \left\|u\right\|_4^2 \leq C \left\|u\right\|_4^2.$$

Then, from Hölder's inequality, we have

$$\int_{\mathbb{R}^3} \phi_u u^2 \mathrm{d}x \leq \left\|\phi_u\right\|_2 \left\|u^2\right\|_2 \leq \frac{4\pi}{\kappa^2} \left\|u\right\|_4^4 \leq C \left\|u\right\|_4^4.$$

(iv) It is only necessary to check that if $u \in H_r^1(\mathbb{R}^3)$, then $\phi_u \in H_r^1(\mathbb{R}^3)$. Let $u \in H_r^1(\mathbb{R}^3)$, and let $O(3)$ denote the three-dimensional orthogonal group. Then for any $A \in O(3)$ and x, $y \in \mathbb{R}^3$, it holds that $|Ax| = |x|$ and $|Ax - Ay| = |x - y|$. Thus, we get that $\phi_u(Ax) = \phi_u(x)$ by applying a change of variable in the integrals.

(v) Since $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$ and $u_n \rightharpoonup u$ in $H^1(\mathbb{R}^3)$, then, up to a subsequence, $u_n \to u$ in $L_{\mathrm{loc}}^r(\mathbb{R}^3)$ with $r \in [1, 6)$ and $u_n(x) \to u(x)$ a.e. in $\mathbb{R}^3$ as $n \to \infty$. Since $\{\phi_{u_n}\}$ is bounded in $H^1(\mathbb{R}^3)$ from (ii), there exists $\bar{\phi}_u \in H^1(\mathbb{R}^3)$ such that, up to a subsequence, $\phi_{u_n} \rightharpoonup \bar{\phi}_u$ in $H^1(\mathbb{R}^3)$, $\phi_{u_n} \to \bar{\phi}_u$ in $L_{\mathrm{loc}}^r(\mathbb{R}^3)$ with $r \in [1, 6)$ and $\phi_{u_n} \to \bar{\phi}_u$ a.e. in $\mathbb{R}^3$. Next, we claim that $\bar{\phi}_u = \phi_u$. Indeed, for any $\psi \in C_c^\infty(\mathbb{R}^3)$, it holds that

$$\int_{\mathbb{R}^3} \nabla\phi_{u_n} \nabla\psi \,\mathrm{d}x + \kappa^2 \int_{\mathbb{R}^3} \phi_{u_n} \psi \,\mathrm{d}x = 4\pi \int_{\mathbb{R}^3} u_n^2 \psi \,\mathrm{d}x.$$

Since $\nabla\phi_{u_n} \rightharpoonup \nabla\bar{\phi}_u$ in $L^2(\mathbb{R}^3)$ and $\nabla\psi \in L^2(\mathbb{R}^3)$, we infer that

$$\int_{\mathbb{R}^3} \nabla\phi_{u_n} \nabla\psi \,\mathrm{d}x \to \int_{\mathbb{R}^3} \nabla\bar{\phi}_u \nabla\psi \,\mathrm{d}x.$$

From $\phi_{u_n} \to \bar{\phi}_u$, $u_n \to u$ in $L_{\mathrm{loc}}^r(\mathbb{R}^3)$ with $r \in [1, 6)$, $\psi \in C_c^\infty(\mathbb{R}^3)$ and Hölder's inequality, we have

$$\left| \int_{\mathbb{R}^3} \left(\phi_{u_n} - \bar{\phi}_u\right) \psi \,\mathrm{d}x \right| \leq \int_{\mathrm{supp}\,\psi} \left|\left(\phi_{u_n} - \bar{\phi}_u\right) \psi\right| \,\mathrm{d}x \leq \left\|\phi_{u_n} - \bar{\phi}_u\right\|_{L^2(\mathrm{supp}\,\psi)} \left\|\psi\right\|_2 \to 0$$

and

$$\begin{aligned}\left|\int_{\mathbb{R}^3}\left(u_n^2-u^2\right)\psi\,\mathrm{d}x\right| &\le \int_{\operatorname{supp}\psi}\left|\left(u_n^2-u^2\right)\psi\right|\,\mathrm{d}x\\ &\le \|u_n+u\|_{L^4(\operatorname{supp}\psi)}\,\|u_n-u\|_{L^4(\operatorname{supp}\psi)}\,\|\psi\|_2\to 0\end{aligned}$$

as $n\to\infty$. Therefore, it holds that

$$\int_{\mathbb{R}^3}\nabla\bar{\phi}_u\nabla\psi\,\mathrm{d}x+\kappa^2\int_{\mathbb{R}^3}\bar{\phi}_u\psi\,\mathrm{d}x=4\pi\int_{\mathbb{R}^3}u^2\psi\,\mathrm{d}x,$$

which implies that $\bar{\phi}_u$ solves (2.17) in the weak sense. By the uniqueness of the solution to (2.17) according to (i), we have $\bar{\phi}_u=\phi_u$. Thus, it follows from $\phi_u\in H^1(\mathbb{R}^3)$ that, up to a subsequence, $\phi_{u_n}\rightharpoonup\phi_u$ in $H^1(\mathbb{R}^3)$, $\phi_{u_n}\to\phi_u$ in $L^r_{\mathrm{loc}}(\mathbb{R}^3)$ with $r\in[1,6)$ and $\phi_{u_n}\to\phi_u$ a.e. in $\mathbb{R}^3$.

We claim that up to a subsequence, $\nabla\phi_{u_n}\to\nabla\phi_u$ a.e. in $\mathbb{R}^3$ as $n\to\infty$. Indeed, it follows from (iii) that

$$\nabla\phi_u=\int_{\mathbb{R}^3}\nabla G^\kappa(x-y)u^2(y)\mathrm{d}y.$$

Thus, from (2.4), we infer that

$$\begin{aligned}|\nabla\phi_{u_n}-\nabla\phi_u| &= \left|\int_{\mathbb{R}^3}\left(u_n^2(y)-u^2(y)\right)\nabla G^\kappa(x-y)\mathrm{d}y\right|\\ &\le \int_{\mathbb{R}^3}\left|u_n^2(y)-u^2(y)\right|\left|\kappa\frac{x-y}{|x-y|^2}+\frac{x-y}{|x-y|^3}\right|e^{-\kappa|x-y|}\mathrm{d}y\\ &\le \int_{\mathbb{R}^3}\left|u_n^2(y)-u^2(y)\right|\frac{\kappa e^{-\kappa|x-y|}}{|x-y|}\mathrm{d}y+\int_{\mathbb{R}^3}\left|u_n^2(y)-u^2(y)\right|\frac{e^{-\kappa|x-y|}}{|x-y|^2}\mathrm{d}y\\ &=: J_n^1+J_n^2.\end{aligned}$$

Let $R\ge 1$. By Hölder's inequality and the facts that $e^{-t}\le 1$ and $e^t\ge\frac{t^2}{2}$ for $t\ge 0$, we deduce that

$$\begin{aligned}J_n^1 &\le \|u_n+u\|_{L^4(B_R(x))}\,\|u_n-u\|_{L^4(B_R(x))}\left(\int_{|y-x|\le R}\frac{\kappa^2e^{-2\kappa|x-y|}}{|x-y|^2}\mathrm{d}y\right)^{\frac{1}{2}}\\ &\quad+\|u_n+u\|_{L^4(B_R^c(x))}\,\|u_n-u\|_{L^4(B_R^c(x))}\left(\int_{|y-x|\ge R}\frac{\kappa^2}{|x-y|^2e^{2\kappa|x-y|}}\mathrm{d}y\right)^{\frac{1}{2}}\\ &\le \|u_n+u\|_{L^4(\mathbb{R}^3)}\,\|u_n-u\|_{L^4(B_R(x))}\left(\int_{|y-x|\le R}\frac{\kappa^2}{|x-y|^2}\mathrm{d}y\right)^{\frac{1}{2}}\\ &\quad+\|u_n+u\|_{L^4(\mathbb{R}^3)}\,\|u_n-u\|_{L^4(B_R^c(x))}\left(\int_{|y-x|\ge R}\frac{1}{2\,|x-y|^4}\mathrm{d}y\right)^{\frac{1}{2}}\end{aligned}$$

and

$$
\begin{aligned}
J_n^2 &= \int_{|y-x|\le R} \left|u_n^2(y)-u^2(y)\right| \frac{e^{-\kappa|x-y|}}{|x-y|^2}\mathrm{d}y + \int_{|y-x|\ge R} \left|u_n^2(y)-u^2(y)\right| \frac{e^{-\kappa|x-y|}}{|x-y|^2}\mathrm{d}y \\
&\le \int_{|y-x|\le R} \frac{|u_n(y)+u(y)|}{|x-y|}\frac{|u_n(y)-u(y)|}{|x-y|}\mathrm{d}y \\
&\quad + \int_{|y-x|\ge R} |u_n(y)+u(y)|\,|u_n(y)-u(y)|\,\frac{e^{-\kappa|x-y|}}{|x-y|}\mathrm{d}y \\
&\le \left(\int_{|y-x|\le R} (|u_n(y)|+|u(y)|)^2\,\frac{1}{|x-y|^2}\mathrm{d}y\right)^{\frac{1}{2}} \left(\int_{|y-x|\le R} |u_n(y)-u(y)|^2\,\frac{1}{|x-y|^2}\mathrm{d}y\right)^{\frac{1}{2}} \\
&\quad + \|u_n+u\|_{L^4(B_R^c(x))}\,\|u_n-u\|_{L^4(B_R^c(x))} \left(\int_{|y-x|\ge R} \frac{1}{|x-y|^2\,e^{2\kappa|x-y|}}\mathrm{d}y\right)^{\frac{1}{2}} \\
&\le C(R)\left(\|u_n\|_{L^2(\mathbb{R}^3)}+\|u\|_{L^2(\mathbb{R}^3)}\right)\|u_n-u\|_{L^2(B_R(x))} \\
&\quad + \|u_n+u\|_{L^4(\mathbb{R}^3)}\,\|u_n-u\|_{L^4(B_R^c(x))} \left(\int_{|y-x|\ge R} \frac{1}{2\kappa^2\,|x-y|^4}\mathrm{d}y\right)^{\frac{1}{2}}.
\end{aligned}
$$

Fix R, then let $n\to\infty$, and subsequently let $R\to\infty$, since $u_n\to u$ in $L^r_{\mathrm{loc}}(\mathbb{R}^3)$ with $r\in[1,6)$, we conclude that both $J_n^1\to 0$ and $J_n^2\to 0$. Thus, $\nabla\phi_{u_n}\to\nabla\phi_u$ a.e. in $\mathbb{R}^3$ as $n\to\infty$. Since $\{\phi_{u_n}\}$ is bounded in $H^1(\mathbb{R}^3)$, $\phi_u\in H^1(\mathbb{R}^3)$ and $\phi_{u_n}\to\phi_u$ a.e. in $\mathbb{R}^3$ as $n\to\infty$, from Brezis–Lieb lemma ([36, Lemma 1.32]), we deduce that

$$
\|\phi_{u_n}\|_2^2 = \|\phi_{u_n}-\phi_u\|_2^2+\|\phi_u\|_2^2+o_n(1) \text{ and } \|\nabla\phi_{u_n}\|_2^2 = \|\nabla\phi_{u_n}-\nabla\phi_u\|_2^2+\|\nabla\phi_u\|_2^2+o_n(1).
$$

Finally, for any $\psi\in C_c^\infty(\mathbb{R}^3)$, we infer that

$$
\begin{aligned}
\left|\int_{\mathbb{R}^3}\left(\phi_{u_n}u_n\psi-\phi_u u\psi\right)\mathrm{d}x\right| &\le \int_{\mathbb{R}^3}\left|\left(\phi_{u_n}-\phi_u\right)u_n\psi\right|\mathrm{d}x+\int_{\mathbb{R}^3}\left|\phi_u\left(u_n-u\right)\psi\right|\mathrm{d}x \\
&\le \|\phi_{u_n}-\phi_u\|_{L^4(\operatorname{supp}\psi)}\,\|u_n\|_4\,\|\psi\|_2+\|\phi_u\|_2\,\|u_n-u\|_{L^4(\operatorname{supp}\psi)}\,\|\psi\|_4 \\
&\to 0
\end{aligned}
$$

as $n\to\infty$, namely, (2.18) holds since $C_c^\infty(\mathbb{R}^3)$ is dense in $H^1(\mathbb{R}^3)$. □

2.3 The functional setting

It is easy to see that the critical points (u,ϕ) of the C^1 functional

$$
F(u,\phi) := \frac{1}{2}\|\nabla u\|_2^2+\frac{1}{2}\int_{\mathbb{R}^3}\phi u^2\mathrm{d}x-\frac{1}{16\pi}\|\nabla\phi\|_2^2-\frac{\kappa^2}{16\pi}\|\phi\|_2^2-\frac{1}{p}\|u\|_p^p
$$

on $H^1(\mathbb{R}^3)\times H^1(\mathbb{R}^3)$ restricted to the sphere S_a are the weak solutions of system (1.5). Since the constrained functional $F|_{S_a}$ is strongly unbounded from below and above, the usual techniques of the critical point theory cannot be used directly. To deal with this issue, we shall reduce the functional F to another functional I depending on the single variable u, following a procedure introduced by Benci and Fortunato in [5] for this kind of problem.

From Lemma 2.6, we find that system (1.5) can be written as the following nonlocal equation on the constraint S_a

$$
-\Delta u+\lambda u+\phi_u u=|u|^{p-2}u \quad \text{in } \mathbb{R}^3,
$$

where $\phi_u = \frac{e^{-\kappa|x|}}{|x|} * u^2 \in H^1(\mathbb{R}^3)$. By multiplying the second equation of (1.5) by $\frac{1}{16\pi}\phi_u$ and integrating in $\mathbb{R}^3$, we obtain that

$$\frac{1}{16\pi}\|\nabla\phi_u\|_2^2 + \frac{\kappa^2}{16\pi}\|\phi_u\|_2^2 = \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2 \mathrm{d}x.$$

Then, by substituting the above equation into $F(u,\phi)$, we obtain the energy functional

$$I(u) := \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2 \mathrm{d}x - \frac{1}{p}\|u\|_p^p$$

with the constraint S_a. Obviously, I is well defined and is of class C^1 in $H^1(\mathbb{R}^3)$. Then, for any $\varphi \in H^1(\mathbb{R}^3)$, we have

$$\langle I'(u), \varphi\rangle = \int_{\mathbb{R}^3}\nabla u\nabla\varphi\,\mathrm{d}x + \int_{\mathbb{R}^3}\phi_u u\varphi\,\mathrm{d}x - \int_{\mathbb{R}^3}|u|^{p-2}u\varphi\,\mathrm{d}x.$$

Hence, the critical point (u,ϕ) of $F|_{S_a}$ is equivalent to the critical point u of $I|_{S_a}$.

2.4 The regularity of solutions

We remark here that the weak solutions are classical solutions. Indeed, let $(u,\phi_u) \in H^1(\mathbb{R}^3)\times H^1(\mathbb{R}^3)$ be a weak solution of system (1.5), namely, u and ϕ_u satisfy (1.6). From (1.6) and the fact that $\phi_u \in L^p(\mathbb{R}^3)$ with $1 \le p \le 3$, it follows that $u \in W^{2,2}_{\mathrm{loc}}(\mathbb{R}^3)$ by applying Sobolev embedding theorem and L^p estimates (see [14, Theorem 9.9]). By reapplying Sobolev embedding theorem to u, we conclude that $u \in C^{0,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$ with $0 < \alpha \le \frac{1}{2}$. Similarly, we have $\phi_u \in W^{2,3}_{\mathrm{loc}}(\mathbb{R}^3)$, and thus $\phi_u \in C^{0,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$ with $0 < \alpha \le 1 - \frac{3}{p}$, $p > 3$. Therefore, from (1.6) and Schauder estimates (see [34, Theorem B.1]), we get that $u, \phi_u \in C^{2,\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$.

2.5 The Pohožaev identity

The following lemma presents two forms of the Pohožaev identity of system (1.5), which are widely used in the study of the fixed mass problem.

Lemma 2.7. *Let $2 < p < 6$ and $a, \kappa > 0$. Then, for any nontrivial solution $(u,\phi_u) \in H^1(\mathbb{R}^3)\times H^1(\mathbb{R}^3)$ of system (1.5), the following two Pohožaev identities*

$$\frac{1}{2}\|\nabla u\|_2^2 + \frac{3}{2}\lambda\|u\|_2^2 + \frac{5}{4}\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x - \frac{\kappa}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} e^{-\kappa|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{3}{p}\|u\|_p^p = 0 \quad (2.19)$$

and

$$P(u) := \|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x + \frac{\kappa}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} e^{-\kappa|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{3(p-2)}{2p}\|u\|_p^p = 0 \quad (2.20)$$

hold, where ϕ_u is defined in Lemma 2.6-(iii).

Proof. For any nontrivial solution $(u,\phi_u) \in H^1(\mathbb{R}^3)\times H^1(\mathbb{R}^3)$ of system (1.5), we have

$$\|\nabla u\|_2^2 + \lambda\|u\|_2^2 + \int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x - \|u\|_p^p = 0 \quad (2.21)$$

and

$$\|\nabla\phi_u\|_2^2 + \kappa^2\|\phi_u\|_2^2 = 4\pi\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x. \quad (2.22)$$

We claim that u satisfies (2.19). Indeed, if (u, ϕ_u) solves system (1.5), from Section 2.4, we have $u, \phi_u \in C^2(B_R)$, where B_R is an arbitrary ball in $\mathbb{R}^3$ centered at the origin with radius R. Thus, from [11, Appendix A.3], we deduce that

$$\int_{B_R} -\Delta u\,(x\cdot\nabla u)\,\mathrm{d}x = -\frac{1}{2}\int_{B_R}|\nabla u|^2\,\mathrm{d}x - \frac{1}{R}\int_{\partial B_R}|x\cdot\nabla u|^2\,\mathrm{d}\sigma + \frac{R}{2}\int_{\partial B_R}|\nabla u|^2\,\mathrm{d}\sigma,$$

$$\int_{B_R}\phi_u u\,(x\cdot\nabla u)\,\mathrm{d}x = -\frac{1}{2}\int_{B_R}u^2\,(x\cdot\nabla\phi_u)\,\mathrm{d}x - \frac{3}{2}\int_{B_R}\phi_u u^2\mathrm{d}x + \frac{R}{2}\int_{\partial B_R}\phi_u u^2\mathrm{d}\sigma,$$

$$\int_{B_R} u\,(x\cdot\nabla u)\,\mathrm{d}x = -\frac{3}{2}\int_{B_R}u^2\mathrm{d}x + \frac{R}{2}\int_{\partial B_R}u^2\mathrm{d}\sigma,$$

and

$$\int_{B_R}|u|^{p-2}u\,(x\cdot\nabla u)\,\mathrm{d}x = -\frac{3}{p}\int_{B_R}|u|^p\,\mathrm{d}x + \frac{R}{p}\int_{\partial B_R}|u|^p\,\mathrm{d}\sigma,$$

where $\mathrm{d}\sigma$ represents the surface area element on the sphere ∂B_R.

By multiplying the first equation of system (1.5) by $x\cdot\nabla u$, multiplying the second equation by $x\cdot\nabla\phi_u$, and integrating over B_R, and according to the above four equations, we get

$$\begin{aligned}
&-\frac{1}{2}\int_{B_R}|\nabla u|^2\,\mathrm{d}x - \frac{1}{R}\int_{\partial B_R}|x\cdot\nabla u|^2\,\mathrm{d}\sigma + \frac{R}{2}\int_{\partial B_R}|\nabla u|^2\,\mathrm{d}\sigma - \frac{3}{2}\lambda\int_{B_R}u^2\mathrm{d}x + \frac{R}{2}\lambda\int_{\partial B_R}u^2\mathrm{d}\sigma\\
&\quad -\frac{1}{2}\int_{B_R}u^2\,(x\cdot\nabla\phi_u)\,\mathrm{d}x - \frac{3}{2}\int_{B_R}\phi_u u^2\mathrm{d}x + \frac{R}{2}\int_{\partial B_R}\phi_u u^2\mathrm{d}\sigma\\
&= -\frac{3}{p}\int_{B_R}|u|^p\,\mathrm{d}x + \frac{R}{p}\int_{\partial B_R}|u|^p\,\mathrm{d}\sigma
\end{aligned}\tag{2.23}$$

and

$$\begin{aligned}
4\pi\int_{B_R}u^2\,(x\cdot\nabla\phi_u)\,\mathrm{d}x &= \int_{B_R}-\Delta\phi_u\,(x\cdot\nabla\phi_u)\,\mathrm{d}x + \kappa^2\int_{B_R}\phi_u\,(x\cdot\nabla\phi_u)\,\mathrm{d}x\\
&= -\frac{1}{2}\int_{B_R}|\nabla\phi_u|^2\,\mathrm{d}x - \frac{1}{R}\int_{\partial B_R}|x\cdot\nabla\phi_u|^2\,\mathrm{d}\sigma + \frac{R}{2}\int_{\partial B_R}|\nabla\phi_u|^2\,\mathrm{d}\sigma\\
&\quad -\frac{3}{2}\kappa^2\int_{B_R}\phi_u^2\,\mathrm{d}x + \frac{R}{2}\kappa^2\int_{\partial B_R}\phi_u^2\,\mathrm{d}\sigma.
\end{aligned}\tag{2.24}$$

Substituting (2.24) into (2.23), we obtain that

$$\begin{aligned}
&-\frac{1}{2}\int_{B_R}|\nabla u|^2\,\mathrm{d}x + \frac{1}{16\pi}\int_{B_R}|\nabla\phi_u|^2\,\mathrm{d}x + \frac{3\kappa^2}{16\pi}\int_{B_R}\phi_u^2\,\mathrm{d}x\\
&\quad -\frac{3}{2}\lambda\int_{B_R}u^2\mathrm{d}x - \frac{3}{2}\int_{B_R}\phi_u u^2\mathrm{d}x + \frac{3}{p}\int_{B_R}|u|^p\,\mathrm{d}x\\
&= \frac{1}{R}\int_{\partial B_R}\left(|x\cdot\nabla u|^2 - \frac{1}{8\pi}|x\cdot\nabla\phi_u|^2\right)\mathrm{d}\sigma - \frac{R}{2}\int_{\partial B_R}\left(|\nabla u|^2 + \lambda u^2 + \phi_u u^2 - \frac{1}{8\pi}|\nabla\phi_u|^2\right)\mathrm{d}\sigma\\
&\quad + \frac{R}{16\pi}\kappa^2\int_{\partial B_R}\phi_u^2\mathrm{d}\sigma + \frac{R}{p}\int_{\partial B_R}|u|^p\,\mathrm{d}\sigma.
\end{aligned}$$

Now, let $R = R_n$ with $R_n \to \infty$ as $n \to \infty$. Then, we have that $B_{R_n} \to \mathbb{R}^3$ and the right-hand side of the above equation tends to zero as $n \to \infty$. Thus, we get that

$$\begin{aligned}
&\frac{1}{2}\int_{\mathbb{R}^3}|\nabla u|^2\,\mathrm{d}x - \frac{1}{16\pi}\int_{\mathbb{R}^3}|\nabla\phi_u|^2\,\mathrm{d}x - \frac{3\kappa^2}{16\pi}\int_{\mathbb{R}^3}\phi_u^2\mathrm{d}x\\
&\qquad + \frac{3}{2}\lambda\int_{\mathbb{R}^3}u^2\mathrm{d}x + \frac{3}{2}\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x - \frac{3}{p}\int_{\mathbb{R}^3}|u|^p\,\mathrm{d}x = 0.
\end{aligned}$$

Then, by inserting (2.22) into the above equation, we infer that

$$\frac{1}{2}\|\nabla u\|_2^2+\frac{3}{2}\lambda\|u\|_2^2+\frac{5}{4}\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x-\frac{\kappa^2}{8\pi}\|\phi_u\|_2^2-\frac{3}{p}\|u\|_p^p=0. \tag{2.25}$$

For the convenience of subsequent calculations, we will adopt the method in [11, Appendix A.2] to transform $\|\phi_u\|_2^2$ in (2.25) into another form. For any $f\in L^1(\mathbb{R}^3)$, we define the following Fourier transform

$$\mathcal{F}[f](x):=\frac{1}{(2\pi)^{\frac{3}{2}}}\int_{\mathbb{R}^3}e^{-ix\cdot y}f(y)\,\mathrm{d}y.$$

For any $f,g\in L^2(\mathbb{R}^3)$, it holds that

$$\mathcal{F}[f*g]=(2\pi)^{\frac{3}{2}}\mathcal{F}[f]\mathcal{F}[g]\quad\text{and}\quad\int_{\mathbb{R}^3}\mathcal{F}[f]\mathcal{F}[g]\,\mathrm{d}x=\int_{\mathbb{R}^3}fg\,\mathrm{d}x.$$

Moreover, when $f\in L^1(\mathbb{R}^3)\cap L^2(\mathbb{R}^3)$, it follows from [26, Theorem 5.3] that $\mathcal{F}[f]\in L^2(\mathbb{R}^3)$ and $\|\mathcal{F}[f]\|_2^2=\|f\|_2^2$. Since

$$\mathcal{F}\left[e^{-\kappa|\cdot|}\right](x)=\sqrt{\frac{2}{\pi}}\frac{2\kappa}{\left(\kappa^2+|x|^2\right)^2}\quad\text{and}\quad\mathcal{F}[G^\kappa](x)=\mathcal{F}\left[\frac{e^{-\kappa|\cdot|}}{|\cdot|}\right](x)=\sqrt{\frac{2}{\pi}}\frac{1}{\kappa^2+|x|^2},$$

we have

$$\mathcal{F}[G^\kappa*G^\kappa]=(2\pi)^{\frac{3}{2}}\mathcal{F}[G^\kappa]\mathcal{F}[G^\kappa]=\frac{4\sqrt{2\pi}}{\left(\kappa^2+|x|^2\right)^2}\quad\text{and}\quad(G^\kappa*G^\kappa)(x)=\frac{2\pi}{\kappa}e^{-\kappa|x|}.$$

Since $\phi_u\in L^p(\mathbb{R}^3)$ with $1\le p\le 3$, we conclude that

$$\begin{aligned}\frac{\kappa^2}{8\pi}\|\phi_u\|_2^2&=\frac{\kappa^2}{8\pi}\int_{\mathbb{R}^3}|\mathcal{F}[\phi_u]|^2\,\mathrm{d}x=\frac{\kappa^2}{8\pi}(2\pi)^{\frac{3}{2}}\int_{\mathbb{R}^3}\mathcal{F}\left[u^2\right]\mathcal{F}[G^\kappa]\mathcal{F}[\phi_u]\,\mathrm{d}x\\&=\frac{\kappa^2}{8\pi}\int_{\mathbb{R}^3}\mathcal{F}\left[u^2\right]\mathcal{F}[G^\kappa*\phi_u]\,\mathrm{d}x=\frac{\kappa^2}{8\pi}\int_{\mathbb{R}^3}\left((G^\kappa*G^\kappa)*u^2\right)u^2\,\mathrm{d}x\\&=\frac{\kappa}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}e^{-\kappa|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y.\end{aligned}$$

Then by substituting the above result into (2.25), we obtain (2.19), and thus (2.20) follows from (2.19) and (2.21). This completes the proof of Lemma 2.7. □

2.6 The abstract minimization problem

In [6] and [7], Bellazzini and Siciliano developed an abstract framework to prove the existence of solutions to constrained minimization problems. We shall follow this framework in our proofs of Theorems 1.1 and 1.2. Next, we define the following functionals which will be frequently used in subsequent results:

$$A(u):=\|\nabla u\|_2^2,\quad B(u):=\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x,\quad C(u):=\|u\|_p^p,\quad T(u):=\frac{1}{4}B(u)-\frac{1}{p}C(u).$$

For any $u\in H^1(\mathbb{R}^3)$, $\beta\in\mathbb{R}$ and $\theta>0$, we define $u^\theta\in H^1(\mathbb{R}^3)$ as the scaling

$$u^\theta(x):=\theta^{1-\frac{3}{2}\beta}u\left(\frac{x}{\theta^\beta}\right)\quad\text{for a.e. } x\in\mathbb{R}^3 \tag{2.26}$$

such that $\left\|u^\theta\right\|_2=\theta\|u\|_2$. Then, the following proposition is a corollary of [6, Theorem 2.1].

Proposition 2.8. *If $2 < p < 3$, let T be a C^1 functional on $H^1(\mathbb{R}^3)$ and let $\{u_n\} \subset S_a$ be a minimizing sequence for I_{a^2} such that, up to a subsequence, $u_n \rightharpoonup \bar{u}$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$ with $\bar{u} \in H^1(\mathbb{R}^3)\setminus\{0\}$. Assume $a, \kappa > 0$ and the following conditions are satisfied.*

(i) If $0 < \mu < a$, then $I_{a^2} \le I_{\mu^2} + I_{a^2-\mu^2}$.

(ii) For all $a > 0$, $-\infty < I_{a^2} < 0$ with $I(0) = 0$.

(iii) The function $a \mapsto I_{a^2}$ is continuous and $I_{a^2}/a^2 \to 0$ as $a \to 0^+$.

(iv) Let $\alpha_n := \left(a^2 - \|\bar{u}\|_2^2\right)\|u_n - \bar{u}\|_2^{-2}$, then the functional T satisfies

$$T(u_n - \bar{u}) + T(\bar{u}) = T(u_n) + o_n(1) \tag{2.27}$$

and

$$T\left(\alpha_n(u_n - \bar{u})\right) - T(u_n - \bar{u}) = o_n(1). \tag{2.28}$$

Then, for every $a > 0$, the set $M(a)$ is nonempty, where

$$M(a) := \bigcup_{\mu\in(0,a]} \left\{ u \in S_\mu : I(u) = I_{\mu^2} = \inf_{u\in S_\mu} I(u) \right\}.$$

If we suppose further that for any $u \in M(a)$, there exists $\beta \in \mathbb{R}$ such that for any $\theta > 0$,

$$h_\beta^u(\theta) := I(u^\theta) - \theta^2 I(u)$$

is differentiable and $\left(h_\beta^u\right)'(1) \neq 0$, then, for any $\mu \in (0, a)$, the function $\mu \mapsto I_{\mu^2}/\mu^2$ is monotone decreasing. Thus, for any $\mu \in (0, a)$, the following strong subadditivity inequality holds

$$I_{a^2} = \frac{\mu^2}{a^2} I_{a^2} + \frac{a^2-\mu^2}{a^2} I_{a^2} < I_{\mu^2} + I_{a^2-\mu^2}. \tag{2.29}$$

Therefore, it follows that $\bar{u} \in S_a$ and $I(\bar{u}) = I_{a^2} = \inf_{u\in S_a} I(u) < 0$.

If we suppose further that

$$\left\langle T'(u_n), u_n \right\rangle = O_n(1) \tag{2.30}$$

and

$$\left\langle T'(u_n) - T'(u_m), u_n - u_m \right\rangle = o_n(1) \quad \text{as } n, m \to \infty, \tag{2.31}$$

then, $\|u_n - \bar{u}\|_{H^1} \to 0$ as $n \to \infty$.

Proposition 2.9 ([6, Lemma 2.1])**.** *Let $3 < p < \frac{10}{3}$, $a, \kappa > 0$ and $\mu := \|\bar{u}\|_2 \in (0, a]$. Suppose that $\{u_n\} \subset S_a$ is a minimizing sequence for I_{a^2} such that, up to a subsequence, $u_n \rightharpoonup \bar{u}$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$ with $\bar{u} \in H^1(\mathbb{R}^3)\setminus\{0\}$, and let $T : H^1(\mathbb{R}^3) \to \mathbb{R}$ be a C^1 functional satisfying (2.27)–(2.29), then $\bar{u} \in S_a$ and $I(\bar{u}) = I_{a^2}$. If we further assume that (2.30) and (2.31) also hold, then, $\|u_n - \bar{u}\|_{H^1} \to 0$ as $n \to \infty$.*

After introducing the above abstract framework, we now state some results showing how this framework applies to the minimization problem (1.8).

Lemma 2.10. *Assume that $2 < p < \frac{10}{3}$ and $a, \kappa > 0$, then the functional I is coercive and bounded from below on S_a. Moreover, it holds that $I_{a^2} = \inf_{u\in S_a} I(u) \in (-\infty, 0]$.*

Proof. For any $u \in S_a$, it follows from $\frac{3(p-2)}{2} < 2$ and Lemma 2.1 that

$$I(u) = \frac{1}{2}\|\nabla u\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\phi_u u^2 \mathrm{d}x - \frac{1}{p}\|u\|_p^p \geq \frac{1}{2}\|\nabla u\|_2^2 - \frac{C_{3,p}^p a^{\frac{6-p}{2}}}{p}\|\nabla u\|_2^{\frac{3(p-2)}{2}},$$

which implies that I is coercive on S_a and then I is bounded from below on S_a, namely, $I_{a^2} := \inf_{S_a} I(u) > -\infty$. Moreover, for any $u \in S_a$ and $t > 0$, let $u_t(x) := t^{\frac{3}{2}}u(tx)$ for a.e. $x \in \mathbb{R}^3$. Then it holds that $u_t \in S_a$ and

$$\begin{aligned} I_{a^2} \leq I(u_t) &= \frac{t^2}{2}\|\nabla u\|_2^2 + \frac{t}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\frac{\kappa}{t}|x-y|}}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{t^{\frac{3(p-2)}{2}}}{p}\|u\|_p^p \\ &\leq \frac{t^2}{2}\|\nabla u\|_2^2 + \frac{t}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{t^{\frac{3(p-2)}{2}}}{p}\|u\|_p^p \to 0 \quad \text{as } t \to 0. \end{aligned}$$

Hence, when $2 < p < \frac{10}{3}$, it holds that $I_{a^2} \in (-\infty, 0]$ for any $a > 0$. □

Lemma 2.11. *If $2 < p < \frac{10}{3}$ and $\kappa > 0$, then I satisfies the following weak subadditivity inequality*

$$I_{a^2} \leq I_{\mu^2} + I_{a^2-\mu^2} \quad \text{for any } 0 < \mu < a.$$

Proof. Now argue as in the [15, Lemma 3.1], and we complete the proof. □

Lemma 2.12. *For any $\kappa > 0$, we have*

(i) If $2 < p < 3$, then there exists $a_0 > 0$ such that $I_{a^2} < 0$ for any $a \in (0, a_0)$. Moreover, it holds that $I_{a^2} < 0$ for any $a > 0$.

(ii) If $3 < p < \frac{10}{3}$, then there exists $a_1 > 0$ such that $I_{a^2} < 0$ for any $a \in (a_1, \infty)$.

Proof. From (2.26), we have $u^\theta(x) := \theta^{1-\frac{3}{2}\beta}u\left(\frac{x}{\theta^\beta}\right)$ for a.e. $x \in \mathbb{R}^3$, where $u \in H^1(\mathbb{R}^3)$, $\beta \in \mathbb{R}$ and $\theta > 0$. Then, from direct calculations, we get that $\left\|u^\theta\right\|_2 = \theta\|u\|_2$ and

$$\begin{aligned} &A(u^\theta) = \left\|\nabla u^\theta\right\|_2^2 = \theta^{2-2\beta}A(u), \quad C(u^\theta) = \left\|u^\theta\right\|_p^p = \theta^{\left(1-\frac{3}{2}\beta\right)p+3\beta}C(u), \\ &B(u^\theta) = \theta^{4-\beta}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\kappa\theta^\beta|x-y|}}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y < \theta^{4-\beta}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y. \end{aligned}$$

(i) When $2 < p < 3$, fix $u \in S_1$ and $\beta = -2$ such that $\left(1-\frac{3}{2}\beta\right)p + 3\beta = 4p - 6 < 2 - 2\beta = 4 - \beta = 6$, then $u^a \in S_a$. Thus, as $a \to 0^+$, we have

$$I(u^a) < \frac{a^6}{2}A(u) + \frac{a^6}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{a^{4p-6}}{p}C(u) = \mathcal{J}_0(u_a) \to 0^-,$$

where $\mathcal{J}_0$ is the energy functional of the Schrödinger–Poisson–Slater system (1.14) in Section 1.2. Then, there exists $a_0 > 0$ small enough such that

$$I_{a^2} < 0 \quad \text{for any } a \in (0, a_0].$$

Let $\bar{a} \in \left(a_0, \sqrt{2}a_0\right]$. For every $a \in (a_0, \bar{a}]$, we have $a^2 - a_0^2 \leq \bar{a}^2 - a_0^2 \leq 2a_0^2 - a_0^2 = a_0^2$ and then we deduce from Lemma 2.11 that

$$I_{a^2} \leq I_{a_0^2} + I_{a^2-a_0^2} < 0,$$

which implies that $I_{a^2} < 0$ for any $a \in (0, \bar{a}]$. Thus, for given $\kappa > 0$, by iterating the above procedure, it follows that $I_{a^2} < 0$ for every $a > 0$ and (i) holds.

(ii) When $3 < p < \frac{10}{3}$, fix $u \in S_1$ and $\beta = -2$ such that $\left(1 - \frac{3}{2}\beta\right) p + 3\beta = 4p - 6 > 2 - 2\beta = 4 - \beta = 6$, then $u^a \in S_a$ and as $a \to \infty$, we have

$$I(u^a) < \frac{a^6}{2} A(u) + \frac{a^6}{4} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{1}{|x-y|} u^2(x) u^2(y) \mathrm{d}x\mathrm{d}y - \frac{a^{4p-6}}{p} C(u) = \mathcal{J}_0(u_a) \to -\infty.$$

Thus, for given $\kappa > 0$, it follows that there exists $a_1 > 0$ such that if $a > a_1$, then

$$I_{a^2} \leq I(u^a) < \mathcal{J}_0(u^a) < 0,$$

and this completes the proof of Lemma 2.12. □

Lemma 2.13. *If a, $\kappa > 0$ and $\{u_n\} \subset S_a$ is a minimizing sequence for I_{a^2} such that, up to a subsequence, $u_n \rightharpoonup \bar{u}$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$, then, up to translation, the following statements hold:*

(i) For any $a > 0$ and $2 < p < 3$, $\bar{u} \neq 0$.

(ii) For any $a \in (a_1, \infty)$ and $3 < p < \frac{10}{3}$, $\bar{u} \neq 0$, where a_1 is obtained in Lemma 2.12.

Proof. It follows from Lemma 2.10 that $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$. Let

$$\delta := \lim_{n\to\infty} \left(\sup_{y \in \mathbb{R}^3} \int_{B(y,1)} |u_n|^2 \, \mathrm{d}x \right).$$

If $\delta = 0$, from [29, Lemma I.1] or [36, Lemma 1.21], we conclude that $u_n \to 0$ in $L^p(\mathbb{R}^3)$ as $n \to \infty$ with $p \in (2, 6)$. Hence, from Lemma 2.12-(i), for any $a > 0$ and $2 < p < 3$, it holds that

$$0 \leq \lim_{n\to\infty} I(u_n) = \lim_{n\to\infty} \left(\frac{1}{2} A(u_n) + \frac{1}{4} B(u_n) \right) = I_{a^2} < 0,$$

which leads to a contradiction. Similarly, for any $a \in (a_1, \infty)$ and $3 < p < \frac{10}{3}$, we also obtain a contradiction. Thus, we deduce that $\delta > 0$ in both scenarios (i) and (ii) and then there exists a sequence $\{y_n\} \subset \mathbb{R}^3$ such that

$$\int_{B(y_n,1)} |u_n|^2 \, \mathrm{d}x \geq \frac{\delta}{2} > 0.$$

Let $\tilde{u}_n(\cdot) := u_n(\cdot + y_n)$. Then $\{\tilde{u}_n\} \subset S_a$ is also a bounded minimizing sequence for I_{a^2} and

$$\int_{B(0,1)} |\tilde{u}_n|^2 \, \mathrm{d}x \geq \frac{\delta}{2} > 0 \quad \text{for } n \in \mathbb{N}^+ \text{ large enough.}$$

Hence, it follows that conclusions (i) and (ii) hold. □

Lemma 2.14. *Let $p \in (2, \frac{10}{3})$ and $\{u_n\} \subset S_a$ be a minimizing sequence for I_{a^2} such that, up to a subsequence, $u_n \rightharpoonup \bar{u}$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$ with $\bar{u} \in H^1(\mathbb{R}^3) \setminus \{0\}$. Then the C^1 functional T satisfies (2.27), (2.28) and (2.30). If the strong subadditivity inequality (2.29) holds, then T also satisfies (2.31).*

Proof. From Lemma 2.10 and Lemma 2.6-(i), we know that $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$ and $\|\phi_{u_n}\|_{H^1} \leq C\|u_n\|^2_{H^1}$. Therefore, there exists $\bar{u} \in H^1(\mathbb{R}^3)$ such that, up to a subsequence, $u_n \rightharpoonup \bar{u}$ in $H^1(\mathbb{R}^3)$, $u_n \to \bar{u}$ in $L^r_{\text{loc}}(\mathbb{R}^3)$ with $r \in [1,6)$ and $u_n \to \bar{u}$ a.e. in $\mathbb{R}^3$ as $n \to \infty$. From the conclusions (ii) and (v) of Lemma 2.6, we deduce that $\{\phi_{u_n}\}$ is bounded in $H^1(\mathbb{R}^3)$ and there exists a unique $\phi_{\bar{u}} \in H^1(\mathbb{R}^3)$ solving (2.17) in the weak sense such that, up to a subsequence, $\phi_{u_n} \rightharpoonup \phi_{\bar{u}}$ in $H^1(\mathbb{R}^3)$.

We now introduce the following notations:

$$
\begin{aligned}
&G^\kappa(x,y) := G^\kappa(x-y) = \frac{e^{-\kappa|x-y|}}{|x-y|}, \qquad A := \int_{\mathbb{R}^3} \phi_{\bar{u}}\bar{u}^2 \mathrm{d}x,\\
&I_n^{(1)} := \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} G^\kappa(x,y)u_n^2(y)\bar{u}^2(x)\mathrm{d}x\mathrm{d}y = \int_{\mathbb{R}^3} \phi_{u_n}\bar{u}^2\mathrm{d}x,\\
&I_n^{(2)} := \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} G^\kappa(x,y)u_n(y)\bar{u}(y)u_n(x)\bar{u}(x)\mathrm{d}x\mathrm{d}y,\\
&I_n^{(3)} := \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} G^\kappa(x,y)u_n^2(y)u_n(x)\bar{u}(x)\mathrm{d}x\mathrm{d}y = \int_{\mathbb{R}^3} \phi_{u_n}u_n\bar{u}\mathrm{d}x,\\
&I_n^{(4)} := \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} G^\kappa(x,y)u_n(y)\bar{u}(y)\bar{u}^2(x)\mathrm{d}x\mathrm{d}y.
\end{aligned}
$$

From direct calculation we deduce that

$$
B(u_n-\bar{u}) - B(u_n) + B(\bar{u}) = 2I_n^{(1)} + 4I_n^{(2)} - 4I_n^{(3)} - 4I_n^{(4)} + 2A.
$$

Next, we will show that $\lim_{n\to\infty} I_n^{(i)} = A$, $i = 1,2,3,4$. Since $\phi_{u_n} \rightharpoonup \phi_{\bar{u}}$ in $H^1(\mathbb{R}^3)$, we infer that $\phi_{u_n} \rightharpoonup \phi_{\bar{u}}$ in $L^2(\mathbb{R}^3)$. It follows from $\bar{u}^2 \in L^2(\mathbb{R}^3)$ that $\lim_{n\to\infty} I_n^{(1)} = A$. To prove $\lim_{n\to\infty} I_n^{(2)} = A$, let

$$
\hat{v}_n(x) := \int_{\mathbb{R}^3} \frac{e^{-\kappa|x-y|}}{|x-y|} u_n(y)\bar{u}(y)\mathrm{d}y.
$$

Then we claim that $\hat{v}_n \to \phi_{\bar{u}}$ a.e. in $\mathbb{R}^3$ as $n \to \infty$. Indeed, for any $R \geq 1$, by Hölder's inequality, $e^{-t} \leq 1$ and $e^t \geq \frac{t^2}{2}$ for $t \geq 0$, we deduce that

$$
\begin{aligned}
|\hat{v}_n(x) - \phi_{\bar{u}}(x)| &\leq \|u_n-\bar{u}\|_{L^3(B_R(x))}\|\bar{u}\|_{L^6(B_R(x))}\left(\int_{|y-x|\leq R}\frac{e^{-2\kappa|x-y|}}{|x-y|^2}\mathrm{d}y\right)^{\frac{1}{2}}\\
&\quad + \|u_n-\bar{u}\|_{L^3(B_R^c(x))}\|\bar{u}\|_{L^6(B_R^c(x))}\left(\int_{|y-x|\geq R}\frac{1}{|x-y|^2 e^{2\kappa|x-y|}}\mathrm{d}y\right)^{\frac{1}{2}}\\
&\leq \|u_n-\bar{u}\|_{L^3(B_R(x))}\|\bar{u}\|_{L^6(\mathbb{R}^3)}\left(\int_{|y-x|\leq R}\frac{1}{|x-y|^2}\mathrm{d}y\right)^{\frac{1}{2}}\\
&\quad + \|u_n-\bar{u}\|_{L^3(B_R^c(x))}\|\bar{u}\|_{L^6(\mathbb{R}^3)}\left(\int_{|y-x|\geq R}\frac{1}{2\kappa^2|x-y|^4}\mathrm{d}y\right)^{\frac{1}{2}}.
\end{aligned}
$$

which implies that $\hat{v}_n \to \phi_{\bar{u}}$ a.e. in $\mathbb{R}^3$ by first letting $n \to \infty$ (for fixed R) and then letting $R \to \infty$. Since $\{u_n\} \subset S_a$ and $\bar{u} \in H^1(\mathbb{R}^3)$, from Hölder's inequality and Sobolev embedding theorem, we have

$$
\|u_n\bar{u}\|_{\frac{6}{5}} \leq C\|u_n\|_{\frac{12}{5}}\|\bar{u}\|_{\frac{12}{5}} \leq C\|u_n\|_{H^1}\|\bar{u}\|_{H^1} < \infty,
$$

namely, $u_n\bar{u} \in L^{\frac{6}{5}}(\mathbb{R}^3)$. Let $\alpha = 2$, $N = 3$, $f = |u_n\bar{u}|$, $q = 6$ and $p = \frac{6}{5}$ in Lemma 2.3. Then, we have

$$|\hat{v}_n| \leq \int_{\mathbb{R}^3} \frac{e^{-\kappa|x-y|}}{|x-y|} |u_n(y)\bar{u}(y)| \, \mathrm{d}y \leq \int_{\mathbb{R}^3} \frac{|u_n(y)\bar{u}(y)|}{|x-y|} \mathrm{d}y := J_2(|u_n\bar{u}|)(x),$$

and thus it holds that

$$\|\hat{v}_n\|_6 \leq \|J_2(|u_n\bar{u}|)\|_6 \leq C \|u_n\bar{u}\|_{\frac{6}{5}} \leq C \|u_n\|_{H^1} \|\bar{u}\|_{H^1} < \infty,$$

namely, $\hat{v}_n \in L^6(\mathbb{R}^3)$. It follows from Hölder's inequality and Sobolev embedding theorem that

$$\|\hat{v}_n u_n\|_2 \leq \|\hat{v}_n\|_6 \|u_n\|_3 \leq C \|u_n\|_{H^1}^2 \|\bar{u}\|_{H^1} < \infty.$$

Since $\hat{v}_n \to \phi_{\bar{u}}$, $u_n \to \bar{u}$ a.e. in $\mathbb{R}^3$, we have $\hat{v}_n u_n \to \phi_{\bar{u}}\bar{u}$ a.e. in $\mathbb{R}^3$ and $\hat{v}_n u_n \rightharpoonup \phi_{\bar{u}}\bar{u}$ in $L^2(\mathbb{R}^3)$. Due to $\bar{u} \in L^2(\mathbb{R}^3)$, we get $\lim_{n\to\infty} I_n^{(2)} = A$. Let $\psi = \bar{u}$ in Lemma 2.6-(v), and thus it holds that $\lim_{n\to\infty} I_n^{(3)} = A$. Since $\hat{v}_n \to \phi_{\bar{u}}$ a.e. in $\mathbb{R}^3$ and $\hat{v}_n \in L^6(\mathbb{R}^3)$, we get $\hat{v}_n \rightharpoonup \phi_{\bar{u}}$ in $L^6(\mathbb{R}^3)$ as $n \to \infty$. By the fact that $\bar{u}^2 \in L^{\frac{6}{5}}(\mathbb{R}^3)$, we deduce that $\lim_{n\to\infty} I_n^{(4)} = A$. In summary, we have

$$B(u_n - \bar{u}) + B(\bar{u}) = B(u_n) + o_n(1).$$

Moreover, it follows from the Brezis–Lieb lemma that

$$C(u_n - \bar{u}) + C(\bar{u}) = C(u_n) + o_n(1),$$

and thus (2.27) holds.

From Lemma 2.6-(iii) and Hölder's inequality, we infer that

$$B(u_n) = \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \mathrm{d}x \leq C \|u_n\|_4^4 \leq C \|u_n\|_{H^1}^4 < \infty.$$

It follows from Brezis-Lieb lemma that $\|u_n - \bar{u}\|_2^2 + \|\bar{u}\|_2^2 = \|u_n\|_2^2 + o_n(1) = a^2 + o_n(1)$. Therefore, from Proposition 2.8-(iv), we have $\alpha_n = \left(a^2 - \|\bar{u}\|_2^2\right) \|u_n - \bar{u}\|_2^{-2} \to 1$ as $n \to \infty$, and thus we obtain that

$$\begin{aligned} B(\alpha_n(u_n - \bar{u})) - B(u_n - \bar{u}) &= \left(\alpha_n^4 - 1\right) B(u_n - \bar{u}) = o_n(1), \\ C(\alpha_n(u_n - \bar{u})) - C(u_n - \bar{u}) &= \left(\alpha_n^p - 1\right) C(u_n - \bar{u}) = o_n(1), \end{aligned}$$

thus, (2.28) holds. Since $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$, from Lemma 2.6-(iii), we conclude that

$$\langle T'(u_n), u_n \rangle = \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \mathrm{d}x - \|u_n\|_p^p \leq \int_{\mathbb{R}^3} \phi_{u_n} u_n^2 \mathrm{d}x \leq C \|u_n\|_4^4 \leq C \|u_n\|_{H^1}^4 < \infty,$$

namely, (2.30) holds.

Since (2.27) and (2.28) hold, if the strong subadditivity inequality (2.29) also holds, from Proposition 2.8, we conclude that $\bar{u} \in S_a$, namely, $\|\bar{u}\|_2^2 = a^2$. Thus, $\|u_n - \bar{u}\|_2 = o_n(1)$ and $\|u_n - u_m\|_2 = o_n(1)$ as $n, m \to \infty$. Notice that $2 < p < \frac{10}{3} < 6$, from Lemma 2.1 and interpolation inequality, we have that

$$\|u_n - u_m\|_p \leq \|u_n - u_m\|_2^{\alpha} \|u_n - u_m\|_6^{1-\alpha} \leq \mathcal{S}^{-\frac{1-\alpha}{2}} \|u_n - u_m\|_2^{\alpha} \|\nabla u_n - \nabla u_m\|_2^{1-\alpha} = o_n(1),$$

where $\mathcal{S}$ denotes the sharp constant and α satisfies $\frac{\alpha}{2}+\frac{1-\alpha}{6}=\frac{1}{p}$, therefore, $\|u_n-u_m\|_p = o_n(1)$. From Hölder's inequality and Sobolev's embedding theorem, we have

$$\begin{aligned}\int_{\mathbb{R}^3}|u_n|^{p-1}|u_n-u_m|\,\mathrm{d}x &\le \left(\int_{\mathbb{R}^3}\left||u_n|^{p-1}\right|^{\frac{p}{p-1}}\mathrm{d}x\right)^{\frac{p-1}{p}}\|u_n-u_m\|_p\\ &= \|u_n\|_p^{p-1}\|u_n-u_m\|_p = o_n(1),\end{aligned}$$

and thus

$$\begin{aligned}&\left|\int_{\mathbb{R}^3}\left(|u_n|^{p-2}u_n-|u_m|^{p-2}u_m\right)(u_n-u_m)\,\mathrm{d}x\right|\\ &\quad\le \int_{\mathbb{R}^3}|u_n|^{p-1}|u_n-u_m|\,\mathrm{d}x+\int_{\mathbb{R}^3}|u_m|^{p-1}|u_n-u_m|\,\mathrm{d}x\\ &\quad\le \|u_n\|_p^{p-1}\|u_n-u_m\|_p+\|u_m\|_p^{p-1}\|u_n-u_m\|_p = o_n(1).\end{aligned}$$

Hence, we have $\langle C'(u_n)-C'(u_m),u_n-u_m\rangle = o_n(1)$ as $n,m\to\infty$. From $\phi_{u_n}\in H^1(\mathbb{R}^3)$, Lemma 2.6-$(i)$ and Sobolev's embedding theorem, we infer that $\phi_{u_n}\in L^6(\mathbb{R}^3)$ and $\|\phi_{u_n}\|_6\le C\|\phi_{u_n}\|_{H^1}\le C\|u_n\|_{H^1}^2$. By Hölder's inequality and $\|u_n-u_m\|_p=o_n(1)$ with $p\in\left(2,\frac{10}{3}\right)$, we have

$$\int_{\mathbb{R}^3}\phi_{u_n}u_n|u_n-u_m|\,\mathrm{d}x\le C\|\phi_{u_n}\|_6\|u_n\|_2\|u_n-u_m\|_3\le C\|u_n\|_{H^1}^2\|u_n\|_2\|u_n-u_m\|_3=o_n(1).$$

Therefore, as $n,m\to\infty$, we have $\langle B'(u_n)-B'(u_m),u_n-u_m\rangle=o_n(1)$, and thus

$$\langle T'(u_n)-T'(u_m),u_n-u_m\rangle=o_n(1),$$

namely, (2.31) holds. □

3 Proofs of main results

Based on the preparatory lemmas presented in Section 2, we now proceed to prove the main results.

3.1 Proof of Theorem 1.1

To prove Theorem 1.1, we need to demonstrate the following two crucial lemmas.

Lemma 3.1. *Assume $2<p<\frac{10}{3}$ and $a,\kappa>0$, let $\{u_n\}\subset S_a$ be a minimizing sequence for I_{a^2}. Then the function $a\mapsto I_{a^2}$ is continuous and $I_{a^2}/a^2\to 0$ as $a\to 0^+$.*

Proof. When $2<p<\frac{10}{3}$, we have $\frac{3(p-2)}{2}<2$. Now arguing as in Step 4 in the proof of Theorem 4.1 in [7], we can complete the proof. □

Lemma 3.2. *If $a,\kappa>0$, $2<p<3$ and $M(a)$ is defined in Proposition 2.8, then for any $u\in M(a)$, there exists $\beta\in\mathbb{R}$ such that for any $\theta>0$,*

$$h_\beta^u(\theta):=I(u^\theta)-\theta^2 I(u)$$

is differentiable and $(h_u)'(1)\neq 0$, where $u^\theta(x):=\theta^{1-\frac{3}{2}\beta}u\left(\frac{x}{\theta^\beta}\right)$.

Proof. For any $u \in M(a)$ and $\beta \in \mathbb{R}$, it follows from (1.7) and the definition of u^θ that

$$\begin{aligned} h_\beta^u(\theta) &= I(u^\theta) - \theta^2 I(u) \\ &= \frac{1}{2}\left(\theta^{(2-2\beta)} - \theta^2\right)\|\nabla u\|_2^2 + \frac{1}{4}\left(\theta^{4-\beta}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\kappa\theta^\beta|x-y|}}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \theta^2\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x\right) \\ &\quad - \frac{1}{p}\left(\theta^{(1-\frac{3}{2}\beta)p+3\beta} - \theta^2\right)\|u\|_p^p. \end{aligned}$$

Thus, $h_\beta^u(\theta)$ is differentiable and

$$\begin{aligned} \left(h_\beta^u\right)'(1) &= -\beta\|\nabla u\|_2^2 + \frac{1}{4}\left((2-\beta)\int_{\mathbb{R}^3}\phi_u u^2\mathrm{d}x - \kappa\beta\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}e^{-\kappa|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y\right) \\ &\quad - \frac{1}{p}\left((1-\frac{3}{2}\beta)p + 3\beta - 2\right)\|u\|_p^p. \end{aligned}$$

To prove this lemma, we argue by contradiction. Assume that there exists a sequence $\{u_n\} \subset M(a)$ with $\|u_n\|_2 := \mu_n \le a$ and $\mu_n \to 0$ as $n \to \infty$ such that $\left(h_\beta^{u_n}\right)'(1) = 0$ for all $\beta \in \mathbb{R}$, then we conclude that $I(u_n) = I_{\mu_n^2} \to 0$ as $n \to \infty$ according to Lemma 3.1. Moreover, since (u_n, ϕ_{u_n}) solves system (1.1) under the constraint S_{μ_n}, from Lemma 2.7, we infer that (u_n, ϕ_{u_n}) satisfies the following Pohožaev identity

$$\|\nabla u_n\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x + \frac{\kappa}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}e^{-\kappa|x-y|}u_n^2(x)u_n^2(y)\mathrm{d}x\mathrm{d}y - \frac{3(p-2)}{2p}\|u_n\|_p^p = 0. \tag{3.1}$$

Let $\beta = \frac{2}{3}$, from $\left(h_{\frac{2}{3}}^{u_n}\right)'(1) = 0$, we deduce that

$$\frac{1}{2}\|\nabla u_n\|_2^2 = \frac{1}{4}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x - \frac{\kappa}{8}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}e^{-\kappa|x-y|}u_n^2(x)u_n^2(y)\mathrm{d}x\mathrm{d}y. \tag{3.2}$$

It follows from (3.2), Lemma 2.6 and Lemma 2.1 that

$$\|\nabla u_n\|_2^2 \le \frac{1}{2}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x \le C\|u_n\|_4^4 \le C\|\nabla u_n\|_2^3\|u_n\|_2. \tag{3.3}$$

Let $\beta = 0$, from $(h_0^{u_n})'(1) = 0$, we have

$$\|u_n\|_p^p = \frac{p}{2(p-2)}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x \le C(p)\|\nabla u_n\|_2^3\|u_n\|_2. \tag{3.4}$$

By (3.3), (3.4), $\|u_n\|_2 = \mu_n \to 0$ and $I(u_n) = I_{\mu_n^2} \to 0$ as $n \to \infty$, we infer that

$$\|\nabla u_n\|_2^2,\ \int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x,\ \|u_n\|_p^p \to 0 \quad \text{as } n \to \infty. \tag{3.5}$$

It follows from Lemma 2.2 that

$$\begin{aligned} \int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x &= \int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\kappa|x-y|}}{|x-y|}u_n^2(x)u_n^2(y)\mathrm{d}x\mathrm{d}y \\ &\le \int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}u_n^2(x)u_n^2(y)\mathrm{d}x\mathrm{d}y \le C\|u_n\|_{\frac{12}{5}}^4. \end{aligned} \tag{3.6}$$

Similar to the Cases (a)–(d) of Step 5 in the proof of Theorem 4.1 in [6], when $2 < p \leq \frac{8}{3}$, by applying (3.3)–(3.6), interpolation inequality and Lemma 2.1, we obtain a contradiction in all four cases. Then, we discuss the case when $\frac{8}{3} < p < 3$. Substituting (3.2) into Pohožaev identity (3.1), we obtain that

$$\frac{1}{4}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x = \frac{p-2}{2p}\|u_n\|_p^p, \tag{3.7}$$

and thus we have

$$I(u_n) = \frac{1}{2}\|\nabla u_n\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x - \frac{1}{p}\|u_n\|_p^p = \frac{1}{2}\|\nabla u_n\|_2^2 - \frac{4-p}{2p}\|u_n\|_p^p. \tag{3.8}$$

Let $\{w_n\}, \{v_n\} \subset M(a)$ such that $w_n := v_n^{\mu_n} = \mu_n^{1-\frac{3}{2}\beta}v_n\left(\frac{x}{\mu_n^\beta}\right)$, where $\beta \in \mathbb{R}$, $\|v_n\|_2 = 1$ and $\|w_n\|_2 = \mu_n \to 0$ as $n \to \infty$. Moreover, let $C(p) > 0$ such that when $\|\nabla v_n\|_2^2$ is small enough, it holds that $\frac{1}{2}\|\nabla v_n\|_2^2 - \frac{4-p}{2p}\|v_n\|_p^p < -C(p)$. Now, let $\beta = \frac{2(2-p)}{10-3p}$ such that $-2\beta = (1-\frac{3}{2}\beta)p + 3\beta - 2 = \frac{4(p-2)}{10-3p}$. From (3.8), we have

$$\begin{aligned}\frac{I_{\mu_n^2}}{\mu_n^2} \leq \frac{I(w_n)}{\mu_n^2} &= \frac{\mu_n^{-2\beta}}{2}\|\nabla v_n\|_2^2 - \frac{4-p}{2p}\mu_n^{(1-\frac{3}{2}\beta)p+3\beta-2}\|v_n\|_p^p \\ &= \mu_n^{\frac{4(p-2)}{10-3p}}\left(\frac{1}{2}\|\nabla v_n\|_2^2 - \frac{4-p}{2p}\|v_n\|_p^p\right) \leq -C(p)\mu_n^{\frac{4(p-2)}{10-3p}}.\end{aligned} \tag{3.9}$$

From (3.6), (3.8) and interpolation inequality, we infer that

$$\|u_n\|_p^p = \frac{p}{2(p-2)}\int_{\mathbb{R}^3}\phi_{u_n}u_n^2\mathrm{d}x \leq C(p)\|u_n\|_{\frac{12}{5}}^4 \leq C(p)\|u_n\|_2^{4\alpha}\|u_n\|_p^{4(1-\alpha)} = C(p)\mu_n^{4\alpha}\|u_n\|_p^{4(1-\alpha)},$$

where $\alpha := \frac{5p-12}{6(p-2)}$. Since $\frac{8}{3} < p < 3$, namely, $p > 4(1-\alpha)$, we cannot get a contradiction with $\|u_n\|_p \to 0$ as $n \to \infty$. But we deduce from the above inequality that

$$\|u_n\|_p^p \leq C(p)\mu_n^{\frac{2(5p-12)}{3p-8}} \quad \text{and} \quad \frac{I(u_n)}{\mu_n^2} \geq -\frac{1}{p}\frac{\|u_n\|_p^p}{\mu_n^2} \geq -C(p)\mu_n^{\frac{4(p-2)}{3p-8}}. \tag{3.10}$$

Combining (3.9) and (3.10), we infer that

$$-C(p)\mu_n^{\frac{4(p-2)}{3p-8}} \leq \frac{I_{\mu_n^2}}{\mu_n^2} \leq -C(p)\mu_n^{\frac{4(p-2)}{10-3p}},$$

which contradicts $\mu_n \to 0$ as $n \to \infty$ since $\frac{4(p-2)}{3p-8} > \frac{4(p-2)}{10-3p}$ for any $\frac{8}{3} < p < 3$. In summary, for all the cases where $2 < p < 3$, we have derived contradictions. □

Proof of Theorem 1.1. Let $a_0 > 0$ be given by Lemma 2.12 and fix $a \in (0, a_0)$. Let $\{u_n\} \subset S_a$ be a minimizing sequence for $I_{a^2} < 0$ and then from Ekeland's variational principle ([36, Theorem 2.4]), we can know that $\{u_n\} \subset S_a$ is also a Palais–Smale sequence for I. From Lemma 2.10, we know that $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$. It follows from Lemma 2.13 that there exists $\bar{u} \in H^1(\mathbb{R}^3)\backslash\{0\}$ such that $\|\bar{u}\|_2 \in (0, a]$, then, up to a subsequence, $u_n \rightharpoonup \bar{u}$ as $n \to \infty$. From Lemma 2.14, we know that (2.27), (2.28), (2.30) and (2.31) are satisfied. Further, Lemmas 2.11, 3.1, 3.2 ensure that the assumptions of Proposition 2.8 hold. Then, it follows from Proposition 2.8 that, up to a subsequence, $u_n \to \bar{u}$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$. Moreover,

$\bar{u} \in S_a$ and $I(\bar{u}) = I_{a^2} < 0$. Therefore, $\bar{u}$ is the critical point of the constrained functional $I|_{S_a}$, that is, $\bar{u}$ is the normalized solution to system (1.5). From Section 2.3 and Lemma 2.7, we know that $\bar{u}$ satisfies the Pohožaev identity (2.20). Since $P(\bar{u}) = P(|\bar{u}|) = 0$, it follows that $\bar{u}$ is nonnegative. From Section 2.4 and the strong maximum principle, we conclude that $\bar{u}$ is a classical solution and $\bar{u} > 0$ in $\mathbb{R}^3$. Moreover, there exists a Lagrange multiplier $\lambda \in \mathbb{R}$ such that (2.21) holds.

When $2 < p < 3$, since $I_{a^2} < 0$ for any $a \in (0, a_0)$ from Lemma 2.12, we claim that there exists some constant $\sigma > 0$ such that $\|\nabla \bar{u}\|_2 > \sigma$. Indeed, if $\|\nabla \bar{u}\|_2 = 0$, from the fact that $\int_{\mathbb{R}^3} \phi_{\bar{u}} \bar{u}^2 \mathrm{d}x \le C \|\bar{u}\|_4^4$ and Lemma 2.1, we obtain that $\int_{\mathbb{R}^3} \phi_{\bar{u}} \bar{u}^2 \mathrm{d}x = \|\bar{u}\|_p^p = 0$ and thus $I_{a^2} = 0$, which contradicts $I(\bar{u}) = I_{a^2} < 0$. When $2 < p \le \frac{12}{5}$, from (2.21), Pohožaev identity (2.20) and $\bar{u} > 0$ in $\mathbb{R}^3$, we infer that

$$\begin{aligned}\lambda \|\bar{u}\|_2^2 &= -\|\nabla \bar{u}\|_2^2 - \int_{\mathbb{R}^3} \phi_{\bar{u}} \bar{u}^2 \mathrm{d}x + \|\bar{u}\|_p^p \\ &= 3\|\nabla \bar{u}\|_2^2 + \kappa \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} e^{-\kappa|x-y|} \bar{u}^2(x) \bar{u}^2(y) \mathrm{d}x\mathrm{d}y + \frac{12-5p}{p} \|\bar{u}\|_p^p > 3\sigma^2 > 0.\end{aligned}$$

When $\frac{12}{5} < p < 3$, let $\sigma := \left(\frac{5p-12}{3p} C_{3,p}^p a_0^{\frac{6-p}{2}} \right)^{\frac{2}{10-3p}} > 0$ and we have

$$\begin{aligned}\lambda \|\bar{u}\|_2^2 &= 3\|\nabla \bar{u}\|_2^2 + \kappa \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} e^{-\kappa|x-y|} \bar{u}^2(x) \bar{u}^2(y) \mathrm{d}x\mathrm{d}y - \frac{5p-12}{p} \|\bar{u}\|_p^p \\ &\ge \|\nabla \bar{u}\|_2^{\frac{3(p-2)}{2}} \left(3\|\nabla \bar{u}\|_2^{\frac{10-3p}{2}} - \frac{5p-12}{p} C_{3,p}^p a_0^{\frac{6-p}{2}} \right) > 0.\end{aligned}$$

Thus, it holds that $\lambda > 0$ when $2 < p < 3$ and we have completed the proof. □

3.2 Proof of Theorem 1.2

Lemma 3.3. *Let $a, \kappa > 0$, $3 < p < \frac{10}{3}$ and a_1 be obtained in Lemma 2.12. Moreover, let $\{u_n\} \subset S_a$ be a minimizing sequence for I_{a^2}. Then, for any $0 < a_1 < \mu < a$, the following strong subadditivity inequality holds*

$$I_{a^2} < I_{\mu^2} + I_{a^2-\mu^2}.$$

Proof. Since $\{u_n\} \subset S_a$ is bounded, we claim that there exist positive constants k_1, k_2 such that

$$0 < k_1 \le A(u_n) = \|\nabla u_n\|_2^2 \le k_2. \tag{3.11}$$

Indeed, if $A(u_n) = o_n(1)$, from Lemma 2.6-(i) and Lemma 2.1, we infer that $B(u_n) = C(u_n) = o_n(1)$ and $I_{a^2} = 0$, which contradicts $I_{a^2} < 0$ from Lemma 2.12-(ii).

Let $u_n^\theta(x) := \theta^{1-\frac{3}{2}\beta} u_n\left(\frac{x}{\theta^\beta}\right)$ for a.e. $x \in \mathbb{R}^3$, then $\|u_n^\theta\|_2 = \theta \|u_n\|_2 = \theta a$. Fix $\beta = -2$ and it holds that

$$\begin{aligned}I\left(u_n^\theta\right) &= \frac{\theta^6}{2} A(u_n) + \frac{\theta^6}{4} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{e^{-\kappa\theta^{-2}|x-y|}}{|x-y|} u_n^2(x) u_n^2(y) \mathrm{d}x\mathrm{d}y - \frac{\theta^{4p-6}}{p} C(u_n) \\ &\le \frac{\theta^6}{2} A(u_n) + \frac{\theta^6}{4} N(u_n) - \frac{\theta^{4p-6}}{p} C(u_n) = \mathcal{J}_0\left(u_n^\theta\right) \\ &= \theta^2 \left(I(u_n) + \frac{1}{2}\left(\theta^4 - 1\right) A(u_n) + \frac{1}{4}\left(\theta^4 N(u_n) - B(u_n)\right) - \frac{1}{p}\left(\theta^{4p-8} - 1\right) C(u_n) \right) \\ &=: \theta^2 \left(I(u_n) + f(\theta, u_n) \right), \end{aligned} \tag{3.12}$$

where $N(u_n) := \int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{1}{|x-y|}u_n^2(x)u_n^2(y)\mathrm{d}x\mathrm{d}y$ and $\mathcal{J}_0$ is defined in (1.14). When $a > a_1$, it follows from [7, Lemma 3.2] that

$$\mathcal{J}_0(u_n) = \frac{1}{2}A(u_n) + \frac{1}{4}N(u_n) - \frac{1}{p}C(u_n) < 0. \tag{3.13}$$

Therefore, when $3 < p < \frac{10}{3}$, it follows from (3.11) and (3.13) that

$$f'(\theta, u_n)|_{\theta=1} = 2A(u_n) + N(u_n) - \frac{4p-8}{p}C(u_n) < (6-2p)\,A(u_n) + (3-p)\,N(u_n) < 0. \tag{3.14}$$

Since $(4p-8)(4p-9) > 12$ when $3 < p < \frac{10}{3}$, from (3.11) and (3.13), we derive that

$$\begin{aligned} f''(\theta, u_n)|_{\theta=1} &= 6A(u_n) + 3N(u_n) - \frac{(4p-8)(4p-9)}{p}C(u_n) \\ &< \left(6 - \frac{(4p-8)(4p-9)}{2}\right)A(u_n) + \left(3 - \frac{(4p-8)(4p-9)}{4}\right)N(u_n) < 0. \end{aligned} \tag{3.15}$$

Since $f(1, u_n) = \frac{1}{4}\left(N(u_n) - B(u_n)\right) > 0$ and $f(\theta, u_n) \to -\infty$ as $\theta \to \infty$, we conclude from (3.14) and (3.15) that there exists $\theta_1 > 1$ such that $f(\theta_1, u_n) = 0$. Hence, for any $\theta > \theta_1 > 1$, we get $f(\theta, u_n) < 0$ and from (3.12), we have

$$I_{\theta^2 a^2} \le I\left(u_n^\theta\right) < \theta^2 I(u_n) \to \theta^2 I_{a^2} \quad \text{as } n \to \infty.$$

Therefore, for any $0 < a_1 < \mu < a$, it holds that

$$I_{a^2} = \frac{\mu^2}{a^2} I_{\frac{a^2}{\mu^2}\mu^2} + \frac{a^2-\mu^2}{a^2} I_{\frac{a^2}{a^2-\mu^2}(a^2-\mu^2)} < I_{\mu^2} + I_{a^2-\mu^2}.$$

This completes the proof of Lemma 3.3. □

Proof of Theorem 1.2. Let $a_1 > 0$ be given by Lemma 2.12 and fix $a > a_1$. Let $\{u_n\} \subset S_a$ be a minimizing sequence for $I_{a^2} < 0$ and then from Ekeland's variational principle ([36, Theorem 2.4]), we can know that $\{u_n\} \subset S_a$ is also a Palais–Smale sequence for I. From Lemma 2.10, we know that $\{u_n\}$ is bounded in $H^1(\mathbb{R}^3)$. It follows from Lemma 2.13 that there exists $\bar{u} \in H^1(\mathbb{R}^3)\setminus\{0\}$ such that $\|\bar{u}\|_2 \in (0, a]$, then, up to a subsequence, $u_n \rightharpoonup \bar{u}$ as $n \to \infty$. From Lemma 2.14, we know that (2.27), (2.28), (2.30) and (2.31) are satisfied. Lemma 3.3 guarantees that the strong subadditivity inequality (2.29) holds. Then, it follows from Proposition 2.9 that, up to a subsequence, $u_n \to \bar{u}$ in $H^1(\mathbb{R}^3)$ as $n \to \infty$. Moreover, $\bar{u} \in S_a$ and $I(\bar{u}) = I_{a^2} < 0$ for any $a \in (a_1, \infty)$ from Lemma 2.12. Therefore, $\bar{u}$ is the critical point of the constrained functional $I|_{S_a}$, namely, $\bar{u}$ is the normalized solution to system (1.5). Similar to the proof of Theorem 1.1, we conclude that $\bar{u}$ is a positive classical solution and the corresponding Lagrange multiplier $\lambda > 0$ when $3 < p < \frac{10}{3}$. This completes the proof of Theorem 1.2. □

3.3 Proof of Theorem 1.3

In Section 2.6, we have introduced the scaling $u^\theta(x) := \theta^{1-\frac{3}{2}\beta}u\left(\frac{x}{\theta^\beta}\right)$ for a.e. $x \in \mathbb{R}^3$ and $\left\|u^\theta\right\|_2 = \theta\|u\|_2$. Specifically, when $2 < p < 3$ and $u \in H^1(\mathbb{R}^3)$, let $\beta = \frac{4-2p}{10-3p}$ and $u^a(x) :=$

$a^{\frac{4}{10-3p}}u\left(a^{\frac{2p-4}{10-3p}}x\right)$. Then for any $u \in S_1$, we have $\|u^a\|_2 = a$ and

$$I(u^a) = a^{\frac{12-2p}{10-3p}}\left(\frac{1}{2}\|\nabla u\|_2^2 + \frac{a^{\alpha(p)}}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\kappa a^{\frac{4-2p}{10-3p}}|x-y|}}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{1}{p}\|u\|_p^p\right)$$
$$=: a^{\frac{12-2p}{10-3p}}\mathcal{I}(u),$$

where $\alpha(p) := \frac{8(3-p)}{10-3p} > 0$. Therefore, the minimization problem (1.8) is equivalent to the following one

$$\mathcal{I}_{a^2} := \inf_{u\in S_1}\mathcal{I}(u).$$

According to the arguments in [13], we introduce the following minimization problem

$$K_{a,p} := \inf_{u\in S_1}\mathcal{E}_{a,p}(u),$$

where

$$\mathcal{E}_{a,p}(u) := \frac{1}{2}\|\nabla u\|_2^2 + \frac{a^{\alpha(p)}}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\kappa a^{\frac{4-2p}{10-3p}}|x-y|}}{|x-y|}u^2(x)u^2(y)\mathrm{d}x\mathrm{d}y - \frac{1}{p}\|u\|_p^p.$$

We denote by $\mathcal{N}_{a,p}$ the corresponding set of minimizers

$$\mathcal{N}_{a,p} := \left\{u \in S_1 : \mathcal{E}_{a,p}(u) = K_{a,p}\right\}.$$

Thus, Theorem 1.3 is equivalent to the following proposition.

Proposition 3.4. *Let $2 < p < 3$ and a_0 be obtained in Theorem 1.1. Then, there exists $a_2 = a_2(p) \in (0, a_0]$ such that for any $0 < a < a_2$, every function $u \in \mathcal{N}_{a,p}$ is radially symmetric. Consequently, $\phi_u \in H_r^1(\mathbb{R}^3)$ up to translation.*

Remark 3.5. It follows from Lemma 2.6-(iv) and the implicit function argument in [13] that Proposition 3.4 holds. Therefore, the detailed proof of Theorem 1.3 will not be presented here, and readers can refer to [13].

3.4 Proof of Theorem 1.4

In this section, we shall study the limit behavior of the ground state normalized solutions $(u_\kappa, \phi_\kappa, \lambda_\kappa)$ to system (1.5) as $\kappa \to 0$.

Lemma 3.6. *([12, Lemma 3.4]) Let $p \in (2,3)$, $\kappa > 0$ and $a \in (0, a_2)$ with $a_2 > 0$ obtained in Theorem 1.3. Moreover, let $\mathcal{J}_0$ be defined in (1.14) and let*

$$I_\kappa(u_\kappa) := \frac{1}{2}\|\nabla u_\kappa\|_2^2 + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\frac{e^{-\kappa|x-y|}}{|x-y|}u_\kappa^2(x)u_\kappa^2(y)\mathrm{d}x\mathrm{d}y - \frac{1}{p}\|u_\kappa\|_p^p.$$

If

$$\left\{u_\kappa \in S_a\setminus\{0\} : I_\kappa(u_\kappa) = I_{\kappa,a^2} := \inf_{u_\kappa\in S_a} I_\kappa(u_\kappa) < 0\right\}$$

is a family of minimizers for the functional I_κ, then it holds that $I_{\kappa,a^2} \to \mathcal{J}_{0,a^2} := \inf_{u\in S_a}\mathcal{J}_0(u) < 0$ as $\kappa \to 0$.

Proof. According to $\frac{e^{-\kappa|x|}}{|x|} \leq \frac{1}{|x|}$, we know that $I_{\kappa,a^2} \leq \mathcal{J}_{0,a^2}$ for any $\kappa \geq 0$. Therefore, it suffices to prove that $\mathcal{J}_{0,a^2} \leq \liminf_{\kappa\to 0} I_{\kappa,a^2}$. Given $\kappa > 0$, we have

$$\mathcal{J}_{0,a^2} \leq \mathcal{J}_0(u_\kappa) = I_\kappa(u_\kappa) + \frac{1}{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{1-e^{-\kappa|x-y|}}{|x-y|} u_\kappa^2(x)u_\kappa^2(y)\mathrm{d}x\mathrm{d}y =: I_\kappa(u_\kappa) + \frac{1}{4}g(\kappa).$$

In this situation, we only need to prove that $g(\kappa) \to 0$ as $\kappa \to 0$. Fix $\kappa \in (0,1)$. It follows from a change of variable that

$$\begin{aligned} |g(\kappa)| \leq & \int_{\left\{z\in\mathbb{R}^3:|z|\leq\frac{1}{\kappa}\right\}} \frac{1-e^{-\kappa|z|}}{|z|} \int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z \\ & + \int_{\left\{z\in\mathbb{R}^3:|z|\geq\frac{1}{\kappa}\right\}} \frac{1-e^{-\kappa|z|}}{|z|} \int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z =: g_1(\kappa) + g_2(\kappa). \end{aligned}$$

For any $u_\kappa \in S_a$, since $1 - e^{-t} \leq t$ for all $t \geq 0$, let $t = \kappa|z| > 0$, we have

$$\begin{aligned} g_1(\kappa) &\leq \int_{\left\{z\in\mathbb{R}^3:|z|\leq\frac{1}{\kappa}\right\}} \kappa \int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z \\ &\leq \kappa \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z = \kappa a^4. \end{aligned}$$

For any $u_\kappa \in S_a$, it follows from $1 - e^{-t} \leq 1$ for all $t \geq 0$ that

$$\begin{aligned} g_2(\kappa) &\leq \int_{\left\{z\in\mathbb{R}^3:|z|\geq\frac{1}{\kappa}\right\}} \frac{1}{|z|} \int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z \\ &\leq \kappa \int_{\left\{z\in\mathbb{R}^3:|z|\geq\frac{1}{\kappa}\right\}} \int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z \\ &\leq \kappa \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} |u_\kappa(x)|^2 |u_\kappa(x-z)|^2 \,\mathrm{d}x\mathrm{d}z = \kappa a^4. \end{aligned}$$

Therefore, it holds that $g_1(\kappa), g_2(\kappa) \to 0$ as $\kappa \to 0$, that is, $g(\kappa) \to 0$ as $\kappa \to 0$, which implies that $I_{\kappa,a^2} \to \mathcal{J}_{0,a^2}$ as $\kappa \to 0$. Moreover, from $p \in (2,3)$, $a \in (0, a_2)$, (1.14), [7] and Lemma 2.12-(i), we have $\mathcal{J}_{0,a^2} < 0$. □

Lemma 3.7 ([12, Lemma 3.5]). *Let $\{f_0\} \cup \{f_\kappa : 0 < \kappa < 1\} \subset L^{\frac{6}{5}}(\mathbb{R}^3)$. Let $\varphi_0 \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ be the unique solution to the following equation*

$$-\Delta\varphi = f_0. \tag{3.16}$$

Given $\kappa \in (0,1)$, let $\phi_\kappa \in H^1(\mathbb{R}^3)$ be the unique solution to the following equation

$$-\Delta\phi + \kappa^2\phi = f_\kappa. \tag{3.17}$$

As $\kappa \to 0$, it holds that

(i) If $f_\kappa \rightharpoonup f_0$ in $L^{\frac{6}{5}}(\mathbb{R}^3)$, then $\phi_\kappa \rightharpoonup \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$.

(ii) If $f_\kappa \to f_0$ in $L^{\frac{6}{5}}(\mathbb{R}^3)$, then $\phi_\kappa \to \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ and $\kappa^2\phi_\kappa \to 0$ in $L^2(\mathbb{R}^3)$.

Proof. (i) It follows from $\phi_\kappa \in H^1(\mathbb{R}^3)$ and Sobolev's embedding theorem that $\|\phi_\kappa\|_6 \leq C\|\phi_\kappa\|_{H^1}$, and thus $\phi_\kappa \in \mathcal{D}^{1,2}(\mathbb{R}^3)$. Fix $\kappa \in (0,1)$, since $\phi_\kappa \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ is the unique solution to (3.17), from Hölder's inequality and Lemma 2.1, we deduce that

$$\|\nabla\phi_\kappa\|_2^2 \leq \|\nabla\phi_\kappa\|_2^2 + \kappa^2\|\phi_\kappa\|_2^2 = \int_{\mathbb{R}^3} f_\kappa\phi_\kappa \mathrm{d}x \leq C\|f_\kappa\|_{\frac{6}{5}}\|\phi_\kappa\|_6 \leq C\|f_\kappa\|_{\frac{6}{5}}\|\nabla\phi_\kappa\|_2, \tag{3.18}$$

thus, $\|\nabla\phi_\kappa\|_2 \leq C\|f_\kappa\|_{\frac{6}{5}}$. Since $f_\kappa \rightharpoonup f_0$ in $L^{\frac{6}{5}}(\mathbb{R}^3)$ as $\kappa \to 0$, we deduce that $\{f_\kappa : 0 < \kappa < 1\}$ is a bounded subset of $L^{\frac{6}{5}}(\mathbb{R}^3)$. It follows from $\phi_\kappa \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ that $\{\phi_\kappa : 0 < \kappa < 1\}$ is a bounded subset of $\mathcal{D}^{1,2}(\mathbb{R}^3)$. In particular, we conclude that for any $\{\kappa_n\}_{n\in\mathbb{N}} \subset (0,1)$ satisfying $\lim_{n\to\infty}\kappa_n = 0$, there exists $\phi_* \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ such that, up to a subsequence, $\phi_{\kappa_n} \rightharpoonup \phi_*$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $n \to \infty$. Next, it suffices to prove that if $\{\kappa_n\}_{n\in\mathbb{N}} \subset (0,1)$ satisfies $\kappa_n \to 0$ and $\phi_{\kappa_n} \rightharpoonup \phi_*$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $n \to \infty$, then $\phi_* = \varphi_0$.

Fix $n \in \mathbb{N}^+$, since the function ϕ_{κ_n} is a solution to (3.17), for any $\psi \in C_c^\infty(\mathbb{R}^3)$, it holds that

$$\int_{\mathbb{R}^3} \nabla\phi_{\kappa_n}\nabla\psi \mathrm{d}x + \kappa_n^2 \int_{\mathbb{R}^3} \phi_{\kappa_n}\psi \mathrm{d}x = \int_{\mathbb{R}^3} f_{\kappa_n}\psi \mathrm{d}x. \tag{3.19}$$

Since $\phi_{\kappa_n} \in L^6(\mathbb{R}^3)$, $\phi_{\kappa_n} \rightharpoonup \phi_*$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ and $\kappa_n^2\int_{\mathbb{R}^3}\phi_{\kappa_n}\psi \mathrm{d}x \leq \kappa_n^2 C\|\phi_{\kappa_n}\|_6\|\psi\|_{\frac{6}{5}} \to 0$ as $n \to \infty$, from (3.19), we take the limit as $n \to \infty$ to conclude that

$$\int_{\mathbb{R}^3} \nabla\phi_*\nabla\psi \mathrm{d}x = \int_{\mathbb{R}^3} f_0\psi \mathrm{d}x \quad \text{for any } \psi \in C_c^\infty(\mathbb{R}^3). \tag{3.20}$$

Therefore, we infer that $\phi_* = \varphi_0$ according to (3.20) and the uniqueness of the solution $\varphi_0 \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ to (3.16).

(ii) Since $f_\kappa \to f_0$ in $L^{\frac{6}{5}}(\mathbb{R}^3)$, we deduce from (i) that $\phi_\kappa \rightharpoonup \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $\kappa \to 0$. According to the weak lower semicontinuity of $\|\nabla\cdot\|_2^2$, we conclude that

$$\|\nabla\varphi_0\|_2^2 \leq \liminf_{\kappa\to 0}\|\nabla\phi_\kappa\|_2^2. \tag{3.21}$$

Let $\{\psi_n\}_{n\in\mathbb{N}} \subset C_c^\infty(\mathbb{R}^3)$ be a sequence such that $\psi_n \to \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $n \to \infty$. Fix $\kappa \in (0,1)$, let $E_\kappa : \mathcal{D}^{1,2}(\mathbb{R}^3) \to \mathbb{R}$ be the energy functional of (3.17), which is given by

$$E_\kappa(\phi) = \frac{1}{2}\|\nabla\phi\|_2^2 + \frac{\kappa^2}{2}\|\phi\|_2^2 - \int_{\mathbb{R}^3} f_\kappa\phi \,\mathrm{d}x.$$

By the facts that $\phi_\kappa \in H^1(\mathbb{R}^3)$ is the unique solution to (3.17) and $H^1(\mathbb{R}^3) \hookrightarrow \mathcal{D}^{1,2}(\mathbb{R}^3)$, we deduce from (i) that $E_\kappa(\phi_\kappa) = \inf_{\phi\in\mathcal{D}^{1,2}(\mathbb{R}^3)} E_\kappa(\phi)$. It follows from $\{\psi_n\}_{n\in\mathbb{N}} \subset C_c^\infty(\mathbb{R}^3)$ and $C_c^\infty(\mathbb{R}^3)$ is dense in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ that

$$\begin{aligned}\frac{1}{2}\|\nabla\phi_\kappa\|_2^2 &= E_\kappa(\phi_\kappa) - \frac{\kappa^2}{2}\|\phi_\kappa\|_2^2 + \int_{\mathbb{R}^3} f_\kappa\phi_\kappa \,\mathrm{d}x \leq E_\kappa(\psi_n) + \int_{\mathbb{R}^3} f_\kappa\phi_\kappa \,\mathrm{d}x \\ &= \frac{1}{2}\|\nabla\psi_n\|_2^2 + \frac{\kappa^2}{2}\|\psi_n\|_2^2 - \int_{\mathbb{R}^3} f_\kappa\left(\psi_n - \phi_\kappa\right)\mathrm{d}x.\end{aligned} \tag{3.22}$$

Since $f_\kappa \to f_0$ in $L^{\frac{6}{5}}(\mathbb{R}^3)$ and $\phi_\kappa \rightharpoonup \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $\kappa \to 0$, we deduce that

$$\int_{\mathbb{R}^3} f_\kappa\psi_n \mathrm{d}x \to \int_{\mathbb{R}^3} f_0\psi_n \mathrm{d}x \quad \text{and} \quad \int_{\mathbb{R}^3} f_\kappa\phi_\kappa \mathrm{d}x \to \int_{\mathbb{R}^3} f_0\varphi_0 \mathrm{d}x. \tag{3.23}$$

Thus, from (3.22) and (3.23), we infer that

$$\limsup_{\kappa\to 0}\frac{1}{2}\|\nabla\phi_\kappa\|_2^2 \leq \frac{1}{2}\|\nabla\psi_n\|_2^2 - \int_{\mathbb{R}^3} f_0\left(\psi_n - \phi_0\right)\mathrm{d}x.$$

From $\psi_n \to \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $n \to \infty$, we obtain that

$$\limsup_{\kappa\to 0}\|\nabla\phi_\kappa\|_2^2 \leq \|\nabla\varphi_0\|_2^2 \quad \text{as } n \to \infty. \tag{3.24}$$

It follows from (3.21) and (3.24) that $\|\nabla\phi_\kappa\|_2^2 \to \|\nabla\varphi_0\|_2^2$ as $\kappa \to 0$, and thus $\phi_\kappa \to \varphi_0$ in $\mathcal{D}^{1,2}(\mathbb{R}^3)$ as $\kappa \to 0$.

Finally, since $\varphi_0 \in \mathcal{D}^{1,2}(\mathbb{R}^3)$ is the unique solution to equation (3.16), we conclude that

$$\kappa^2 \|\phi_\kappa\|_2^2 = \int_{\mathbb{R}^3} f_\kappa \phi_\kappa \mathrm{d}x - \|\nabla\phi_\kappa\|_2^2 \to \int_{\mathbb{R}^3} f_0\varphi_0 \mathrm{d}x - \|\nabla\varphi_0\|_2^2 = 0 \quad \text{as } \kappa \to 0,$$

namely, (ii) holds. □

The following proposition shows that if $p \in (2,3)$, then the Lagrange multipliers of solutions to the Schrödinger–Poisson–Slater system (1.13) tend to a certain $\tilde{\lambda} > 0$ as $a \to 0$.

Proposition 3.8 ([13, Proposition 1.3]). *Assume $p \in (2,3)$, $\kappa > 0$ and $\tilde{\lambda} > 0$, when $a \in (0, a_2)$, where a_2 is obtained in Theorem 1.3, for every $\varepsilon > 0$, there exists $a(\varepsilon) \in (0, a_2)$ such that*

$$\sup_{\lambda \in \mathcal{A}_a} |\lambda - \tilde{\lambda}| < \varepsilon \quad \forall\, 0 < a < a(\varepsilon),$$

where

$$\mathcal{A}_a := \{\lambda \in \mathbb{R} : \text{there exists } u \in H^1(\mathbb{R}^3) \text{ such that } (u,\varphi,\lambda) \in H^1(\mathbb{R}^3) \times \mathcal{D}^{1,2}(\mathbb{R}^3) \times \mathbb{R} \text{ is a ground state solution to the Schrödinger–Poisson–Slater system (1.13)}\}.$$

Proof of Theorem 1.4. Since $\kappa > 0$, $2 < p < 3$ and $0 < a < a_2$, according to Theorems 1.1 and 1.3, for any ground state normalized solution $(u_\kappa, \phi_\kappa, \lambda_\kappa)$ to system (1.5) with $u_\kappa \in S_a \setminus \{0\}$ and $I_\kappa(u_\kappa) = I_{\kappa,a^2} < 0$, we deduce that up to translation, $(u_\kappa, \phi_\kappa, \lambda_\kappa) \in S_a^r \times H_r^1(\mathbb{R}^3) \times (0,\infty)$, which implies that $(u_\kappa, \phi_\kappa, \lambda_\kappa) \in S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times (0,\infty)$.

It follows from Lemma 2.10 that the set $\{u_\kappa \in S_a : I_\kappa(u_\kappa) = I_{\kappa,a^2} < 0\}$ is bounded in $H_r^1(\mathbb{R}^3)$ for any $\kappa > 0$. Let $\{\kappa_n\}_{n\in\mathbb{N}^+} \subset (0,1)$ be a sequence such that $\kappa_n \to 0$ as $n \to \infty$. Then, for any $n \in \mathbb{N}^+$, both $\{u_{\kappa_n}\} \subset S_a^r$ and $\{\phi_{\kappa_n}\} \subset \mathcal{D}_r^{1,2}(\mathbb{R}^3)$ are bounded and thus there exists $u_0 \in H_r^1(\mathbb{R}^3)$ such that, up to a subsequence, $u_{\kappa_n} \rightharpoonup u_0$ in $H_r^1(\mathbb{R}^3)$ as $n \to \infty$, $u_{\kappa_n} \to u_0$ in $L^p(\mathbb{R}^3)$ with $p \in (2,6)$ and $u_{\kappa_n} \to u_0$ a.e. in $\mathbb{R}^3$. Since $u_{\kappa_n}^2 \to u_0^2$ in $L^{\frac{6}{5}}(\mathbb{R}^3)$, from Lemma 3.7, we deduce that as $n \to \infty$, up to a subsequence, $\phi_{\kappa_n} \to \varphi_0$ in $\mathcal{D}_r^{1,2}(\mathbb{R}^3)$, where φ_0 is the unique solution of $-\Delta\varphi = 4\pi u_0^2$ in $\mathbb{R}^3$. Since for any $n \in \mathbb{N}^+$, $(u_{\kappa_n}, \phi_{\kappa_n}, \lambda_{\kappa_n}) \in S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times (0,\infty)$ is a ground state normalized solution to (1.5), from (2.21), Lemmas 2.1 and 2.6-(iii), we infer that

$$\begin{aligned} |\lambda_{\kappa_n}| &= \frac{1}{a^2}\left|\|u_{\kappa_n}\|_p^p - \|\nabla u_{\kappa_n}\|_2^2 - \int_{\mathbb{R}^3} \phi_{\kappa_n} u_{\kappa_n}^2 \mathrm{d}x\right| \\ &\le \frac{1}{a^2}\left(C\|\nabla u_{\kappa_n}\|_2^{\frac{3(p-2)}{2}} a^{\frac{6-p}{2}} + \|\nabla u_{\kappa_n}\|_2^2 + C\|\nabla u_{\kappa_n}\|_2^3 a\right) < \infty, \end{aligned}$$

namely, $\{\lambda_{\kappa_n}\} \subset (0,\infty)$ is a bounded sequence, and then there exists $\lambda_0 \in [0,\infty)$ such that, up to a subsequence, $\lambda_{\kappa_n} \to \lambda_0$ as $n \to \infty$.

Moreover, since $\mathcal{J}_0$, defined in (1.14), is the functional of the Schrödinger–Poisson–Slater system (1.13), it follows from Lemma 3.6 that $\{u_{\kappa_n}\}$ is a minimizing sequence for $\mathcal{J}_0$ at level $\mathcal{J}_{0,a^2} < 0$. Hence, from $u_{\kappa_n} \rightharpoonup u_0$ in $H_r^1(\mathbb{R}^3)$, $\phi_{\kappa_n} \to \varphi_0$ in $\mathcal{D}_r^{1,2}(\mathbb{R}^3)$, $\lambda_{\kappa_n} \to \lambda_0$, Proposition 2.8, Lemma 2.13 and [7], we conclude that $u_0 \in S_a^r \setminus \{0\}$, $u_{\kappa_n} \to u_0$ in $H_r^1(\mathbb{R}^3)$ as $n \to \infty$ and $\mathcal{J}_0(u_0) = \mathcal{J}_{0,a^2} < 0$. Thus, $(u_0, \varphi_0, \lambda_0) \in S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times [0,\infty)$ is a ground state normalized solution to the Schrödinger–Poisson–Slater system (1.13) with

$$\lambda_0 := \frac{1}{a^2}\left(\|u_0\|_p^p - \|\nabla u_0\|_2^2 - \int_{\mathbb{R}^3} \varphi_0 u_0^2 \,\mathrm{d}x\right).$$

According to Proposition 3.8, for every $\varepsilon > 0$, there exists $a(\varepsilon) \in (0, a_2)$ such that $\lambda_0 > 0$ when $a \in (0, a_2)$ is sufficiently small. Therefore, we conclude that, up to a subsequence and up to translation, it holds that

$$(u_\kappa, \phi_\kappa, \lambda_\kappa) \to (u_0, \varphi_0, \lambda_0) \quad \text{in } S_a^r \times \mathcal{D}_r^{1,2}(\mathbb{R}^3) \times (0, \infty) \quad \text{as } \kappa \to 0.$$

That is, (1.15) holds. Thus, we have completed the proof of Theorem 1.4. □

Abstract. This paper is devoted to the study of semi-stable radial solutions $u \in H^1(B_1)$ of $-\Delta u = |x|^\alpha f(u)$ in $B_1 \setminus \{0\}$, where $f \in C^1(\mathbb{R})$ is a general nonlinearity, $\alpha > -2$ and B_1 is the unit ball of $\mathbb{R}^N$, $N > 1$. We establish the boundedness of such solutions for dimensions $2 \le N < 10 + 4\alpha$ and sharp pointwise estimates in the case $N \ge 10 + 4\alpha$. In addition, we provide, for this range of dimensions, a large family of semi-stable radially decreasing unbounded $H^1(B_1)$ solutions.

Keywords: Hardy–Hénon equation, regularity estimates, semi-stable solutions.

2020 Mathematics Subject Classification: 35B45, 35B35, 35J61.

1 Introduction

This paper deals with the semi-stability of radial solutions $u \in H^1(B_1)$ of

$$-\Delta u = |x|^\alpha f(u) \quad \text{in } B_1 \setminus \{0\}, \tag{P}$$

where $x = (x_1, \dots, x_N)$ and B_1 the unit ball of $\mathbb{R}^N$ with measure ω_N/N for $N > 1$. In the whole paper we assume $\alpha > -2$, and $f \in C^1(\mathbb{R})$. We deal with the regularity of semi-stable radially symmetric energy solutions $u \in H^1(B_1)$ of (P). Denoting by $r := |x|$ standard arguments show that these radial solutions $u = u(|x|) \equiv u(r)$ are continuous in $r \in (0,1]$ and can be viewed as classical solutions. We denote as usual $u_r := \frac{\langle x, \nabla u \rangle}{|x|}$ and constants by capital letters $C, K, C', K' \dots$ that may vary throughout the discussion and computations, with subscripts that determine the dependence of the constants on other parameters.

The equation (P) corresponds to the Euler–Lagrange equation of the energy functional

$$E(u) := \int_{B_1} \left(\frac{|\nabla u|^2}{2} - |x|^\alpha F(u) \right) dx, \tag{1.1}$$

where $F(t) = \int_0^t f(s)ds$. Since $f \in C^1(\mathbb{R})$ and u is continuous, then $f'(u)$ is continuous. It is meaningful to call a solution $u \in H^1(B_1)$ semi-stable if the second variation of the energy is nonnegative definite, i.e.,

$$d^2E(\varphi, \varphi) = \int_{B_1} \left(|\nabla \varphi|^2 - |x|^\alpha f'(u)\varphi^2 \right) dx \ge 0, \tag{1.2}$$

✉ Corresponding author. Email: jsilverio@ugr.es

for all $\varphi \in C^1(B_1)$ with compact support in $B_1 \setminus \{0\}$.

Equation (P) can be regarded as a generalized version of the so called Hardy–Hénon equation which corresponds to power-type nonlinearity $f(u) = |u|^{p-1}u$. That equation is in particular called the Lane–Emden equation in the autonomous case $\alpha = 0$. Another nomenclature has been used for $f(u) = e^u$, the Hénon–Gelfand problem.

The study of this problem is preceded by the study of the so called Hénon equation whose origins goes back to the celebrated work of S. Chandrasekhar [3, Chapter IV, 87–88] on the stellar structure in polytropic equilibrium in astrophysics.

The pioneering contribution in the autonomous case $\alpha = 0$ is due to [12] where the authors prove that for power-type nonlinearity $f(u) = |u|^{p-1}u$ and posed in the whole space $\mathbb{R}^N$, there is no positive solution for $p \in (1, p_S(N))$, where $p_S(N) := 2^* - 1 = \frac{N+2}{N-2}$ if $N \leq 3$ and $p_S = +\infty$ if $N \leq 2$ is the classical critical Sobolev exponent.

For $p = p_S(N)$, the same equation is known to have (up to translation and rescaling) a unique positive solution, which is radial and explicit (see [2]).

Let now $p_{JL}(N) > p_S(N)$ denote the so called Joseph–Lundgren exponent:

$$p_{JL}(N) = \begin{cases} +\infty & \text{if } N \leq 10, \\ \frac{(N-2)^2 - 4N + 8\sqrt{N-1}}{(N-2)(N-10)} & \text{if } N \geq 11. \end{cases}$$

This exponent can be characterized as follows: for $p \geq p_S(n)$, the explicit function $u_s(x) = C_{p,N}|x|^{-\frac{2}{p-1}}$ for an appropriate constant $C_{p,N}$ depending only on p and N, is a singular solution of the Lane–Emden equation, which is stable if and only if $p \geq p_{JL}(N)$. It was proved in [9] that Lane–Emden equation has no nontrivial finite Morse index solution whenever $1 < p < p_{JL}(N)$, $p \neq p_S(N)$. Through the application of some blow-up analysis technique, such Liouville-type theorems imply interior regularity for solutions of a large class of semilinear elliptic equations: they are known to be equivalent to universal estimates for solutions of

$$-Lu = f(x, u, \nabla u) \quad \text{in } \Omega, \tag{1.3}$$

where L is a uniformly elliptic operator with smooth coefficients, the nonlinearity f scales like $|u|^{p-1}u$ for large values of u, and Ω is an open set of $\mathbb{R}^N$. For precise statements, see the work [17] in the subcritical setting, as well as its adaptation to the supercritical case by [6].

In [10], the authors consider Liouville-type theorems for Hénon–Lane–Emden systems, as well as solutions of the fourth-order Hénon equation with finite Morse index.

For the Hénon–Hardy equation (i.e. $\alpha \neq 0$, $f(u) = |u|^{p-1}u$), there are also an extensive literature. In [5], the authors show the following:

Theorem 1.1 (Dancer, Du, Guo [5])). *Let u be a stable solution of the Hénon–Hardy equation with $\alpha > -2$, $\Omega = \mathbb{R}^N$, and one of the following hypothesis is true: $2 \leq N \leq 10 + 4\alpha$ and $p > 1$; or $N > 10 + 4\alpha$ and $1 < p < p_{JL}(N, \alpha)$; where we have defined*

$$p_{JL}(N, \alpha) = \begin{cases} +\infty & \text{if } 2 \leq N \leq 10 + 4\alpha, \\ \frac{(N-2)^2 - 2(\alpha+2)(\alpha+N) + 2\sqrt{(\alpha+2)^3(\alpha+2N-2)}}{(N-2)(N-4\alpha-10)} & \text{if } N > 10 + 4\alpha. \end{cases}$$

Then $u \equiv 0$. On the contrary, for $p \geq p_{JL}(N, \alpha)$ the equation admits a family of radially symmetric positive stable solutions.

These results were later generalized in [19] for sign-changing solutions where the authors also proved that assuming $0 \in \Omega$, no weak solution exists for $\alpha \leq -2$. As they remark in

their proof, the result remains valid for any positive, convex and nondecreasing nonlinearity f. This indicates that the case $\alpha \leq -2$ carries additional pathological behavior, highlighting the necessity of avoiding that values for α. For $\alpha > -2$, $\Omega = \mathbb{R}^N$ they also prove the following two results:

(i) If $2 \leq N < 10 + 4\alpha$, there is no weak stable solution of the Gelfand–Hénon equation.

(ii) If $2 < N < 10 + 4\alpha^-$ where $\alpha^- = \min\{\alpha, 0\}$, then any weak solution of the Gelfand–Hénon equation has infinite Morse index.

Remark 1.2. The dimension range $2 \leq N < 10 + 4\alpha$ is optimal, since for $N \geq 10 + 4\alpha$

$$u(x) = -(2+\alpha)\log|x| + \log[(2+\alpha)(N-2)],$$

is a radial stable weak solution to the Gelfand–Hénon equation.

For analogous recent results in the fractional/non local setting we refer to [8,11,13–15] and even with a Hardy potential term $|x|^{-2s}u$ on the right-hand side [16] or concerning systems [4,7] and references therein.

In our case, we are mainly concerned with the regularity of semi-stable radial solutions of the general Hénon–Hardy equation, although we think that our results can be further developed in several directions involving extensions of what is known in the autonomous case. For instance, it would be interesting to investigate the existence and regularity of a critical solution of the equation $-\Delta u = \lambda|x|^{\alpha} f(u)$ with the appropriate set of hypothesis over α and f in the spirit of [1]. The content is developed through a series of lemmas and propositions, arriving at the end to the proof of the theorem stated at the beginning of the next section.

2 Statement of the main result and steps of the proof

We directly proceed to state the main result of the paper: a classification of the behavior of semi-stable radial solutions of (P) depending on the dimension.

Theorem 2.1. *Let $N \geq 2$, $f \in C^1(\mathbb{R})$, $\alpha > -2$ and $u \in H^1(B_1)$ be a semi-stable radial solution of (P). Then there exists a constant $C_{\alpha,N}$ depending only on α and N such that:*

(i) if $N < 10 + 4\alpha$, then $\|u\|_{L^\infty(B_1)} \leq C_{\alpha,N}\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}$;

(ii) if $N = 10 + 4\alpha$, then $|u(r)| \leq C_{\alpha,10+4\alpha}\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}\left(|\log r| + 1\right)$, $\forall r \in (0,1]$;

(iii) if $N > 10 + 4\alpha$, then $|u(r)| \leq C_{\alpha,N}\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}\, r^{\gamma(N,\alpha)}$, $\forall r \in (0,1]$,

where we have defined the exponent $\gamma(N,\alpha) := 2 - N/2 + \alpha/2 + \sqrt{(\alpha+2)(\alpha+2N-2)}/2$.

Remark 2.2. Observe that $\gamma(N,\alpha) = 0$ if and only if $N = 10 + 4\alpha$ and $\gamma(N,\alpha) < 0$ if and only if $N > 10 + 4\alpha$ so that the pointwise estimates *ii)* and *iii)* do not give rise to boundedness of u.

We shall divide the proof in several lemmas and propositions.

Lemma 2.3. *Let $N \geq 2$, $f \in C^1(\mathbb{R})$, $\alpha > -2$ and $u \in H^1(B_1)$ be a semi-stable radial solution of (P). Let $v \in C^{0,1}(0,1]$ such that $v(1) = 0$. Then*

$$\int_{r_0}^1 t^{N-1} u_r^2(t) \left(v'(t)^2 + \alpha \frac{v'(t)v(t)}{t} + \left(1 - N - \alpha \frac{N}{2}\right) \frac{v(t)^2}{t^2} \right) dt \geq 0, \tag{2.1}$$

for every $r_0 \in (0,1)$.

Proof. Assume, as a first step, that $v \in C^\infty(0,1)$ has compact support and $v \equiv 0$ in $(0, r_0]$ (later we will prove it for any $v \in C^{0,1}(0,1]$ with $v(1) = 0$). Differentiating (P) with respect to r we obtain

$$(-\Delta u)_r = -\Delta u_r + \frac{N-1}{r^2} u_r = \alpha r^{\alpha-1} f(u) + r^\alpha f'(u) u_r.$$

Multiplying by the radial function $u_r v^2$ and integrating by parts yields

$$\int_{B_1} \left(\nabla u_r \nabla (u_r v^2) + \frac{N-1}{r^2} u_r^2 v^2 \right) dx = \int_{B_1} \left(\alpha r^{\alpha-1} f(u) + r^\alpha f'(u) u_r \right) u_r v^2 dx.$$

Therefore

$$\int_{B_1} \left(v^2 |\nabla u_r|^2 + 2 u_r v \nabla u_r \nabla v + \frac{N-1}{r^2} u_r^2 v^2 \right) dx = \int_{B_1} \left(\alpha r^{\alpha-1} f(u) u_r v^2 + r^\alpha f'(u) u_r^2 v^2 \right) dx. \tag{2.2}$$

On the other hand, since u is stable, we can consider the radial function $u_r v$ (which is a $C^1(B_1)$ function with compact support in $B_1 \setminus \{0\}$) obtaining

$$\int_{B_1} |\nabla (u_r v)|^2 dx \geq \int_{B_1} r^\alpha f'(u) (u_r v)^2 dx. \tag{2.3}$$

Subtracting (2.2) from (2.3) we can assert that

$$\int_{B_1} \left(u_r^2 v_r^2 - \frac{N-1}{r^2} u_r^2 v^2 \right) \geq -\alpha \int_{B_1} r^{\alpha-1} f(u) u_r v^2 dx. \tag{2.4}$$

Let us expand this last term:

$$\begin{aligned} \int_{B_1} r^{\alpha-1} f(u) u_r v^2 dx &= \int_{B_1} (-\Delta u) \frac{u_r v^2}{r} dx = \omega_N \int_{r_0}^1 t^{N-1} \left(-u_{rr} - \frac{N-1}{t} u_r \right) \frac{u_r v^2}{t} dt \\ &= -\frac{\omega_N}{2} \int_{r_0}^1 \left(t^{2N-2} u_r^2 \right)' t^{-N} v^2 dt = \frac{\omega_N}{2} \int_{r_0}^1 t^{2N-2} u_r^2 (t^{-N} v^2)' dt \\ &= \omega_N \int_{r_0}^1 t^{N-1} \left(\frac{-N}{2} \frac{u_r^2 v^2}{t^2} + \frac{u_r^2 v v'}{t} \right) dt. \end{aligned}$$

Combining this and (2.4) we obtain

$$\omega_N \int_{r_0}^1 t^{N-1} \left(u_r^2 v'^2 - \frac{N-1}{t^2} u_r^2 v^2 \right) dt \geq -\alpha\, \omega_N \int_{r_0}^1 t^{N-1} \left(\frac{-N}{2} \frac{u_r^2 v^2}{t^2} + \frac{u_r^2 v v'}{t} \right) dt,$$

which is the desired conclusion.

In fact, by standard density arguments, the above formula is also true if we consider a $C^{0,1}(0,1]$ function vanishing in $(0, r_0] \cup \{1\}$.

Now, for the sake of clarity of the exposition let us denote

$$I(a, b; v) := \int_a^b t^{N-1} u_r^2(t) \left(v'(t)^2 + \alpha \frac{v'(t)v(t)}{t} + \left(1 - N - \alpha \frac{N}{2}\right) \frac{v(t)^2}{t^2} \right) dt. \tag{2.5}$$

For an arbitrary $v \in C^{0,1}(0,1]$ vanishing at $t = 1$, we define a radial truncated function

$$\bar{v}_\varepsilon(t) = \begin{cases} 0 & \text{if } 0 < t < \varepsilon, \\ \frac{v(r_0)}{r_0 - \varepsilon}(t - \varepsilon) & \text{if } \varepsilon \le t \le r_0, \\ v(t) & \text{if } r_0 < t \le 1, \end{cases} \tag{2.6}$$

for any $0 < \varepsilon < r_0$. Now, applying the first step of the lemma to the function $\bar{v}_\varepsilon$ we have that $I(\varepsilon, 1; \bar{v}_\varepsilon) \ge 0$ and thus

$$\begin{aligned} I(r_0, 1; v) &\ge -I(\varepsilon, r_0; \bar{v}_\varepsilon) \\ &= -\left(\frac{v(r_0)}{r_0 - \varepsilon}\right)^2 \int_\varepsilon^{r_0} t^{N-1} u_r(t)^2 \left[1 + \alpha\frac{t-\varepsilon}{t} + \left(1 - N - \alpha\frac{N}{2}\right)\frac{(t-\varepsilon)^2}{t^2}\right] dt. \end{aligned}$$

Observe that since $u \in H^1(B_1)$ the whole right hand side is uniformly bounded for $\epsilon \in (0, r_0)$. Therefore

$$I(r_0, 1; v) \ge -\lim_{\varepsilon \to 0} I(\varepsilon, r_0; \bar{v}_\varepsilon) = -\left(\frac{v(r_0)}{r_0}\right)^2 (2 + \alpha)\left(1 - \frac{N}{2}\right) \int_0^{r_0} t^{N-1} u_r(t)^2 dt \ge 0,$$

as we claimed. □

Remark 2.4. In the last step, it is shown that the assumption $u \in H^1(B_1)$ is essential. Indeed, it is well known (see for instance [1]), that there exists semi-stable weak solutions to $-\Delta u = C_{N,q}(1+u)^{\frac{q-2}{q}}$ in B_1 of the form $u(x) = |x|^q - 1$ such that $u \notin H^1(B_1)$ in the range $q \in \left(-\frac{N}{2} + 2 - \sqrt{N-1},\ -\frac{N}{2} + 1\right]$, $N \ge 3$.

Proposition 2.5. *Let $N \ge 2$, $f \in C^1(\mathbb{R})$, $\alpha > -2$ and $u \in H^1(B_1)$ be a non constant semi-stable radial solution of (P). Then $u_r \ne 0$ in $(0,1]$.*

Proof. Assume by contradiction that there exists $r_1 \in (0,1]$ such that $u_r(r_1) = 0$. From $u \in H^1(B_1)$, $f \in C^1(\mathbb{R})$ and the radial symmetry we know that $u(r) \in C^3((0,1])$. Thus, in particular there is a constant $C_{r_1} > 0$ such that $|u_r(r)| \le C_{r_1}|r - r_1|$ for any $r \in [r_1/2, r_1]$. On the other hand, we take the following test function

$$v(t) = \begin{cases} \frac{t}{r_1 - \varepsilon} & \text{if } 0 < t < r_1 - \varepsilon, \\ \frac{r_1 - t}{\varepsilon} & \text{if } r_1 - \varepsilon \le t \le r_1, \\ 0 & \text{if } r_1 < t \le 1, \end{cases}$$

with $0 < \varepsilon < r_1/2$. Applying Lemma 2.3 we have that $-I(r_0, r_1 - \varepsilon; v) \le I(r_1 - \varepsilon, r_1; v)$ for any $0 < r_0 < r_1 - \varepsilon$. Therefore

$$\begin{aligned} &-\frac{1}{(r_1 - \varepsilon)^2} \int_{r_0}^{r_1 - \varepsilon} t^{N-1} u_r^2(t)(2 + \alpha)\left(1 - \frac{N}{2}\right) dt \\ &\quad \le \int_{r_1 - \epsilon}^{r_1} \frac{t^{N-1} u_r^2(t)}{\varepsilon^2}\left[1 - \alpha\frac{(r_1 - t)}{t} + \left(1 - N - \alpha\frac{N}{2}\right)\frac{(r_1 - t)^2}{t^2}\right] dt \\ &\quad \le K \int_{r_1 - \epsilon}^{r_1} \frac{u_r^2(t)}{\varepsilon^2} dt \le K C_{r_1}^2 \int_{r_1 - \epsilon}^{r_1} \frac{(t - r_1)^2}{\varepsilon^2} dt = \frac{K C_{r_1}^2}{3}\,\varepsilon. \end{aligned}$$

Taking limit as $\varepsilon \to 0$ we have that

$$-\frac{1}{r_1^2}(2 + \alpha)\left(1 - \frac{N}{2}\right) \int_{r_0}^{r_1} t^{N-1} u_r^2(t) dt \le 0,$$

that implies that $u_r \equiv 0$ in $[r_0, r_1]$ if $N > 2$. By the uniqueness of the corresponding Cauchy problem, $u_r \equiv 0$ in $(0, 1]$ which gives the contradiction for $N > 2$. Finally, if $N = 2$ we change the test function by

$$v(t) = \begin{cases} \left(\frac{t}{r_1-\varepsilon}\right)^\beta & \text{if } 0 < t < r_1 - \varepsilon, \\ \frac{r_1-t}{\varepsilon} & \text{if } r_1 - \varepsilon \le t \le r_1, \\ 0 & \text{if } r_1 < t \le 1, \end{cases}$$

with $\beta \in \mathbb{R}$ to be chosen later. With similar arguments we can conclude

$$-\frac{1}{r_1^{2\beta}}(\beta - 1)\,(\beta + \alpha + 1) \int_{r_0}^{r_1} t^{N-1+2\beta-2} u_r^2(t) dt \le 0.$$

Choosing any $\beta \in (-1-\alpha, 1)$, we obtain $u_r \equiv 0$ in $[r_0, r_1]$ which is again a contradiction. □

Lemma 2.6. *Let $N \ge 2$, $f \in C^1(\mathbb{R})$, $\alpha > -2$ and $u \in H^1(B_1)$ be a non constant semi-stable radial solution of (P). Then*

$$\int_{r/2}^{r} u_r^2\, dt \le K_{\alpha,N} \|\nabla u\|^2_{L^2(B_1 \setminus \overline{B_{1/2}})}\, r^{3-N+\alpha+\sqrt{(2+\alpha)(2N-2+\alpha)}},$$

for any $r \in (0, 1]$.

Proof. We first consider the case $0 < r \le 1/2$ and define

$$v(t) = \begin{cases} r^{s-1} t & \text{if } 0 < t < r, \\ t^s & \text{if } r \le t \le 1/2, \\ 2^{1-s}(1-t) & \text{if } 1/2 < t \le 1 \end{cases}$$

with $s \in \mathbb{R}$ to be determined. By Lemma 2.3 applied for $r_0 = r/2$, we have

$$\begin{aligned} 0 \le\ & r^{2s-2} \int_{r/2}^{r} t^{N-1} u_r^2(t)\,(2+\alpha) \left(1 - \frac{N}{2}\right) dt \\ & + \int_{r}^{1/2} t^{N-3+2s} u_r^2(t) \left(s^2 + \alpha s + 1 - N - \alpha \frac{N}{2}\right) dt \\ & + \int_{1/2}^{1} t^{N-1} u_r^2(t)\, 2^{2-2s} \left[1 - \alpha \frac{1-t}{t} + \left(1 - N - \alpha \frac{N}{2}\right) \left(\frac{1-t}{t}\right)^2\right] dt. \end{aligned}$$

Choosing $s_\alpha = -\alpha/2 - \sqrt{(2+\alpha)(2N-2+\alpha)}/2$, the second term is indeed zero. Therefore, we deduce

$$\begin{aligned} & - r^{2s_\alpha - 2} \int_{r/2}^{r} t^{N-1} u_r^2(t) (2+\alpha) \left(1 - \frac{N}{2}\right) dt \\ & \le \int_{1/2}^{1} t^{N-1} u_r^2(t)\, 2^{2-2s_\alpha} \left[1 - \alpha \frac{1-t}{t} + \left(1 - N - \alpha \frac{N}{2}\right) \left(\frac{1-t}{t}\right)^2\right] dt. \end{aligned}$$

As a result

$$\begin{aligned}
&- r^{2s_\alpha-2}\int_{r/2}^{r}\left(\frac{r}{2}\right)^{N-1}u_r^2(t)(2+\alpha)\left(1-\frac{N}{2}\right)dt\\
&\le r^{2s_\alpha-2}\int_{r/2}^{r}t^{N-1}u_r^2(t)(2+\alpha)\left(1-\frac{N}{2}\right)dt\\
&\le \int_{1/2}^{1}t^{N-1}u_r^2(t)\,2^{2-2s_\alpha}\left[1-\alpha\frac{1-t}{t}+\left(1-N-\alpha\frac{N}{2}\right)\left(\frac{1-t}{t}\right)^2\right]dt\\
&\le C\int_{1/2}^{1}t^{N-1}u_r^2(t)dt,
\end{aligned}$$

Finally, we obtain

$$-\frac{(2+\alpha)\left(1-\frac{N}{2}\right)}{2^{N-1}}r^{2s_\alpha-3+N}\int_{r/2}^{r}u_r^2(t)dt\le\frac{C}{\omega_N}\|\nabla u\|^2_{L^2(B_1\setminus\overline{B_{1/2}})}$$

which is the desired conclusion if $N>2$. If $N=2$, we change the test function by

$$v(t)=\begin{cases}r^{-1-\alpha-\beta}t^\beta & \text{if } 0<t<r,\\ t^{-1-\alpha} & \text{if } r\le t\le 1/2,\\ 2^{2+\alpha}(1-t) & \text{if } 1/2<t\le 1.\end{cases}$$

with $\beta\in(-1-\alpha,1)$ as in the previous proposition. We have

$$\begin{aligned}
&-r^{-2-2\alpha-2\beta}\int_{r/2}^{r}t^{-1+2\beta}\,u_r^2(t)(\beta-1)(\beta+\alpha+1)\,dt\\
&\qquad\le\int_{1/2}^{1}t\,u_r^2(t)\,2^{4+2\alpha}\left[1-\alpha\frac{1-t}{t}-(1+\alpha)\left(\frac{1-t}{t}\right)^2\right]dt,
\end{aligned}$$

that gives the desired conclusion once the same argument as above is employed for the last integral.

On the other hand, let us call $R_{\alpha,N}$ a constant such that $0<R_{\alpha,N}<r^{3-N-2s_\alpha}$ for all $r\in[1/2,1]$. Hence, applying the above conclusion for $r=1/2$

$$\begin{aligned}
\int_{r/2}^{r}u_r^2(t)dt&\le\int_{1/4}^{1/2}u_r^2(t)dt+\int_{1/2}^{1}u_r^2(t)dt\\
&\le K_{\alpha,N}\left(\frac12\right)^{3-N-2s_\alpha}\|\nabla u\|^2_{L^2(B_1\setminus\overline{B_{1/2}})}+\frac{1}{\omega_N}\|\nabla u\|^2_{L^2(B_1\setminus\overline{B_{1/2}})}\\
&=\left(K_{\alpha,N}\left(\frac12\right)^{3-N-2s_\alpha}+\frac{1}{\omega_N}\right)\|\nabla u\|^2_{L^2(B_1\setminus\overline{B_{1/2}})}\\
&\le\frac{1}{R_{\alpha,N}}\left[K_{\alpha,N}\left(\frac12\right)^{3-N-2s_\alpha}+\frac{1}{\omega_N}\right]\|\nabla u\|^2_{L^2(B_1\setminus\overline{B_{1/2}})}r^{3-N-2s_\alpha},
\end{aligned}$$

giving rise to the same conclusion again. □

Proposition 2.7. *Let $N\ge2$, $f\in C^1(\mathbb{R})$, $\alpha>-2$ and $u\in H^1(B_1)$ be a non constant semi-stable radial solution of (P). Then*

$$|u(r)-u(r/2)|\le K'_{\alpha,N}\|\nabla u\|_{L^2(B_1\setminus\overline{B_{1/2}})}\,r^{2-N/2+\alpha/2+\sqrt{(2+\alpha)(2N-2+\alpha)}/2},$$

for all $r\in(0,1]$.

Proof. Fix $r \in (0,1/2)$, using the Cauchy–Schwarz inequality and Lemma 2.6, we have the following chain of inequalities:

$$\begin{aligned}|u(r)-u(r/2)| &= \left|\int_{r/2}^{r} u_r(t)\,dt\right| \le \int_{r/2}^{r} |u_r(t)|\,dt \le \left(\int_{r/2}^{r} u_r^2(t)dt\right)^{1/2}\left(\int_{r/2}^{r} dt\right)^{1/2}\\ &\le K_{\alpha,N}\|\nabla u\|_{L^2(B_1\setminus\overline{B_{1/2}})} r^{\frac{3-N+\alpha+\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}}\left(\frac{r}{2}\right)^{\frac{1}{2}}\\ &\le K'_{\alpha,N}\|\nabla u\|^2_{L^2(B_1\setminus\overline{B_{1/2}})} r^{\frac{4-N+\alpha+\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}}.\end{aligned}$$

□

Proof of Theorem 2.1. Following the reasoning of [18], let $r \in (0,1]$, there exists $r_1 \in (1/2,1]$ such that $r = r_1/2^{m-1}$ for some $m \in \mathbb{N}$. By Sobolev embedding in dimension one we observe that $u(r_1) \le \|u\|_{L^\infty(B_1\setminus B_{1/2})} \le \mathfrak{s}_N\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}$. Therefore

$$\begin{aligned}|u(r)| &\le |u(r_1)-u(r)| + |u(r_1)| \le \sum_{k=1}^{m-1}\left|u\left(\frac{r_1}{2^{k-1}}\right)-u\left(\frac{r_1}{2^k}\right)\right| + |u(r_1)|\\ &\le K'_{\alpha,N}\|\nabla u\|_{L^2(B_1\setminus\overline{B_{1/2}})}\sum_{k=1}^{m-1}\left(\frac{r_1}{2^{k-1}}\right)^{2-\frac{N}{2}+\frac{\alpha+\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}} + \mathfrak{s}_N\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}\\ &\le \left(K''_{\alpha,N}\sum_{k=1}^{m-1}\left(\frac{r_1}{2^{k-1}}\right)^{2-\frac{N}{2}+\frac{\alpha+\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}} + \mathfrak{s}_N\right)\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}. \qquad (2.7)\end{aligned}$$

- If $2 \le N < 10+4\alpha$, we have $2-N/2+\alpha/2+\sqrt{(2+\alpha)(2N-2+\alpha)}/2 > 0$. Then

$$\sum_{i=1}^{m-1}\left(\frac{r_1}{2^{i-1}}\right)^{2-\frac{N}{2}+\alpha/2+\sqrt{(2+\alpha)(2N-2+\alpha)}/2} \le \sum_{i=1}^{\infty}\left(\frac{1}{2^{i-1}}\right)^{2-\frac{N}{2}+\alpha/2+\sqrt{(2+\alpha)(2N-2+\alpha)}/2},$$

  which is a convergent series. Hence, equation (2.7) implies statement i) of the theorem.

- If $N = 10+4\alpha$, we have $2-N/2+\alpha/2+\sqrt{(2+\alpha)(2N-2+\alpha)}/2 = 0$. From (2.7) we obtain

$$\begin{aligned}|u(r)| &\le \left(K'_{\alpha,N}(m-1)+\mathfrak{s}_N\right)\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}\\ &= \left(K'_{\alpha,N}\left(\frac{\log r_1-\log r}{\log 2}\right)+\mathfrak{s}_N\right)\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})}\\ &\le \left(\frac{K'_{\alpha,N}}{\log 2}+\mathfrak{s}_N\right)(|\log r|+1)\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})},\end{aligned}$$

  which proves statement ii).

- Finally, if $N > 10+4\alpha$, we have $2-N/2+\alpha/2+\sqrt{(2+\alpha)(2N-2+\alpha)}/2 < 0$. Then

$$\sum_{i=1}^{m-1}\left(\frac{r_1}{2^{i-1}}\right)^{2-\frac{N}{2}+\frac{\alpha}{2}+\frac{\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}} = \frac{r^{2-\frac{N}{2}+\frac{\alpha}{2}+\frac{\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}} - r_1^{2-\frac{N}{2}+\frac{\alpha}{2}+\frac{\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}}}{(1/2)^{2-\frac{N}{2}+\frac{\alpha}{2}+\frac{\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}}-1}.$$

  From this and again (2.7), we deduce

$$|u(r)| \le \left(\frac{K'_{\alpha,N}}{(1/2)^{2-\frac{N}{2}+\frac{\alpha}{2}+\frac{\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}}-1}+\mathfrak{s}_N\right) r^{2-\frac{N}{2}+\frac{\alpha}{2}+\frac{\sqrt{(2+\alpha)(2N-2+\alpha)}}{2}}\|u\|_{H^1(B_1\setminus\overline{B_{1/2}})},$$

  which completes the proof. □

3 Optimality of Theorem 2.1

These a priori estimates are indeed optimal as one can see with the following examples:

- If $N = 10 + 4\alpha$, then the function $u(x) = |\log|x||$ is a solution to the Hénon–Gelfand equation
$$-\Delta u = (N-2)|x|^{\alpha} e^{u(2+\alpha)} \quad \text{in } B_1 \setminus \{0\},$$
such that $|x|^{\alpha} f'(u) = \frac{(N-2)^2}{4|x|^2}$. This implies that the stability inequality (1.2) attaining exactly the optimal Hardy constant and hence it is a stable solution.

- If $N > 10 + 4\alpha$, recall that we have that for any $\alpha > -2$, $\gamma(\alpha, N) < 0$. We consider the function $u(|x|) = |x|^{\gamma} - 1$ for any
$$\gamma(\alpha, N) \leq \gamma < 0, \tag{3.1}$$
which is the solution to the power-type equation
$$-\Delta u = |x|^{\alpha}(-\gamma)(\gamma + N - 2)(1+u)^{1+\frac{2+\alpha}{-\gamma}} \quad \text{in } B_1 \setminus \{0\}.$$
In this case
$$|x|^{\alpha} f'(u) = \frac{(-\gamma + \alpha + 2)(\gamma + N - 2)}{|x|^2}. \tag{3.2}$$
Taking into account (3.1), (3.2) and comparing again the stability inequality (1.2) with the hardy inequality, the constants satisfies:
$$(-\gamma + \alpha + 2)(\gamma + N - 2) \leq \frac{(N-2)^2}{4},$$
implying the stability of u.

Abstract. In this work we study the local and global existence, uniqueness and well-posedness of solutions for abstract integro-differential equations with state-dependent delay. We establish these results without requiring the conventional assumption of local Lipschitz continuity in the forcing terms. Furthermore, our goal is to apply the abstract theory to the study of a problem involving a memory and diffusion-coupled integro-differential system with state-dependent delay.

Keywords: integro-differential equations, state-dependent delay, local and global existence of solutions, uniqueness of solutions, local well-posedness, diffusion-coupled system.

2020 Mathematics Subject Classification: 34K30, 35R09, 47A55.

1 Introduction

In this work, we are first interested in the investigation of the existence and uniqueness, regularity, well-posedness, and global existence of solutions, problems that are crucial and challenging when dealing with differential equations involving state-dependent delays. In this article, we study the integro-differential abstract equations modeled by

$$\frac{d}{dt}\left(u(t)+\int_0^t P(t-s)u(s)ds\right) = Au(t)+\int_0^t Q(t-s)u(s)ds+G(t,u(t-\sigma(t,u_t))), t\in[0,a], \tag{1.1}$$

$$u_0=\varphi\in\mathcal{B}=C([-p,0];Z), \tag{1.2}$$

where A and $Q(t)$ for $t \geq 0$ are closed linear operators defined on a common domain $D(A)$ that is dense in Z, while $(P(t))_{t\geq 0}$ is a family of bounded linear operators on Z. The variable u_t represents the history of $u(\cdot)$ at time t ($u_t \in \mathcal{B}$ and $u_t(\theta) = u(t+\theta)$ for $\theta \in [-p, 0]$, $t > 0$) and $G(\cdot)$ and $\sigma(\cdot)$ are continuous functions.

Secondly, we apply abstract theory to study the existence and uniqueness of mild and classical local and global solutions for a diffusion-coupled integro-differential system with state-dependent delay described by

$$
\begin{aligned}
&\frac{\partial}{\partial t}\left[u(t,x) + \int_0^t (t-s)^{\alpha} e^{-\omega(t-s)} v(s,x)ds\right] \\
&\qquad = \Delta u(t,x) + \int_0^t B(t-s)\Delta v(s,x)ds + \zeta(t)\int_\Omega b(u(\varrho(t,u_t),y))f(x-y)dy, \\
&\frac{\partial}{\partial t}\left[v(t,x) + \int_0^t (t-s)^{\alpha} e^{-\gamma(t-s)} u(s,x)ds\right] \\
&\qquad = \Delta v(t,x) + \int_0^t C(t-s)\Delta u(s,x)ds + g(v(\varrho(t,u_t),x)), \\
&u(t,\cdot)|_{\partial\Omega} = 0, \quad v(t,\cdot)|_{\partial\Omega} = 0 \\
&u(\theta,y) = \varphi(\theta,y), \quad v(\theta,y) = \phi(\theta,y), \qquad \theta \in [-p,0],\ y \in \Omega,
\end{aligned}
$$

for $t \in [0,a]$ and $x \in \Omega$, where $f \in C(\widetilde{\Omega};\mathbb{R})$, $\widetilde{\Omega} = \{x-y : x,y \in \Omega\}$, $g \in C_{\mathrm{Lip}}(\mathbb{R}^n;\mathbb{R}^n)$, $b \in C_{\mathrm{Lip}}(\mathbb{R}^n;\mathbb{R}^n)$, $\varrho \in C_{\mathrm{Lip}}([0,a]\times\mathcal{B};\mathbb{R})$, $d-p \leq \varrho(t,\psi) \leq t$ for all $(t,\psi) \in [0,a]\times\mathcal{B}$ and $\zeta \in C_{\mathrm{Lip}}(\mathbb{R};\mathbb{R})$.

It is well-known that integro-differential equations in abstract spaces play a significant role in the literature due to their ability to model a wide range of important equations arising in physical and biological systems. For example, in the classical theory developed by Gurtin and Pipkin [14], Miller [27], and Nunziato [29], integro-differential equations are employed to describe heat conduction in materials with fading memory. They are also used to model the non-equilibrium thermal response of glass-forming substances with dynamic (time-dependent) heat capacity under fast thermal perturbations (see [28] for more details).

In [2], the author considers a coupled linear integro-differential wave system with memory. In this work, the existence and uniqueness of global solutions are studied, and the uniform stabilization of the total energy is proved as time goes to infinity. Another example of the importance of integro-differential equations is the McKean–Vlasov equation, which has attracted considerable attention due to its broad applicability. It models not only continuous phenomena in areas such as statistical physics, stochastic control, mean field games, financial mathematics, Bayesian inference, and neural networks, but also discontinuous phenomena in mean-field dynamics—such as the motion of particles in polymer dynamics, the onset of financial crises, and discontinuities in control systems [23].

An important framework for analyzing partial integro-differential equations in abstract spaces is the theory of resolvent operators. This theory is widely used to establish the existence, uniqueness, and qualitative properties of solutions to such equations. The resolvent operator approach has been developed in several works. Firstly, by Grimmer et al. [11–13]. Secondly, Da Prato et al. [3,4] and Lunardi [24,25] studied systems with $P \equiv 0$. Recently, Dos Santos et al. [7,8,16] addressed the general case where both $P \neq 0$ and $Q \neq 0$.

An important topic in the theory of differential equations, abstract differential equations with state-dependent delay are a field of great significance due to their applications (see [1,15]) and because their qualitative theory is rather different from the usual theory on functional differential equations with constant time-dependent delay. The literature on state-dependent delay problems is extensive. For ordinary differential equations (ODE) in finite-dimensional

spaces, notable works include [1, 9, 10, 15] and their associated references. For ODEs and partial differential equations (PDEs) with state-dependent delay, one can refer to the papers [17–19, 19–22, 26]. Many works in the literature prove the existence of solutions of integro-differential equations with state-dependent delay [5,7,30,32]. But these papers establish only local solutions by fixed point results using compactness; they do not address uniqueness, the regularity of solutions, or the existence and uniqueness of maximal solutions for integro-differential equations. The central difference emerges from the fact that functions of the form $u \mapsto u(\cdot - \sigma(\cdot, u_{(\cdot)}))$ and $u \mapsto u_{\mu(\cdot,u_{(\cdot)})}$ are not Lipschitz in spaces of continuous functions, and this has implications concerning the uniqueness of solutions and the well-posedness of certain differential equations with state-dependent delay.

Inspired by the ideas from [17–19], we establish the local and global existence, uniqueness and local well-posedness of the problem (1.1)–(1.2) in spaces of Lipschitz functions. In this context, we emphasize the importance of inequalities like the following:

$$\begin{aligned}&\|u(\sigma(\cdot,u(\cdot))) \;-\; v(\sigma(\cdot,v(\cdot)))\|_{C([0,b];Z)}\\&\quad\leq (1+[v]_{C_{\mathrm{Lip}}([-p,b];Z)}[\sigma]_{C_{\mathrm{Lip}}([0,b]\times X;\mathbb{R})})\|u-v\|_{C([0,b];Z)}.\end{aligned}$$

where

$$[v]_{C_{\mathrm{Lip}}([-p,b];Z)} := \sup_{t,s\in[-p,b],t\neq s}\frac{\|v(t)-v(s)\|_Z}{|t-s|}.$$

Moreover, such analysis becomes even more challenging in the context of integro-differential equations, since the associated resolvent operator does not satisfy the semigroup property. This difficulty motivates the present work, whose main contributions can be summarized as follows:

First, we establish existence and uniqueness results—both local and global—as well as well-posedness for the integro-differential problem described above in spaces of Lipschitz functions. This contribution is significant because the absence of the semigroup property in the associated resolvent operator makes the construction of maximal solutions considerably more intricate. Our results therefore extend the theory beyond the scope of classical semigroup-based approaches.

Second, we introduce and rigorously analyze a new class of coupled integro-differential systems that incorporate fading memory terms and diffusion operators with state-dependent delays. To the best of our knowledge, this paper provides the first systematic treatment of such systems, thereby opening new avenues of research in the field.

Third, we address additional aspects that, to date, have not appeared in the literature, reinforcing the novelty and breadth of our contributions.

Finally, the paper is organized into five sections. Section 2 introduces the notation and preliminary results used throughout the study. Section 3 develops the existence and uniqueness theory for problem (1.1)–(1.2), both locally and globally. Section 4 establishes the local well-posedness of (1.1)–(1.2) in the spaces $\mathcal{D}_a$ and $C([0,a];Z)$. Section 5 concludes with the analysis of a non-trivial coupled diffusive integro-differential system with state-dependent delay, further illustrating the scope of our framework.

2 Preliminaries

Let $(Z,\|\cdot\|_Z)$ and $(W,\|\cdot\|_W)$ be Banach spaces. In this work $\mathcal{B} = C([-p,0];Z)$ endowed with the usual norm $\|\cdot\|_{\mathcal{B}}$, $C_{\mathrm{Lip}}([b,c];Z)$ is the space of the Lipschitz functions from $[b,c]$ into Z endowed with the norm

$$\|\cdot\|_{C_{\mathrm{Lip}}([b,c];Z)} = \|\cdot\|_{C([b,c];Z)} + [\cdot]_{C_{\mathrm{Lip}}([b,c];Z)},$$

where $[\xi]_{C_{\text{Lip}}([b,c];Z)} = \sup_{t,s\in[b,c],t\neq s} \frac{\|\xi(t)-\xi(s)\|_Z}{|t-s|}$ and $C^\gamma([b,c];Z)$, with $\gamma \in (0,1)$, is the space of the γ-Hölder functions from $[b,c]$ into Z, endowed with the norm

$$\|\cdot\|_{C^\gamma([b,c];Z)} = \|\cdot\|_{C([b,c];Z)} + [\cdot]_{C^\gamma([b,c];Z)},$$

where $[\xi]_{C^\gamma([b,c];Z)} = \sup_{t,s\in[b,c],t\neq s} \frac{\|\xi(t)-\xi(s)\|_Z}{|t-s|^\gamma}$.

Furthermore, $\mathcal{L}(Z,W)$ is the space of bounded linear operators from Z into W endowed with the operator norm $\|\cdot\|_{\mathcal{L}(Z,W)}$ and we write $\mathcal{L}(Z)$ and $\|\cdot\|$ if $Z = W$. Finally, for $r > 0$ and $z \in Z$, $B_r(z,Z) = \{x \in Z; \|x-z\|_Z \leq r\}$.

As cited in the introduction, our results on existence and uniqueness of solutions are proved without assuming that $G(\cdot)$ and $\sigma(\cdot)$ are locally Lipschitz, they belong to a more general class of functions. The next definition comes from [18].

Definition 2.1. Let Y_i, $i = 1,2$, be Banach spaces and $p \geq 1$. A function $G \in C([c,d]\times Y_1;Y_2)$ is a L^p-Lipschitz function, if there exists an integrable function $[G]_{(\cdot,\cdot)} : [c,d]\times[c,d] \to \mathbb{R}^+$ and a non-decreasing function $\mathcal{W}_G : \mathbb{R}^+ \to \mathbb{R}^+$ such that $[G]_{(t,\cdot)} \in L^p([c,t];\mathbb{R}^+)$ and $[G]_{(\cdot,0)} \in L^p([c,t];\mathbb{R}^+)$ for all $t \in (c,d]$, and

$$\|G(t,x)-G(s,y)\|_{Y_2} \leq \mathcal{W}_G(\max\{\|x\|_{Y_1},\|y\|_{Y_1}\})[G]_{(t,s)}(|t-s|+\|x-y\|_{Y_1}),$$

for all $x,y \in Y_1$ and $c \leq s \leq t \leq d$. We use the notation $L^p_{\text{Lip}}([c,d]\times Y_1;Y_2)$ for the set formed by this type of functions.

The next result can be found in [18, Lemma 1] and there for $p,b > 0$, $u \in C([-p,b];Z)$ and $\sigma \in C([0,a]\times\mathcal{B};[0,p])$, $u^\sigma : [0,b] \to Z$ is the function given by $u^\sigma(t) = u(t-\sigma(t,u_t))$.

Lemma 2.2 ([18, Lemma 1]). *Assume $0 < b \leq a$, $u,v \in C([-p,b];Z)$, $\sigma \in L^r_{\text{Lip}}([0,a]\times\mathcal{B};[0,p])$ and let $\rho = \max\{\|u\|_{C([-p,b];Z)},\|v\|_{C([-p,b];Z)}\}$. If $u_{|_{[-p,0]}} \in C_{\text{Lip}}([-p,0];Z)$ and $u_{|_{[0,b]}} \in C_{\text{Lip}}([0,b];Z)$, then $u \in C_{\text{Lip}}([-p,b];Z)$, $u_{(\cdot)} \in C_{\text{Lip}}([0,b];\mathcal{B})$ and*

$$\begin{aligned}
\max\{[u]_{C_{\text{Lip}}([-p,b];Z)},[u_{(\cdot)}]_{C_{\text{Lip}}([0,b];\mathcal{B})}\} &\leq [u_0]_{C_{\text{Lip}}([-p,0];Z)} + [u_{|_{[0,b]}}]_{C_{\text{Lip}}([0,b];\mathcal{B})},\\
\|u^\sigma(s+h)-u^\sigma(s)\| &\leq [u]_{C_{\text{Lip}}([-p,b];Z)}(1+[\sigma]_{(s+h,s)}\mathcal{W}_\sigma(\rho)(1+[u]_{C_{\text{Lip}}([-p,b];Z)}))h,\\
\|u^\sigma(s)-v^\sigma(s)\| &\leq (1+[u]_{C_{\text{Lip}}([-p,b];Z)}[\sigma]_{(s,s)}\mathcal{W}_\sigma(\rho))\|u-v\|_{C([-p,b];Z)},
\end{aligned}$$

for all $h,s \in [0,b]$ with $s+h \in [0,b]$.

In addition, if $w \in C([-p,b];Z)$, $\alpha \in (0,1)$, $w_{|_{[0,b]}} \in C^\alpha([0,b];Z)$ and $w_0 \in C^\alpha([-p,0];Z)$, then $w_{(\cdot)} \in C^\alpha([0,b];\mathcal{B})$, $w^\sigma \in C^{\alpha^2}([0,b];Z)$ and

$$\begin{aligned}
[w_{(\cdot)}]_{C^\alpha([0,b];\mathcal{B})} &\leq \varpi(w,\alpha) := [w]_{C^\alpha([0,b];X)} + [w_0]_{C^\alpha([-p,0];Z)},\\
[w^\sigma]_{C^{\alpha^2}([0,b];Z)} &\leq [w]_{C^\alpha([-p,b];X)}(b^{1-\alpha} + [\sigma]_{C_{\text{Lip}}([0,a]\times\mathcal{B};[0,p])}(b^{1-\alpha}+[w]_{C^\alpha([-p,b];Z)}))^\alpha,\\
[w^\sigma]_{C^{\alpha^2}([0,b];Z)} &\leq [w]_{C^\alpha([-p,b];Z)}(b^{\alpha-\alpha^2} + [\sigma]^\alpha_{C_{\text{Lip}}([0,a]\times\mathcal{B};[0,p])}(b^{\alpha-\alpha^2}+[w]^\alpha_{C^\alpha([-p,b];Z)})).
\end{aligned}$$

To achieve our results, we mention the main points about the theory of the resolvent operator $(\mathcal{V}(t))_{t\geq 0}$ on Z to the integro-differential abstract Cauchy problem.

$$\frac{d}{dt}\left[u(t)+\int_0^t P(t-s)u(s)\,ds\right] = Au(t)+\int_0^t Q(t-s)u(s)\,ds, \tag{2.1}$$

$$u(0) = z \in Z. \tag{2.2}$$

where $A : D(A) \subseteq Z \to Z$, is a closed linear operator and the notation $[D(A)]$ represents the domain of A endowed with the graph norm, $\|z\|_1 = \|z\|_Z + \|Az\|_W$, $z \in D(A)$, and $Q(t)$ for $t \geq 0$ are closed linear operators defined on a common domain $D(A)$ that is dense in Z, while $P(t)$ for $t \geq 0$ is a family of bounded linear operators on Z.

Next we present the definition of resolvent operator family for the problem (2.1)–(2.2).

Definition 2.3. A one parameter family of bounded linear operators $(\mathcal{V}(t))_{t\geq 0}$ on Z is called a resolvent operator of (2.1)–(2.2) if the following conditions are verified.

(a) The function $\mathcal{V}(\cdot) : [0,\infty) \to \mathcal{L}(Z)$ is strongly continuous, exponentially bounded and $\mathcal{V}(0)z = z$ for all $z \in Z$.

(b) For $z \in D(A)$, $\mathcal{V}(\cdot)z \in C([0,\infty); [D(A)]) \bigcap C^1((0,\infty); Z)$, and

$$\frac{d}{dt}\left[\mathcal{V}(t)z + \int_0^t P(t-s)\mathcal{V}(s)zds\right] = A\mathcal{V}(t)z + \int_0^t Q(t-s)\mathcal{V}(s)zds, \tag{2.3}$$

$$\frac{d}{dt}\left[\mathcal{V}(t)z + \int_0^t \mathcal{V}(t-s)P(s)zds\right] = \mathcal{V}(t)Az + \int_0^t \mathcal{V}(t-s)Q(s)zds, \tag{2.4}$$

for every $t \geq 0$.

The existence of a resolvent operator for problem (2.1)–(2.2) was studied in [7,8]. In these works we considered the following conditions:

(C1) The operator $A : D(A) \subseteq Z \to Z$ is the infinitesimal generator of an analytic semigroup $(T(t))_{t\geq 0}$ on Z, and there are constants $M_0 > 0$ and $\vartheta \in (\pi/2, \pi)$ such that $\rho(A) \supseteq \Lambda_\vartheta = \{\lambda \in \mathbb{C} \setminus \{0\} : |\arg(\lambda)| < \vartheta\}$ and $\|R(\lambda, A)\| \leq M_0|\lambda|^{-1}$ for all $\lambda \in \Lambda_\vartheta$.

(C2) The function $P : [0,\infty) \to \mathcal{L}(Z)$ is strongly continuous and $\widehat{P}(\lambda)z$ is absolutely convergent for $z \in Z$ and $Re(\lambda) > 0$. There exists $\alpha > 0$ and an analytical extension of $\widehat{P}(\lambda)$ (still denoted by $\widehat{P}(\lambda)$) to Λ_ϑ such that $\|\widehat{P}(\lambda)\| \leq N_0|\lambda|^{-\alpha}$ for every $\lambda \in \Lambda_\vartheta$, and $\|\widehat{P}(\lambda)z\| \leq N_1|\lambda|^{-1}\|z\|_1$ for every $\lambda \in \Lambda_\vartheta$ and $z \in D(A)$.

(C3) For all $t \geq 0$, $Q(t) : D(Q(t)) \subseteq Z \to Z$ is a closed linear operator, $D(A) \subseteq D(Q(t))$ and $Q(\cdot)z$ is strongly measurable on $(0,\infty)$ for each $z \in D(A)$. There exists $q(\cdot) \in L^1_{\text{loc}}(\mathbb{R}^+)$ such that $\widehat{q}(\lambda)$ exists for $Re(\lambda) > 0$ and $\|Q(t)z\| \leq q(t)\|z\|_1$ for all $t > 0$ and $z \in D(A)$. Moreover, the operator valued function $\widehat{Q} : \Lambda_{\pi/2} \to \mathcal{L}([D(A)]; Z)$ has an analytical extension (still denoted by $\widehat{Q}$) to Λ_ϑ such that $\|\widehat{Q}(\lambda)z\| \leq \|\widehat{Q}(\lambda)\|\,\|z\|_1$ for all $z \in D(A)$, and $\|\widehat{Q}(\lambda)\| \to 0$ as $|\lambda| \to \infty$.

(C4) There exists a subspace $D \subseteq D(A)$ dense in $[D(A)]$ and positive constants C_i, $i = 1, 2$, such that $A(D) \subseteq D(A)$, $\widehat{Q}(\lambda)(D) \subseteq D(A)$, $\widehat{P}(\lambda)(D) \subseteq D(A)$, $\|A\widehat{Q}(\lambda)z\| \leq C_1\|z\|$ and $\|\widehat{P}(\lambda)z\|_1 \leq C_2|\lambda|^{-\alpha}\|z\|_1$ for every $z \in D$ and all $\lambda \in \Lambda_\vartheta$.

The following result has been established in [8, Theorem 2.1].

Theorem 2.4 ([8, Theorem 2.1])**.** *Assume that conditions* **(C1)–(C4)** *are fulfilled. Then there exists a unique resolvent operator for problem* (2.1)–(2.2).

For the development of this work we will assume that the conditions **(C1)–(C4)** are satisfied.

Remark 2.5. From Theorem 2.4 it follows that there exists a constant $M > 0$ such that the resolvent satisfies $\|\mathcal{V}(t)\| \leq M$, for all $t \in [0, a]$ and there exists a constant $C > 0$ such that $\|A\mathcal{V}(t)\| \leq \frac{C}{t}$ for all $t \in (0, a]$ and $z \in Z$.

Let E be the space consisting of $z \in Z$ such that

$$\mathcal{V}(\cdot)z \in C([0,\infty),[D(A)]) \cap C^1([0,\infty);Z).$$

It is clear that $E \subseteq D(A)$ and $\frac{d}{dt}\mathcal{V}(t)z|_{t=0} = Az - P(0)z$ for $z \in E$. For more details see [8, Remark 2.2]

The following definitions and results are related to the non-homogeneous problem

$$\frac{d}{dt}\left[u(t) + \int_0^t P(t-s)u(s)ds\right] = Au(t) + \int_0^t Q(t-s)u(s)\,ds + G(t), \qquad t \in I = [0,b], \quad (2.5)$$

with initial condition (2.2), where $G : [0,b] \to Z$ is a continuous function.

Definition 2.6. A function $u \in C([0,b];Z)$, $0 < b \leq a$ is called a mild solution of (2.5)–(2.2) on $[0,b]$ if $u(0) = z$ and

$$u(t) = \mathcal{V}(t)z + \int_0^t \mathcal{V}(t-s)G(s)ds, \qquad \forall\, t \in [0,b]. \quad (2.6)$$

Definition 2.7. A function $u : [0,b] \to Z$, $0 < b \leq a$, is called a classical solution of (2.5)–(2.2) on $[0,b]$ if $u \in C([0,b],[D(A)]) \cap C^1((0,b];Z)$, the condition (2.2) holds and the equation (2.5) is verified on $[0,b]$. Moreover, if $u \in C([0,b],[D(A)]) \cap C^1([0,b];Z)$, the function u is said to be a strict solution of (2.5)–(2.2) on $[0,b]$.

Remark 2.8. From the above definition, it is clear that $\mathcal{V}(\cdot)z$ is a classical solution of problem (2.5)–(2.2) on $(0,\infty)$ for $z \in D(A)$ and $G(t) \equiv 0$.

In the work [8] the following results are established for the problem (2.5)–(2.2)

Theorem 2.9 ([8, Theorem 2.4]). *Let $z \in D(A)$. Assume that $G \in C([0,b];Z)$ and $u(\cdot)$ is a classical solution of problem (2.5)–(2.2) on $(0,b]$. Then*

$$u(t) = \mathcal{V}(t)z + \int_0^t \mathcal{V}(t-s)G(s)\,ds, \qquad t \in [0,b]. \quad (2.7)$$

Theorem 2.10 ([8, Lemma 3.1.1]). *If $R(\lambda_0, A)$ is compact for some $\lambda_0 \in \rho(A)$, then $\mathcal{V}(t)$ is compact for all $t > 0$.*

Theorem 2.11 ([8, Theorem 2.6]). *Let $z \in D(A)$ and let $G \in W^{1,1}([0,a];Z)$. Then the mild solution $u(\cdot)$ of problem (2.5)–(2.2) is a classical solution on $[0,a]$. Further, if $z \in E$, then $u(\cdot)$ is a strict solution on $[0,a]$.*

Corollary 2.12 ([8, Corollary 2.2]). *Let $z \in D(A)$ and $G \in C([0,a];Z)$. Let $u(\cdot)$ be the mild solution of problem (2.5)–(2.2). If $u \in C([0,a],[D(A)])$, then $u(\cdot)$ is a classical solution on $(0,a]$.*

3 Existence and uniqueness of solution

In this section we begin by studying the existence and uniqueness of mild solution for the integro-differential problem (1.1)–(1.2). First, we establish some concepts and assumptions that will be used in this work. For this remember that for $p, b > 0$, $u \in C([-p,b];Z)$ and $\sigma \in C([0,a] \times \mathcal{B};[0,p])$, $u^\sigma : [0,b] \to Z$ denotes the function given by $u^\sigma(t) = u(t - \sigma(t,u_t))$.

Definition 3.1. A function $u \in C([-p,b];Z)$, $0 < b \leq a$ is called a mild solution of (1.1)–(1.2) on $[-p,b]$ if $u_0 = \varphi$ on $[-p,0]$ and

$$u(t) = \mathcal{V}(t)\varphi(0) + \int_0^t \mathcal{V}(t-s)G\left(s,u^\sigma(s)\right)ds, \qquad \forall\, t \in [0,b]. \quad (3.1)$$

Definition 3.2. A function $u \in C([-p,b];Z)$, $0 < b \leq a$, is said to be a strict solution (resp. a classical solution) of (1.1)–(1.2) on $[-p,b]$ if $u_{|_{[0,b]}} \in C^1([0,b];Z) \cap C([0,b];[D(A)])$ (resp. $u_{|_{[0,b]}} \in C^1((0,b];Z) \cap C((0,b];[D(A)])$), $u_0 = \varphi$ and $u(\cdot)$ satisfies (1.1) on $[0,b]$ (resp. satisfies (1.1) on $(0,b]$).

To establish the main results of this section, we introduce the following condition.

Condition $H^{q,r}_{G,\sigma,a}$: $q, r \geq 1$, $\Theta(q,r) = \frac{1}{q} + \frac{1}{r} \leq 1$, $G \in L^q_{\text{Lip}}([0,a] \times Z;Z)$ and $\sigma \in L^r_{\text{Lip}}([0,a] \times \mathcal{B};[0,p])$.

Notation 3.3. If condition $H^{q,r}_{G,\sigma,a}$ holds, we use the notations

$$\Sigma_1(b) := \sup_{h,c \in [0,b], h+c \in [0,b]} \|[G]_{(\cdot+h,\cdot)}(1 + [\sigma]_{(\cdot+h,\cdot)})\|_{L^1([0,c])},$$
$$\Sigma_2(b) := \sup_{c \in [0,b]} \|[G]_{(\cdot,0)}(1 + [\sigma]_{(\cdot,0)})\|_{L^1([0,c])}.$$

In addition, if $\Theta(q,r) < 1$, $\Lambda(q,r)$ is the number defined by the relation $\Theta(q,r) + \frac{1}{\Lambda(q,r)} = 1$.

Now we can present the first theorem of this work.

Theorem 3.4. *Suppose $\varphi \in C_{\text{Lip}}([-p,0];Z)$, $\mathcal{V}(\cdot)\varphi(0) \in C_{\text{Lip}}([0,a];Z)$. If condition $H^{q,r}_{G,\sigma,a}$ is satisfied and $\Sigma_1(b) + \Sigma_2(b) \to 0$ as $b \to 0$, then there exists a unique mild solution $u \in C_{\text{Lip}}([-p,b];Z)$ of the problem (1.1)–(1.2) on $[-p,b]$ for some $0 < b \leq a$.*

Proof. Consider $R_\varphi > [\mathcal{V}(\cdot)\varphi(0)]_{C_{\text{Lip}}([0,a];Z)} + \partial|\varphi\|_{C_{\text{Lip}}([-p,0];Z)} + M\|G(0,\varphi(-\sigma(0,\varphi)))\|$. From the hypothesis on $\Sigma_i(\cdot)$, $i = 1,2$, we can choose $0 < b \leq a$ such that

$$[\mathcal{V}(\cdot)\varphi(0)]_{C_{\text{Lip}}([0,a];Z)} + \|\varphi\|_{C_{\text{Lip}}([-p,0];Z)} + M\|G(0,\varphi(-\sigma(0,\varphi)))\| + (1+R_\varphi)^2\mathcal{W}_G(\rho)(1+\mathcal{W}_\sigma(\rho))M\left(\Sigma_1(b)+\Sigma_2(b)\right) < R_\varphi, \tag{3.2}$$

$$(1+R_\varphi)\mathcal{W}_G(\rho)M(1+\mathcal{W}_\sigma(\rho))\Sigma_1(b) < 1 \tag{3.3}$$

with $\rho := R_\varphi(b+p) + \|\varphi\|_{\mathcal{B}}$.

Define the space

$$\mathcal{Z}(b,R_\varphi) = \{u \in C([-p,b];Z) : u_0 = \varphi,\ [u]_{C_{\text{Lip}}([-p,b];Z)} \leq R_\varphi\},$$

endowed with the metric $d(u,v) = \|u-v\|_{C([0,b];Z)}$ and let $\Gamma : \mathcal{Z}(b,R_\varphi) \to C([-p,b];Z)$ be the map defined by $\Gamma u(t) = \varphi(t)$ for $t \in [-p,0]$ and

$$\Gamma u(t) = \mathcal{V}(t)\varphi(0) + \int_0^t \mathcal{V}(t-s)G\left(s,u^\sigma(s)\right)ds, \quad \text{for } t \in [0,b].$$

We state that $\Gamma(\cdot)$ is a contraction. Indeed, for $u \in \mathcal{Z}(b,R_\varphi)$ and $s \in [0,b]$, we note that

$$\begin{aligned}\max\{\|u(s)\|, \|u^\sigma(s)\|, \|u_s\|_{\mathcal{B}}\} &\leq \sup_{\tau \in [-p,b]} \|u(\tau) - \varphi(0)\| + \|\varphi(0)\| \\ &\leq [u]_{C_{\text{Lip}}([-p,b];X)}(b+p) + \|\varphi\|_{\mathcal{B}} \\ &\leq R_\varphi(b+p) + \|\varphi\|_{\mathcal{B}} \leq \rho. \end{aligned} \tag{3.4}$$

Using the former estimate and Lemma 2.2, for $s, h \in [0, b]$ with $s + h \in [0, b]$, we have that

$$\begin{aligned}
&\|G(s+h, u^\sigma(s+h)) - G(s, u^\sigma(s))\| \\
&\quad \le [G]_{(s+h,s)} \mathcal{W}_G(\rho)(h + [u]_{C_{\mathrm{Lip}}([-p,b];Z)}(h + \mathcal{W}_\sigma(\rho)[\sigma]_{(s+h,s)}(h + [u]_{C_{\mathrm{Lip}}([-p,b];Z)}h)) \\
&\quad \le [G]_{(s+h,s)} \mathcal{W}_G(\rho)(1 + R_\varphi(1 + \mathcal{W}_\sigma(\rho)[\sigma]_{(s+h,s)}(1 + R_\varphi)))h \\
&\quad \le (1 + R_\varphi)^2 \mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))[G]_{(s+h,s)}(1 + [\sigma]_{(s+h,s)})h. \qquad (3.5)
\end{aligned}$$

For $0 \le s \le h \le b$ and arguing as above, we also have that

$$\|G(s, u^\sigma(s)) - G(0, \varphi(-\sigma(0,\varphi)))\| \le (1 + R_\varphi)^2 \mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))[G]_{(s,0)}(1 + [\sigma]_{(s,0)})h. \quad (3.6)$$

Using the previous inequalities, for $h, t \in [0, b]$ with $t + h \in [0, b]$, we obtain

$$\begin{aligned}
&\|\Gamma u(t+h) - \Gamma u(t)\| \\
&\quad \le [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,b];Z)}h + \int_0^h \|\mathcal{V}(t+h-s))G(0, \varphi(-\sigma(0,\varphi)))\|ds \\
&\qquad + \int_0^h \|\mathcal{V}(t+h-s))\|\|G(s, u^\sigma(s)) - G(0, \varphi(-\sigma(0,\varphi)))\|ds \\
&\qquad + \int_0^t \|\mathcal{V}(t-s)\|\|G(s+h, u^\sigma(s+h)) - G(s, u^\sigma(s))\|ds \\
&\quad \le [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,b];Z)}h + M\|G(0, \varphi(-\sigma(0,\varphi))\|h \\
&\qquad + (1 + R_\varphi)^2 \mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))M \int_0^h [G]_{(s,0)}(1 + [\sigma]_{(s,0)})sds \\
&\qquad + (1 + R_\varphi)^2 \mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))M \int_0^t [G]_{(s+h,s)}(1 + [\sigma]_{(s+h,s)})hds \\
&\quad \le [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,b];Z)}h + M\|G(0, \varphi(-\sigma(0,\varphi))\|h \\
&\qquad + (1 + R_\varphi)^2 \mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))M(\Sigma_1(b) + \Sigma_2(b))h. \qquad (3.7)
\end{aligned}$$

Then $[\Gamma u]_{C_{\mathrm{Lip}}([0,b];Z)} \le R_\varphi$ and $[\Gamma u]_{C_{\mathrm{Lip}}([-p,b];Z)} \le R_\varphi$ since $\|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)} < R_\varphi$. This proves that $\Gamma(\cdot)$ is a $\mathcal{Z}(b, R_\varphi)$-valued function.

Also, from Lemma 2.2, for $u, v \in \mathcal{Z}(b, R_\varphi)$ and $t \in [0, b]$ it follows that

$$\begin{aligned}
&\|\Gamma u(t) - \Gamma v(t)\| \\
&\quad \le \int_0^t \|\mathcal{V}(t-s)\|\|G(s, u^\sigma(s)) - G(s, v^\sigma(s))\|ds \\
&\quad \le \mathcal{W}_G(\rho) \int_0^t M[G]_{(s,s)}\|u^\sigma(s) - v^\sigma(s)\|ds \\
&\quad \le \mathcal{W}_G(\rho) \int_0^t M[G]_{(s,s)}(1 + [u]_{C_{\mathrm{Lip}}([-p,b];Z)}\mathcal{W}_\sigma(\rho)[\sigma]_{(s,s)})\|u - v\|_{C([0,s];Z)}ds \\
&\quad \le \mathcal{W}_G(\rho) \int_0^t M[G]_{(s,s)}(1 + R_\varphi \mathcal{W}_\sigma(\rho)[\sigma]_{(s,s)})\|u - v\|_{C([0,s];Z)}ds \\
&\quad \le (1 + R_\varphi)\mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))M \int_0^t [G]_{(s,s)}(1 + [\sigma]_{(s,s)})ds\|u - v\|_{C([0,b];Z)} \\
&\quad \le (1 + R_\varphi)\mathcal{W}_G(\rho)(1 + \mathcal{W}_\sigma(\rho))\Sigma_1(b)M\|u - v\|_{C([0,b];Z)}, \qquad (3.8)
\end{aligned}$$

and, from (3.3), we conclude that $\Gamma(\cdot)$ is a contraction on $\mathcal{Z}(b, R_\varphi)$ and then there exists a unique mild solution $u \in C_{\mathrm{Lip}}([-p, b]; Z)$ of (1.1)–(1.2) on $[-p, b]$. □

For the next result we will use the Radon–Nikodym property. It is well-known that every reflexive space has the Radon–Nikodym property (abbreviated, RNP) and that there are non reflexive spaces that have the RNP. We refer to [6] several characterizations of the RNP. For this reason, in the sequel, we consider spaces that have the RNP.

Proposition 3.5. *If conditions in Theorem 3.4 are valid, Z has the RNP, the functions $[G]_{(\cdot,\cdot)}$ and $[\sigma]_{(\cdot,\cdot)}$ are continuous, and $u \in C_{\mathrm{Lip}}([-p,b];Z)$ is the unique associated mild solution of the problem (1.1)–(1.2), then $u(\cdot)$ is a classical solution if $\varphi(0) \in D(A)$ and a strict solution if $\varphi(0) \in E$.*

Proof. Note that

$$\begin{aligned}
&\|G(t,u^\sigma(t)) - G(s,u^\sigma(s))\| \\
&\quad \le [G]_{(t,s)}\mathcal{W}_G(\rho)(1+[u]_{C_{\mathrm{Lip}}([-p,b];Z)}(1+\mathcal{W}_\sigma(\rho)[\sigma]_{(t,s)}(1+[u]_{C_{\mathrm{Lip}}([-p,b];Z)}))(t-s) \\
&\quad \le \mathcal{K}|t-s|,
\end{aligned}$$

where $\rho = \|u\|_{C([-p,b];Z)}$ and

$$\mathcal{K} = \sup_{(t,s)\in[0,a]\times[0,a]} ([G]_{(t,s)}\mathcal{W}_G(\rho)(1+[u]_{C_{\mathrm{Lip}}([-p,b];Z)}(1+\mathcal{W}_\sigma(\rho)[\sigma]_{(t,s)}(1+[u]_{C_{\mathrm{Lip}}([-p,b];Z)}))).$$

Consequently, the function $t \mapsto G(t) = G(t,u^\sigma(t))$ is Lipschitz continuous and since the space Z has satisfies the RNP, the function $G(\cdot) \in W^{1,1}([0,b];Z)$. The statement is now consequence of Theorem 2.11. □

In the next corollary, $\Theta(q,r)$ and $\Lambda(q,r)$ are the numbers defined in Notation 3.3.

Corollary 3.6. *Suppose that $\varphi \in C_{\mathrm{Lip}}([-p,0];Z)$, $\mathcal{V}(\cdot)\varphi(0) \in C_{\mathrm{Lip}}([0,a];Z)$ and assume that $\Theta(q,r) < 1$. If there exists $0 < c \le a$ such that*

$$\Sigma_3(c) = \sup_{b\in[0,c],d,h\in[0,b],d+h\le b} \|[G]_{(\cdot+h,\cdot)}\|_{L^q([0,d])}\|(1+[\sigma]_{(\cdot+h,\cdot)})\|_{L^r([0,d])} < \infty.$$

Then there exists a unique mild solution $u \in C_{\mathrm{Lip}}([-p,b];Z)$ of the problem (1.1)–(1.2) on $[-p,b]$ for some $0 < b \le a$. In particular, the assertion is valid if $G(\cdot)$ and $\sigma(\cdot)$ are Lipschitz.

Proof. From Theorem 3.4, it is sufficient to show that $\Sigma_1(b) + \Sigma_2(b) \to 0$ as $b \to 0$. For $b \in [0,c]$, $t,h \in [0,b)$ with $t+h \le b$, it is easy to see that

$$\begin{aligned}
&\int_0^t [G]_{(s+h,s)}(1+[\sigma]_{(s+h,s)})ds \le \Sigma_3(c), \\
&\int_0^t [G]_{(s,0)}(1+[\sigma]_{(s,0)})ds \le \|[G]_{(\cdot,0)}\|_{L^q([0,b])}\|(1+[\sigma]_{(\cdot,0)})\|_{L^r([0,b])},
\end{aligned}$$

which implies that $\Sigma_1(b) + \Sigma_2(b) \to 0$ as $b \to 0$. The last claim is direct. □

Now we will discuss solutions defined on a pre-defined interval $[-p,a]$ and on the whole semi-axis $[-p,\infty)$.

Remark 3.7. If condition $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ is satisfied, for $x > 0$ and $b \in [0,a]$, we assume that

$$\begin{aligned}
\Sigma_{1,b}(x) &:= \sup_{h,c\in[0,b],h+c\in[0,b]} \|\mathcal{W}_{F,\sigma}(\rho(x,\cdot))[G]_{(\cdot+h,\cdot)}(1+[\sigma]_{(\cdot+h,\cdot)})\|_{L^1([0,c])}, \\
\Sigma_{2,b}(x) &:= \sup_{c\in[0,b]} \|\mathcal{W}_{F,\sigma}(\rho(x,\cdot))[G]_{(\cdot,0)}(1+[\sigma]_{(\cdot,0)})\|_{L^1([0,c])},
\end{aligned}$$

where $\mathcal{W}_{F,\sigma}(\rho(x,s)) = \mathcal{W}_G(\rho(x,s))(1+\mathcal{W}_\sigma(\rho(x,s)))$ and $\rho(x,s) = x(s+p) + \|\varphi\|_{\mathcal{B}}$, are finite. Additionally, if the condition $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ is satisfied for all $a > 0$, we use the notations $\Sigma_{1,\infty}(x) := \sup_{b\ge0}\Sigma_{1,b}(x)$ and $\Sigma_{2,\infty}(x) := \sup_{b\ge0}\Sigma_{2,b}(x)$.

From the proof of Theorem 3.4, we deduce the next result.

Proposition 3.8. *Suppose that condition* $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ *is satisfied,* $\varphi \in C_{\mathrm{Lip}}([-p,0];Z)$, $\mathcal{V}(\cdot)\varphi(0) \in C_{\mathrm{Lip}}([0,a];Z)$ *and let* $\mathcal{P}_a : \mathbb{R} \mapsto \mathbb{R}$ *be the function given by*

$$\begin{aligned}\mathcal{P}_a(x) := [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];Z)} + \|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)} + M\|G(0,\varphi(-\sigma(0,\varphi))\| \\ + (1+x)^2 M(\Sigma_{1,a}(x) + \Sigma_{2,a}(x)) + (1+x)M\Sigma_{1,a}(x)x - x.\end{aligned}$$

If $\mathcal{P}_a(R_\varphi) < 0$ *for some* $R_\varphi > 0$, *then there exists a unique mild solution* $u \in C_{\mathrm{Lip}}([-p,a];Z)$ *of problem* (1.1)–(1.2) *on* $[-p,a]$.

Proof. The demonstration of this proposition follows from the proof of Theorem 3.4 and we will include some details to complete the proof. We remark, from the definition of $\mathcal{P}_a(\cdot)$ and our hypothesis about $\mathcal{P}_a(R_\varphi)$, that

$$\begin{aligned}[\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];X)} + \|\varphi\|_{C_{\mathrm{Lip}}([-p,0];X)} + M\|G(0,\varphi(-\sigma(0,\varphi))\| \\ + M(1+R_\varphi)^2\left(\Sigma_{1,a}(R_\varphi) + \Sigma_{2,a}(R_\varphi)\right) + M(1+R_\varphi)\Sigma_{1,a}(R_\varphi)R_\varphi < R_\varphi. \quad (3.9)\end{aligned}$$

Consider $\mathcal{Z}(a,R_\varphi)$ and $\Gamma(\cdot)$ as in the proof Theorem 3.4, but using a instead of b and let $u \in \mathcal{Z}(a,R_\varphi)$.

Proceeding as in the proof of Theorem 3.4 and from the definition of $\rho(R_\varphi,s)$, for $s \in [0,a]$ we obtain

$$\max\{\|u(s)\|, \|u^\sigma(s)\|, \|u_s\|_{\mathcal{B}}\} \leq R_\varphi(a+p) + \|\varphi\|_{\mathcal{B}} \leq \rho(R_\varphi,s).$$

From the inequality above and the proof of Theorem 3.4, for $s \in [0,a]$ and $\tau, h \in [0,a]$ with $\tau + h \in [0,a]$, it follows that

$$\begin{aligned}&\|G(\tau+h,u^\sigma(\tau+h)) - G(\tau,u^\sigma(\tau))\| \\ &\quad \leq (1+R_\varphi)^2\mathcal{W}_G(\rho(R_\varphi,\tau)))(1+\mathcal{W}_\sigma(\rho(R_\varphi,\tau)))[G]_{(\tau+h,\tau)}(1+[\sigma]_{(\tau+h,\tau)})h,\end{aligned}$$

$$\begin{aligned}&\|G(s,u^\sigma(s)) - G(0,\varphi(-\sigma(0,\varphi)))\| \\ &\quad \leq (1+R_\varphi)^2\mathcal{W}_G(\rho(R_\varphi,s))(1+\mathcal{W}_\sigma(\rho(R_\varphi,s)))[G]_{(s,0)}(1+[\sigma]_{(s,0)})h.\end{aligned}$$

From the previous inequalities and arguing as in the estimates (3.7) and (3.8) we have that

$$\begin{aligned}\|\Gamma u(t+h) - \Gamma u(t)\| &\leq [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];X)}h + M\|G(0,\varphi(-\sigma(0,\varphi))\|h \\ &\quad + (1+R_\varphi)^2 M(\Sigma_{1,a}(R_\varphi) + \Sigma_{2,a,}(R_\varphi))h, \\ \|\Gamma u(t) - \Gamma v(t)\| &\leq (1+R_\varphi)M\Sigma_{1,a}(R_\varphi)\|u-v\|_{C([0,a];X)},\end{aligned}$$

for all $t \in [0,a]$. Then, $\Gamma(\cdot)$ is a contraction on $\mathcal{Z}(a,R_\varphi)$ and we conclude that there exists a unique mild solution $u \in C_{\mathrm{Lip}}([-p,a];X)$ of (1.1)–(1.2) on $[-p,a]$. □

Proceeding as in the proof of the Proposition 3.8, we can demonstrate the next result.

Corollary 3.9. *Let* $\varphi \in C_{\mathrm{Lip}}([-p,0];Z)$ *and* $\mathcal{V}(\cdot)\varphi(0) \in C_{\mathrm{Lip}}([0,a];Z)$.

(a) *Assume that* $G \in C_{\mathrm{Lip}}([0,a] \times B_r(0,X);Z)$ *and that* $\sigma \in C_{\mathrm{Lip}}([0,a] \times B_r(0,\mathcal{B});[0,p])$ *for all* $r > 0$ *and let* $\mathcal{P}_a : \mathbb{R} \mapsto \mathbb{R}$ *be the function given by*

$$\begin{aligned}\mathcal{P}_a(x) = [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];Z)} + \|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)} + M\|G(0,\varphi(-\sigma(0,\varphi))\| \\ + [(1+x)^2 + (1+x)][G]_{C_{\mathrm{Lip},\rho(x)}}(1+[\sigma]_{C_{\mathrm{Lip},\rho(x)}})Ma - x,\end{aligned}$$

where $\rho(x) = x(a+2p) + \|\varphi\|_{\mathcal{B}}$ *and* $[G]_{C_{\mathrm{Lip},\rho(x)}}, [\sigma]_{C_{\mathrm{Lip},\rho(x)}}$ *are the Lipschitz constants of* $G(\cdot)$ *and* $\sigma(\cdot)$ *on* $[0,a] \times B_{\rho(x)}(0,X)$ *and* $[0,a] \times B_{\rho(x)}(0,\mathcal{B})$. *If* $\mathcal{P}_a(y) < 0$ *for some* $y > 0$, *then there exists a unique mild solution* $u \in C_{\mathrm{Lip}}([-p,a];Z)$ *of* (1.1)–(1.2) *on* $[-p,a]$.

(b) *If $G(\cdot)$ and $\sigma(\cdot)$ are Lipschitz and $\mathcal{P}_a(y) < 0$ for some $y > 0$, where*

$$\begin{aligned}\mathcal{P}_a(x) &= [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];Z)} + \|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)} + M\|G(0,\varphi(-\sigma(0,\varphi))\| \\ &\quad + (1+x)^2[G]_{C_{\mathrm{Lip}}}(1+[\sigma]_{C_{\mathrm{Lip}}})Ma + (1+x)[G]_{C_{\mathrm{Lip},\rho(x)}}(1+[\sigma]_{C_{\mathrm{Lip},\rho(x)}})Ma - x \\ &= \theta + (1+x)^2\mu_a + (1+x)\mu_a - x, \end{aligned} \tag{3.10}$$

then there exists a unique mild solution $u \in C_{\mathrm{Lip}}([-p,a];Z)$ of (1.1)–(1.2) on $[-p,a]$. In particular, the affirmation holds if $1 > \frac{4\mu_a(\theta+2\mu_a)}{(3\mu_a-1)^2}$.

With respect to the existence and uniqueness of the solutions defined in $[-p,\infty)$, we have the next corollary.

Corollary 3.10. *Assume that $\mathcal{V}(\cdot)\varphi(0) \in C_{\mathrm{Lip}}([0,\infty);Z)$, $\varphi \in C_{\mathrm{Lip}}([-p,0];Z)$, that the condition $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ is satisfied for all $a > 0$ and that $\Sigma_{i,\infty}(x) < \infty$ for $i = 1,2$ and every $x > 0$. Let $\mathcal{P}_\infty : [0,\infty) \mapsto [0,\infty)$ be the function given by*

$$\begin{aligned}\mathcal{P}_\infty(x) &= [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,\infty;Z)} + \|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)} + M\|G(0,\varphi(-\sigma(0,\varphi))\| \\ &\quad + (1+x)^2M(\Sigma_{1,\infty}(x) + \Sigma_{2,\infty}(x)) + (1+x)M\Sigma_{1,\infty}(x)x - x. \end{aligned} \tag{3.11}$$

If $\mathcal{P}_\infty(y) < 0$ for some $y > 0$, then there exists a unique locally Lipschitz mild solution $u \in C([-p,\infty);Z)$ of the problem (1.1)–(1.2) on $[-p,\infty)$.

Proof. Given $a > 0$, let $\mathcal{P}_a(\cdot)$ be the function in Proposition 3.8. As $0 < \mathcal{P}_a(x) \leq \mathcal{P}_\infty(x)$ for all $x \geq 0$, it follows that $0 < \mathcal{P}_a(y) < 0$ for all $a > 0$.

From Proposition 3.8, there exists a unique mild solution $u^a \in C_{\mathrm{Lip}}([-p,a];Z)$ of (1.1)–(1.2) on $[-p,a]$. Since the solution is unique and setting $u : [0,\infty) \mapsto X$ as $u(t) = u^a(t)$ for $t \in [0,a]$, we get a unique locally Lipschitz mild solution of (1.1)–(1.2) defined on the semi-axis $[-p,\infty)$. □

Remark 3.11. The first example of Section 5 contains comments with respect to the existence of the numbers $\Sigma_{i,\infty}(x)$ and an application of Corollary 3.10.

In the next result we investigate the existence and uniqueness of a maximal locally Lipschitz mild solution for (1.1)–(1.2). For this purpose, we say that $\eta : [c,d] \to \mathbb{R}$ is a Grönwall's type function, if the Grönwall's inequality is valid for inequalities of the form $\gamma(t) \leq l_1 + l_2\int_c^t \eta(s)\gamma(s)ds$ with $\gamma(\cdot)$ continuous, that is, this inequality implies that $\gamma(t) \leq l_1 e^{l_2\int_0^t \eta(s)ds}$ for all $t \in [c,d]$.

Proposition 3.12. *Suppose that the hypotheses of Theorem 3.4 hold, $q > 1$, $[G]_{(s,s)}$ is a Grönwall-type function, $\mathcal{W}_\infty := \sup_{s\geq 0}\mathcal{W}_G(s)(1+\mathcal{W}_\sigma(s)) < \infty$, and there is $\alpha \in (0,\frac{1}{q'})$, such that*

$$\sup_{t\in[0,a]}\left\|\frac{[G]_{(t,\cdot)}}{(t-\cdot)^{1-\alpha}}[\sigma]^\alpha_{(t,\cdot)}\right\|_{L^1([0,t])} < \infty$$

and that

$$\Sigma_3(c,\nu) := \sup_{h\in[0,\nu],d\in[c,c+\nu]}\|[G]_{(\cdot+h,\cdot)}(1+[\sigma]_{(\cdot+h,\cdot)})\|_{L^1([c-\nu,d])} \to 0, \tag{3.12}$$

as $\nu \downarrow 0$, for all $c \in [0,a]$. Then there exists a unique maximal mild solution $u \in C_{\mathrm{Lip}}([-p,a];Z)$ of the problem (1.1)–(1.2) on $[-p,a]$.

Proof. Let $u \in C_{\text{Lip}}([-p,b];Z)$ be the mild solution obtained in Theorem 3.4. From the demonstration of Theorem 3.4, we can show that there exists $\delta > 0$ and a unique mild solution $v \in C_{\text{Lip}}([-p,b+\delta];Z)$ of (1.1)–(1.2) such that $v = u$ on $[-p,b]$.

Indeed, let R_φ, b and ρ presented in the proof of Theorem 3.4 and assume $a > b$. Consider $R_1 > [\mathcal{V}(\cdot)\varphi(0)]_{C_{\text{Lip}}([b,a];Z)} + 2R_\varphi$. Using (3.12), we can choose $0 < \delta < b$ small such that

$$2R_\varphi + [\mathcal{V}(\cdot)\varphi(0)]_{C_{\text{Lip}}([b,a];X)} + (1+R_1)^2\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))M\Sigma_3(b,\delta) < R_1,$$

where $\rho_1 := R_1(2b+p) + \|\varphi\|_{\mathcal{B}}$. Now consider the space

$$\mathfrak{Y} = \{w \in C([-p,b+\delta];Z)\,;\, w_{|_{[-p,b]}} = u_{|_{[-p,b]}},\, [w]_{C_{\text{Lip}}([-p,b+\delta];Z)} \le R_1\}, \tag{3.13}$$

endowed with the metric $d(u,v) = \|u-v\|_{C([0,b+\delta];Z)}$ and define the map $\Gamma : \mathfrak{Y} \to C([-p,b+\delta];Z)$ as $(\Gamma w)_{|_{[-p,b]}} = u_{|_{[-p,b]}}$ and

$$\Gamma w(t) = \mathcal{V}(t)\varphi(0) + \int_0^b \mathcal{V}(t-s)G\left(s,u^\sigma(s)\right)ds + \int_b^t \mathcal{V}(t-s)G\left(s,w^\sigma(s)\right)ds, \tag{3.14}$$

for $t \in [b,b+\delta]$.

Let $w \in \mathfrak{Y}$. Then, $[\Gamma w]_{C_{\text{Lip}}([-p,b];Z)} \le R_\varphi$ since $\Gamma w(\cdot) = u(\cdot)$ on $[-p,b]$. We remark that the inequalities (3.4), (3.5) and (3.6) are verified. Moreover, using (3.4), for $s \in [b,b+\delta]$ we obtain

$$\begin{aligned}
&\max\{\|w(s)\|, \|w^\sigma(s)\|, \|w_s\|_{\mathcal{B}}\}\\
&\quad\le \max\{\|w(\cdot)\|_{C([b,b+\delta];Z)}, \|w\|_{C([b-p,b+\delta];Z)}, \|w\|_{C([b-p,b+\delta];Z)}\}\\
&\quad\le \max\{\|w(\cdot)\|_{C([b,b+\delta];Z)}, \|u\|_{C([b-p,b];Z)}\}\\
&\quad\le \max\{\|w-u(b)\|_{C([b,b+\delta];X)} + \|u(b)\|, \|u\|_{C([b-p,b];Z)}\}\\
&\quad\le [w]_{C_{\text{Lip}}([b,b+\delta];Z)}\delta + R_\varphi(b+p) + \|\varphi\|_{\mathcal{B}}\\
&\quad\le R_1\delta + R_\varphi(b+p) + \|\varphi\|_{\mathcal{B}}\\
&\quad\le R_1 b + R_1(b+p) + \|\varphi\|_{\mathcal{B}} \le \rho_1.
\end{aligned}$$

In addition, since $R_\varphi \le R_1$ and $\rho \le \rho_1$ and , for $s,h \in [0,b+\delta]$ with $s+h \in [b,b+\delta]$ and arguing as in the estimate (3.5), it follows that

$$\begin{aligned}
&\|G(s+h,w^\sigma(s+h)) - G(s,w^\sigma(s))\|\\
&\quad\le \mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))(1+R_1)^2[G]_{(s+h,s)}(1+[\sigma]_{(s+h,s)})h.
\end{aligned}$$

Let $t \in [b,b+\delta)$ and $h > 0$ with $t+h \in [b,b+\delta]$. From the above inequalities, the inequalities (3.4)–(3.6), the fact that $0 < h < \delta < b$, and proceeding as in the estimate (3.7), we get

$$\begin{aligned}
&\|\Gamma w(t+h) - \Gamma w(t)\|\\
&\quad\le [\mathcal{V}(\cdot)\varphi(0)]_{C_{\text{Lip}}([b,b+\delta];Z)}h + \int_0^h \|\mathcal{V}(t+h-s))G(0,\varphi(-\sigma(0,\varphi)))\|ds\\
&\qquad + \int_0^h \|\mathcal{V}(t+h-s))\|\|G(s,u^\sigma(s)) - G(0,\varphi(-\sigma(0,\varphi)))\|ds\\
&\qquad + \int_0^t \|\mathcal{V}(t-s)\|\|G(s+h,w^\sigma(s+h)) - G(s,w^\sigma(s))\|ds
\end{aligned}$$

$$
\begin{aligned}
&\leq [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([b,b+\delta];Z)}h+M\|G(0,\varphi(-\sigma(0,\varphi))\|h\\
&\quad+\mathcal{W}_G(\rho)(1+\mathcal{W}_\sigma(\rho))(1+R_\varphi)^2\int_0^h M[G]_{(s,0)}(1+[\sigma]_{(s,0)})hds\\
&\quad+\int_0^{b-h}\|\mathcal{V}(t-s)(G(s+h,u^\sigma(s+h))-G(s,u^\sigma(s)))\|ds\\
&\quad+\int_{b-h}^t\|\mathcal{V}(t-s)(G(s+h,w^\sigma(s+h))-G(s,w^\sigma(s)))\|ds\\
&\leq [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([b,b+\delta];Z)}h+M\|G(0,\varphi(-\sigma(0,\varphi))\|h\\
&\quad+\mathcal{W}_G(\rho)(1+\mathcal{W}_\sigma(\rho))(1+R_\varphi)^2\int_0^h M[G]_{(s,0)}(1+[\sigma]_{(s,0)})hds\\
&\quad+\mathcal{W}_G(\rho)(1+\mathcal{W}_\sigma(\rho))(1+R_\varphi)^2\int_0^{b-h} M[G]_{(s+h,s)}(1+[\sigma]_{(s+h,s)})hds\\
&\quad+\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))(1+R_1)^2\int_{b-h}^t M[G]_{(s+h,s)}(1+[\sigma]_{(s+h,s)})hds\\
&\leq [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([b,b+\delta];Z)}h+I_1+I_2+I_3\\
&\quad+\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))(1+R_1)^2\int_{b-h}^t M[G]_{(s+h,s)}(1+[\sigma]_{(s+h,s)})hds.
\end{aligned}
$$

Observing that in the estimate (3.7) the term $I_1+I_2+I_3$ also appears, we deduce that

$$
\begin{aligned}
&\|\Gamma w(t+h)-\Gamma w(t)\|\\
&\quad\leq [\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([b,b+\delta];Z)}h+R_\varphi h\\
&\qquad+\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))(1+R_1)^2M\int_{b-h}^t[G]_{(s+h,s)}(1+[\sigma]_{(s+h,s)})hds\\
&\quad\leq R_\varphi h+[\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([b,a];Z)}h+\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))(1+R_1)^2M\Sigma_3(b,\delta)h\leq R_1h,
\end{aligned}
$$

which allows us to conclude that $[w_{|_{[b,b+\delta]}}]_{C_{\mathrm{Lip}}([b,b+\delta];Z)}\leq R_1$ and $[w]_{C_{\mathrm{Lip}}([-p,b+\delta];Z)}\leq R_1$ because $[w_{|_{[-p,b]}}]_{C_{\mathrm{Lip}}([-p,b];Z)}=[u_{|_{[-p,b]}}]_{C_{\mathrm{Lip}}([-p,b];Z)}\leq R_\varphi\leq R_1$. Then, $\Gamma(\cdot)$ is a $\mathfrak{Y}$-valued function.

Moreover, arguing as in (3.8), for $t\in[b,b+\delta]$ and $w,v\in\mathfrak{Y}$ we have that

$$
\begin{aligned}
&\|\Gamma w(t)-\Gamma v(t)\|\\
&\quad\leq\int_b^t M\mathcal{W}_G(\rho_1)[G]_{(s,s)}\|w^\sigma(s)-v^\sigma(s)\|ds\\
&\quad\leq\int_b^t M\mathcal{W}_G(\rho_1)[G]_{(s,s)}(1+[w]_{C_{\mathrm{Lip}}([-p,b+\delta];Z)}\mathcal{W}_\sigma(\rho_1)[\sigma]_{(s,s)})\|w-v\|_{C([0,s];Z)}ds\\
&\quad\leq M(1+R_1)\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))\int_b^t[G]_{(s,s)}(1+[\sigma]_{(s,s)})ds\|w-v\|_{C([b,b+\delta];Z)}\\
&\quad\leq M(1+R_1)\mathcal{W}_G(\rho_1)(1+\mathcal{W}_\sigma(\rho_1))\Sigma_3(b,\delta)\|w-v\|_{C([b,b+\delta];Z)},
\end{aligned}
$$

and then $\Gamma(\cdot)$ is a contraction and there exists unique mild solution $w\in C_{\mathrm{Lip}}([-p,b+\delta];Z)$ of (1.1)–(1.2) on $[-p,b+\delta]$ such that $w=u$ on $[-p,b]$.

Proceeding this way, we obtain a maximal "locally Lipschitz" mild solution $u\in C(I_{\max};Z)$ of (1.1)–(1.2).

Now let $b_\varphi=\sup I_{\max}$. We state that $I_{\max}=[-p,b_\varphi]$ and that $u\in C_{\mathrm{Lip}}([0,b_\varphi];Z)$. Indeed,

note that $\|u^\sigma(t)\| \leq \|\varphi\|_{\mathcal{B}} + \|u\|_{C([0,t];Z)}$, for all $t \in [0, b_\varphi)$ and then

$$\begin{aligned}\|u(t)\| &\leq \|\mathcal{V}(\cdot)\|\|\varphi(0)\| + \int_0^t \|\mathcal{V}(t-s)G(s,\varphi(-\sigma(0,\varphi)))\|ds \\ &\quad + \int_0^t \|\mathcal{V}(t-s)\|\|G(s,u^\sigma(s)) - G(s,\varphi(-\sigma(0,\varphi)))\|ds \\ &\leq M(\|\varphi\|_{\mathcal{B}} + \int_0^t \|G(s,\varphi(-\sigma(0,\varphi)))\|ds) \\ &\quad + M\int_0^t \mathcal{W}_\infty[G]_{(s,s)}(\|u\|_{C([0,s];Z)} + 2\|\varphi\|_{\mathcal{B}})ds,\end{aligned}$$

that is, $u(\cdot)$ is bounded on $[0, b_\varphi)$ and $G(\cdot, u^\sigma(\cdot)) \in L^q([0,b_\varphi);Z) \cap C([0,b_\varphi);Z)$ because $[G]_{(\cdot,\cdot)}$ is a Grönwall-type function.

Moreover, we can adapt the argument in [3, Proposition 6.3] to the resolvent family and show that $u \in C^\alpha([b,b_\varphi);Z)$ and $\lim_{t\to b_\varphi} u(t)$ exists. Let $v : [-p, b_\varphi] \to Z$ be defined by $v(t) = u(t)$ for $t < b_\varphi$ and $v(b_\varphi) = \lim_{t\to b_\varphi} u(t)$. Obviously, $v \in C([0,b_\varphi];Z), v(\cdot)$ is a mild solution of (1.1)–(1.2) on $[-p, b_\varphi]$ and $v \in C^\alpha([0,b_\varphi];Z)$. From the above, for $t \in (0, b_\varphi]$ and $\rho = [v]_{C^\alpha([-p,b_\varphi);Z)} + \|v\|_{C([-p,b_\varphi];Z)}$, we have that

$$\begin{aligned}&\int_0^t \|A\mathcal{V}(t-s)(G(s,v^\sigma(s)) - G(t,v^\sigma(t)))\|ds \\ &\quad \leq \int_0^t C\mathcal{W}_\infty \frac{[G]_{(t,s)}}{(t-s)}((t-s) + \rho(a^{\alpha-\alpha^2} + \mathcal{W}_\sigma(\rho)^\alpha[\sigma]^\alpha_{(t,s)}(a^{\alpha-\alpha^2}) + \rho^\alpha)(t-s)^{\alpha^2})ds \\ &\quad \leq C\mathcal{W}_\infty \sup_{t\in[0,a]} \left\| [G]_{(t,\cdot)} + \frac{[G]_{(t,\cdot)}}{(t-\cdot)^{1-\alpha^2}}\rho(a^{\alpha-\alpha^2} + \mathcal{W}_\sigma(\rho)^\alpha[\sigma]^\alpha_{(t,\cdot)}(a^{\alpha-\alpha^2}) + \rho^\alpha) \right\|_{L^1([0,t])}. \quad (3.15)\end{aligned}$$

Denote by $\mathcal{L}_\infty$ the right hand side of (3.15) and note that

$$\begin{aligned}v(t) &= \mathcal{V}(t)\varphi(0) + \int_0^t \mathcal{V}(t-s)G(t,v^\sigma(t))ds + \int_0^t \mathcal{V}(t-s)(G(s,v^\sigma(s)) - G(t,v^\sigma(t)))ds \\ &= \mathcal{V}(t)\varphi(0) + \int_0^t \mathcal{V}(s)G(t,v^\sigma(t))ds + \int_0^t \mathcal{V}(t-s)(G(s,v^\sigma(s)) - G(t,v^\sigma(t)))ds. \quad (3.16)\end{aligned}$$

Defining $V(t) = \int_0^t \mathcal{V}(s)G(t,v^\sigma(t))ds$ and using the same argument of the [8, Lemma 2.10] we can show the function $AV(t) : [0,b_\varphi] \to Z$ is continuous. Now we infer

$$\begin{aligned}\sup_{t\in[b,b_\varphi]} \|Av(t)\| &\leq \sup_{t\in[b,b_\varphi]} \left(\|A\mathcal{V}(t)\varphi(0)\| + \left\| A\int_0^t \mathcal{R}(s)G(t,v^\sigma(t))ds \right\| + \mathcal{L}_\infty \right) \\ &\leq \frac{C_1}{b}\|\varphi(0)\| + \|AV(\cdot)\|_{C([0,b_\varphi];Z)} + \mathcal{L}_\infty. \quad (3.17)\end{aligned}$$

We get $v(t) \in D(A)$ for all $t \in (0, b_\varphi]$, and from Corollary 2.12 we conclude that $v(\cdot)$ is a classical solution of (1.1)–(1.2) on $[-p, b_\varphi]$, which implies that $\sup_{t\in[b,b_\varphi]} \|v'(t)\| < \infty$, $v \in C_{\text{Lip}}([-p,b_\varphi];Z)$, $u(\cdot) = v(\cdot)$ on $[0,b_\varphi]$ and $I_{\max} = [-p,b_\varphi]$.

Assume $b_\varphi < a$. This fact allows us to conclude that there exists $\delta' > 0$ and a unique Lipschitz mild solution $w \in C_{\text{Lip}}([-p, b_\varphi + \delta'];Z)$ of (1.1)–(1.2) on $[-p, b_\varphi + \delta']$ such that $w = u$ on $[-p,b_\varphi]$, which is contrary to the maximality of $u(\cdot)$. Thus, $b_\varphi = a$, $u \in C_{\text{Lip}}([-p,a];Z)$ and $u(\cdot)$ is the unique mild solution of (1.1)–(1.2) on $[-p,a]$. □

For the next result we use Schauder's fixed point Theorem to investigate the existence of a mild solution.

Proposition 3.13. *Assume that condition* $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ *holds,* $\varphi \in \mathcal{B}$ *and* $\mathcal{V}(t)$ *is compact for all* $t > 0$. *Then there exists a mild solution* $u \in C([-p,b];Z)$ *of the problem* (1.1)–(1.2) *on* $[-p,b]$ *for some* $0 < b \leq a$.

Proof. Let $r > 0$, $\rho := r + \|\varphi\|_{\mathcal{B}}$ and $\Lambda(r) := \mathcal{W}_G(\rho)\rho$. Since $s \to [G]_{(s,s)}$ is integrable on $[0,t]$ for all $t \in [0,a]$ then

$$\Sigma_4(0,c) := \sup_{t\in[0,c]} \int_0^t [G]_{(s,s)} ds \to 0,$$

as $c \to 0$. Moreover, as $\lim_{t\downarrow 0} \mathcal{V}(t)\varphi(0) = \varphi(0)$, we can choose $b > 0$ such that

$$\|\mathcal{V}(\cdot)\varphi(0) - \varphi(0)\|_{C([0,b];Z)} + M\left(\Sigma_4(0,b)\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,a];Z)}b\right) < r. \tag{3.18}$$

Consider the space

$$\mathfrak{Y}(b) = \{u \in C([-p,b];Z) : u_0 = \varphi, \|u(\cdot) - \varphi(0)\|_{C([0,b];Z)} \leq r\},$$

endowed with the metric $d(u,v) = \|u - v\|_{C([0,b];Z)}$ and define $\Gamma : \mathfrak{Y}(b) \to C([-p,b];Z)$ as in the proof of Theorem 3.4.

If $u \in \mathfrak{Y}(b)$, from the definition of $\mathfrak{Y}(b)$, for $s \in [0,b]$ we note that

$$\begin{aligned}\max\{\|u(s)\|, \|u^\sigma(s)\|, \|u_s\|_{\mathcal{B}}\} &\leq \sup_{\tau\in[0,b]} \|u(\tau) - \varphi(0)\| + \|\varphi\|_{\mathcal{B}} \\ &\leq r + \|\varphi\|_{\mathcal{B}} \ = \ \rho,\end{aligned}$$

which shows that

$$\begin{aligned}\|G(s,u^\sigma(s))\| &\leq \|G(s,u^\sigma(s)) - G(s,0)\| + \|G(\cdot,0)\|_{C([0,b];Z)} \\ &\leq [G]_{(s,s)}\mathcal{W}_G(\rho)\|u^\sigma(s)\| + \|G(\cdot,0)\|_{C([0,b];Z)} \\ &\leq [G]_{(s,s)}\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,b];Z)}.\end{aligned}$$

Using the previous inequalities, it is easy to see that

$$\begin{aligned}\|\Gamma u(t) - \varphi(0)\| &\leq \|\mathcal{V}(t)\varphi(0) - \varphi(0)\| + M\int_0^t [G]_{(s,s)}\mathcal{W}_G(\rho)\rho ds \\ &\quad + M\|G(\cdot,0)\|_{C([0,b];Z)}b \\ &\leq \|\mathcal{V}(\cdot)\varphi(0) - \varphi(0)\|_{C([0,b];Z)} \\ &\quad + M(\Sigma_4(0,b)\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,a];Z)}b) \leq r,\end{aligned}$$

which implies that $\Gamma(\cdot)$ is a $\mathfrak{Y}(b)$-valued function.

Furthermore, for $t \in (0,b]$ and $h > 0$ with $t + h < b$, we obtain

$$\begin{aligned}&\|\Gamma u(t+h) - \Gamma u(t)\| \\ &\quad\leq \|\mathcal{V}(t+h)\varphi(0) - \mathcal{V}(t)\varphi(0)\| \\ &\qquad + \int_0^t \|\mathcal{V}(t+h-s) - \mathcal{V}(t-s)\|([G]_{(s,s)}\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,b];Z)})ds \\ &\qquad + \int_t^{t+h} M([G]_{(s,s)}\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,b];Z)})ds \\ &\quad\leq \|\mathcal{V}(t+h)\varphi(0) - \mathcal{V}(t)\varphi(0)\| \\ &\qquad + \int_0^t \|\mathcal{V}(t+h-s) - \mathcal{V}(t-s)\|([G]_{(s,s)}\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,b];Z)})ds \\ &\qquad + M(\|[G]_{(\cdot,\cdot)}\|_{L^1([0,a])}\mathcal{W}_G(\rho)\rho + \|G(\cdot,0)\|_{C([0,b];Z)})h.\end{aligned}$$

We can write the last inequality in the form

$$\|\Gamma u(t+h) - \Gamma u(t)\| \leq \epsilon_{\varphi}^{1}(t, t+h) + \int_{0}^{t} \epsilon_{\varphi}^{2}(t, t+h, s) G(s) ds,$$

where $G(s) = [G]_{(s,s)} \mathcal{W}_G(\rho)\rho + \|G(\cdot, 0)\|_{C([0,b];Z)}$.

Note that $\epsilon_{\varphi}^{1}(t, t+h) \to 0$ as $h \to 0$ uniformly for $(t, u) \in [0, b] \times \mathfrak{Y}(b)$. Moreover, since $\epsilon_{\varphi}^{2}(t, t+h, s)G(s) \to 0$ for all $s \in [0, t]$ as $h \downarrow 0$, $\epsilon_{\varphi}^{2}(t, t+h, s)G(s) \leq MG(s)$ and $MG(\cdot)$ is integrable on $[0, t]$, we conclude that the second term at the right hand side converge to zero as $h \to 0$, uniformly for $u \in \mathfrak{Y}(b)$.

Then, the set $\{\Gamma u : u \in \mathfrak{Y}(b)\}$ is right equicontinuous at t. Similarly, we show the left equicontinuity at $t \in (0, b]$ and the right equicontinuity at $t = 0$.

Now, we need to prove that $\{\Gamma u(t) : u \in \mathfrak{Y}(b)\}$ is relatively compact in Z for all $t \in [0, b]$. Let $t \in (0, b]$ and $\varepsilon > 0$. By noting that

$$\int_{t-\delta}^{t} \|\mathcal{V}(t-s)\| \|G(s, u^{\sigma}(s))\| ds \leq M\delta^{\frac{1}{q}} \|G(\cdot)\|_{L^q([0,a])},$$

for $u \in \mathfrak{Y}(b)$, we can select $0 < \delta < t$ such that

$$\int_{t-\delta}^{t} \|\mathcal{V}(t-s)\| \|G(s, u^{\sigma}(s))\| ds \leq \varepsilon, \qquad \forall u \in \mathfrak{Y}(b).$$

From the continuity of $\mathcal{V}(\cdot)$ on $[\delta, t]$, we can choose $N \in \mathbb{N}$ and numbers $0 < t_1 < t_2 < \ldots < t_N = t - \delta < t_{N+1} = t$ such that $\|\mathcal{V}(t-s) - \mathcal{V}(t-t_i)\| \leq \frac{\varepsilon}{1+R}$ for all $s \in [t_i, t_{i+1}]$ and $i = 1, \ldots, N-1$.

Under the previous conditions and remarking that

$$\int_{\mu}^{t_{i+1}} \|G(s, u^{\sigma}(s))\| ds \leq \int_{0}^{t} \|G(s)\| ds \leq \Theta := b^{\frac{1}{q}} \|G(\cdot)\|_{L^q([0,a])},$$

for all $i = 1, \ldots, N-1$ and every $\mu < t$, for $u \in \mathfrak{Y}(b)$ we obtain

$$\begin{aligned}
\Gamma u(t) &= \mathcal{V}(t)\varphi(0) + \int_{t_N}^{t} \mathcal{V}(t-s) G(s, u^{\sigma}(s)) ds + \sum_{i=1}^{N-1} \mathcal{V}(t-t_i) \int_{t_i}^{t_{i+1}} G(s, u^{\sigma}(s)) ds \\
&\quad + \sum_{i=1}^{N-1} \int_{t_i}^{t_{i+1}} (\mathcal{V}(t-s) - \mathcal{V}(t-t_i)) G(s, u^{\sigma}(s)) ds \\
&\in \mathcal{V}(t)\varphi(0) + B_{\varepsilon}(0; Z) + \sum_{i=1}^{N-1} \mathcal{V}(t-t_i) B_{\Theta}(0; Z) + \varepsilon B_{\Theta}(0; Z),
\end{aligned}$$

and hence, $\{\Gamma u(t) : u \in \mathfrak{Y}(b)\} \subset D_{\varepsilon} + K_{\varepsilon}$, where the diameter of D_{ε} go to 0 as $\varepsilon \to 0$ and K_{ε} is relatively compact in Z. Then, $\{\Gamma u(t) : u \in \mathfrak{Y}(b)\}$ is relatively compact in Z.

By hypothesis $\boldsymbol{H}_{G,\sigma,a}^{q,r}$ it follows that $\Gamma(\cdot)$ is continuous and from the previous commentaries we can conclude that $\Gamma(\cdot)$ is completely continuous. Therefore, from Schauder's Fixed Point Theorem, there exists a mild solution $u \in C([-p, b]; Z)$ of (1.1)–(1.2) on $[-p, b]$. □

4 Well-posedness

To begin our study on the local well-posedness of the problem (1.1)–(1.2), we first introduce the next concept.

Definition 4.1. Let $(\mathcal{D}, \|\cdot\|_{\mathcal{D}}) \hookrightarrow (\mathcal{B}, \|\cdot\|_{\mathcal{B}})$ be a Banach space and $a > 0$. We say that the problem (1.1)–(1.2) is locally well-posed related to the spaces $(\mathcal{D}, \|\cdot\|_{\mathcal{D}})$ and $C([0,a];Z)$, if for all $\varphi \in \mathcal{D}$ and $r > 0$, there exists $c_\varphi > 0$ such that, for all $\psi \in B_r(\varphi, \mathcal{D})$ there exists a unique mild solution $u(\cdot,\psi) \in C([-p, c_\varphi];Z)$ of the problem (1.1)–(1.2) on $[-p, c_\varphi]$ and

$$\|u(\cdot,\varphi) - u(\cdot,\psi)\|_{C([0,c_\varphi];Z)} \to 0 \quad \text{as } \|\varphi - \psi\|_{\mathcal{D}} \to 0. \tag{4.1}$$

Combining the proofs of Theorem 3.4 and Corollary 3.6, we have the next result, with

$$\mathcal{D} = \mathcal{D}_a = \{\psi \in C_{\text{Lip}}([-p,0];Z) : \mathcal{V}(\cdot)\psi(0) \in C_{\text{Lip}}([0,a];Z),\ \psi(0) \in E\},$$

endowed with the metric $d(\psi_1,\psi_2) = \|\psi_1 - \psi_2\|_{C_{\text{Lip}}([-p,0];Z)} + \|\mathcal{V}(\cdot)(\psi_1(0) - \psi_2(0))\|_{C_{\text{Lip}}([0,a];Z)}$.

Proposition 4.2. *Suppose that condition* $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ *is satisfied and* $\Theta(q,r) < 1$. *Then the problem* (1.1)–1.2 *is locally well-posed related to the spaces* $(\mathcal{D}_a, \|\cdot\|_{\mathcal{D}_a})$ *and* $C([0,a];Z)$.

Proof. Let $\varphi \in \mathcal{D}_a$, $r > 0$ and $R^*_\varphi > 0$ be such that

$$R^*_\varphi > \Lambda := \sup_{\psi \in B_r(\varphi;\mathcal{D}_a)} \left([\mathcal{V}(\cdot)\psi(0)]_{C_{\text{Lip}}([0,a];Z)} + \|\psi\|_{C_{\text{Lip}}([-p,0];Z)} + M\|G(0,\psi(-\sigma(0,\psi)))\| \right).$$

Since $\Sigma_i(c) \to 0$ as $c \to 0$ for $i = 1,2$, we can choose $0 < c_\varphi \le a$ such that

$$\Lambda + (1+R^*_\varphi)^2 \mathcal{W}_G(\rho^*)(1+\mathcal{W}_\sigma(\rho^*))\left(\Sigma_1(c_\varphi) + \Sigma_2(c_\varphi)\right) < R^*_\varphi,$$

where $\rho^* := R^*_\varphi(a+2p) + \|\varphi\|_{\mathcal{B}} + r$.

Consider $\psi \in B_r(\varphi, \mathcal{D}_a)$. Proceeding as in the proof of Theorem 3.4, with $\psi(\cdot)$ instead of $\varphi(\cdot)$, we can show that there exists a unique mild solution $u(\cdot,\psi) \in C_{\text{Lip}}([-p,c_\varphi];Z)$ of the problem (1.1) with initial condition $\psi(\cdot)$. In addition, it follows that $[u(\cdot,\psi)]_{C_{\text{Lip}}([-p,c_\varphi];Z)} \le R^*_\varphi$ and $\|u(\cdot,\psi)\|_{C([-p,c_\varphi];Z)} \le \rho^*$.

We define $\mathcal{K}(\cdot,R^*_\varphi) = [G]_{(\cdot,\cdot)}(1 + [\sigma]_{(\cdot,\cdot)})$. Let $\psi \in B_r(\varphi;\mathcal{D}_a)$, $u(\cdot) = u(\cdot,\varphi)$ and $v(\cdot) = u(\cdot,\psi)$. From the above remarks and the last inequality in Lemma 2.2, for $t \in [0,c_\varphi]$ we get

$$\begin{aligned}
&\|u(t) - v(t)\| \\
&\quad \le \|\mathcal{V}(t)\varphi(0) - \mathcal{V}(t)\psi(0)\| + \int_0^t \|\mathcal{V}(t-s)\|\|G(s,u^\sigma(s)) - G(s,v^\sigma(s))\|ds \\
&\quad \le d(\varphi,\psi) + \mathcal{W}_G(\rho^*)\int_0^t M[G]_{(s,s)}\|u^\sigma(s) - v^\sigma(s)\|ds \\
&\quad \le d(\varphi,\psi) + \mathcal{W}_G(\rho^*)\int_0^t M[G]_{(s,s)}(1 + R^*_\varphi \mathcal{W}_\sigma(\rho^*)[\sigma]_{(s,s)})\|u - v\|_{C([0,s];Z)}ds \\
&\quad \le d(\varphi,\psi) + (1+R^*_\varphi)\mathcal{W}_G(\rho^*)(1+\mathcal{W}_\sigma(\rho^*))M\int_0^t \mathcal{K}(s,R^*_\varphi)\|u - v\|_{C([0,s];Z)}ds,
\end{aligned}$$

and hence,

$$\|u - v\|_{C([0,t];Z)} \le d(\varphi,\psi)e^{(1+R^*_\varphi)\mathcal{W}_G(\rho^*)(1+\mathcal{W}_\sigma(\rho^*))M\|\mathcal{K}(\cdot,R^*_\varphi)\|_{L^1([0,c_\varphi])}}.$$

Therefore, there exists $\Lambda > 0$ such that $\|u(\cdot,\varphi) - v(\cdot,\psi)\|_{C([0,c_\varphi];Z)} \le \Lambda d(\varphi,\psi)$, for all $\psi \in B_r(\varphi;\mathcal{D})$, which completes the proof. □

Remark 4.3. Every result proved in this work can be easily adapted for the integro-differential equations

$$\frac{du(t)}{dt} = Au(t) + \int_0^t Q(t-s)u(s)ds + G(t,u(t-\sigma(t,u_t))), t \in [0,a], \tag{4.2}$$

$$u_0 = \varphi \in \mathcal{B} = C([-p,0];Z), \tag{4.3}$$

where A and $Q(t)$ for $t \geq 0$ are closed linear operators defined on a common domain $D(A)$ that is dense in Z where the functions $G(\cdot)$ and $\sigma(\cdot)$ are continuous. Simply use the resolvent theory for integro-differential equations developed by Grimmer et al. [11–13].

5 Memory and diffusion-coupled system

To finish this paper, we study now the existence of solutions for a problem concerning the coupled memory and diffusive integro-differential system with state-dependent delay. Specifically, we consider the integro-differential system

$$\begin{aligned}
&\frac{\partial}{\partial t}\left[u(t,x)+\int_0^t (t-s)^{\alpha}e^{-\omega(t-s)}v(s,x)ds\right]\\
&\quad=\Delta u(t,x)+\int_0^t B(t-s)\Delta v(s,x)ds+\zeta(t)\int_\Omega b(u(\varrho(t,u_t),y))f(x-y)dy, \qquad (5.1)\\
&\frac{\partial}{\partial t}\left[v(t,x)+\int_0^t (t-s)^{\alpha}e^{-\gamma(t-s)}u(s,x)ds\right]\\
&\quad=\Delta v(t,x)+\int_0^t C(t-s)\Delta u(s,x)ds+g(v(\varrho(t,u_t),x)), \qquad (5.2)\\
&u(t,\cdot)|_{\partial\Omega}=0,\quad v(t,\cdot)|_{\partial\Omega}=0, \qquad (5.3)\\
&u(\theta,y)=\varphi(\theta,y),\quad v(\theta,y)=\phi(\theta,y),\qquad \theta\in[-p,0],\ y\in\Omega, \qquad (5.4)
\end{aligned}$$

for $t \in [0,a]$ and $x \in \Omega$, where $f \in C(\widetilde{\Omega};\mathbb{R})$, $\widetilde{\Omega}=\{x-y : x,y\in\Omega\}$, $g \in C_{\mathrm{Lip}}(\mathbb{R}^n;\mathbb{R}^n)$, $b \in C_{\mathrm{Lip}}(\mathbb{R}^n;\mathbb{R}^n)$, $\varrho \in C_{\mathrm{Lip}}([0,a]\times\mathcal{B};\mathbb{R}), d-p \leq \varrho(t,\psi) \leq t$ for all $(t,\psi)\in[0,a]\times\mathcal{B}$ and $\zeta \in C_{\mathrm{Lip}}(\mathbb{R};\mathbb{R})$.

To show the existence of solutions for the problem (5.1)–(5.4) we consider the operators $A, Q(t) : D(A) \subseteq X \to X$, $t \geq 0$, where $X = L^2(\Omega;\mathbb{R})$ given by $Ax = \Delta x$, for $x \in D(A) = H^2(\Omega)\cap H_0^1(\Omega)$ and $P_\omega(t)x = t^\alpha e^{-\omega t}x$ and $P_\gamma(t)x = t^\alpha e^{-\gamma t}x$ for $x \in X$. The operator A is the infinitesimal generator of an analytic semigroup and for all $\vartheta \in (\pi/2,\pi)$ there exists constant $M_\vartheta > 0$ such that $\|R(\lambda,A)\| \leq M_\vartheta|\lambda|^{-1}$ for all $\lambda \in \Lambda_\vartheta$. We assume that $B(\cdot)$ and $C(\cdot)$ in $L^1_{\mathrm{loc}}(\mathbb{R}^+)$, furthermore $B(\cdot)$ and $C(\cdot)$ has Laplace transformed absolutely convergent for $Re(\lambda) > 0$ which analytical extension to Λ_ϑ and $|\widehat{B}(\lambda)| + |\widehat{C}(\lambda)| = O(\frac{1}{|\lambda|})$, as $|\lambda| \to \infty$. To study this problem, we define the functions $\sigma : [0,\infty)\times\mathcal{B} \to \mathbb{R}$ by $\sigma(t,\psi) = t - \varrho(t,\psi), F_1(t,u)(x) = \zeta(t)\int_\Omega b(u(y))f(x-y)dy$ and $F_2(u)(x) = g(u(x))$.

Let $\mathcal{U} = \binom{u}{v}$ in this problem the space Z is defined by $Z = L^2(\Omega;\mathbb{R})\times L^2(\Omega;\mathbb{R})$ under the norm $\|\binom{u}{v}\| = \left(\int_\Omega |u|^2+|v|^2dx\right)^{\frac{1}{2}}$, it is easy to see that Z is a Hilbert space. We define the $D(\mathcal{A})$ by $D(\mathcal{A}) = \left\{\binom{u}{v}\in X : u,v\in H^2(\Omega)\cap H_0^1(\Omega)\right\}$, and $\mathcal{G} : [0,a]\times Z \to Z$

$$\begin{aligned}
&\frac{\partial}{\partial t}\left[\begin{pmatrix}u(t,x)\\ v(t,x)\end{pmatrix}+\int_0^t\begin{pmatrix}0 & (t-s)^\alpha e^{-\omega(t-s)}\\ (t-s)^\alpha e^{-\gamma(t-s)} & 0\end{pmatrix}\begin{pmatrix}u(s,x)\\ v(s,x)\end{pmatrix}ds\right]\\
&\quad=\begin{pmatrix}\Delta & 0\\ 0 & \Delta\end{pmatrix}\begin{pmatrix}u(t,x)\\ v(t,x)\end{pmatrix}+\int_0^t\begin{pmatrix}0 & B(t-s)\Delta\\ C(t-s)\Delta & 0\end{pmatrix}\begin{pmatrix}u(s,x)\\ v(s,x)\end{pmatrix}ds\\
&\qquad+\begin{pmatrix}F_1(t,u^\sigma(t,x))\\ F_2(t,v^\sigma(t,x))\end{pmatrix}.
\end{aligned}$$

Therefore, we can represent the system (5.1)–(5.4) in the abstract form

$$\frac{\partial}{\partial t}\left(\mathcal{U}(t)+\int_0^t \mathcal{P}(t-s)\mathcal{U}(s)ds\right)=\mathcal{A}\mathcal{U}(t)+\int_0^t \mathcal{Q}(t-s)\mathcal{U}(s)ds+\mathcal{G}(t,\mathcal{U}^\sigma(t)), \tag{5.5}$$

$$\mathcal{U}_0=\begin{pmatrix}\varphi\\ \phi\end{pmatrix}\in\mathcal{B}\times\mathcal{B}, \tag{5.6}$$

where

$$\mathcal{A}=\begin{pmatrix}\Delta & 0\\ 0 & \Delta\end{pmatrix},\ \mathcal{P}(t)=\begin{pmatrix}0 & P_\omega(t)\\ P_\gamma(t) & 0\end{pmatrix},\ \mathcal{Q}(t)=\begin{pmatrix}0 & A(t)\Delta\\ B(t)\Delta & 0\end{pmatrix},\ \text{and}$$

$$\mathcal{G}(t,\mathcal{U}^\sigma(t))=\begin{pmatrix}F_1(t,u^\sigma(t,x))\\ F_2(t,v^\sigma(t,x))\end{pmatrix}.$$

Now we show that $\mathcal{A}$ is a sectorial operator, this fact follows that

$$(\lambda-\mathcal{A})\begin{pmatrix}u_1\\ u_2\end{pmatrix}=\begin{pmatrix}f_1,\\ f_2.\end{pmatrix},$$

this is equivalent to

$$\begin{cases}(\lambda-A)u_1=f_1,\\ (\lambda-A)u_2=f_2.\end{cases}$$

Assume that $|\arg(\lambda)|<\vartheta$. Then $\lambda\in\rho(\mathcal{A})$, and the resolvent is written as

$$\begin{cases}u_1=(\lambda-A)^{-1}f_1,\\ u_2=(\lambda-A)^{-1}f_2.\end{cases}$$

we get

$$\begin{pmatrix}u_1\\ u_2\end{pmatrix}=\begin{pmatrix}(\lambda-A)^{-1} & 0\\ 0 & (\lambda-A)^{-1}\end{pmatrix}\begin{pmatrix}f_1\\ f_2\end{pmatrix}.$$

Now we can show

$$\begin{aligned}\|(\lambda I-\mathcal{A})^{-1}\|&\le\|(\lambda-A)^{-1}\|+\|(\lambda-A)^{-1}\|\\ &\le 2M_\vartheta|\lambda|^{-1}.\end{aligned}$$

The previous argument shows that $\mathcal{A}$ is a sectorial operator.

From the definitions of $\mathcal{Q}(t)$ we have for $\mathcal{U}\in D(\mathcal{A})$

$$\begin{aligned}\|\mathcal{Q}(t)\mathcal{U}\|^2&=\left\|\begin{pmatrix}0 & A(t)\Delta x\\ B(t)\Delta x & 0\end{pmatrix}\begin{pmatrix}u\\ v\end{pmatrix}\right\|^2\\ &=\int_\Omega \|B(t)\Delta v\|^2+\|A(t)\Delta u\|^2dx\\ &\le (A(t)+B(t))^2\left(\int_\Omega\|\Delta v\|^2dx+\int_\Omega\|\Delta u\|^2dx\right)\\ &\le (A(t)+B(t))^2(\|\mathcal{A}\mathcal{U}\|+\|\mathcal{U}\|)^2.\end{aligned}$$

Therefore

$$\|\mathcal{Q}(t)U\|\le k(t)(\|\mathcal{A}\mathcal{U}\|+\|\mathcal{U}\|), \tag{5.7}$$

where $k(t) = A(t) + B(t)$. From (5.7) we obtain the Laplace transform of $(\mathcal{Q}(t))_{t\geq 0}$ is absolutely convergent for $Re(\lambda) > 0$, admits an analytical extension to Λ_ϑ and

$$\|\widehat{\mathcal{Q}}(\lambda)\|_{\mathcal{L}([D(\mathcal{A}),X])} = O\left(\frac{1}{|\lambda|}\right), \quad \text{as } |\lambda| \to \infty.$$

By the definitions of $\mathcal{P}(t)$ we get for $\mathcal{U} \in Z$

$$\begin{aligned}
\|\mathcal{P}(t)\mathcal{U}\|^2 &= \left\| \begin{pmatrix} 0 & P_\omega(t) \\ P_\gamma(t) & 0 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} \right\|^2 \\
&= \int_\Omega \|P_\gamma(t)u\|^2 + \|P_\omega(t)v\|^2 dx \\
&\leq (P_\omega(t) + P_\gamma(t))^2 \left(\int_\Omega \|u\|^2 dx + \int_\Omega \|v\|^2 dx \right) \\
&\leq (P_\omega(t) + P_\gamma(t))^2 \|\mathcal{U}\|^2.
\end{aligned}$$

It is clear that the function $\mathcal{P} : [0,\infty) \to \mathcal{L}(Z)$ is strongly continuous and $\widehat{\mathcal{P}}(\lambda)z$ is absolutely convergent for $z \in Z$ and $Re(\lambda) > 0$. There exists an analytical extension of $\widehat{\mathcal{P}}(\lambda)$ (still denoted by $\widehat{\mathcal{P}}(\lambda)$) to Λ_ϑ such that $\|\widehat{\mathcal{P}}(\lambda)\| \leq N_0|\lambda|^{-\alpha-1}$ for every $\lambda \in \Lambda_\vartheta$, and $\|\widehat{\mathcal{P}}(\lambda)z\| \leq N_1|\lambda|^{-1}\|z\|_1$ for every $\lambda \in \Lambda_\vartheta$ and $z \in D(\mathcal{A})$. As well as $D = C_0^\infty(\Omega) \times C_0^\infty(\Omega)$, where $C_0^\infty(\Omega)$ is the space of infinitely differentiable functions that vanish at $\partial\Omega$. It is easy to see that conditions **(C1)–(C4)** are satisfied with the previous conditions.

By the [8, Theorem 2.] we obtain the next result.

Proposition 5.1. *Assume that the above conditions are fulfilled. Then, there exists an analytical resolvent operator family $(\mathcal{V}(t))_{t\geq 0}$ associated to (5.5)–(5.6).*

Next, we prove that $\mathcal{G}(\cdot)$ is a L^q- Lipschitz function. Assume $(\int_\Omega \int_\Omega f(x-y)^2 dydx) < \infty$. It is easy to see that

$$\begin{aligned}
&\|F_1(t,u) - F_1(s,v)\| \\
&\quad \leq (\|b\|_{C_{\text{Lip}}} \int_\Omega \int_\Omega f(x-y)^2 dydx) m(\Omega))(\|u\|)([\zeta]_{(t,s)} + \zeta(s))(|t-s| + \|u-v\|), \\
&\qquad \|F_2(t,u) - F_2(s,v)\| \leq \|g\|_{C_{\text{Lip}}}(|t-s| + \|u-v\|),
\end{aligned}$$

where $m(\Omega)$ represent the measure of Ω. Thus, $\mathcal{G}(\cdot)$ is a L^q-Lipschitz function, the condition $\boldsymbol{H}^{q,r}_{G,\sigma,a}$ is satisfied with $W_\sigma(r) = 1$, $[\sigma]_{C_{\text{Lip}}} = [\varrho]_{C_{\text{Lip}}} + 1$ and

$$\begin{aligned}
&\mathcal{W}_\mathcal{G}(r) = r + 1, \\
&[\mathcal{G}]_{(t,s)} = (\|b\|_{C_{\text{Lip}}} \int_\Omega \int_\Omega f(x-y)^2 dydx) m(\Omega) + \|g\|_{C_{\text{Lip}}})([\zeta]_{(t,s)} + \zeta(s)).
\end{aligned}$$

We have the next result.

Proposition 5.2. *Assume $q > 1$ and $\mathcal{V}(\cdot)\varphi(0) \in C_{\text{Lip}}([0,a];Z)$.*

(a) If $\sup_{b\in[0,c],d,h\in[0,b],d+h\leq b} \|[\zeta]_{(\cdot+h,\cdot)}\|_{L^q([0,d])} < \infty$, for some $0 < c \leq a$ or $\zeta(\cdot)$ is Lipschitz, then there exists a unique mild solution $u \in C_{\text{Lip}}([-p,b];Z)$ of the problem (5.1)–(5.4) on $[-p,b]$ for some $0 < b \leq a$.

(b) If $\sup_{b\in[0,c],d,h\in[0,b],d+h\leq b} \|[\zeta]_{(\cdot+h,\cdot)}\|_{L^q([0,d])} < \infty$, for some $0 < c \leq a$ or $\zeta(\cdot)$ is Lipschitz, then if $\varphi(0,\cdot)$ and $\phi(0,\cdot) \in H^2(\Omega) \cap H_0^1(\Omega)$, then there exists a unique classical solution $u(\cdot)$ of the problem (5.1)–(5.4) on $[-p,b]$ for some $0 < b \leq a$.

(c) If $\sup_{b\in[0,c],d,h\in[0,b],d+h\leq b}\|[\zeta]_{(\cdot+h,\cdot)}\|_{L^q([0,d])}<\infty$, *for some* $0<c\leq a$ *or* $\zeta(\cdot)$ *is Lipschitz, moreover, if* $\zeta(\cdot)$ *is Lipschitz and* $1>\frac{4\beta(\theta+2\beta)}{(3\beta-1)^2}$. *where* $\theta:=[\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];Z)}+\|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)}+M\|G(0,\varphi(-\sigma(0,\varphi))\|$ *and* $\beta:=(\|b\|_{C_{\mathrm{Lip}}}\int_\Omega\int_\Omega f(x-y)^2dydx)m(\Omega)+\|g\|_{C_{\mathrm{Lip}}})Ma$, *then there exists a unique mild solution* $u\in C_{\mathrm{Lip}}([-p,a];X)$ *of* (5.1)–(5.4) *on* $[-p,a]$.

Proof. The first assumption (a) follows from Corollary 3.6.

It is well-known that every reflexive Banach space has the Radon–Nikodym property (RNP). Since Hilbert spaces are reflexive, they automatically enjoy the RNP. By $\varphi(0,\cdot),\phi(0,\cdot)\in H^2(\Omega)\cap H_0^1(\Omega)$, $[\mathcal{G}]_{(t,s)}$ and $\zeta(\cdot)$ are continuous, the second assumption (b) follows from Proposition 3.5.

The assumption (c), the existence of a Lipschitz mild solution defined on $[-p,a]$ follows from Proposition 3.8 noting that the function $P_a:\mathbb{R}\mapsto\mathbb{R}$ given by

$$\begin{aligned}\mathcal{P}_a(x)&=[\mathcal{V}(\cdot)\varphi(0)]_{C_{\mathrm{Lip}}([0,a];Z)}+\|\varphi\|_{C_{\mathrm{Lip}}([-p,0];Z)}+M\|G(0,\varphi(-\sigma(0,\varphi))\|\\&\quad+(1+x)^2(\|b\|_{C_{\mathrm{Lip}}}\int_\Omega\int_\Omega f(x-y)^2dydx)m(\Omega)+\|g\|_{C_{\mathrm{Lip}}})Ma\\&\quad+(1+x)(\|b\|_{C_{\mathrm{Lip}}}\int_\Omega\int_\Omega f(x-y)^2dydx)m(\Omega)+\|g\|_{C_{\mathrm{Lip}}})Ma\\&=\theta+(1+x)^2\beta+(1+x)\beta-x,\end{aligned}$$

has two positive root if $1>\frac{4\beta(\theta+2\beta)}{(3\beta-1)^2}$, the results follow by Corollary 2.12 □

Received 1 July 2025, appeared 15 December 2025
Communicated by Paul Eloe

Abstract. We analyze a mathematical model recently proposed by Mehmood *et al.* [*J. Appl. Mech. Tech. Phys.* **63**(2022), 782–789] of unsteady fluid flow over a shrinking porous disk. Mehmood *et al.* conjectured that solutions to the model exist only for sufficiently strong suction of fluid through the disk surface. Here we prove that solutions in fact exist for both suction and injection. However, with injection, the solutions are very difficult to determine numerically. In this case, we derive precise bounds on the skin friction coefficient as a function of injection velocity. These bounds are then used to pinpoint the solutions computationally.

Keywords: existence, nonexistence, boundary-layer flow, nonlinear boundary value problem.

2020 Mathematics Subject Classification: 34B15, 76D10.

1 Introduction

Fluid flow induced by a stretching surface is a classic problem in mechanics, first considered by Crane [3] in 1970 for a two dimensional case in which a horizontal boundary stretches away from a fixed point with a velocity proportional to the distance from the fixed point. Since that time, the analysis has been expanded to include mathematical models of various other geometries and configurations (See e.g. [2,5–7,13–16]). For the case of *stretching* surfaces, solutions generally turn out to be unique. (For Crane's [3] original model, see for example [9] or [12].)

In the case of *shrinking* surfaces, the solution sets turn out to be much more varied, and can include parameter regimes with two [1], three (or more) [10], or even a whole continuum of solutions [11]. There can also be ranges of parameters where no solutions exist [10,11].

Recently, Mehmood *et al.* [8] proposed a model for axisymmetric two-dimensional unsteady flow induced by a shrinking porous disk, with accelerated and decelerated flow situations. Using a dimensionless similarity variable transformation, they reduce the governing partial differential equations to an ordinary differential equation boundary value problem.

✉ Corresponding author. Email: jep7@psu.edu

Using numerical integration, Mehmood *et al.* [8] analyze the model and make several conjectures regarding the nature of the solutions. The purpose of this note is to study the problem analytically and compare the results to the computational results of [8].

The model involves two physical parameters governing injection/suction of fluid through the disk surface and acceleration/deceleration of the radial coordinate of the disk as it shrinks. Based on numerical integration of the differential equation, Mehmood *et al.* [8] find solutions to the problem only in the case of sufficiently strong suction. These solutions are found for both accelerating and decelerating disks. However, we will prove that, at least in the case of an *accelerating* disk, solutions exist for both suction *and* injection. But it should be noted that, in the case of injection, these solutions are very difficult to pinpoint numerically. Thus we can readily understand how Mehmood *et al.* [8] came to the conclusion that they might not exist.

The numerical search for solutions to many fluid flow problems can be aided by a-priori knowledge about the skin friction coefficient, and for an *accelerated* disk we are able to derive precise bounds on this coefficient. These bounds become increasingly more accurate as the fluid injection velocity is increased, and can be used to guide numerical calculations.

Existence or nonexistence of a solution for a *decelerating* disk is much less clear cut. In this case we prove that for a large portion of parameter space, any solution must contain a region of flow reversal in the radial direction. In other regions of parameter space it does appear that solutions without flow reversal exist. Mehmood *et al.* [8], in fact, find dual solutions for a decelerating disk. However, we conjecture that there are actually infinitely many solutions for a decelerating disk with suction.

The plan of the paper is as follows. In Section 2, we state the problem and consider the case of an accelerated disk. Section 3 explores a decelerated disk. In Section 4, we use the results of the previous sections to help pinpoint the solutions computationally. Even with the precise bounds on the skin friction coefficient derived in Section 2, we still find it difficult to track the solutions using standard numerical integration routines. We conclude by discussing these numerical issues and state some open problems regarding the model.

2 Accelerated disk

The model proposed by Mehmood *et al.* [8] is the following: Find $f(\eta)$ satisfying

$$f''' - \left(2f + \frac{\beta\eta}{2}\right) f'' + f'(f' - \beta) = 0, \quad 0 < \eta < \infty, \tag{2.1}$$

subject to

$$f(0) = S, \quad f'(0) = 1, \quad f'(\infty) = 0, \tag{2.2}$$

where $\beta > 0$ denotes an accelerating disk, $\beta < 0$ denotes a decelerating disk, $S > 0$ corresponds to fluid injection through the disk surface, and $S < 0$ corresponds to fluid suction. The radial and axial fluid velocities are proportional to $f'(\eta)$ and $f(\eta)$, respectively, where η is the dimensionless similarity variable.

To explore the existence or nonexistence of solutions to the boundary value problem (BVP) (2.1–2.2) in β-S parameter space, we will find it useful to consider a family of related initial value problems (IVP), namely, equations (2.1), $(2.2)_1$, and $(2.2)_2$ along with a third initial condition:

$$f''(0) = \alpha. \tag{2.3}$$

This IVP will have a unique local solution for any value of α. The question then becomes: Can α be chosen so that the solution of the IVP exists for all $\eta > 0$ *and* satisfies $(2.2)_3$, giving a solution to the BVP? Our first result along these lines is a topological shooting argument to prove existence for $\beta > 1$.

Theorem 2.1. *If $\beta > 1$ and $S \in \mathbb{R}$, then a solution to the BVP exists. Further, this solution satisfies $f' > 0$, $f'' < 0$ $f''' > 0$, $f^{(4)} < 0$, and $f^{(5)} > 0$ for all $\eta > 0$.*

Proof. For the family of initial value problems (2.1), $(2.2)_1$, $(2.2)_2$ and (2.3) defined above, consider the two sets:

$$\mathcal{A} = \{\alpha < 0 : f'' = 0 \text{ strictly before } f' = 0\}, \tag{2.4}$$

$$\mathcal{B} = \{\alpha < 0 : f' = 0 \text{ strictly before } f'' = 0\}. \tag{2.5}$$

By construction, the two sets are disjoint. We next show that they are nonempty and open as well. For $\mathcal{A}$ this follows directly from continuity of solutions of the IVP in its initial conditions. First note that when $f''(0) = \alpha = 0$, we have $f'''(0) = \beta - 1 > 0$. Thus $f'(\eta; \alpha = 0) > 1$ for $\eta \in (0, \varepsilon]$ for some $\varepsilon > 0$. By continuity of the solutions of the IVP in its initial conditions, for small $\alpha < 0$, we can arrange that $f'(\varepsilon; \alpha) > 1$. But since $f''(0) = \alpha < 0$, $f'(\eta)$ initially decreases below 1. Thus, f' must attain a minimum where $f'' = 0$. Also, for small $\alpha < 0$ we can ensure that $f' > 0$ on $[0, \varepsilon]$. Thus $f'' = 0$ strictly before $f' = 0$ for small $\alpha < 0$. Thus $\mathcal{A}$ is nonempty. Further note that we cannot have $f'' = f''' = 0$ simultaneously, since the ODE (2.1) then implies that $f' \equiv 0$ or $f' \equiv \beta$, which cannot be the case since $f''(0) = \alpha < 0$. Thus, when $f'' = 0$, $f''' \neq 0$ and so $\mathcal{A}$ is open.

To prove that $\mathcal{B}$ is nonempty and open we consider large $\alpha < 0$. We claim that for $\alpha < 0$ and $|\alpha|$ sufficiently large, we must have $f' = 0$ before $f'' = 0$ in the interval $[0, 1]$, say. Suppose for contradiction that the assertion is false, then one of following three possibilities must occur: (1) there exists a first $\eta_0 \in (0, 1]$ such that $f''(\eta_0) = 0$ with $0 < f' < 1$ on $(0, \eta_0]$ and $f'' < 0$ on $(0, \eta_0)$, (2) $0 < f' < 1$ and $f'' < 0$ on all of $(0, 1]$, or (3) $f' = f'' = 0$ simultaneously.

First consider possibility (1). Since $0 < f' < 1$ on $(0, \eta_0] \subset (0, 1]$, on integration and using $(2.2)_1$ we have $S < f < S + 1$ on $(0, \eta_0]$. Next, an integration of (2.1) from 0 to $\eta > 0$ results in

$$f'' = \alpha + \left(2f + \frac{\beta\eta}{2}\right) f' - 2S + \frac{\beta}{2}(f - S) - 3\int_0^\eta f'(t)^2\, dt. \tag{2.6}$$

Using the bounds on f and f' on $(0, \eta_0]$ in (2.6) we have

$$f'' < \alpha + \beta + 2, \quad \forall\, \eta \in (0, \eta_0]. \tag{2.7}$$

Choosing $\alpha < -(\beta + 2)$ in (2.7) implies that $f''(\eta_0) < 0$, contradicting the assumption that $f''(\eta_0) = 0$.

Next, consider possibility (2). In this case the bounds on f, f', and f'' from the previous paragraph hold on the entire interval $(0, 1]$, and choosing $\alpha < -(\beta + 3)$ implies that $f'' < -1$ on $(0, 1]$. On integration we then have that $f'(1) < 0$, contradicting the assumption that $f' > 0$ on $(0, 1]$. Thus possibility (2) cannot occur.

Finally, as we have seen previously, f' and f'' cannot vanish simultaneously, which precludes possibility (3). Thus if $\alpha < -(\beta + 3)$, then $\alpha \in \mathcal{B}$ and $\mathcal{B}$ is nonempty. And since from (2.1) we must have $f'' \neq 0$ when $f' = 0$, we see that $\mathcal{B}$ is open.

Since the interval $(-\infty, 0)$ is connected, it cannot be expressed as the union of $\mathcal{A}$ and $\mathcal{B}$. Thus there exists an α^* with $\alpha^* \notin \mathcal{A}$ and $\alpha^* \notin \mathcal{B}$. Thus for $f(\eta; \alpha^*)$ we cannot have $f'' = 0$

before $f' = 0$ nor can we have $f' = 0$ before $f'' = 0$. Also, as we have seen, $f' = f'' = 0$ simultaneously leads to a contradiction.

Thus we must have $0 < f' < 1$ and $f'' < 0$ for as long as $f(\eta;\alpha^*)$ exists. Let $[0,\overline{\eta})$ denote the maximal interval of existence of $f(\eta;\alpha^*)$. We wish to show that $\overline{\eta} = \infty$. Since $0 < f' < 1$ we have that f' is bounded on $[0,\overline{\eta})$, and on integration we conclude that f is also bounded on $[0,\overline{\eta})$. From (2.6) we then have f'' is bounded on any finite interval as well. Thus the solution can be continued past any finite $\overline{\eta}$ so that $\overline{\eta} = \infty$.

Since $f' > 0$ and $f'' < 0$ for all $\eta > 0$ we have that $f'(\infty) = L$ exists with $0 \leq L < 1$. We wish to show that $L = 0$, giving a solution to the BVP. If $L > 0$, then $0 < L < f' < 1$ for all $\eta > 0$ and using (2.1) we then have

$$f''' - \left(2f + \frac{\beta\eta}{2}\right) f'' = f'(\beta - f') > L(\beta - 1) = K > 0, \quad \forall\, \eta > 0. \tag{2.8}$$

Next note that when $f'' < 0$, f''' cannot increase through zero, since at such a point we would need $f^{(4)} \geq 0$, but a differentiation of (2.1) implies that $f^{(4)} = 3\beta f''/2 < 0$ at a root of f''', giving a contradiction. Thus if f''' were ever to equal zero, it would thereafter remain negative, which would then eventually force f' negative, contradicting the fact that $f' > 0$ for all η. Therefore we need $f''' > 0$ for all $\eta \geq 0$.

Using a similar argument and further differentiations of (2.1) it can be shown that $f^{(4)} < 0$ and $f^{(5)} > 0$ for all $\eta \geq 0$. Therefore, f'' and f''' are both monotonic and bounded, so that their limits as $\eta \to \infty$ exist. However, since $f'(\infty) = L$ exists, we must have $f''(\infty) = f'''(\infty) = 0$.

Next, note that $2L + \beta/2 < 2f' + \beta/2 < 2 + \beta/2$ for all $\eta > 0$ and so on integration from 0 to $\eta > 0$ we have

$$2S + \left(\frac{\beta + 4L}{2}\right)\eta < 2f + \frac{\beta\eta}{2} < 2S + \left(\frac{\beta + 4}{2}\right)\eta, \quad \forall\, \eta > 0. \tag{2.9}$$

Further, note that $2S + (\beta + 4L)\eta/2 > 0$ for η sufficiently large, and so by (2.9), $2f + \beta\eta/2 > 0$ for η sufficiently large.

Using these facts in (2.8), we can find $\hat{\eta}$ sufficiently large so that

$$f'' < \frac{-K}{2\left(2S + \frac{\beta+4}{2}\eta\right)}, \quad \forall\, \eta \geq \hat{\eta}. \tag{2.10}$$

Integrating (2.10) from $\hat{\eta}$ to $\eta > \hat{\eta}$ we have

$$f' < f'(\hat{\eta}) - \frac{K}{\beta + 4}\left[\ln\left(2S + \frac{\beta + 4}{2}\eta\right) - \ln\left(2S + \frac{\beta + 4}{2}\hat{\eta}\right)\right], \quad \forall\, \eta \geq \hat{\eta}, \tag{2.11}$$

which tends to $-\infty$ as $\eta \to \infty$, contradicting $f' \to L > 0$. Thus we must have $f'(\infty;\alpha^*) = L = 0$, giving a solution to the BVP and proving the theorem. □

Physically, this theorem states that for a sufficiently accelerated disk ($\beta > 1$) solutions to the problem exist for both injection ($S > 0$) and suction ($S < 0$) of fluid through the disk surface, as well as for an impermeable disk ($S = 0$).

Based on numerical integration of the problem, Mehmood *et al.* conjectured that for any value of $\beta \in \mathbb{R}$, no solution exists when $S > 0$. Theorem 2.1 above shows that, at least for $\beta > 1$, this conjecture is incorrect. However, when $\beta > 1$ and $S > 0$, the solutions are very difficult to pinpoint numerically, so that a conjecture of their nonexistence is understandable.

Theorem 2.1 guarantees at least one value of α which gives a solution to the BVP, but gives little indication of its value other than $-(\beta+3) < \alpha < 0$. In the next theorem we obtain much more precise bounds on α. This, in turn, gives bounds on the skin friction coefficient, which is proportional to α.

Theorem 2.2. *If $\beta > 1$ and $S > 0$, then the solution to the BVP given in Theorem 2.1 must satisfy $f''(0) = \alpha$ where*

$$\frac{2(1-\beta)(2S^2+\beta+1)}{8S^3+7S\beta+4S} < \alpha < \frac{2S(1-\beta)}{4S^2+3\beta/2}. \tag{2.12}$$

Proof. The bounds on α will involve the initial values of several derivatives of f. Using (2.1) and its derivatives we have

$$f'''(0) = 2S\alpha + \beta - 1, \tag{2.13}$$

$$f^{(4)}(0) = \left(4S^2 + \frac{3\beta}{2}\right)\alpha + 2S(\beta-1), \tag{2.14}$$

and

$$f^{(5)}(0) = (8S^3+7S\beta+4S)\alpha + 2(\beta-1)(2S^2+\beta+1). \tag{2.15}$$

Recall that the solution of Theorem 2.1 satisfies $0 < f' < 1$ and $f'' < 0$ for all $\eta > 0$. In the proof of Theorem 2.1 it was further shown that $f''' > 0$, $f^{(4)} < 0$, and $f^{(5)} > 0$ for all $\eta \geq 0$. In particular, $f^{(4)}(0) < 0$, and $f^{(5)}(0) > 0$. Using these inequalities in (2.14) and (2.15) results in (2.12). □

The coefficient of wall skin friction, C_f, of the fluid is given as [8]:

$$C_f = -Re_x^{-1/2} f''(0) = -Re_x^{-1/2}\alpha, \tag{2.16}$$

where Re_x is the Reynolds number. Thus the results of Theorem 2.2 give ever more precise bounds on the skin friction coefficient as the injection rate ($S > 0$) increases.

Remark 2.3. The results of this section do not touch on the question of uniqueness of a solution, but for the $\beta > 1$ and $S > 0$ case, we can conclude that for *any* solution, α must satisfy the bounds given in Theorem 2.2. To see this, first note that when $\beta > 0$, f' cannot attain a minimum at or below zero. Thus any solution must satisfy $f' > 0$ for all $\eta \geq 0$. Next, if $\alpha \geq 0$ and $\beta > 1$, then f' is initially increasing. In order to satisfy the boundary condition at infinity, f' would have to first attain a maximum where $f''' < 0$. However, as in the proof of Theorem 2.2, f''' could not thereafter increase through zero, and so $f'(\infty) = 0$ could not be achieved.

So far we have been concerned with existence of a solution and its properties, however there are parameter values for which no solution exists. Specifically:

Theorem 2.4. *For $0 < \beta \leq 1$ and $S \geq 0$, the BVP has no solution.*

Proof. Recall that for $\beta > 0$, f' cannot have a minimum at or below 0, thus any solution must satisfy $f' > 0$ for all $\eta \geq 0$. Also, when $\beta > 0$, f''' cannot increase through zero when $f'' < 0$, so that $f''' > 0$ for all $\eta \geq 0$. However $f'''(0) = 2S\alpha + \beta - 1 > 0$ implies that $\alpha > (1-\beta)/2S \geq 0$. This then implies that $\alpha > 0$ and arguing as in the Remark 2.3, f' could not then satisfy the boundary condition at infinity. □

The results of Theorems 2.1 and 2.4 imply that in the case of fluid injection ($S > 0$), solutions to the problem only exist for a sufficiently accelerating disk ($\beta > 1$) whereas no solution exists for insufficient acceleration ($0 < \beta \leq 1$).

3 Decelerated disk

The analysis regarding a decelerating disk is much less comprehensive than the accelerating case. For $\beta < 0$ and $S > 0$, we conjecture that no solution exists, but have only been able to prove this for a relatively small portion of parameter space (see Theorem 3.2 below). However, in the next theorem we show that for a decelerating disk ($\beta < 0$) and sufficient fluid injection ($S > 0$ sufficiently large) there is no solution to the BVP with the property $f' > 0$ for all $\eta \geq 0$. Thus, if a solution does exist in this case, f' must at some point become negative. Physically, this implies a region of flow reversal in the radial direction. This implication is discussed further in Section 4.

Theorem 3.1. *If $-4 \leq \beta < 0$ and $S > 0$, then the BVP has no solution that satisfies $f' > 0$ for all $\eta \geq 0$. Further, if $\beta < -4$ and*

$$S \geq \frac{1}{8}\left[25\beta^4 + \left(\frac{28\beta^3}{3} - 128\beta + \frac{256}{3}\right)(\beta+4)\right]^{\frac{1}{4}} \equiv p(\beta), \tag{3.1}$$

then the BVP has no solution that satisfies $f' > 0$ for all $\eta \geq 0$.

Proof. We will assume the existence of a solution satisfying $f' > 0$ for all $\eta \geq 0$ and derive a contradiction. We first list some properties that such a solution must possess. When $\beta < 0$, from (2.1) we see that f' cannot have a positive minimum. Also note that when $\beta < 0$, f''' cannot decrease through zero when $f'' < 0$. Thus as f' approaches zero from above, we must have $f'' < 0$ and $f''' > 0$ for η large. Thus $f''(\infty) = 0$. Finally, note that the quantity $u = 2f + \beta\eta/2$ is negative for large η since $\beta < 0$ and $f > 0$ grows sublinearly.

If some value of $f''(0) = \alpha \leq 0$ gives a solution to the BVP, then using (2.6) we have

$$f'' = \alpha + \left(2f + \frac{\beta\eta}{2}\right)f' - 2S + \frac{\beta}{2}(f - S) - 3\int_0^\eta f'(t)^2\,dt. \tag{3.2}$$

As η tends to infinity, the left side of (3.2) tends to zero while the right side is strictly negative, giving a contradiction.

If some value of $f''(0) = \alpha > 0$ gives a solution to the BVP, then f' must attain a positive maximum, say at η_2, where $f''(\eta_2) = 0$. Integrating the ODE (2.1) from η_2 to $\eta > \eta_2$ we have

$$f'' + \left(2f(\eta_2) + \frac{\beta\eta_2}{2}\right)f'(\eta_2) = \left(2f + \frac{\beta\eta}{2}\right)f' + \frac{\beta}{2}(f - f(\eta_2)) - 3\int_{\eta_2}^\eta f'(t)^2\,dt. \tag{3.3}$$

As $\eta \to \infty$ and $f'' \to 0$, the right side of (3.3) is strictly negative, implying that

$$2f(\eta_2) + \frac{\beta\eta_2}{2} < 0. \tag{3.4}$$

But the quantity

$$u(\eta) = 2f(\eta) + \frac{\beta\eta}{2}, \tag{3.5}$$

is initially positive since $u(0) = 2S > 0$. Thus a root of $u = 2f + \beta\eta/2$ must occur as f' increases towards its maximum. However, $f' > f'(0) = 1$ as it increases to its max. But if $-4 \leq \beta < 0$, then

$$u'(\eta) = 2f'(\eta) + \frac{\beta}{2} \geq 0, \quad \forall\, \eta \in [0, \eta_2]. \tag{3.6}$$

Thus $u = 2f + \beta\eta/2$ cannot decrease through zero, giving a contradiction. Thus if $-4 \le \beta < 0$ and $S > 0$, the BVP cannot have a solution that satisfies $f' > 0$ for all $\eta > 0$.

If $\beta < -4$, we need additional conditions on S in order to obtain our final contradiction regarding the root of $u = 2f + \beta\eta/2$. Recall that $f''(\eta_2) = 0$ at the maximum of f' and let $\eta_1 < \eta_2$ be the point where $u(\eta_1) = 2f(\eta_1) + \beta\eta_1/2 = 0$ first decreases through zero.

Integrating the ODE (2.1) from zero to η_1 we have

$$\alpha - 2S + \frac{\beta}{2}(f(\eta_1) - S) - 3\int_0^{\eta_1} f'(t)^2\,dt = f''(\eta_1) > 0 \tag{3.7}$$

from which we conclude that

$$\alpha > 2S > 0, \tag{3.8}$$

since $\beta(f(\eta_1) - S)/2$ and $-3\int_0^{\eta_1} f'^2\,dt$ are both strictly negative.

Next, note from (3.8) and the assumption $S \ge p(\beta) > \sqrt{1-\beta}/2$ we have that

$$f'''(0) = 2S\alpha + \beta - 1 > 0, \tag{3.9}$$

so that f'' initially increases above its starting value of α. As f' increases towards its max, f''' must at some first point decrease through zero (and cannot subsequently increase through zero for $\eta \le \eta_2$). Thus, there must exist a point η_0 such that

$$f''(\eta_0) = \alpha \;\text{ with }\; f''(\eta) > \alpha \quad \forall\,\eta \in (0,\eta_0) \;\text{ and }\; f''(\eta) < \alpha \quad \forall\,\eta \in (\eta_0,\eta_2]. \tag{3.10}$$

Note that $\eta_0 < \eta_1$. To see this, note that (2.6) evaluated at η_0 gives

$$\left(2f(\eta_0) - \frac{\beta\eta_0}{2}\right) f'(\eta_0) = 2S - \frac{\beta}{2}(f(\eta_0) - S) + 3\int_0^{\eta_0} f'(t)^2\,dt > 0, \tag{3.11}$$

which implies that $u(\eta_0) = 2f(\eta_0) + \beta\eta_0 > 0$. But $u = 2f + \beta\eta/2$ first decreases through zero at η_1. If $\eta_0 > \eta_1$, then there would have to exist a intermediate point, $\eta^* \in (\eta_1, \eta_0)$, where $u = 2f + \beta\eta/2$ increases back through zero with $f''(\eta^*) > \alpha$ by (3.10). Evaluating (2.6) at such a point gives

$$f''(\eta^*) - \alpha = -2S + \frac{\beta}{2}(f(\eta^*) - S) - 3\int_0^{\eta^*} f'(t)^2\,dt < 0, \tag{3.12}$$

contradicting $f''(\eta^*) > \alpha$. Thus $\eta_0 < \eta_1$.

Next note that when $u(\eta_1) = 2f(\eta_1) + \beta\eta_1/2 = 0$, we need $u'(\eta_1) = 2f'(\eta_1) + \beta/2 \le 0$, thus $f'(\eta_1) \le -\beta/4$. Since f' is increasing on $(0,\eta_1)$ we then have that

$$1 < f'(\eta) \le -\frac{\beta}{4}, \quad \forall\,\eta \in (0,\eta_1). \tag{3.13}$$

Subsequently,

$$\frac{\beta+4}{2} \le 2f' + \frac{\beta}{2}, \quad \forall\,\eta \in (0,\eta_1), \tag{3.14}$$

and on integration from zero to $\eta > 0$ we have

$$2S + \frac{\beta+4}{2}\eta < u(\eta) = 2f(\eta) + \frac{\beta\eta}{2}, \quad \forall\,\eta \in (0,\eta_1). \tag{3.15}$$

Further, note that when $f'' = \alpha$ at $\eta_0 < \eta_1$ we have from (2.1) that

$$\left(2f(\eta_0) + \frac{\beta\eta_0}{2}\right) f''(\eta_0) = f'(\eta_0)(f'(\eta_0) - \beta) + f'''(\eta_0) < f'(\eta_0)(f'(\eta_0) - \beta), \tag{3.16}$$

since $f'''(\eta_0) < 0$. Next, using (3.8) and (3.13) in (3.16) we obtain

$$2f(\eta_0) + \frac{\beta\eta_0}{2} < \frac{5\beta^2}{32S}. \tag{3.17}$$

Combining (3.15) and (3.17) we conclude that

$$2S + \frac{\beta+4}{2}\eta_0 < 2f(\eta_0) + \frac{\beta\eta_0}{2} < \frac{5\beta^2}{32S}, \tag{3.18}$$

or (using $S \geq p(\beta) > \sqrt{5}|\beta|/8$)

$$\eta_0 > \frac{5\beta^2 - 64S^2}{16S(\beta+4)} > 0. \tag{3.19}$$

Next, multiply the ODE (2.1) by f'' and integrate from zero to η_1 to obtain

$$\int_0^{\eta_0} \left(2f(t) + \frac{\beta t}{2}\right) f''(t)^2\, dt = \frac{1}{3}(f'(\eta_0)^3 - 1) - \frac{\beta}{2}(f'(\eta_0)^2 - 1). \tag{3.20}$$

Using (3.13) to bound the right hand side of (3.20) we have

$$\int_0^{\eta_0} \left(2f(t) + \frac{\beta t}{2}\right) f''(t)^2\, dt < \frac{-7\beta^3}{192} - \frac{1}{3} + \frac{\beta}{2}. \tag{3.21}$$

However, using (3.8), (3.15) and (3.19) we also have

$$\frac{25\beta^4 - 4096S^4}{256(\beta+4)} < \int_0^{\frac{5\beta^2-64S^2}{16S(\beta+4)}} \left(2S + \frac{\beta+4}{2}t\right) 4S^2\, dt < \int_0^{\eta_0} \left(2f(t) + \frac{\beta t}{2}\right) f''(t)^2\, dt. \tag{3.22}$$

Combing (3.21) and (3.22) gives

$$\frac{25\beta^4 - 4096S^4}{256(\beta+4)} < \frac{-7\beta^3}{192} - \frac{1}{3} + \frac{\beta}{2} \tag{3.23}$$

which is contradicted if

$$S \geq \frac{1}{8}\left[25\beta^4 + \left(\frac{28\beta^3}{3} - 128\beta + \frac{256}{3}\right)(\beta+4)\right]^{\frac{1}{4}}. \tag{3.24}$$

Thus if $\beta < -4$ and (3.24) holds, then the BVP has no solution with the property $f' > 0$ for all $\eta > 0$. □

Physically, the results of this Theorem 3.1 imply that for a decelerating disk ($\beta < 0$) and sufficiently strong fluid injection ($S > 0$ if $-4 \leq \beta < 0$ and $S > p(\beta)$ if $\beta < -4$), any solution to the BVP must contain a region where $f'(\eta)$ becomes negative. As $f'(\eta)$ is proportional to the fluid velocity in the radial direction, this implies a region of flow reversal in the boundary layer, and such solutions are unlikely to be stable in the full governing PDE and thus are not physically realizable. Thus this theorem gives strong evidence that no solution exists for the parameter values given in the theorem statement. In fact, we can eliminate the possibility of these non-physical solutions mathematically, but only for a small range of parameter space (see Theorem 3.2 below).

Theorem 3.2. *If $-4 \leq \beta < 0$ and $S \geq 3\beta^2/2 - 5\beta/8$, then the BVP has no solution.*

Proof. We will assume a solution exists and derive a contradiction. By Theorem 3.1, for $-4 \leq \beta < 0$, if a solution exists, then f' at some point must become negative. Let η_A be the first point at which f' decreases through zero, $f'(\eta_A) = 0$. Let η_B be the first point, if ever, that the quantity $u = 2f + \beta\eta/2$ decreases through zero, $u(\eta_B) = 2f(\eta_B) + \beta\eta_B/2 = 0$. Let

$$\eta_1 = \min\{\eta_A, \eta_B\}. \tag{3.25}$$

Note that for $\beta < 0$, f' cannot have a minimum at or below $f' = \beta$. Also note that $u' = 2f' + \beta/2 \geq 0$ for $f' \geq -\beta/4$. Thus if a root of $u = 2f + \beta\eta/2$ occurs, it must occur with f' in the range $\beta < f' < -\beta/4$.

With these preliminaries out of the way, we will show that for $-4 \leq \beta < 0$ and $S > 0$ sufficiently large, f' must fall below $f' = \beta$ at some point in the interval $[\eta_1, \eta_1 + 1]$, and thus cannot be a solution to the BVP.

To see this, first consider a value $f''(0) = \alpha \leq 0$ that gives a solution to the BVP. An integration of the ODE (2.1) evaluated at η_1 gives

$$f''(\eta_1) = \alpha - 2S + \frac{\beta}{2}(f(\eta_1) - S) - 3\int_0^{\eta_1} f'(t)^2\,dt < -2S, \tag{3.26}$$

since each term of the right hand side of (3.26) is nonpositive.

In order to satisfy the boundary condition $f'(\infty) = 0$, f' must attain a first negative minimum at some point $\eta_2 > \eta_1$ with

$$\beta < f', \quad \forall \eta \in [\eta_1, \eta_2]. \tag{3.27}$$

Integrating (3.27) from η_1 to $\eta > \eta_1$ and multiplying by $\beta/2 < 0$ we have

$$\frac{\beta}{2}(f - f(\eta_1)) < \frac{\beta^2}{2}(\eta - \eta_1), \quad \forall \eta \in [\eta_1, \eta_2]. \tag{3.28}$$

Again using (3.27), we also have

$$\frac{5\beta}{2} < u' = 2f' + \frac{\beta}{2}, \quad \forall \eta \in [\eta_1, \eta_2]. \tag{3.29}$$

Integrating (3.29) from η_1 to $\eta > \eta_1$ we have

$$\frac{5\beta}{2}(\eta - \eta_1) < 2f(\eta_1) + \frac{\beta\eta_1}{2} + \frac{5\beta}{2}(\eta - \eta_1) < 2f + \frac{\beta\eta}{2}, \quad \forall \eta \in [\eta_1, \eta_2]. \tag{3.30}$$

Taking the worst case scenario where $2f + \beta\eta/2 < 0$ and $f' < 0$ on $(\eta_1, \eta_2]$ in (3.30) we derive the bound

$$\left(2f + \frac{\beta\eta}{2}\right) f' < \frac{5\beta^2}{2}(\eta - \eta_1), \quad \forall \eta \in (\eta_1, \eta_2]. \tag{3.31}$$

Next, integrating the ODE (2.1) from η_1 to $\eta > \eta_1$ we have

$$f'' = f''(\eta_1) + \left(2f + \frac{\beta\eta}{2}\right) f' + \frac{\beta}{2}(f - f'(\eta_1)) - 3\int_{\eta_1}^{\eta} f'(t)^2\,dt. \tag{3.32}$$

Using (3.26), (3.28), and (3.31) in (3.32) we then have

$$f'' < -2S + \frac{5\beta^2}{2}(\eta - \eta_1) + \frac{\beta^2}{2}(\eta - \eta_1), \quad \forall \eta \in (\eta_1, \eta_2]. \tag{3.33}$$

Next, consider the line through the points $(\eta_1, -\beta/4)$ and (η_1+1, β), which has slope $m = 5\beta/4$. Choosing $S > 0$ sufficiently large in (3.33) we can ensure that $f'' < 5\beta/4$ on the interval $(\eta_1, \eta_1+1]$, thus forcing the minimum of f' to occur at $\eta_2 > \eta_1 + 1$. However, this then implies that

$$f'' < -2S + 3\beta^2 \leq \frac{5\beta}{4}, \quad \forall \eta \in (\eta_1, \eta_1+1], \tag{3.34}$$

which, on integration from η_1 to $\eta > \eta_1$, then implies that

$$f' < f'(\eta_1) + \frac{5\beta}{4}(\eta - \eta_1) \leq \frac{5\beta}{4}(\eta - \eta_1) - \frac{\beta}{4}, \quad \forall \eta \in (\eta_1, \eta_1+1], \tag{3.35}$$

since $f'(\eta_1) \leq -\beta/4$. Evaluating at $\eta_1 + 1$ we have

$$f'(\eta_1 + 1) < \beta, \tag{3.36}$$

at which point f' can no longer attain a minimum and therefore cannot be a solution to the BVP.

Inequality (3.34) is satisfied if

$$S \geq \frac{3\beta^2}{2} - \frac{5\beta}{8}. \tag{3.37}$$

Thus if $-4 \leq \beta < 0$ and (3.37) is satisfied, then no value of $f''(0) = \alpha \leq 0$ gives a solution to the BVP.

Next consider the case that a value $f''(0) = \alpha > 0$ gives a solution to the BVP. Then f' is initially increasing and must at some first point, η_0, attain a maximum above $f'(0) = 1$ where $f''(\eta_0) = 0$. Again let η_A be the first subsequent point where f' vanishes, $f'(\eta_A) = 0$. Integrating the ODE (2.1) from η_0 to η_A we have

$$f''(\eta_A) = -\left(2f(\eta_0) + \frac{\beta\eta_0}{2}\right) f'(\eta_0) + \frac{\beta}{2}(f(\eta_A) - f(\eta_0)) - 3\int_{\eta_0}^{\eta_A} f'(t)^2\, dt. \tag{3.38}$$

Note that all of $u = 2f + \beta\eta/2$, f', and f are positive and increasing on $(0, \eta_0)$. Thus $(2f(\eta_0) + \beta\eta_0/2)f'(\eta_0) > 2S$. Thus from (3.38) we have

$$f''(\eta_A) < -2S, \tag{3.39}$$

and the proof proceeds as in the case $f''(0) = \alpha \leq 0$. Thus if $-4 \leq \beta < 0$ and $S \geq 3\beta^2/2 - 5\beta/8$, then the BVP has no solution. □

4 Discussion and numerical results

In this section we discuss the mathematical and physical implications of the results obtained in Sections 2 and 3. These results are summarized graphically in Figure 4.1. The region shaded in green indicates parameter values for which at least one solution to the BVP exists. This solution satisfies $f' > 0$, $f'' < 0$, $f''' > 0$, $f^{(4)} < 0$, and $f^{(5)} > 0$ for all $\eta > 0$. The area shaded in red denotes parameter values for which no solution exists. Finally, the region shaded in orange indicates parameter values for which no solution exists that satisfies $f' > 0$ for all $\eta > 0$. Thus, if a solution to the BVP exists for parameter values in this range, f' must at some point become negative. Physically, this represents a region of flow reversal in the radial direction, and such solutions are unlikely to be stable in the full governing PDEs, and thus are not physically realizable.

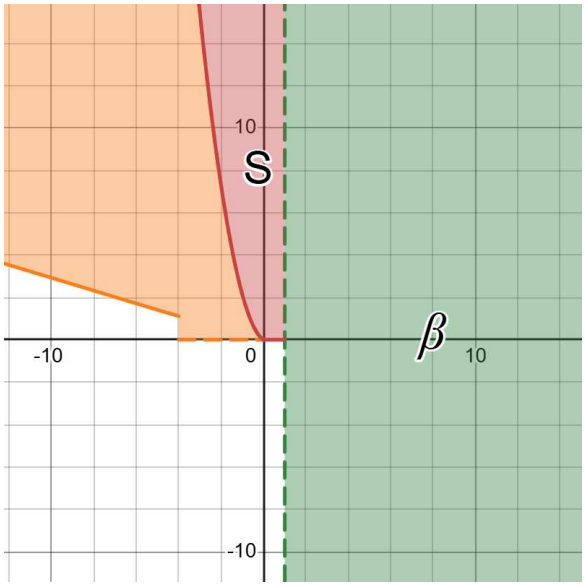

Figure 4.1: β-S parameter space showing regions of existence (green) and nonexistence (red) of solutions to the BVP (2.1–2.2). The region shaded in orange shows parameter values for which no solution exists that satisfies $f' > 0$ for all $\eta > 0$.

To study the problem numerically, we began by replicating the numerical results given in Mehmood *et al.* [8]. Using the same parameter values we found that we could not improve on the results given in [8]. These values include various levels of deceleration ($\beta < 0$) and fluid injection ($S < 0$). A comparison of our results and the results of [8] are given in Tables 4.1 and 4.2.

S	β	α [8]	α
-1.35	-1.14000950	-1.0990	-1.0990
-1.36	-1.66710229	-0.8947	-0.89475
-1.38	-3.17491743	-0.3142	-0.31428
-1.40	-5.57621580	0.5940	-0.5944

Table 4.1: Comparison of numerical values of $f''(0) = \alpha$ between [8] and current results.

Next, based on numerical integration of the problem, it was conjectured in [8] that solutions to the BVP (2.1–2.2) do not exist in the case of fluid injection ($S > 0$). The results given here indicate that, at least for a sufficiently accelerated disk ($\beta > 1$), this conjecture is incorrect. Theorem 2.1 establishes existence of a solution for all $\beta > 1$ and any $S \in \mathbb{R}$.

However, for $\beta > 1$ and $S > 0$, we had difficulty finding these solutions numerically. We employed the numerical integration software XPP-Aut [4]. Using a fourth order Runge–Kutta scheme with a stepsize $d\eta = .0001$ and an interval length $\eta_{\max} = 5$, the automated boundary value solver was unable to converge to a solution.

Consequently, we attempted to pinpoint the solution with manual numerical shooting. We used the bounds on the shooting parameter α given in Theorem 2.2 as a guide. In Figure 4.2,

β	S	α [8]	α
-1	-1.34688680700	-1.1532	-1.1532
-2	-1.36528410900	-0.7659	-0.76596
-3	-1.37810278220	-0.3812	-0.38124
-4	-1.38796975330	0	0
-5	-1.39598577367	0.3779	0.37796

Table 4.2: Comparison of numerical values of $f''(0) = \alpha$ between [8] and current results.

a graph of these bounds on α are given as a function of S for $\beta = 8$. Such bounds greatly narrowed the search for the appropriate value of α, but we were still unable to obtain convergence to a solution.

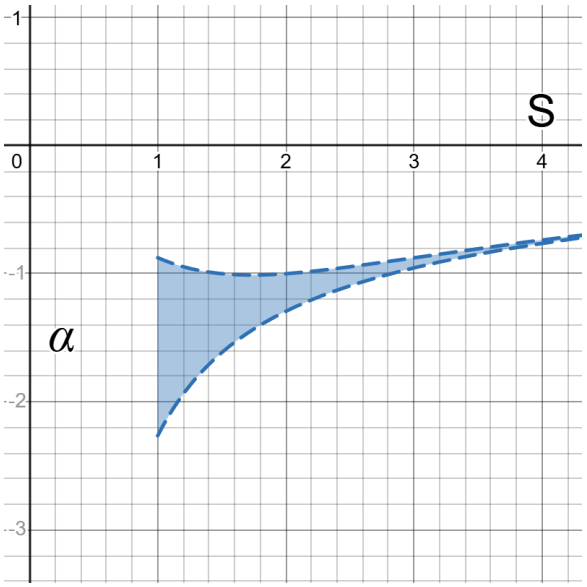

Figure 4.2: Bounds from Theorem 2.2 on $f''(0) = \alpha$ as a function of S for $\beta = 8$. A solution to the BVP (2.1–2.2) must have $f''(0) = \alpha$, where α lies is in this range.

As an example, consider parameter values $\beta = 2$ and $S = 2$. The bounds given in Theorem 2.2 then indicate that a value of α giving a solution to the boundary value problem must lie in the range $-.22 \approx -\frac{11}{50} < \alpha < -\frac{4}{19} \approx -.2105263$. We numerically integrated the differential equation using fourth order Runge–Kutta with a stepsize of $d\eta = .0001$ and an integration length of $\eta_{\max} = 5$. Our manual search resulted in a value of $\alpha \approx -0.217830769818888$ which does lie in the range given by Theorem 2.2. However, the convergence of the solution to the boundary condition at infinity is very slow, and our numerical software lost track of the solution even before $\eta = 4$. Figure 4.3 graphs two numerically integrated solutions to the initial value problem for values of α near the suspected true value. Note the quick divergence at a relatively small value of the independent variable η. Reducing the stepsize from $d\eta = .0001$ to $d\eta = .00001$ did not materially effect the results.

This numerical difficulty can arise from several sources. First, for $\beta > 0$ and $S > 0$,

the coefficient $-(2f + \beta\eta/2)$ of f'' in the ODE (2.1) can lead to rapid growth of the solution of the IVP (2.1), $(2.2)_1$, $(2.2)_2$, and (2.3) away from the solution of the BVP (2.1–2.2) during numerical shooting. Also, for positive β and S, the convergence of the solution is algebraic, not exponential, as η tends to infinity, adding further difficulty.

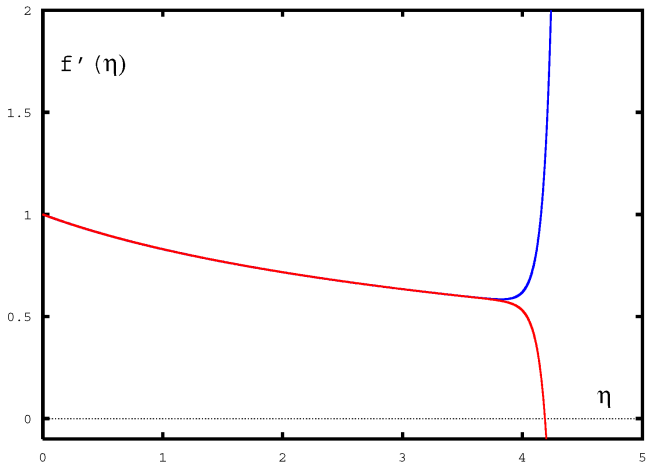

Figure 4.3: Two numerically integrated solutions to the IVP for $\beta = 2$ and $S = 2$ using fourth order Runge–Kutta with $d\eta = .0001$. Upper curve: $\alpha = -.2178307698188879$; lower curve: $\alpha = -.217830769818888$. Theorem 2.2 indicates that the value of α must satisfy $-.22 < \alpha < -.2105263$.

Finally, we note that for $\beta < 0$ and $S < 0$ we were unable to attain any analytical results. In this parameter range, Mehmood *et al.* [8] report dual solutions. However, we conjecture that for $\beta < 0$ and $S < 0$ there exists a continuum of infinitely many solutions. In Figure 4.4 we graph several solutions to the boundary value problem for $\beta = -2$ and $S = -2$. For these parameter values the solutions converge to the boundary condition at infinity very quickly, thus we increased the stepsize to $d\eta = .001$ and increased $\eta_{\max} = 10$. In Figure 4.4, the values of α ranged from 0 up to 5 in increments of 0.5. All solutions still converged to zero as $\eta_{\max}$ was increased. The graph shows the solutions on the range $0 \le \eta \le 10$, however, the interval of integration was increased and $f'(\eta)$ continued to show convergence to zero on any interval examined.

A similar graph can be produced using values of α ranging from -5 to 0. The maximal range of α which produces solutions to the BVP could not be determined exactly since for larger values of $|\alpha|$, the convergence of the solution became very slow.

Using a combination of direct analysis of the BVP (2.1–2.2) and numerical integration of the problem, we were able to extend and refine the results initiated in [8]. However, questions remain regarding the solution set of (2.1–2.2). Specifically, we end this note with two open conjectures:

Conjecture 1. For $\beta < 0$ and $S \ge 0$, no solution to the BVP (2.1–2.2) exists. (Theorems 3.1 and 3.2 above give partial results regarding this conjecture.)

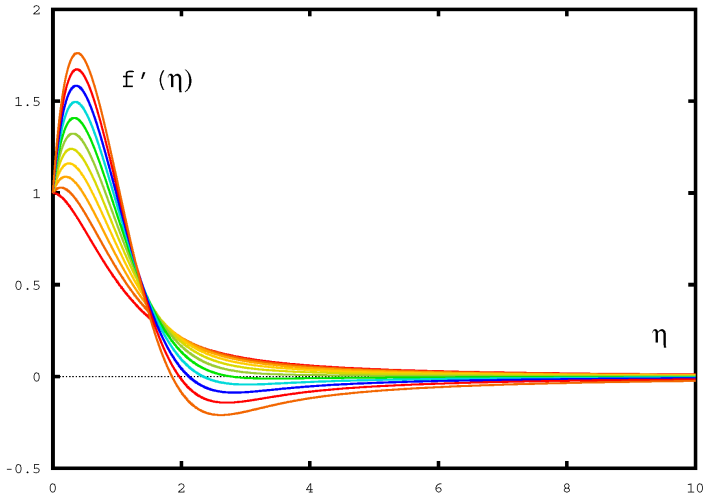

Figure 4.4: Graph of continuum of solutions to the BVP (2.1–2.2) for $\beta = -2$ and $S = -2$. Initial conditions on $f''(0) = \alpha$ range from 0 to 5 in increments of 0.5.

This would imply that for a decelerating disk ($\beta < 0$) and for any amount of fluid injection ($S > 0$), or even an impermeable disk ($S = 0$), no solution exists. However, numerically, it does appear that for a decelerating disk ($\beta < 0$) solutions do exist for sufficiently strong suction (S sufficiently negative). This implies that there exists a critical value for suction, $S_0 < 0$, below which solutions will exist. This critical value is likely to depend on β. Thus we are led to the following conjecture:

Conjecture 2. For $\beta < 0$, there exists an $S_0(\beta) < 0$ such that for all $S < S_0(\beta)$, the BVP (2.1–2.2) possesses a continuum of infinitely many solutions.

Abstract. We are concerned with the semipositone problem with Minkowski-curvature operator

$$\begin{cases} -\operatorname{div}\left(\dfrac{\nabla u}{\sqrt{1-|\nabla u|^2}}\right) = \lambda a(|x|)(u^\gamma - \epsilon), & x \in B(R), \\ u = 0, & x \in \partial B(R), \end{cases}$$

where $B(R) = \{x \in \mathbb{R}^N : |x| < R\}$, $N \geq 2$, $R > 0$, $\epsilon > 0$, $\gamma > 1$ and $a : [0,\infty) \to (0,\infty)$ is a continuous function. We show that there exist the constants $\Lambda > 2N/(\max_{r\in[0,R]} a(r)R^{\gamma+1})$ and $\epsilon_0(\Lambda) > 0$ such that, if $\epsilon < \epsilon_0(\Lambda)$, then the problem has least two positive radial solution for any $\lambda \in (\Lambda, \Lambda^*)$, where Λ^* is a constant that depends on ϵ. The proof of our main result is based upon degree theory.

Keywords: mean curvature operator, semipositone, positive solutions, degree theory.

1 Introduction

In this paper, we are concerned with the problem with Minkowski-curvature operator

$$\begin{cases} -\operatorname{div}\left(\dfrac{\nabla u}{\sqrt{1-|\nabla u|^2}}\right) = \lambda a(|x|)(u^\gamma - \epsilon), & x \in B(R), \\ u = 0, & x \in \partial B(R), \end{cases} \tag{1.1}$$

where $B(R) = \{x \in \mathbb{R}^N : |x| < R\}$, $N \geq 2$, $R > 0$, $\epsilon > 0$, $\gamma > 1$ and $a : [0,\infty) \to (0,\infty)$ is a continuous function.

Boundary value problem of differential equation

$$\begin{cases} -\Delta u = f(x,u) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega \end{cases} \tag{1.2}$$

✉ Email: zhaozz@sxdtdx.edu.cn

is called a semipositone problem if $f(\cdot,0)<0$; and it is called a positone problem if $f(\cdot,0)\geq 0$, where Ω is a strictly convex bounded domain in $\mathbb{R}^N$, $N\geq 1$, with C^2 boundary $\partial\Omega$. Semipositone problem has been largely investigated for semilinear elliptic equations (1.2) since the late 1980s, with increasing interest after the paper Castro *et al.* [11] and Brown *et al.* [9], see [4,16,20] and the references therein.

It is well documented (see [8,21]) that, if compared with the positone problems, the study of positive solutions of the semipositone problem is mathematically challenging. For example, the absence of maximum principle, the difficulty in constructing sub and super solutions, and the trivial solution $u\equiv 0$ is not a solution of problem (1.2) with $f(\cdot,0)<0$. These three factors make it unclear how to apply the methods based on the theory of positive operators for cones in Banach spaces, the method of sub and super solutions and bifurcation from the trivial solution.

For quasilinear semipositone problems, there have been some recent papers on the problems with the p-Laplacian operator, see Alves, de Holanda and Santos [2, 3], Castro, de Figueredo and Lopera [10], Chhetri, Drábek and Shivaji [12], Morris, Shivaji and Sim [23]. In particular, Chhetri, Drábek and Shivaji [12] considered a quasilinear elliptic problem of the form

$$\begin{cases} -\Delta_p u=\lambda g(u) & \text{in } \Omega,\\ u=0 & \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

where $\Delta_p u:=\operatorname{div}(|\nabla u|^{p-2}\nabla u)$ is the p-Laplacian operator with $1<p<2$, and $\lambda>0$ is a parameter. The nonlinearity $g:[0,\infty)\to\mathbb{R}$ is a continuous function that satisfies $g(0)<0, g(s)>0$ for $s\gg 1$. They said that λ_∞ is a bifurcation point from infinity if the solution set $S:=\{(\lambda,u)\in\mathbb{R}\times W_0^{1,p}(\Omega): \lambda \text{ and } u \text{ solves (1.3)}\}$ contains a sequence $\{(\lambda_n,u_n)\}$ such that

$$\lambda_n\to\lambda_\infty \quad \text{and} \quad \|u_n\|_\infty\to\infty. \tag{1.4}$$

And they proved the following result.

Theorem A. *Assume $1<p<2$ and $N>p$. Let $g:[0,\infty)\to\mathbb{R}$ be a continuous function satisfying the following conditions:*

(i) $g(0)<0$;

(ii) there exist $b>0$ and $q\in(p-1,N(p-1)/(N-p)]$ such that

$$\lim_{s\to\infty}\frac{g(s)}{s^q}=b.$$

Then (1.1) has a positive solution (λ,u) for $\lambda>0$ small.

The key points of the proof of Theorem A are that rescale the parameter and the solution variable using $\gamma=\lambda^{\frac{1}{q-p+1}}$ and $w=\gamma u$, respectively, then w formally satisfies

$$-\Delta_p w=-\operatorname{div}(|\nabla\gamma u|^{p-2}\nabla\gamma u)=-\gamma^{p-1}\operatorname{div}(|\nabla u|^{p-2}\nabla u)=\gamma^q g(w/\gamma). \tag{1.5}$$

The theory of positive operators for (1.5) can be applied when $\gamma>0$ is small (i.e., $\lambda>0$ is small). This is the standard technique of dealing with semipositone elliptic problems.

However, the mean curvature operator in semipositone problem (1.1) prevents the application of the above standard technique, since $\varphi(ks)\neq k\varphi(s)$ (where $\varphi(s)=\frac{s}{\sqrt{1-s^2}}$) for any

constant $k \in \mathbb{R}\backslash\{0,1\}$ and any solution u of (1.1) is bounded (see Remark 2.1 below). So although there have been significant paper on the problems with mean curvature operator (see Azzollini [5], Bereanu and Mawhin [7], Bereanu, Jebelean and Torres [6], Ma, Gao and Lu [22] and Dai [15] and the references therein) in the last decade, they have had to require that the nonlinearity f be non-negative at 0. In particular, Bereanu, Jebelean and Torres [6] studied the problem (1.1) with $\epsilon = 0$ and proved that there exists $\Lambda > 2N/(\max_{r\in[0,R]} a(r)R^{\gamma+1})$ such that the problem has at least two positive radial solutions according to $\lambda > \Lambda$.

Thus, this paper appears to be the first contribution where consider the problem with mean curvature operator is faced in a semipositone setting. And the aim of this brief paper is to provide a result about the existence of positive solution of the semipositone problem (1.1).

To state our results precisely we recall the following hypothesis,

(H0) $\epsilon > 0$, $\gamma > 1$ and $a : [0,\infty) \to (0,\infty)$ is a continuous function.

Theorem 1.1. *Let (H0) hold. There exist the constants $\Lambda > 2N/(\max_{r\in[0,R]} a(r)R^{\gamma+1})$ and $\epsilon_0(\Lambda) > 0$ such that, for any $\epsilon < \epsilon_0(\Lambda)$ there is $\Lambda^*(\epsilon)$ such that problem (1.1) has at least two positive radial solutions for any $\lambda \in (\Lambda, \Lambda^*)$.*

Remark 1.2. The nonlinearity in (1.1) is related to *pure-power* model $g(s) = s^\gamma$, see W. Allegretto, P. Nistri, P. Zecca [1], D. Costa, H. Ramos Quoirin, H. Tehrani [14], Q. Morris, R. Shivaji, I. Sim [23]. In recent years, for the existence of positive solutions to the semipositone elliptic equation, see, D. D. Hai, A. Muthunayake, R. Shivaji [17], A. Joseph, L. Sankar [18], R. Kajikiya, E. Ko [19] and their references.

2 Preliminary results

Setting, as usual, $r = |x|$ and $u(x) = u(r)$, we reduce the Dirichlet problem (1.1) to the mixed boundary value problem

$$\begin{cases} -(r^{N-1}\varphi(u'(r)))' = \lambda r^{N-1}a(r)(u^\gamma - \epsilon), \quad r \in (0,R), \\ u'(0) = u(R) = 0, \end{cases} \tag{2.1}$$

where $\varphi(s) = \frac{s}{\sqrt{1-s^2}}$. The space $C := C[0,R]$ will be endowed with the usual sup-norm $\|\cdot\|_\infty$ and $C^1 := C^1[0,R]$ will be considered with the norm $\|u\| = \|u\|_\infty + \|u'\|_\infty$. Also, we shall use the closed subspace of C^1 defined by

$$C^1_M = \{u \in C^1 : u'(0) = 0 = u(R)\}.$$

Let

$$W := \left\{w \in C^1_M : \max_{[0,R]} |w'| < 1 \text{ and } \varphi(w') \in C^1[0,R]\right\}.$$

A solution of (2.1) is a function $u \in W$ satisfying (2.1). Function $\Psi = \varphi^{-1}$ is smooth, $w' \in C^1$ can be obtained immediately.

Remark 2.1. Combined with the boundary condition $u(R) = 0$, it is easy to find that the solution $u \in W$ of (2.1) is bounded.

In the sequel, let us consider an auxiliary problem

$$\begin{cases} -(r^{N-1}\varphi(u'(r)))' = \lambda r^{N-1}a(r)(u(r))^{\gamma}, & r \in (0,R), \\ u'(0) = u(R) = 0. \end{cases} \tag{2.2}$$

We introduce the linear operators

$$S : C \to C, \qquad Su(r) = \frac{1}{r^{N-1}}\int_0^r t^{N-1}u(t)dt \qquad (r \in (0,R]), \quad Su(0) = 0;$$

$$K : C \to C^1, \qquad Ku(r) = \int_r^R u(t)dt \qquad (r \in [0,R]).$$

It is easy to see that K is bounded and standard arguments, invoking the Arzelà–Ascoli theorem, show that S is compact. This implies that the nonlinear operator $K \circ \varphi^{-1} \circ S : C \to C^1$ is compact. Let N_λ be the Nemytskii operator associated to $\lambda a(r)u^{\gamma}$, i.e,

$$N_\lambda : C \to C, \qquad N_\lambda(u) = \lambda a(\cdot)u^{\gamma}(\cdot).$$

From [6, Lemma 1], a function $u \in C^1_M$ is a solution of (2.2) if and only if it is a fixed point of the compact nonlinear operator

$$\mathcal{N}_\lambda : C^1_M \to C^1_M, \qquad \mathcal{N}_\lambda = K \circ \varphi^{-1} \circ S \circ N_\lambda. \tag{2.3}$$

A lower solution of (2.2) is a function $\alpha \in C^1$ such that $\|\alpha'\|_\infty < 1$, $r^{N-1}\varphi(\alpha') \in C^1$ and

$$(r^{N-1}\varphi(\alpha'(r)))' + \lambda r^{N-1}a(r)\alpha(r)^{\gamma} \geq 0, \qquad r \in [0,R], \quad \alpha(R) \leq 0.$$

Further, we say that a lower solution α of (2.2) is strict if every solution u of (2.2) with $u \geq \alpha$ in $[0,R]$ satisfies $u \gg \alpha$ in $[0,R)$ (i.e., $u(r) > \alpha(r)$ for any $r \in [0,R)$).

Similarly, a upper solution of (2.2) is a function $\beta \in C^1$ such that $\|\beta'\|_\infty < 1$, $r^{N-1}\varphi(\beta') \in C^1$ and

$$(r^{N-1}\varphi(\beta'(r)))' + \lambda r^{N-1}a(r)\beta(r)^{\gamma} \leq 0, \qquad r \in [0,R], \quad \beta(R) \geq 0.$$

Further, we say that a upper solution β of (2.2) is strict if every solution u of (2.2) with $u \leq \beta$ in $[0,R]$ satisfies $u \ll \beta$ in $[0,R)$ (i.e., $u(r) < \beta(r)$ for any $r \in [0,R)$).

Lemma 2.2 ([13]). *For any fixed $\lambda > 0$, suppose that there exist a lower solution α and an upper solution β of (2.2) with $\alpha \leq \beta$ in $[0,R]$. Then problem (2.2) has solutions v, w with $\alpha \leq v \leq w \leq \beta$ in $[0,R]$ such that every solution u of (2.2) with $\alpha \leq u \leq \beta$ in $[0,R]$ satisfies $v \leq u \leq w$ in $[0,R]$. Further, if α and β are strict, then*

$$\deg(I - \mathcal{N}_\lambda, U^\beta_\alpha, 0) = 1,$$

where $\mathcal{N}_\lambda$ is defined by (2.3) and

$$U^\beta_\alpha = \{z \in C^1_M : \alpha \ll z \ll \beta \text{ in } [0,R) \text{ and } \|z'\|_\infty < 1\}.$$

From [6, Theorem 1.1], there exists

$$\Lambda > 2N/(a_M R^{\gamma+1}),$$

where $a_M := \max_{r\in[0,R]} a(r)$, such that problem (2.2) has at least one positive solutions according to $\lambda = \Lambda$. Let $\lambda_0 > \Lambda$ be arbitrarily chosen. Let $\widetilde{\alpha}$ be a positive solution for (2.2) corresponding to $\lambda = \Lambda$. It is easy to see that $\widetilde{\alpha}$ is a lower solution for (2.2) with $\lambda = \lambda_0$. For fixed $\lambda_2 > \lambda_0$, let $\widetilde{\beta}$ be the unique (positive) solution of

$$\begin{cases} (r^{N-1}\varphi(u'(r)))' + \lambda_2 r^{N-1} a_M \widetilde{R}^\gamma = 0, \quad r \in (0, \widetilde{R}), \\ u'(0) = u(\widetilde{R}) = 0, \end{cases}$$

where $\widetilde{R} > R$. Using that $\widetilde{\beta}(R) > 0$ and

$$\lambda_0 a(r) u^\gamma(r) < \lambda_2 a_M \widetilde{R}^\gamma, \qquad r \in [0, R],$$

it follows that $\widetilde{\beta}$ is an upper solution for (2.2) with $\lambda = \lambda_0$. We can find $\widetilde{R}$ sufficiently large, such that $\widetilde{\alpha}(0) < \widetilde{\beta}(R)$. For any $r \in [0, R)$,

$$\widetilde{\alpha}'(r) = -\varphi^{-1}\Big(\frac{1}{r^{N-1}} \int_0^r t^{N-1}[\Lambda a(t)(\widetilde{\alpha}(t))^\gamma]dt\Big) < 0$$

and

$$\widetilde{\beta}'(r) = -\varphi^{-1}\Big(\frac{1}{r^{N-1}} \int_0^r t^{N-1}[\lambda_2 a_M \widetilde{R}^\gamma]dt\Big) < 0.$$

Then, taking into account that $\widetilde{\alpha}, \widetilde{\beta}$ are strictly decreasing, we infer that $\widetilde{\alpha} < \widetilde{\beta}$ on $[0, R]$.

From Lemma 2.2, problem (2.2) has a solution u_0 satisfies $\widetilde{\alpha} \le u_0 \le \widetilde{\beta}$ in $[0, R]$, i.e., $u_0 \in U_{\widetilde{\alpha}}^{\widetilde{\beta}}$. We will show that $\widetilde{\alpha}$ and $\widetilde{\beta}$ are strict. In fact, for all $r \in [0, R)$, one has

$$\begin{aligned} \widetilde{\beta}(r) &= \int_r^{\widetilde{R}} \varphi^{-1}\Big(\frac{1}{t^{N-1}} \int_0^t s^{N-1}[\lambda_2 a_M \widetilde{R}^\gamma]ds\Big)dt \\ &> \int_r^R \varphi^{-1}\Big(\frac{1}{t^{N-1}} \int_0^t s^{N-1}[\lambda_0 a(s)(u_0(s))^\gamma]ds\Big)dt = u_0(r). \end{aligned}$$

Similarly, for all $r \in [0, R)$,

$$\begin{aligned} \widetilde{\alpha}(r) &= \int_r^R \varphi^{-1}\Big(\frac{1}{t^{N-1}} \int_0^t s^{N-1}[\Lambda a(s)(\widetilde{\alpha}(s))^\gamma]ds\Big)dt \\ &< \int_r^R \varphi^{-1}\Big(\frac{1}{t^{N-1}} \int_0^t s^{N-1}[\lambda_0 a(s)(u_0(s))^\gamma]ds\Big)dt = u_0(r). \end{aligned}$$

This suggests that

$$\deg\Big(I - \mathcal{N}_{\lambda_0}, U_{\widetilde{\alpha}}^{\widetilde{\beta}}, 0\Big) = 1.$$

For any $\rho > 0$, set $B_\rho := \{u \in C_M^1 : \|u\| < \rho\}$. Consider $\rho_1 > 0$ sufficiently small and $\rho_2 \ge R + 1$ such that $U_{\widetilde{\alpha}}^{\widetilde{\beta}} \cap B_{\rho_1} = \emptyset$ and $(U_{\widetilde{\alpha}}^{\widetilde{\beta}} \cup B_{\rho_1}) \subset B_{\rho_2}$. By [6, Lemma 1 and Lemma 4], one has

$$\deg(I - \mathcal{N}_{\lambda_0}, B_{\rho_1}, 0) = 1$$

and

$$\deg(I - \mathcal{N}_{\lambda_0}, B_{\rho_2}, 0) = 1.$$

Then, from the additivity-excision property of the Leray–Schauder degree it follows that

$$\deg(I - \mathcal{N}_{\lambda_0}, B_{\rho_2} \setminus [\overline{U}_{u_1}^{u_2} \cup \overline{B}_{\rho_1}], 0) = -1.$$

3 The proof of main result

Lemma 3.1. *For any fixed $\lambda_0 > \Lambda$, there exists $\delta > 0$ such that if $F_1 : C^1 \to C^1_M$ is a compact map with $\|F_1(v)\| < \delta$ for v in $U^{\widetilde{\beta}}_{\widetilde{\alpha}}$ and $\|F_1(w)\| < \delta$ for w in $B_{\rho_2} \setminus [\overline{U}^{\widetilde{\beta}}_{\widetilde{\alpha}} \cup \overline{B}_{\rho_1}]$, $v, w > 0$, then there exist $u_1 \in U^{\widetilde{\beta}}_{\widetilde{\alpha}}$, $u_2 \in B_{\rho_2} \setminus [\overline{U}^{\widetilde{\beta}}_{\widetilde{\alpha}} \cup \overline{B}_{\rho_1}]$ and $u_1, u_2 > 0$ such that $u_i = \mathcal{N}_{\lambda_0}(u_i) + F_1(u_i)$, $i = 1, 2$.*

Proof. Denote

$$S_1 := \left\{ u \in U^{\widetilde{\beta}}_{\widetilde{\alpha}} : u \text{ is a solution of (2.2) with } \lambda = \lambda_0 \right\}.$$

Choose $\varepsilon_1 > 0$ small and set $\overline{N}_{1,\varepsilon_1} = \bigcup_{u \in S_1} B_{\varepsilon_1}(u)$, where $B_{\varepsilon_1}(u)$ denotes the open ball of radius ε_1 in C^1_M centered at u. Obviously, $\overline{N}_{1,\varepsilon_1}$ is open. Since $\mathcal{N}_{\lambda_0} : C^1_M \to C^1_M$ is compact, there exists $\delta > 0$ such that $\|(I - \mathcal{N}_{\lambda_0})(v)\|_{C^1} > \delta$ if $v \in \partial \overline{N}_{1,\varepsilon_1}$.

Claim. if $v \in \overline{N}_{1,\varepsilon_1}$ and ε_1 is small enough, then $v > 0$ in the interval $[0, R)$.

Suppose on the contrary that there exists $v_\varepsilon \in C^1_M$, $u_\varepsilon \in S_1$ such that $\|v_\varepsilon - u_\varepsilon\| \to 0$ and $v_\varepsilon(r_0) \le 0$ for some $r_0 \in [0, R)$. Since S_1 is compact, without loss of generality, we can assume that $u_\varepsilon \to u$ (as $\varepsilon \to 0$) for some $u \in S_1$, (i.e. $v_\varepsilon \to u$). From $u \in S_1$ and the monotonicity of u, we obtain that $u > 0$ in $[0, R)$ and $u'(R) < 0$. Since $v'_\varepsilon(0) = v_\varepsilon(R) = 0$, it follows that $v_\varepsilon > 0$ in $[0, R)$ for ε small enough. This contradiction ends the proof of Claim.

If $\|F_1(v)\| < \delta$ for v in $U^{\widetilde{\beta}}_{\widetilde{\alpha}}$, we conclude that

$$\deg\left((I - \mathcal{N}_{\lambda_0} - F_1), \overline{N}_{1,\varepsilon_1}, 0\right) = \deg(I - \mathcal{N}_{\lambda_0}, \overline{N}_{1,\varepsilon_1}, 0) = \deg(I - \mathcal{N}_{\lambda_0}, U^{\widetilde{\beta}}_{\widetilde{\alpha}}, 0) = 1.$$

Similarly, let

$$S_2 := \left\{ u \in B_{\rho_2} \setminus [\overline{U}^{\widetilde{\beta}}_{\widetilde{\alpha}} \cup \overline{B}_{\rho_1}] : u \text{ is a solution of (2.2) with } \lambda = \lambda_0 \right\}.$$

Choose $\varepsilon_2 > 0$ small and set $\overline{N}_{2,\varepsilon_2} = \bigcup_{u \in S_2} B_{\varepsilon_2}(u)$. If $\|F_1(v)\| < \delta$ for v in $B_{\rho_2} \setminus [\overline{U}^{\widetilde{\beta}}_{\widetilde{\alpha}} \cup \overline{B}_{\rho_1}]$, we conclude that

$$\deg\left((I - \mathcal{N}_{\lambda_0} - F_1), \overline{N}_{2,\varepsilon_2}, 0\right) = \deg(I - \mathcal{N}_{\lambda_0}, \overline{N}_{2,\varepsilon_2}, 0) = \deg(I - \mathcal{N}_{\lambda_0}, B_{\rho_2} \setminus [\overline{U}^{\widetilde{\beta}}_{\widetilde{\alpha}} \cup \overline{B}_{\rho_1}], 0) = -1.$$

□

The proof of Theorem 1.1. Select δ as in Lemma 3.1. Define

$$\Lambda^* := \frac{N\varphi(\delta/(R+1))}{a_M \epsilon R},$$

where $\epsilon > 0$ is defined in (1.1) and $a_M = \max_{r \in [0,R]} a(r)$. There exist a constant $\epsilon_0(\Lambda) > 0$ such that $\Lambda < \Lambda^*$ for any $\epsilon < \epsilon_0(\Lambda)$, where $\Lambda > 2N/(a_M R^{\gamma+1})$ is the constant that appears in Theorem 1.1 of [6]. Let $\lambda_0 \in [\Lambda, \Lambda^*]$ be arbitrarily chosen.

Let

$$F_1(u)(r) = -\int_r^R \varphi^{-1}\left(\frac{\lambda_0 \epsilon}{t^{N-1}} \int_0^t \tau^{N-1} a(\tau) d\tau\right) dt.$$

With these choices, we obtain that

$$\begin{aligned}\|F_1(u)\| &= \max_{r\in[0,R]}\left|\int_r^R \varphi^{-1}\left(\frac{\lambda_0\epsilon}{t^{N-1}}\int_0^t \tau^{N-1}a(\tau)d\tau\right)dt\right| + \max_{r\in[0,R]}\left|\varphi^{-1}\left(\frac{\lambda_0\epsilon}{r^{N-1}}\int_0^r \tau^{N-1}a(\tau)d\tau\right)\right| \\ &\le \max_{r\in[0,R]}\left|\int_r^R \varphi^{-1}\left(\frac{\lambda_0 a_M\epsilon R}{N}\right)dt\right| + \varphi^{-1}\left(\frac{\lambda_0 a_M\epsilon R}{N}\right) \\ &\le \varphi^{-1}\left(\frac{\lambda_0 a_M\epsilon R}{N}\right)(R+1) < \delta.\end{aligned}$$

By Lemma 3.1, we can conclude the existence of the $\widetilde{u}_1, \widetilde{u}_2 > 0$ such that

$$\widetilde{u}_i = \int_r^R \varphi^{-1}\left(\frac{\lambda_0}{t^{N-1}}\int_0^t \tau^{N-1}a(\tau)(\widetilde{u}_i(\tau)-\epsilon)d\tau\right)dt, \qquad i = 1,2.$$

This suggests that $\widetilde{u}_1, \widetilde{u}_2 > 0$ are the solutions of (2.1). The proof of Theorem 1.1 is complete. □

Abstract. The existence of solutions to a family of inclusion systems with fractional, possibly competing, elliptic operators, fractional convection, and homogeneous Dirichlet boundary conditions is established. The proof uses Galerkin's method, a surjectivity result for multifunctions in finite dimensional spaces, and approximation techniques.

Keywords: differential inclusion system, fractional competing operator, fractional convection, Dirichlet boundary condition, Galerkin's method.

2020 Mathematics Subject Classification: 35H30, 35J92, 35D30.

1 Introduction

Let Ω be a bounded domain in $\mathbb{R}^N$, $N \geq 3$, with a smooth boundary $\partial\Omega$, let $\mu_1, \mu_2 \in \mathbb{R}$, and let $F_1, F_2 : \Omega \times \mathbb{R}^2 \times \mathbb{R}^{2N} \to 2^{\mathbb{R}}$ be two compact convex-valued multifunctions. Consider the differential inclusion system

$$\begin{cases} (-\Delta)_{p_1}^{s_1} u_1 + \mu_1 (-\Delta)_{q_1}^{t_1} u_1 \in F_1(x, u_1, u_2, D^{r_1} u_1, D^{r_2} u_2) & \text{in } \Omega, \\ (-\Delta)_{p_2}^{s_2} u_2 + \mu_2 (-\Delta)_{q_2}^{t_2} u_2 \in F_2(x, u_1, u_2, D^{r_1} u_1, D^{r_2} u_2) & \text{in } \Omega, \\ u_1 = u_2 = 0 & \text{in } \mathbb{R}^N \setminus \Omega, \end{cases} \tag{1.1}$$

where

(H_1) $0 < t_i < r_i < s_i \leq 1$ and $1 < q_i < p_i < \frac{N}{s_i}$ for each $i = 1, 2$.

The symbol $(-\Delta)_p^s$, with $p > 1$ and $0 < s < 1$, denotes the fractional p-Laplacian, defined by setting, provided u is smooth enough,

$$(-\Delta)_p^s u(x) := 2 \lim_{\varepsilon \to 0^+} \int_{\mathbb{R}^N \setminus B_\varepsilon(x)} \frac{|u(x) - u(y)|^{p-2}(u(x) - u(y))}{|x - y|^{N+ps}} \, \mathrm{d}y, \quad x \in \mathbb{R}^N,$$

✉Corresponding author. Email: samarano@unict.it

with $B_\varepsilon(x) := \{z \in \mathbb{R}^N : \|z-x\|_{\mathbb{R}^N} < \varepsilon\}$. When $s = 1$ it becomes the classical p-Laplacian, namely

$$-\Delta_p u := -\operatorname{div}(|\nabla u|^{p-2}\nabla u).$$

Moreover, $D^s u$ indicates the *distributional Riesz fractional gradient* of u in the sense of [19,20]. If u appropriately decays and is sufficiently smooth then, setting

$$c_{N,s} := -\frac{2^s\,\Gamma\left(\frac{N+s+1}{2}\right)}{\pi^{\frac{N}{2}}\,\Gamma\left(\frac{1-s}{2}\right)},$$

one has [20, pp. 289 and 298]

$$D^s u(x) := c_{N,s}\lim_{\varepsilon\to 0^+}\int_{\mathbb{R}^N\setminus B_\varepsilon(x)}\frac{u(x)-u(y)}{|x-y|^{N+s}}\,\frac{x-y}{|x-y|}\mathrm{d}y, \quad x \in \mathbb{R}^N.$$

The right-hand sides F_1 and F_2 satisfy the conditions below, where, to avoid cumbersome formulae, we shall write

$$y := (y_1, y_2), \quad z := (z_1, z_2), \quad p_i^* := \frac{Np_i}{N - s_i p_i}, \quad i = 1, 2. \tag{1.2}$$

(H_2) $x \mapsto F_i(x,y,z)$ is measurable on Ω for all $(y,z) \in \mathbb{R}^2 \times \mathbb{R}^{2N}$ and $(y,z) \mapsto F_i(x,y,z)$ is upper semi-continuous for almost every $x \in \Omega$.

(H_3) There exist $m_i > 0$, $\delta_i \in L^{(p_i^*)'}(\Omega)$, $i = 1,2$, such that

$$\sup_{w_i \in F_i(x,y,z)} |w_i| \le m_i\left(|y_1|^{\frac{p_1^*}{(p_i^*)'}} + |y_2|^{\frac{p_2^*}{(p_i^*)'}} + |z_1|^{\frac{p_1}{(p_i^*)'}} + |z_2|^{\frac{p_2}{(p_i^*)'}}\right) + \delta_i(x)$$

a.e. in Ω and for all $(y,z) \in \mathbb{R}^2 \times \mathbb{R}^{2N}$.

(H_4) There are $M_i, M_i' > 0$, $\sigma_i \in L^1(\Omega)_+$, $i = 1,2$, fulfilling

$$w_i y_i \le M_i(|y_1|^{p_1} + |y_2|^{p_2}) + M_i'(|z_1|^{p_1} + |z_2|^{p_2}) + \sigma_i(x)$$

a.e. in Ω and for all $(y,z) \in \mathbb{R}^2 \times \mathbb{R}^{2N}$, $w_i \in F_i(x,y,z)$.

The involved differential operators are of the type

$$A_\mu(u) := (-\Delta)_p^s u + \mu(-\Delta)_q^t u, \quad u \in W_0^{s,p}(\Omega),$$

where $\mu \in \mathbb{R}$, $0 < t \le r \le s \le 1$, $1 < q < p < \frac{N}{s}$, while convection comes from the presence of fractional gradients $D^r u$ at right-hand sides. A_μ exhibits different behaviors depending on the values of $t, s \in (0,1]$. Precisely, if $t = 1$, then $t = r = s = 1$. Problem (1.1) falls inside the local framework, which has already been investigated in some recent works; see, e.g., [9] for single-valued reactions and [4,18] as regards multi-valued ones. Moreover, the nature of A_μ drastically changes depending on μ. When $\mu > 0$, the operator A_μ is basically patterned after the (possibly) fractional (p,q)-Laplacian, which is non-homogeneous because $p \ne q$. If $\mu = 0$ it coincides with the fractional p-Laplacian. Both cases have been widely studied, and meaningful results are by now available in the literature. On the other hand, for $\mu < 0$ the operator A_μ contains the *difference* between the fractional p- and q-Laplacians. It is usually called competitive and, as already pointed out in [14,17], does not satisfy any ellipticity or

monotonicity condition. In fact, given $u_0 \in W_0^{s,p}(\Omega) \setminus \{0\}$ and chosen $u := \tau u_0$, $\tau > 0$, the expression

$$\langle A_\mu(u), u\rangle = \tau^p \langle (-\Delta)_p^s u_0, u_0\rangle + \mu\, \tau^q \langle (-\Delta)_q^t u_0, u_0\rangle$$

turns out negative for τ small and positive when τ is large, because

$$u_0 \neq 0 \quad \Longrightarrow \quad \langle (-\Delta)_p^s u_0, u_0\rangle > 0,\ \langle (-\Delta)_q^t u_0, u_0\rangle > 0;$$

cf. Section 2. Hence, nonlinear regularity theory, comparison principles, as well as existence theorems for pseudo-monotone maps cannot be employed. Moreover, since the reactions are multi-valued and contain the fractional gradient of the solutions, also variational techniques are no longer directly usable. To overcome these difficulties we first exploit Galerkin's method, thus working with a sequence $\{E_n\}$ of finite dimensional functional spaces. For each integer $n \geq 1$, an *approximate solution* $(u_{1,n}, u_{2,n}) \in E_n$ to (1.1) is obtained via a suitable version (see Proposition 2.3) of a classical surjectivity result. Next, letting $n \to +\infty$ yields a solution in a generalized sense (cf. Definitions 3.3 and 3.5), which turns out weak sense once $\min\{\mu_1, \mu_2\} \geq 0$.

Fractional gradients were first introduced more than sixty years ago by Horváth [12], but they garnered significant interest especially after the works of Shieh and Spector [5,19,20]. The operator $D^s u$ appears as a natural non-local version of ∇u, to which $D^s u$ formally converges when $s \to 1^-$. It possesses favorable geometric and physical properties [2,21], like invariance under translations or rotations, homogeneity of order s, continuity, etc.

Section 2 contains some auxiliary results and the functional framework needed for handling both fractional gradients and the fractional p-Laplacian. The existence of (generalized, strong generalized, or weak) solutions to (1.1) is established in Section 3.

2 Preliminaries

Let X, Y be two nonempty sets. A multifunction $\Phi : X \to 2^Y$ is a map from X into the family of all nonempty subsets of Y. A function $\varphi : X \to Y$ is called a selection of Φ when $\varphi(x) \in \Phi(x)$ for every $x \in X$. Given $B \subseteq Y$, put $\Phi^-(B) := \{x \in X \mid \Phi(x) \cap B \neq \emptyset\}$. If X, Y are topological spaces and $\Phi^-(B)$ turns out closed in X for all closed sets $B \subseteq Y$ then we say that Φ is upper semi-continuous. Suppose $(X, \mathcal{F})$ is a measurable space and Y is a topological space. The multifunction Φ is called measurable when $\Phi^-(B) \in \mathcal{F}$ for every open set $B \subseteq Y$. The result below, stated in [1, p. 215], will be repeatedly useful.

Proposition 2.1. *Let $F : \Omega \times \mathbb{R}^h \to 2^{\mathbb{R}}$ be a closed-valued multifunction such that:*

- *$x \mapsto F(x, \xi)$ is measurable for all $\xi \in \mathbb{R}^h$;*
- *$\xi \mapsto F(x, \xi)$ is upper semi-continuous for almost every $x \in \Omega$.*

Let $w : \Omega \to \mathbb{R}^h$ be measurable. Then the multifunction $x \mapsto F(x, w(x))$ admits a measurable selection.

Let $(X, \|\cdot\|)$ be a real normed space with topological dual X^* and duality brackets $\langle \cdot, \cdot \rangle$. Given a nonempty set $A \subseteq X$, define $|A| := \sup_{x \in A} \|x\|$. We say that $\varphi : X \to X^*$ is *monotone* when

$$\langle \varphi(x) - \varphi(z), x - z\rangle \geq 0 \quad \forall\, x, z \in X,$$

and *of type* $(\mathrm{S})_+$ provided

$$x_n \rightharpoonup x \quad \text{in } X, \quad \limsup_{n\to+\infty} \langle \varphi(x_n), x_n - x\rangle \le 0 \implies x_n \to x \quad \text{in } X.$$

The next elementary result [8, Proposition 2.1] will ensure that condition $(\mathrm{S})_+$ holds true for the differential operators we deal with.

Proposition 2.2. *Let $\varphi : X \to X^*$ be of type $(\mathrm{S})_+$ and let $\psi : X \to X^*$ be monotone. Then $\varphi + \psi$ satisfies condition $(\mathrm{S})_+$.*

A multifunction $\Phi : X \to 2^{X^*}$ is called coercive provided

$$\lim_{\|x\|\to\infty} \frac{\inf\{\langle x^*, x\rangle \mid x \in X,\ x^* \in \Phi(x)\}}{\|x\|} = +\infty\,.$$

The following result is a direct consequence of [11, Proposition 3.2.33].

Theorem 2.3. *Let X be a finite-dimensional normed space and let $\Phi : X \to 2^{X^*}$ be a convex compact-valued multifunction. Suppose Φ is upper semi-continuous and coercive. Then there exists $\hat{x} \in X$ satisfying $0 \in \Phi(\hat{x})$.*

Hereafter, if X and Y are two topological spaces, the symbol $X \hookrightarrow Y$ means that X continuously embeds in Y. Given $p > 1$, put $p' := \frac{p}{p-1}$, denote by $\|\cdot\|_p$ the usual norm of $L^p(\Omega)$, and indicate with $\|\cdot\|_{1,p}$ the norm on $W_0^{1,p}(\Omega)$ arising from Poincaré's inequality, namely

$$\|u\|_{1,p} := \|\nabla u\|_p\,, \quad u \in W_0^{1,p}(\Omega).$$

If $u \in W_0^{1,p}(\Omega)$, we set $u(x) = 0$ on $\mathbb{R}^N \setminus \Omega$; cf. [6, Section 5]. Fix $s \in (0,1)$. The Gagliardo seminorm of a measurable function $u : \mathbb{R}^N \to \mathbb{R}$ is

$$[u]_{s,p} := \left(\int_{\mathbb{R}^N\times\mathbb{R}^N} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\mathrm{d}x\mathrm{d}y\right)^{\frac{1}{p}},$$

while $W^{s,p}(\mathbb{R}^N)$ denotes the fractional Sobolev space

$$W^{s,p}(\mathbb{R}^N) := \left\{u \in L^p(\mathbb{R}^N) :\ [u]_{s,p} < \infty\right\},$$

endowed with the norm

$$\|u\|_{W^{s,p}(\mathbb{R}^N)} := \left(\|u\|^p_{L^p(\mathbb{R}^N)} + [u]^p_{s,p}\right)^{\frac{1}{p}}.$$

As usual, on the space

$$W_0^{s,p}(\Omega) := \{u \in W^{s,p}(\mathbb{R}^N) : u = 0 \text{ a.e. in } \mathbb{R}^N \setminus \Omega\}$$

we will consider the equivalent norm

$$\|u\|_{s,p} := [u]_{s,p}, \quad u \in W_0^{s,p}(\Omega).$$

Let $W^{-s,p'}(\Omega) := (W_0^{s,p}(\Omega))^*$ and let p_s^* be the fractional Sobolev critical exponent, i.e., $p_s^* = \frac{Np}{N-sp}$ when $sp < N$, $p_s^* = +\infty$ otherwise. Thanks to Propositions 2.1–2.2, Theorem 6.7, and Corollary 7.2 of [6] one has

Proposition 2.4. *If* $1 \le p < +\infty$ *then:*

(a) $0 < s' \le s'' \le 1 \implies W_0^{s'',p}(\Omega) \hookrightarrow W_0^{s',p}(\Omega)$.

(b) $sp < N \implies W_0^{s,p}(\Omega) \hookrightarrow L^r(\Omega)$ *for all* $r \in [1, p_s^*]$.

(c) *The embedding in* (b) *is also compact once* $r \in [1, p_s^*)$.

However, contrary to the non-fractional case, we know [15] that

$$1 \le q < p \le +\infty \quad \not\Longrightarrow \quad W_0^{s,p}(\Omega) \subseteq W_0^{s,q}(\Omega).$$

Define, for every $u, v \in W_0^{s,p}(\Omega)$,

$$\langle (-\Delta)_p^s u, v\rangle := \int_{\mathbb{R}^N \times \mathbb{R}^N} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(v(x)-v(y))}{|x-y|^{N+ps}} \mathrm{d}x\mathrm{d}y\,.$$

The operator $(-\Delta)_p^s$ is called (negative) s-fractional p-Laplacian. It possesses the following properties.

(p_1) $(-\Delta)_p^s : W_0^{s,p}(\Omega) \to W^{-s,p'}(\Omega)$ turns out monotone, continuous, and of type $(\mathrm{S})_+$; vide, e.g., [7, Lemma 2.1].

(p_2) One has

$$\|(-\Delta)_p^s u\|_{W^{-s,p'}(\Omega)} \le \|u\|_{s,p}^{p-1} \quad \forall\, u \in W_0^{s,p}(\Omega).$$

Hence, $(-\Delta)_p^s$ maps bounded sets into bounded sets.

(p_3) The first eigenvalue $\lambda_{1,p,s}$ of $(-\Delta)_p^s$ is given by (cf. [13])

$$\lambda_{1,p,s} = \inf_{u \in W_0^{s,p}(\Omega), u \neq 0} \frac{\|u\|_{s,p}^p}{\|u\|_p^p}\,.$$

To deal with distributional fractional gradients, we first introduce the Bessel potential spaces $L^{\alpha,p}(\mathbb{R}^N)$, where $\alpha > 0$. Set, for every $x \in \mathbb{R}^N$,

$$g_\alpha(x) := \frac{1}{(4\pi)^{\frac{\alpha}{2}}\Gamma\left(\frac{\alpha}{2}\right)} \int_0^{+\infty} e^{\frac{-\pi|x|^2}{\delta}} e^{\frac{-\delta}{4\pi}} \delta^{\frac{\alpha-N}{2}} \frac{\mathrm{d}\delta}{\delta}\,.$$

On account of [16, Section 7.1] one can assert that:

1) $g_\alpha \in L^1(\mathbb{R}^N)$ and $\|g_\alpha\|_{L^1(\mathbb{R}^N)} = 1$.

2) g_α enjoys the semi-group property, i.e., $g_\alpha * g_\beta = g_{\alpha+\beta}$ for any $\alpha, \beta > 0$, with $*$ being the convolution operator.

We consider

$$L^{\alpha,p}(\mathbb{R}^N) := \{u : u = g_\alpha * \tilde{u} \text{ for some } \tilde{u} \in L^p(\mathbb{R}^N)\}.$$

If $u = g_\alpha * \tilde{u} = g_\alpha * \overline{u}$, with $\tilde{u}, \overline{u} \in L^p(\mathbb{R}^N)$, then a standard argument ensures that $\tilde{u} = \overline{u}$ because $g_\alpha > 0$. So, we can define

$$\|u\|_{L^{\alpha,p}(\mathbb{R}^N)} = \|\tilde{u}\|_{L^p(\mathbb{R}^N)} \quad \text{whenever} \quad u = g_\alpha * \tilde{u}.$$

Using 1) and 2) easily entails

$$0 < \alpha < \beta \implies L^{\beta,p}(\mathbb{R}^N) \subseteq L^{\alpha,p}(\mathbb{R}^N) \subseteq L^p(\mathbb{R}^N).$$

Moreover, by [19, Theorem 2.2], one has

Theorem 2.5. *If $1 < p < +\infty$ and $0 < \varepsilon < \alpha$ then*

$$L^{\alpha+\varepsilon,p}(\mathbb{R}^N) \hookrightarrow W^{\alpha,p}(\mathbb{R}^N) \hookrightarrow L^{\alpha-\varepsilon,p}(\mathbb{R}^N).$$

Finally, given $s \in (0,1)$, set

$$L_0^{s,p}(\Omega) := \{u \in L^{s,p}(\mathbb{R}^N) : u = 0 \text{ a.e. in } \mathbb{R}^N \setminus \Omega\}$$

and thanks to Theorem 2.5 we infer

$$L_0^{s+\varepsilon,p}(\Omega) \hookrightarrow W_0^{s,p}(\Omega) \hookrightarrow L_0^{s-\varepsilon,p}(\Omega) \quad \forall\, \varepsilon \in (0,s). \tag{2.1}$$

The next basic notion is taken from [19]. For $0 < \alpha < N$, let

$$\gamma(N,\alpha) := \frac{\Gamma\left(\frac{N-\alpha}{2}\right)}{\pi^{\frac{N}{2}} 2^\alpha \Gamma\left(\frac{\alpha}{2}\right)}, \quad I_\alpha(x) := \frac{\gamma(N,\alpha)}{|x|^{N-\alpha}}, \quad x \in \mathbb{R}^N \setminus \{0\}.$$

If $u \in L^p(\mathbb{R}^N)$ and $I_{1-s} * u$ makes sense then the vector

$$D^s u := \left(\frac{\partial}{\partial x_1}(I_{1-s} * u), \dots, \frac{\partial}{\partial x_N}(I_{1-s} * u)\right),$$

where partial derivatives are understood in a distributional sense, is called distributional Riesz s-fractional gradient of u. Theorem 1.2 in [19] ensures that

$$D^s u = I_{1-s} * Du \quad \forall\, u \in C_c^\infty(\mathbb{R}^N).$$

Further, $D^s u$ looks like the natural extension of ∇u to the fractional framework, Indeed, it exhibits analogous properties and, roughly speaking, $D^s u \to \nabla u$ when $s \to 1^-$; see, e.g., [10, Section 2].

According to [19, Definition 1.5], $X^{s,p}(\mathbb{R}^N)$ denotes the completion of $C_c^\infty(\mathbb{R}^N)$ with respect to the norm

$$\|u\|_{X^{s,p}(\mathbb{R}^N)} := \left(\|u\|^p_{L^p(\mathbb{R}^N)} + \|D^s u\|^p_{L^p(\mathbb{R}^N)}\right)^{\frac{1}{p}}.$$

Since, by [19, Theorem 1.7], $X^{s,p}(\mathbb{R}^N) = L^{s,p}(\mathbb{R}^N)$ we can deduce many facts about $X^{s,p}(\mathbb{R}^N)$ from the existing literature on $L^{s,p}(\mathbb{R}^N)$. Moreover, if

$$X_0^{s,p}(\Omega) := \{u \in X^{s,p}(\mathbb{R}^N) : u = 0 \text{ a.e. in } \mathbb{R}^N \setminus \Omega\},$$

then $X_0^{s,p}(\Omega) = L_0^{s,p}(\Omega)$.

3 Existence results

To shorten notation, for $i = 1,2$, we set $U_i := W_0^{s_i,p_i}(\Omega)$ and denote by $\langle \cdot,\cdot \rangle_i$ the duality brackets of U_i. Lemma 2.6 in [3] guarantees that

$$U_i \hookrightarrow W_0^{t_i,q_i}(\Omega). \tag{3.1}$$

Hence, the differential operator $u \mapsto (-\Delta)^{s_i}_{p_i} u + \mu_i (-\Delta)^{t_i}_{q_i} u$ turns out well-defined on U_i. Let $A_i : U_i \to U_i^*$ be given by

$$\begin{aligned}\langle A_i(u), v\rangle_i := &\int_{\mathbb{R}^N \times \mathbb{R}^N} \frac{|u(x)-u(y)|^{p_i-2}(u(x)-u(y))(v(x)-v(y))}{|x-y|^{N+p_i s_i}} \mathrm{d}x\,\mathrm{d}y \\ &+ \mu_i \int_{\mathbb{R}^N \times \mathbb{R}^N} \frac{|u(x)-u(y)|^{q_i-2}(u(x)-u(y))(v(x)-v(y))}{|x-y|^{N+q_i t_i}} \mathrm{d}x\,\mathrm{d}y\end{aligned}$$

for every $u, v \in U_i$. Thanks to properties (p_1)–(p_2) stated in Section 2, A_i is bounded and continuous. Consequently,

Lemma 3.1. *Under* (H_1)*, the operator* $A : U_1 \times U_2 \to U_1^* \times U_2^*$ *defined by*

$$A(u_1, u_2) := (A_1(u_1), A_2(u_2)) \quad \forall\, (u_1, u_2) \in U_1 \times U_2$$

maps bounded sets into bounded sets and is continuous.

Next, put, provided $(u_1, u_2) \in U_1 \times U_2$,

$$\mathcal{S}_{F_1,F_2}(u_1, u_2) := \{(w_1, w_2) \in L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega) : \\ w_i(\cdot) \in F_i(\cdot, u_1, u_2, D^{r_1}u_1, D^{r_2}u_2) \text{ a.e. in } \Omega,\ i = 1, 2\},$$

with p_i^* as in (1.2).

Lemma 3.2. *Let* (H_1)–(H_3) *be satisfied. Then:*

- (a_1) $\mathcal{S}_{F_1,F_2}(u_1, u_2)$ *turns out nonempty, convex, closed for all* $(u_1, u_2) \in U_1 \times U_2$.
- (a_2) *The multifunction* $\mathcal{S}_{F_1,F_2} : U_1 \times U_2 \to 2^{L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega)}$ *is bounded and strongly-weakly upper semi-continuous.*

Proof. Since $r_i < s_i$, if $\varepsilon \in (0, s_i - r_i)$, combining Proposition 2.4 with (2.1) yields

$$U_i \hookrightarrow W_0^{r_i+\varepsilon, p_i}(\Omega) \hookrightarrow L_0^{r_i, p_i}(\Omega).$$

Thus,

$$(u_1, u_2) \in U_1 \times U_2 \implies (D^{r_1}u_1, D^{r_2}u_2) \in L^{p_1}(\Omega) \times L^{p_2}(\Omega).$$

Now, pick $(u_1, u_2) \in U_1 \times U_2$. Via (H_2) and Proposition 2.1 we see that $F_i(\cdot, u_1, u_2, D^{r_1}u_1, D^{r_2}u_2)$ admits a measurable selection $w_i : \Omega \to \mathbb{R}$. By (H_3) one has

$$\begin{aligned} \|w_1\|_{(p_1^*)'}^{(p_1^*)'} &\le \int_\Omega \left[m_1\Big(|u_1|^{p_1^*-1} + |u_2|^{\frac{p_2^*}{(p_1^*)'}} + |D^{r_1}u_1|^{\frac{p_1}{(p_1^*)'}} + |D^{r_2}u_2|^{\frac{p_2}{(p_1^*)'}} \Big) + \delta_1 \right]^{(p_1^*)'} \mathrm{d}x \\ &\le c\Big(\|\delta_1\|_{(p_1^*)'}^{(p_1^*)'} + \|u_1\|_{p_1^*}^{p_1^*} + \|u_2\|_{p_2^*}^{p_2^*} + \|D^{r_1}u_1\|_{p_1}^{p_1} + \|D^{r_2}u_2\|_{p_2}^{p_2} \Big) \end{aligned}$$

for some $c > 0$, whence $\|w_1\|_{(p_1^*)'} < \infty$. Similarly, $\|w_2\|_{(p_2^*)'} < \infty$. So, $\mathcal{S}_{F_1,F_2}(u_1, u_2) \neq \emptyset$. This proves (a_1), because convexity and closedness follow at once from the analogous properties of F_i. Let us next verify (a_2). The above inequalities also guarantee that $\mathcal{S}_{F_1,F_2}$ maps bounded sets into bounded sets. If B is a nonempty weakly closed subset of $L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega)$ while $\{(u_{1,n}, u_{2,n})\} \subseteq \mathcal{S}^-_{F_1,F_2}(B)$ converges to (u_1, u_2) in $U_1 \times U_2$, then $\{(u_{1,n}, u_{2,n})\} \subseteq U_1 \times U_2$ turns out bounded. The same holds true concerning the set

$$\bigcup_{n \in \mathbb{N}} \mathcal{S}_{F_1,F_2}(u_{1,n}, u_{2,n}) \subseteq L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega).$$

Thus, up to sub-sequences, there exists $(w_{1,n}, w_{2,n}) \in \mathcal{S}_{F_1,F_2}(u_{1,n}, u_{2,n}) \cap B$, $n \in \mathbb{N}$, such that

$$(w_{1,n}, w_{2,n}) \rightharpoonup (w_1, w_2) \quad \text{in} \quad L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega).$$

One evidently has $(w_1, w_2) \in B$, because B is weakly closed. Mazur's principle provides a sequence $\{(\tilde{w}_{1,n}, \tilde{w}_{2,n})\}$ of convex combinations of $\{(w_{1,n}, w_{2,n})\}$ satisfying

$$(\tilde{w}_{1,n}, \tilde{w}_{2,n}) \to (w_1, w_2) \quad \text{in } L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega).$$

By (H_2), after passing to a sub-sequence which converges a.e., this easily entails

$$w_i(x) \in F_i(x, u_1(x), u_2(x), D^{r_1}u_1(x), D^{r_2}u_2(x)) \quad \text{for almost every} \quad x \in \Omega,\ i = 1, 2.$$

Consequently, $(w_1, w_2) \in \mathcal{S}_{F_1,F_2}(u_1, u_2) \cap B$, i.e., $(u_1, u_2) \in \mathcal{S}^-_{F_1,F_2}(B)$, as desired. □

Our existence result can be established after introducing some suitable constants and the notion of generalized solution to (1.1). Since $r_i < s_i$, $i = 1, 2$, embeddings (2.1) produce

$$\|D^{r_1} u_1\|_{p_1}^{p_1} \leq \hat{c}_1 \|u_1\|_{s_1,p_1}^{p_1} \quad \forall\, u_1 \in U_1, \qquad \|D^{r_2} u_2\|_{p_2}^{p_2} \leq \hat{c}_2 \|u_2\|_{s_2,p_2}^{p_2} \quad \forall\, u_2 \in U_2, \tag{3.2}$$

with appropriate $\hat{c}_i > 0$. Via (3.1) and its analogue for couples (s_2, p_2)–(t_2, q_2) we next have

$$\|u_1\|_{t_1,q_1}^{q_1} \leq \tilde{c}_1 \|u_1\|_{s_1,p_1}^{p_1} \quad \forall\, u_1 \in U_1, \qquad \|u_2\|_{t_2,q_2}^{q_2} \leq \tilde{c}_2 \|u_2\|_{s_2,p_2}^{p_2} \quad \forall\, u_2 \in U_2, \tag{3.3}$$

where $\tilde{c}_i > 0$. Finally, given $(T_1, T_2) \in U_1^* \times U_2^*$, set

$$\langle (T_1, T_2), (u_1, u_2) \rangle := \langle T_1, u_1 \rangle_1 + \langle T_2, u_2 \rangle_2, \quad (u_1, u_2) \in U_1 \times U_2.$$

Observe also that, by (b) in Proposition 2.4,

$$L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega) \hookrightarrow U_1^* \times U_2^*.$$

Hence, every $w \in L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega)$, $w = (w_1, w_2)$, defines a functional $T_w \in U_1^* \times U_2^*$ through

$$T_w(u_1, u_2) := \int_\Omega (u_1 w_1 + u_2 w_2) \mathrm{d}x \quad \forall\, (u_1, u_2) \in U_1 \times U_2. \tag{3.4}$$

Definition 3.3. We say that $(u_1, u_2) \in U_1 \times U_2$ is a generalized solution of (1.1) if there exist two sequences $(u_{1,n}, u_{2,n}) \in U_1 \times U_2$ and $w_n \in \mathcal{S}_{F_1,F_2}(u_{1,n}, u_{2,n})$, $w_n = (w_{1,n}, w_{2,n})$, fulfilling:

(i) $(u_{1,n}, u_{2,n}) \rightharpoonup (u_1, u_2)$ in $U_1 \times U_2$;

(ii) $A(u_{1,n}, u_{2,n}) - T_{w_n} \rightharpoonup 0$ in $U_1^* \times U_2^*$;

(iii) $\langle A(u_{1,n}, u_{2,n}), (u_{1,n} - u_1, u_{2,n} - u_2) \rangle - T_{w_n}(u_{1,n} - u_1, u_{2,n} - u_2) \to 0$.

Theorem 3.4. *Suppose* (H_1)–(H_4) *are satisfied and, moreover,*

$$\frac{M_1 + M_2}{\lambda_{1,p_i,s_i}} + \hat{c}_i (M_1' + M_2') + \tilde{c}_i |\mu_i| < 1, \quad i = 1, 2. \tag{3.5}$$

Then Problem (1.1) *admits a generalized solution.*

Proof. The space $U_1 \times U_2$ is separable, therefore it possesses a Galerkin's basis, namely a sequence $\{E_n\}$ of linear sub-spaces of $U_1 \times U_2$ such that:

(i_1) $\dim(E_n) < \infty \quad \forall\, n \in \mathbb{N}$;

(i_2) $E_n \subseteq E_{n+1} \quad \forall\, n \in \mathbb{N}$;

(i_3) $\overline{\cup_{n=1}^{\infty} E_n} = U_1 \times U_2$.

Pick $n \in \mathbb{N}$. Consider the following problem: Find $(u_1, u_2) \in E_n$, $(w_1, w_2) \in \mathcal{S}_{F_1,F_2}(u_1, u_2)$ fulfilling

$$\langle A(u_1, u_2), (v_1, v_2) \rangle - T_w(v_1, v_2) = 0 \quad \forall\, (v_1, v_2) \in E_n^*, \tag{3.6}$$

with T_w as in (3.4). Thanks to Lemma 3.2 the multifunction $\Phi : E_n \to 2^{E_n^*}$ defined by

$$\Phi(u_1, u_2) := \{ (A(u_1, u_2) - T_w) \lfloor_{E_n} : w \in \mathcal{S}_{F_1,F_2}(u_1, u_2), w = (w_1, w_2) \}, \quad (u_1, u_2) \in E_n,$$

takes nonempty, convex, closed values and maps bounded sets into bounded sets. We claim that Φ is upper semi-continuous. In fact, let $B \subseteq E_n^*$ closed. If $\{(u_{1,k}, u_{2,k})\} \subseteq \Phi^-(B)$ and $(u_{1,k}, u_{2,k}) \to (u_1, u_2)$ in E_n then there exists a sequence $w_k \in \mathcal{S}_{F_1,F_2}(u_{1,k}, u_{2,k})$, $w_k = (w_{1,k}, w_{2,k})$, such that

$$(A(u_{1,k}, u_{2,k}) - T_{w_k})\lfloor_{E_n} \in B \quad \forall\, k \in \mathbb{N}. \tag{3.7}$$

The same argument used in the proof of Lemma 3.2 gives $w \in \mathcal{S}_{F_1,F_2}(u_1, u_2)$, $w = (w_1, w_2)$, satisfying $(w_{1,k}, w_{2,k}) \rightharpoonup (w_1, w_2)$ in $L^{(p_1^*)'}(\Omega) \times L^{(p_2^*)'}(\Omega)$. Since $\dim(E_n) < \infty$, one has $T_{w_k}\lfloor_{E_n} \to T_w\lfloor_{E_n}$ in E_n^*. Thus, from Lemma 3.1 and (3.7) it follows

$$(A(u_1, u_2) - T_w)\lfloor_{E_n} \in B, \quad \text{i.e.,} \quad (u_1, u_2) \in \Phi^-(B).$$

This shows that $\Phi^-(B)$ is closed. As B was arbitrary, the multifunction Φ turns out upper semi-continuous. Next, if $(u_1, u_2) \in U_1 \times U_2$ and $w \in \mathcal{S}_{F_1,F_2}(u_1, u_2)$ then, thanks to (H_4), we have

$$\begin{aligned}\langle A(u_1, u_2), (u_1, u_2)\rangle - T_w(u_1, u_2) &\geq \|u_1\|_{s_1,p_1}^{p_1} + \|u_2\|_{s_2,p_2}^{p_2} - |\mu_1|\|u_1\|_{t_1,q_1}^{q_1} - |\mu_2|\|u_2\|_{t_2,q_2}^{q_2} \\ &\quad - \int_\Omega \left[M_1(|u_1|^{p_1} + |u_2|^{p_2}) + M_1'(|D^{r_1}u_1|^{p_1} + |D^{r_2}u_2|^{p_2}) + \sigma_1\right] \mathrm{d}x \\ &\quad - \int_\Omega \left[M_2(|u_1|^{p_1} + |u_2|^{p_2}) + M_2'(|D^{r_1}u_1|^{p_1} + |D^{r_2}u_2|^{p_2}) + \sigma_2\right] \mathrm{d}x.\end{aligned}$$

Exploiting (p_3) yields

$$\begin{aligned}&\langle A(u_1, u_2), (u_1, u_2)\rangle - T_w(u_1, u_2) \\ &\quad \geq \left(1 - \frac{M_1 + M_2}{\lambda_{1,p_1,s_1}}\right)\|u_1\|_{s_1,p_1}^{p_1} + \left(1 - \frac{M_1 + M_2}{\lambda_{1,p_2,s_2}}\right)\|u_2\|_{s_2,p_2}^{p_2} - |\mu_1|\|u_1\|_{t_1,q_1}^{q_1} - |\mu_2|\|u_2\|_{t_2,q_2}^{q_2} \\ &\qquad - \int_\Omega (M_1' + M_2')|D^{r_1}u_1|^{p_1}\mathrm{d}x - \int_\Omega (M_1' + M_2')|D^{r_2}u_2|^{p_2}\mathrm{d}x - \|\sigma_1\|_1 - \|\sigma_2\|_1,\end{aligned}$$

whence, on account of (3.2),

$$\begin{aligned}&\langle A(u_1, u_2), (u_1, u_2)\rangle - T_w(u_1, u_2) \\ &\quad \geq \left[1 - \frac{M_1 + M_2}{\lambda_{1,p_1,s_1}} - \hat{c}_1(M_1' + M_2')\right]\|u_1\|_{s_1,p_1}^{p_1} + \left[1 - \frac{M_1 + M_2}{\lambda_{1,p_2,s_2}} - \hat{c}_2(M_1' + M_2')\right]\|u_2\|_{s_2,p_2}^{p_2} \\ &\qquad - |\mu_1|\|u_1\|_{t_1,q_1}^{q_1} - |\mu_2|\|u_2\|_{t_2,q_2}^{q_2} - \|\sigma_1\|_1 - \|\sigma_2\|_1.\end{aligned}$$

Finally, through (3.3) we obtain

$$\begin{aligned}&\langle A(u_1, u_2), (u_1, u_2)\rangle - T_w(u_1, u_2) \\ &\quad \geq \left[1 - \frac{M_1 + M_2}{\lambda_{1,p_1,s_1}} - \hat{c}_1(M_1' + M_2') - |\mu_1|\tilde{c}_1\right]\|u_1\|_{s_1,p_1}^{p_1} \\ &\qquad + \left[1 - \frac{M_1 + M_2}{\lambda_{1,p_2,s_2}} - \hat{c}_2(M_1' + M_2') - |\mu_2|\tilde{c}_2\right]\|u_2\|_{s_2,p_2}^{p_2} - \|\sigma_1\|_1 - \|\sigma_2\|_1 \\ &\quad \geq \min_{i=1,2}\left[1 - \frac{M_1 + M_2}{\lambda_{1,p_i,s_i}} - \hat{c}_i(M_1' + M_2') - |\mu_i|\tilde{c}_i\right]\left(\|u_1\|_{s_1,p_1}^{p_1} + \|u_2\|_{s_2,p_2}^{p_2}\right) - \|\sigma_1\|_1 - \|\sigma_2\|_1,\end{aligned}$$

namely

$$\langle A(u_1, u_2), (u_1, u_2)\rangle - T_w(u_1, u_2) \geq \alpha\left(\|u_1\|_{s_1,p_1}^{p_1} + \|u_2\|_{s_2,p_2}^{p_2}\right) - \beta, \tag{3.8}$$

where

$$\alpha := \min_{i=1,2}\left[1 - \frac{M_1+M_2}{\lambda_{1,p_i,s_i}} - \hat{c}_i(M_1'+M_2') - |\mu_i|\tilde{c}_i\right], \quad \beta := \|\sigma_1\|_1 + \|\sigma_2\|_1.$$

Since (3.5) holds, the multifunction Φ turns out coercive. Now, Theorem 2.3 can be applied, and there exists a solution $(u_{1,n}, u_{2,n}) \in E_n$, $w_n \in \mathcal{S}_{F_1,F_2}(u_{1,n}, u_{2,n})$, $w_n = (w_{1,n}, w_{2,n})$, to Problem (3.6), i.e.,

$$\langle A(u_{1,n}, u_{2,n}), (v_1, v_2)\rangle - T_{w_n}(v_1, v_2) = 0, \quad (v_1, v_2) \in E_n^*. \tag{3.9}$$

From (3.8), written with $(u_1, u_2) := (u_{1,n}, u_{2,n})$, and (3.9) it follows

$$0 \geq \alpha\left(\|u_{1,n}\|_{s_1,p_1}^{p_1} + \|u_{2,n}\|_{s_2,p_2}^{p_2}\right) - \beta \quad \forall\, n \in \mathbb{N}.$$

Thus, $\{(u_{1,n}, u_{2,n})\} \subseteq U_1 \times U_2$ is bounded. By reflexivity one has $(u_{1,n}, u_{2,n}) \rightharpoonup (u_1, u_2)$ in $U_1 \times U_2$, taking a sub-sequence when necessary. Consequently, (i) of Definition 3.3 holds. Through Lemma 3.2 we next infer that $\{(w_{1,n}, w_{2,n})\} \subseteq L^{(p_1^*)'}(\Omega) \times L^{(p_3^*)'}(\Omega)$ turns out bounded. Therefore, always up to sub-sequences,

$$A(u_{1,n}, u_{2,n}) - T_{w_n} \rightharpoonup T \quad \text{in } U_1^* \times U_2^*. \tag{3.10}$$

Given any $(v_1, v_2) \in \cup_{k=1}^{\infty} E_k$, Property (i_2) and (3.9) yield

$$T(v_1, v_2) = \lim_{n\to\infty}\left(\langle A(u_{1,n}, u_{2,n}), (v_1, v_2)\rangle - T_{w_n}(v_1, v_2)\right) = 0.$$

Because of (i_3) this forces $T = 0$, namely condition (ii) is true. Moreover, using (3.9)–(3.10) entails

$$\begin{aligned}\langle A(u_{1,n}, u_{2,n}), (u_{1,n}-u_1, u_{2,n}-u_2)\rangle - T_{w_n}(u_{1,n}-u_1, u_{2,n}-u_2)\\ = -\langle A(u_{1,n}, u_{2,n}), (u_1, u_2)\rangle + T_{w_n}(u_1, u_2) \to 0,\end{aligned} \tag{3.11}$$

which shows (iii) in Definition 3.3. Summing up, the pair (u_1, u_2) turns out to be a generalized solution to (1.1). □

If we strengthen (H_3) as follows:

$(\mathrm{H}_3)'$ For every $i = 1, 2$ there exist $\rho_i, \sigma_i \in (1, p_i^*)$, $m_i > 0$, and $\delta_i \in L^{\sigma_i'}(\Omega)$ such that

$$|F_i(x, y_1, y_2, z_1, z_2)| \leq m_i\left(|y_1|^{\frac{p_1^*}{\rho_i'}} + |y_2|^{\frac{p_2^*}{\rho_i'}} + |z_1|^{\frac{p_1}{\rho_i'}} + |z_2|^{\frac{p_2}{\rho_i'}}\right) + \delta_i(x)$$

a.e. in Ω and for all $(y_1, y_2, z_1, z_2) \in \mathbb{R}^2 \times \mathbb{R}^{2N}$,

then the next notion of strongly generalized solution can be given. Obviously, $(\mathrm{H}_3)'$ implies (H_3), because $\rho_i < p_i^*$ forces

$$\frac{\kappa}{\rho_i'} < \frac{\kappa}{(p_i^*)'} \quad \forall\, \kappa \in \{p_1, p_2, p_1^*, p_2^*\}.$$

Definition 3.5. We say that $(u_1, u_2) \in U_1 \times U_2$ is a strongly generalized solution to (1.1) if there are two sequences $(u_{1,n}, u_{2,n}) \in U_1 \times U_2$ and $w_n \in \mathcal{S}_{F_1,F_2}(u_{1,n}, u_{2,n})$, $w_n = (w_{1,n}, w_{2,n})$, satisfying (i) and (ii) of Definition 3.3 and, moreover,

$(\mathrm{iii})'$ $\lim_{n\to\infty}\langle A(u_{1,n}, u_{2,n}), (u_{1,n}-u_1, u_{2,n}-u_2)\rangle = 0$.

Theorem 3.6. *Under assumptions* (H_1)–(H_2), $(H_3)'$, (H_4), *and* (3.5), *Problem* (1.1) *admits a strongly generalized solution.*

Proof. Reasoning as in the proof of Theorem 3.4 yields both $(u_1, u_2) \in U_1 \times U_2$ and two sequences $(u_{1,n}, u_{2,n}) \in U_1 \times U_2$, $(w_{1,n}, w_{2,n}) \in \mathcal{S}_{F_1,F_2}(u_{1,n}, u_{2,n})$ that comply with (i)–(ii) in Definition 3.3 as well as (3.11). Thus, it remains to show $(iii)'$. By $(H_3)'$ and Hölder's inequality we have

$$\begin{aligned}
&\left|\int_\Omega w_{i,n}(u_{i,n}-u_i)\mathrm{d}x\right| \\
&\quad\le m_i\int_\Omega\left(|u_{1,n}|^{\frac{p_1^*}{\rho_i'}}+|u_{2,n}|^{\frac{p_2^*}{\rho_i'}}+|\nabla u_{1,n}|^{\frac{p_1}{\rho_i'}}+|\nabla u_{2,n}|^{\frac{p_2}{\rho_i'}}\right)|u_{i,n}-u_i|\mathrm{d}x+\int_\Omega\delta_i|u_{i,n}-u_i|\mathrm{d}x \\
&\quad\le m_i\left(\|u_{1,n}\|_{p_1^*}^{p_1^*/\rho_i'}+\|u_{2,n}\|_{p_2^*}^{p_2^*/\rho_i'}+\|u_{1,n}\|_{1,p_1}^{p_1/\rho_i'}+\|u_{2,n}\|_{1,p_2}^{p_2/\rho_i'}\right)\|u_{i,n}-u_i\|_{\rho_i}+\|\delta_i\|_{\sigma_i'}\|u_{i.n}-u_i\|_{\sigma_i} \\
&\quad\le C\|u_{i,n}-u_i\|_{\rho_i}+\|\delta_i\|_{\sigma_i'}\|u_{i,n}-u_i\|_{\sigma_i}\quad\forall\, n\in\mathbb{N},
\end{aligned}$$

with $C > 0$, because $\{u_{i,n}\} \subseteq U_i$ turns out bounded. The condition $\max\{\rho_i, \sigma_i\} < p_i^*$ forces $u_{i,n} \to u_i$ in $L^{\rho_i}(\Omega) \cap L^{\sigma_i}(\Omega)$, where a sub-sequence is considered if necessary; see Proposition 2.4. Hence,

$$\lim_{n\to\infty}\int_\Omega w_{i,n}(u_{i,n}-u_i)\mathrm{d}x=0,\quad i=1,2. \tag{3.12}$$

Through (3.11)–(3.12), we arrive at

$$\lim_{n\to\infty}\langle A(u_{1,n},u_{2,n}),(u_{1,n}-u_1,u_{2,n}-u_2)\rangle=0,$$

namely $(iii)'$ of Definition 3.5 also holds. □

Finally, recall that $(u_1, u_2) \in U_1 \times U_2$ is called a *weak solution* to (1.1) when there exists $(w_1, w_2) \in \mathcal{S}_{F_1,F_2}(u_1, u_2)$ such that

$$A(u_1,u_2)=(w_1,w_2)\quad\text{in } U_1^*\times U_2^*. \tag{3.13}$$

Corollary 3.7. *Let the hypotheses of Theorem 3.6 be satisfied and let* $\min\{\mu_1, \mu_2\} \ge 0$. *Then Problem* (1.1) *possesses a weak solution.*

Proof. Keep the same notation of the previous proof. Since $\mu_i \ge 0$, gathering (p_1) with Proposition 2.2 together ensures that A_i is of type $(S)_+$. Therefore, from $(iii)'$ it follows $(u_{1,n}, u_{2,n}) \to (u_1, u_2)$ in $U_1 \times U_2$. On the other hand, (a_2) in Lemma 3.2 produces, up to subsequences, $(w_{1,n}, w_{2,n}) \rightharpoonup (w_1, w_2)$ in $U_1^* \times U_2^*$. Now, through (ii) and Lemma 3.1 we easily infer (3.13). □

Abstract. The family of systems

$$\dot{x} = x(y-1) - \beta z, \quad \dot{y} = \alpha(1-x^2) - \kappa y, \quad \dot{z} = x - \lambda z,$$

where $(x, y, z) \in \mathbb{R}^3$ and α, β, κ, λ are real parameters, was proposed by Hide, Skeldon and Acheson in 1996 for the study of self-excited dynamo action in which a Faraday disc and coil are arranged in series with either a capacitor or a motor. Since then it has been studied by several authors.

Here for the first time we provide, taking into account all values of the parameters, all its 13 types of invariant algebraic surfaces, its 2 polynomial and its 2 rational simple first integrals having at most degree two, and its 6 Darboux invariants coming for the invariant algebraic surfaces of degree two. Moreover, we show how to describe its dynamics in the Poincaré ball when the differential system has either a given first integral, or a given Darboux invariant. Describing the dynamics of the differential system in the Poincaré ball we control the orbits of the system that escape or come from the infinity.

Keywords: Hide–Skeldon–Acheson model, polynomial first integral, rational first integral, invariant algebraic surface, Darboux invariant

2020 Mathematics Subject Classification: 34C05.

1 Introduction and statements of the main results

In this work, we give some results about the integrability and the global dynamics of the Hide–Skeldon–Acheson dynamo model (HSA dynamo model), given by 4-parameter family of systems

$$\dot{x} = x(y-1) - \beta z, \quad \dot{y} = \alpha(1-x^2) - \kappa y, \quad \dot{z} = x - \lambda z, \tag{1.1}$$

✉Corresponding author. Email: jaume.llibre@uab.cat

where $(x, y, z) \in \mathbb{R}^3$ and α, β, κ, λ are real parameters.

The family of systems (1.1) was proposed by Hide, Skeldon and Acheson in 1996 [4] for the study of self-excited dynamo action in which a Faraday disc and coil are arranged in series with either a capacitor or a motor. In this case, $x(t)$ is the current flowing through the dynamo, $y(t)$ is the angular rotation rate of the disc, and $z(t)$ is the angular rotation rate of the motor (or the charge in the capacitor). The parameter α is proportional to the steady applied mechanical couple driving the disc into rotation, β^{-1} measures the moment of inertia of the armature of the motor, and κ and λ are the coefficients of friction in the disc and the motor, respectively.

In [9] the authors study the integrability problem of systems (1.1). They provide some first integrals when the parameter $\alpha \neq 0$. They also prove that for $\alpha, \beta, \kappa \neq 0$ the dynamo model does not admit a polynomial or rational first integral.

In [6] the local and global asymptotical stability of the equilibrium point is discussed. All the orbits of the system are proved to be bounded. The existence of periodic orbits and the Hopf bifurcation is studied, and also the coexistence of three types of attractors: equilibria, hidden periodic attractors and hidden chaotic attractors.

In this paper our goal is to show how invariant algebraic surfaces, first integrals and Darboux invariants help in understanding the global dynamics of polynomial vector fields. Here we do this for the HSA dynamo model. More precisely, the existence of invariant surfaces always simplifies the study of the dynamics of a differential system in $\mathbb{R}^3$ because they separate the phase portrait in invariant pieces by the flow. On the other hand, the existence of a first integral, allows to reduce the study of the dynamics of a differential system in one dimension, and the existence of a Darboux invariant allows to determine the α- and ω-limits of the orbits of the system. In summary, to know one of these three objects helps in understanding the dynamics of a differential system.

One can easily check that systems (1.1) are invariant under the change of variables $(x, y, z) \to (-x, y, -z)$. Consequently if $(x(t), y(t), z(t))$ is a solution to one of the systems (1.1), so is $(-x(t), y(t), -z(t))$ (is symmetric with respect to the y-axis).

Let $\mathbb{R}[x, y, z]$ be the ring of the real polynomials in the variables x, y and z. Let $F = F(x, y, z) \in \mathbb{R}[x, y, z]$. We say that $F = F(x, y, z) = 0$ is an *invariant algebraic surface* of system (1.1) if it satisfies

$$\frac{\partial F}{\partial x}(x(y-1) - \beta z) + \frac{\partial F}{\partial y}(\alpha(1-x^2) - \kappa y) + \frac{\partial F}{\partial z}(x - \lambda z) = KF,$$

where $K = K(x, y, z)$ is a real polynomial of degree at most 1, called the *cofactor* of $F(x, y, z)$. In the next proposition we classify all invariant algebraic surfaces of degree at most two of the HSA dynamo model.

Proposition 1.1. *All the invariant algebraic surfaces of degree one or two that could occur for systems* (1.1) *are given in Table* 1.1 *together with their domains of existence in the parameter space .*

Proposition 1.1 will be proved in Section 3.

Let U be an open and dense subset of $\mathbb{R}^3$. Let $H\colon U \to \mathbb{R}$ a C^1 function non-locally constant. We say that H is a *first integral* of a system (1.1) if H is constant in all the solutions $(x(t), y(t), z(t))$ of that system contained in U. In other words, H must satisfy

$$\frac{\partial H}{\partial x}(x(y-1) - \beta z) + \frac{\partial H}{\partial y}(\alpha(1-x^2) - \kappa y) + \frac{\partial H}{\partial z}(x - \lambda z) = 0,$$

Conditions	$F_k = 0$	**Cofactor**
$\alpha = \beta = \lambda = \kappa = 0$	$F_1 = a - bx + cy - bz + dy^2 + byz$	$K_1 = 0$
$\alpha = \kappa = 0$	$F_2 = a + by + cy^2$	$K_2 = 0$
$\alpha = 0, \beta = \kappa = -\lambda$	$F_3 = a - x - z + yz$	$K_3 = 0$
$\beta = 0$	$F_4 = x$	$K_4 = y - 1$
$\alpha = 0$	$F_5 = y$	$K_5 = -\kappa$
$\alpha = \lambda = 0, \beta = \kappa(1-\kappa),$	$F_6 = -x + ay + (\kappa - 1)z + yz$	$K_6 = -\kappa$
$\alpha = 0, \beta = \kappa(1+\kappa), \lambda = -2\kappa$	$F_7 = -x - (\kappa + 1)z + yz$	$K_7 = \kappa$
$\alpha = 0, \beta = \kappa(1-2\kappa), \lambda = \kappa$	$F_8 = -x + ay^2 + (2\kappa - 1)z + yz$	$K_8 = -2\kappa$
$\alpha = \kappa(1-\kappa) < 0, \beta = 0$	$F_9 = \kappa - 1 - \sqrt{\kappa(\kappa-1)}x + y$	$K_9 = -\kappa - \sqrt{\kappa(\kappa-1)}x$
$\alpha = \kappa(1-\kappa) < 0, \beta = 0$	$F_{10} = \kappa - 1 + \sqrt{\kappa(\kappa-1)}x + y$	$K_{10} = -\kappa + \sqrt{\kappa(\kappa-1)}x$
$\alpha = \kappa(1-\kappa) > 0, \beta = 0$	$F_{11} = (y - (1-\kappa))^2 + \kappa(1-\kappa)x^2$	$K_{11} = -2\kappa$
$\alpha = \kappa(1-\kappa), \lambda = \kappa$	$F_{12} = (y - (1-\kappa))^2 + \kappa(1-\kappa)x^2 + \beta\kappa(1-\kappa)z^2$	$K_{12} = -2\kappa$
$\alpha = 0, \beta = \kappa\lambda - \kappa(1+\kappa)$	$F_{13} = \beta x + \kappa xy - \beta\kappa z$	$K_{13} = y - (1+\kappa)$

Table 1.1: Invariant algebraic surfaces of system (1.1), $F_k = F_k(x, y, z) = 0$, for $1 \leq k \leq 13$. Here $a, b, c, d \in \mathbb{R}$.

on the solutions $(x(t), y(t), z(t))$ of the system (1.1), with fixed $\alpha, \beta, \kappa, \lambda \in \mathbb{R}$, contained in U. A first integral is called *simple* if it is not a function of other first integrals, and the first integral H is called *polynomial* (respectively *rational*) if H is a polynomial (respectively a rational) function. The degree of a polynomial first integral is the *degree* of the polynomial, and the *degree* of a rational function, say $G = P_1/P_2$ being $P_1, P_2 \in \mathbb{R}[x, y, z]$ is the maximum of the degrees of the polynomials P_1 and P_2.

In the next two results we characterize, first all polynomial first integrals of degree at most two of systems (1.1), and second all rational first integrals of degree at most two of systems (1.1).

Proposition 1.2. *All simple polynomial first integrals of degree one or two of systems* (1.1)*, together with the corresponding parameters of existence, are listed in Table* 1.2*.*

The proof of Propositions 1.2 and 1.3 are given in Section 3.

Proposition 1.3. *All simple rational first integrals of degree one or two of systems* (1.1) *that are not polynomial, together with the corresponding parameters of existence, are listed in Table* 1.3*.*

Conditions	**Polynomial first integral**
$\alpha = \kappa = 0$	$H_1 = y$
$\alpha = 0, \beta = \kappa = -\lambda$	$H_2 = x + z - yz$

Table 1.2: Simple polynomial first integrals of systems (1.1), $H_k = H_k(x, y, z)$ for $1 \leq k \leq 2$.

Conditions	Rational first integrals
$\alpha=0$, $\beta=\kappa(1-2\kappa)$, $\lambda=\kappa$	$G_1=(-x+(2\kappa-1)z+yz)/y^2$
$\alpha=0$, $\beta=\kappa(1-\kappa)$, $\lambda=0$	$G_2=(-x+(\kappa-1)z+yz)/y$

Table 1.3: Simple rational first integrals of systems (1.1), $G_k=G_k(x,y,z)$ for $1\leq k\leq 2$.

We say that a differential system (1.1) is *completely integrable* if there are two first integrals functionally independent, i.e. the gradients of both first integrals are linear independent except perhaps in a zero Lebesgue measure set.

Corollary 1.4. *If $\alpha=\beta=\kappa=\lambda=0$, the differential system (1.1) is completely integrable with the two first integrals H_1 and H_2 of Table 1.2.*

Corollary 1.4 is given in Section 3. Note that the first integrals H_1 and H_2 are all the rational first integrals of degree one or two, but the systems can have other rational first integrals of higher degree.

An *invariant* of a differential system (1.1) on an open and dense subset U of $\mathbb{R}^3$ is a non-constant C^1 function $I=I(x,y,z,t)$, such that $I(x(t),y(t),z(t),t)$ is constant on all solutions $(x(t),y(t),z(t))$ of that system (1.1) contained in U, i.e.

$$\frac{\partial I}{\partial x}(x(y-1)-\beta z)+\frac{\partial I}{\partial y}(\alpha(1-x^2)-\kappa y)+\frac{\partial I}{\partial z}(x-\lambda z)+\frac{\partial I}{\partial t}=0$$

for all $(x(t),y(t),z(t))\in U$. Note that if an invariant is independent of t it is a first integral.

If the invariant is of the form $I=f(x,y,z)e^{st}$ with f an analytic function in U and $s\in\mathbb{R}\setminus\{0\}$ we say that I is a *Darboux invariant*. A Darboux invariant is *simple* if it is not a function of other Darboux invariants.

Proposition 1.5. *All Darboux invariants $I=f(x,y,z)e^{st}$ with $f(x,y,z)$ formed by the polynomials F_k with $k=1,\ldots,13$ of Table 1.1 are given in Table 1.4.*

Conditions	Darboux invariant
$\alpha=0$	$I_1=ye^{\kappa t}$
$\alpha=0$, $\beta=\kappa(1-\kappa)$, $\lambda=0$	$I_2=(-x+(\kappa-1)z+yz)e^{\kappa t}$
$\alpha=0$, $\beta=\kappa(1+\kappa)$, $\lambda=-2\kappa$	$I_3=(-x-(\kappa+1)z+yz)e^{-\kappa t}$,
$\alpha=0$, $\beta=\kappa(1-2\kappa)$, $\lambda=\kappa$	$I_4=(-x+(2\kappa-1)z+yz)e^{2\kappa t}$
$\alpha=\kappa(1-\kappa)$, $\beta=0$	$I_5=((y-(1-\kappa))^2+\kappa(1-\kappa)x^2)e^{2\kappa t}$
$\alpha=\kappa(1-\kappa)$, $\lambda=\kappa$	$I_6=((y-(1-\kappa))^2+\kappa(1-\kappa)x^2+\beta\kappa(1-\kappa)z^2)e^{2\kappa t}$

Table 1.4: Darboux invariants of systems (1.1), $I_k=I_k(x,y,z)$ for $1\leq k\leq 6$.

Proposition 1.5 is also proved in Section 3.

Let $\phi_p(t)$ be the solution of a system (1.1) such that $\phi_p(0)=p$, defined on its maximal interval (α_p,ω_p). If $\omega_p=+\infty$, we define the ω-limit set of p as

$$\omega(p)=\left\{q\in\mathbb{R}^3:\ \exists\{t_n\}\subset\mathbb{R}\text{ with }\lim_{n\to\infty}t_n=\infty\text{ and }\lim_{n\to\infty}\phi_p(t_n)=q\right\}.$$

In the same way, if $\alpha_p = -\infty$, we define the α-limit set of p as

$$\alpha(p) = \left\{ q \in \mathbb{R}^3 : \exists \{t_n\} \subset \mathbb{R} \text{ with } \lim_{n\to\infty} t_n = -\infty \text{ and } \lim_{n\to\infty} \phi_p(t_n) = q \right\}.$$

While the existence of a first integral allows to reduce in one dimension the study of the dynamics of a differential system in $\mathbb{R}^3$, the existence of a Darboux invariant provides information on the α- and ω-limits of the orbits of the differential system (see Proposition 5 of [8], or Proposition 2.4 in Section 2).

In order to illustrate how to use the existence of a first integral or a Darboux invariant in the study of the global dynamics of the 4-parameter family of systems (1.1) we take the first integral H_2 and the Darboux invariant I_5. This is the content of the next two main results.

Systems (1.1) under the conditions $\alpha = 0$ and $\beta = \kappa = -\lambda$ have the first integral $H_2 = x + z - yz$. In the next theorem we characterize their phase portraits on each level $H_2 = h \in \mathbb{R}$.

Theorem 1.6. *The phase portraits in the Poincaré disc of the differential systems* (1.1) *restricted to the invariant surface* $H_2(x, y, z) = h \in \mathbb{R}$ *under the conditions* $\alpha = 0$ *and* $\beta = \kappa = -\lambda$ *are topologically equivalent to one of the six phase portraits of Figure 1.1. The phase portrait G1 occurs for* $\kappa = 0, h \neq 0$*; G2 for* $\kappa = 0, h = 0$*; G3 for* $\kappa \in (0, 1)$*; G4 for* $k = 1, h \neq 0$*; G5* $\kappa = 1, h = 0$ *and G6 for* $\kappa > 1$ *or* $\kappa = 0$.

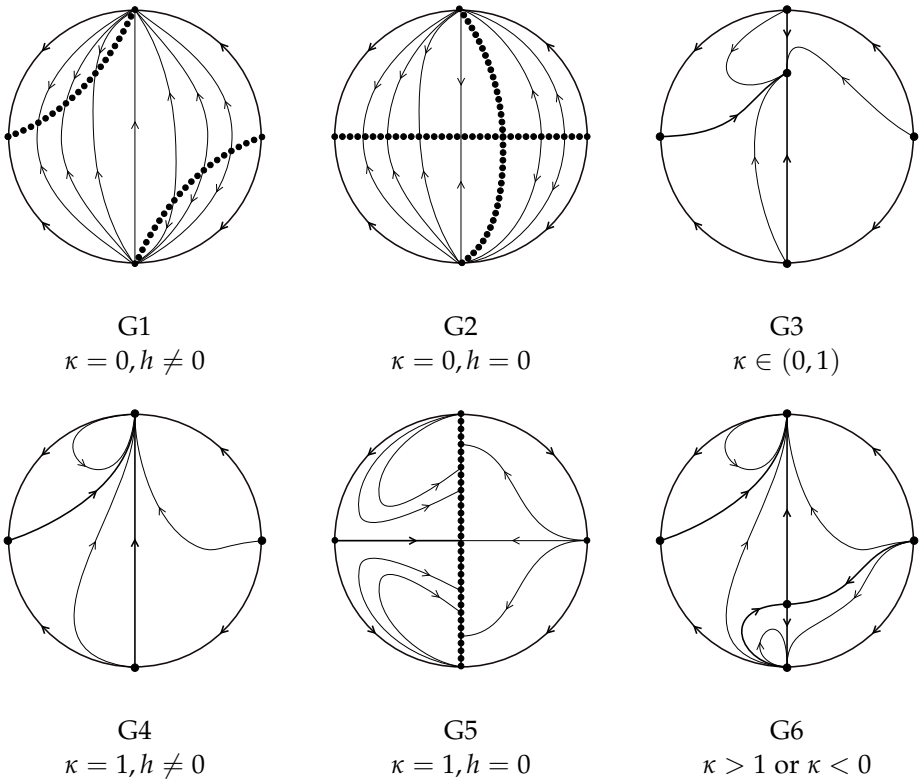

Figure 1.1: Phase portraits of systems (1.1) with $\alpha = 0$ and $\beta = \kappa = -\lambda$ at any level $H_2 = h \in \mathbb{R}$ in the Poincaré disc.

Theorem 1.6 is proved in Section 4.

Systems (1.1) under the conditions $\alpha = \kappa(1 - \kappa) \neq 0$ and $\beta = 0$, have the Darboux invariant $I_5 = ((\kappa - 1 + y)^2 + \kappa(1 - \kappa)x^2)e^{2\kappa t}$. In the next theorem we characterize their dynamics in the Poincaré ball.

We define the infinite equilibrium $S_1 = (\sqrt{\kappa(\kappa-1)}, 0, 0)$ and $S_4 = (-\sqrt{\kappa(\kappa-1)}, 0, 0)$ in the local chart U_1 and $S_3 = (-\sqrt{\kappa(\kappa-1)}, 0, 0)$ and $S_2 = (\sqrt{\kappa(\kappa-1)}, 0, 0)$ in the local chart V_1, and the finite equilibrium $P_1 = (0, 1-\kappa, 0)$.

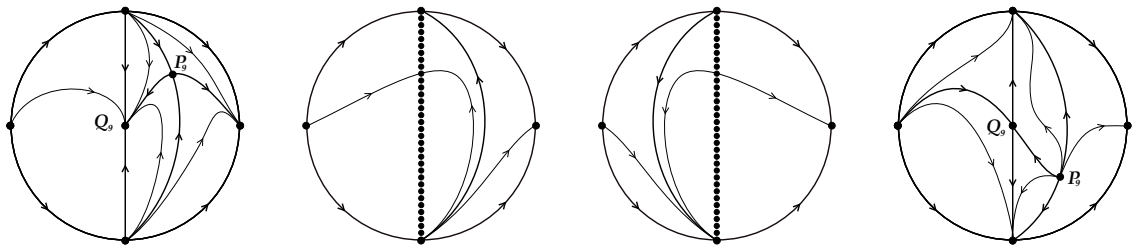
Theorem 1.7. *The dynamics of the differential systems* (1.1) *under the conditions* $\alpha = \kappa(1-\kappa) \neq 0$ *and* $\beta = 0$ *are described below.*

(a) When $\kappa(\kappa-1) > 0$ *and* $\beta = 0$ *they have two invariant algebraic surfaces* $F_9 = 0$ *and* $F_{10} = 0$ *(see Table 1.1). The boundary of these surfaces are the boundary at infinity of the planes* $y - \sqrt{\kappa(\kappa-1)}x = 0$ *and* $y + \sqrt{\kappa(\kappa-1)}x = 0$*, respectively. Up to topological equivalence there are only two phase portraits on the Poincaré ball for both invariant algebraic surfaces (see Figure 1.2). When* $\kappa(\kappa-1) < 0$ *and* $\beta = 0$ *the invariant surface* $F_{11} = 0$ *corresponds to the straight line* $(0, 1-\kappa, z)$ *with* $z \in \mathbb{R}$*. The boundary of this straight line are the endpoints of the z-axis. The dynamics on this straight line is described by the differential equation* $\dot{z} = -\lambda z$*.*

(b) The phase portraits of systems (1.1) *under the conditions* $\alpha = \kappa(1-\kappa) \neq 0$ *and* $\beta = 0$ *on the infinite sphere is shown in Figures 1.3.*

(b1) When $\kappa(\kappa-1) < 0$ *the boundary at infinity of the plane* $x = 0$ *is filled with equilibria. All the orbits that are not equilibria are heteroclinic orbits starting at an infinite equilibrium with its y-coordinate positive and ending at an infinite equilibrium with its y-coordinate negative.*

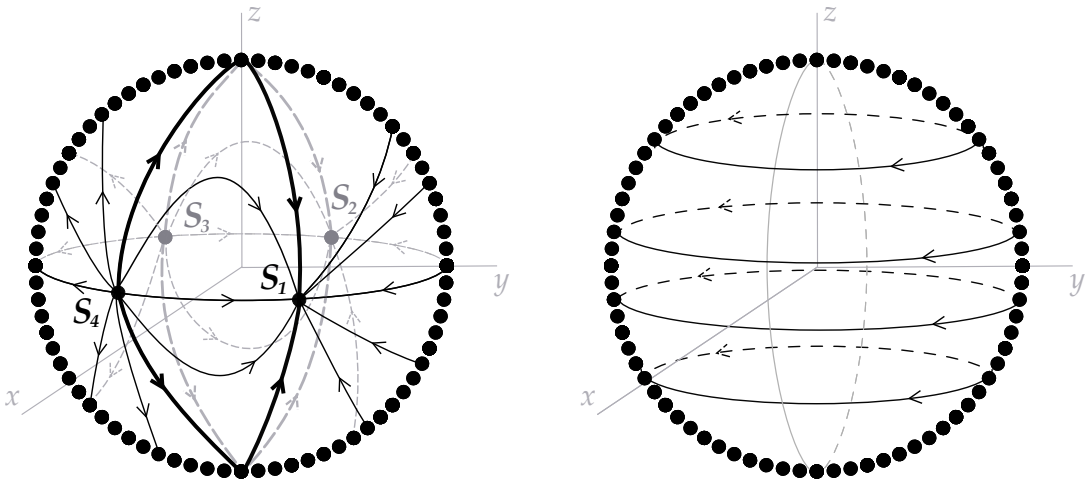
(b2) When $\kappa(\kappa-1) > 0$ *the boundary at infinity of the plane* $x = 0$ *is filled with equilibria and there are four additional isolated equilibria* S_k *for* $k = 1, 2, 3, 4$*. On the infinite sphere there are eight separatrices. The equilibria* S_3 *and* S_4 *are the* α*-limit of two separatrices one having its* ω*-limit at the endpoint of the positive z-axis and the other at the endpoint of the negative z-axis. The equilibria* S_1 *and* S_2 *are the* ω*-limits of two separatrices one having its* α*-limit at the endpoint of the positive z-axis and the other at the endpoint of the negative z-axis. The orbits inside the regions delimited by these separatrices and that do not contain equilibria have either* S_4 *as* α*-limit and* S_1 *as* ω*-limit, or* S_3 *as* α*-limit and* S_2 *as* ω*-limit. For all the other orbits: the ones with* $x, y > 0$ *have their* α*-limit at an infinite equilibrium of the plane* $x = 0$ *with* $y > 0$ *and their* ω*-limit at* S_1*; the ones with* $x > 0$*,* $y < 0$ *have their* ω*-limit at one infinite equilibrium of the plane* $x = 0$ *with* $y < 0$ *and their* α*-limit at* S_4*; the ones with* $x < 0$*,* $y > 0$ *have their* α*-limit at one infinite equilibrium of the plane* $x = 0$ *with* $y > 0$ *and their* ω*-limit at* S_2*; the ones with* $x, y < 0$ *have their* ω*-limit at one infinite equilibrium of the plane* $x = 0$ *with* $y < 0$ *and their* α*-limit at* S_3*.*



(c) All the α*- and* ω*-limits for the orbits inside the Poincaré ball, i.e. in* $\mathbb{R}^3$*, are the following:*

(c1) Assume $\kappa(\kappa-1) < 0$*. If* $\lambda > 0$ *all the orbits in* $\mathbb{R}^3$ *have their* ω*-limit at* P_1 *and their* α*-limit at an infinite equilibrium. If* $\lambda < 0$*, with the exception of the equilibria on the straight line* $(0, 1-k, z)$ *with* $z \in \mathbb{R}$*, all the orbits in* $\mathbb{R}^3$ *have their* ω*-limit at the infinite equilibria* $(0, 0, 1)$ *or* $(0, 0, -1)$ *of the Poincaré ball, and their* α*-limit is an infinite equilibrium. If* $\lambda = 0$ *all the orbits in* $\mathbb{R}^3$ *have their* ω*-limit in one of the equilibria of the straight line* $(0, 1-k, z)$ *with* $z \in \mathbb{R}$*, and their* α*-limit is an infinite equilibrium.*

(c2) Assume $\kappa(\kappa-1) > 0$*. For any value of the parameters the* α*-limits of the orbits in* $\mathbb{R}^3$ *are the infinite equilibria* S_3 *and* S_4 *and also the positive and negative endpoints of the z-axis. If* $\lambda = 0$ *and* $\kappa < 0$ *all the equilibria of the straight line* $(0, 1-\kappa, z)$ *with* $z \in \mathbb{R}$ *can be also* α*-limit. If* $\lambda < 0$ *and* $\kappa < 0$*, then the finite equilibrium point* P_1 *can be also an* α*-limit.*



For any values of the parameters the ω-limits are the infinite points S_1 and S_2 and also the positive and negative endpoints of the z-axis. If $\lambda = 0$ and $\kappa > 0$, all the finite equilibria of the straight line $(0, 1-\kappa, z)$ with $z \in \mathbb{R}$ can be also ω-limits. If $\lambda > 0$ and $\kappa > 0$, then the finite equilibrium point P_1 can be also an ω-limit.

Theorem 1.7 is proved in Section 5.

$\lambda > 0$ $\lambda = 0, k > 0$ $\lambda = 0, k < 0$ $\lambda < 0$

2 Preliminaries

2.1 Poincaré compactification

2.1.1 Poincaré compactification in dimension 2

Here we introduce the Poincaré compactification, a technique that allows to study the behavior of the orbits of a polynomial differential system near the infinity. This will be used in Sections 4 and 5.

First, we consider the sphere $\mathbb{S}^2 = \{y \in \mathbb{R}^3 : y_1^2 + y_2^2 + y_3^2 = 1\}$, and we call it the *Poincaré sphere*. We identify its tangent plane at the point $(0,0,1)$ with $\mathbb{R}^2$. There, in $\mathbb{R}^2$, we consider a polynomial system of degree d:

$$\dot{x_1} = P_1(x_1, x_2), \quad \dot{x_2} = P_2(x_1, x_2).$$

We get an induced vector field in the northern and southern hemispheres of the sphere with the differential Df^+ and Df^- of the central projections $f^+ : \mathbb{R}^2 \to \mathbb{S}^2$ and $f^- : \mathbb{R}^2 \to \mathbb{S}^2$, defined as $f^{\pm}(x) = \pm(x_1, x_2, 1)/\Delta(x)$, with $\Delta(x) = \sqrt{x_1^2 + x_2^2 + 1}$.

Multiplying the field by y_3^d, we can extend analytically the vector field to the equator, which correspond to the points at infinity of $\mathbb{R}^2$.

This extension is called the *Poincaré compactification* of the original vector field, and the study of this new field near $\mathbb{S}^1$ allows to determine the dynamics of the original field near the infinity.

To make computations we work in the local charts (U_i, ϕ_i) and (V_i, ψ_i) of the sphere $\mathbb{S}^2$, where $U_i = \{y \in \mathbb{S}^2 : y_i > 0\}$, $V_i = \{y \in \mathbb{S}^2 : y_i < 0\}$, $\phi_i : U_i \longrightarrow \mathbb{R}^2$ and $\psi_i : V_i \longrightarrow \mathbb{R}^2$ for $i = 1, 2$ with $\phi_i(y) = \psi_i(y) = (y_m/y_i, y_n/y_i)$ for $m < n$ and $m, n \neq i$.

The expression of the Poincaré compactification in the local chart (U_1, ϕ_1) is

$$(\dot{u}, \dot{v}) = v^d(-uP_1 + P_2, -vP_1), \quad P_i = P_i(1/v, u/v),$$

in the local chart (U_2, ϕ_2) is

$$(\dot{u}, \dot{v}) = v^d(-uP_2 + P_1, -vP_2), \quad P_i = P_i(u/v, 1/v).$$

The expression for the Poincaré compactification in the local charts (V_i, ψ_i), with $i = 1, 2, 3$ is the same as in the local charts (U_i, ϕ_i) multiplied by $(-1)^{d-1}$.

As we want to study the behavior near the infinity, we study the *infinite equilibrium points*, i.e., the equilibrium points of the Poincaré compactification over the equator $\mathbb{S}^1$. If $y \in \mathbb{S}^1$ is an infinite equilibrium point, then $-y$ is also an infinite equilibrium point and they have the same or opposite stability depending on the degree of the system. Then, it is enough to study the infinite equilibrium points in the local chart U_1 and the origin of the local chart U_2.

More information about the Poincaré compactification in dimension 2 can be found in Chapter 5 of [3].

2.1.2 Poincaré compactification in dimension 3

The technique of the Poincaré compactification can be extended to higher dimensions. In particular, we use this technique in dimension 3 in Section 5. As the ideas are the same explained before, we just include here the expressions obtained in the local charts U_1, U_2 and U_3 for a polynomial system in $\mathbb{R}^3$ of degree d

$$\dot{x} = P_1(x, y, z), \quad \dot{y} = P_2(x, y, z), \quad \dot{z} = P_3(x, y, z).$$

More details about the Poincaré compactification in dimension n can be found in [1].

The phase portrait in the local chart U_1 is given by the system

$$(\dot{u}, \dot{v}, \dot{w}) = w^d(-uP_1 + P_2, -vP_1 + P_3, -wP_1), \quad P_i = P_i(1/w, u/w, v/w),$$

where u and v are the coordinates of the tangent plane to the sphere $\mathbb{S}^2$ at the point $(1,0,0)$.

The phase portrait in the local chart U_2 is given by the system

$$(\dot{u},\dot{v},\dot{w}) = w^d(-uP_2 + P_1, -vP_2 + P_3, -wP_2), \quad P_i = P_i(u/w, 1/w, v/w),$$

with the coordinates u, v of the tangent plane to the sphere at $(0,1,0)$.

In the local chart U_3 the phase portrait is given by

$$(\dot{u},\dot{v},\dot{w}) = w^d(-uP_3 + P_1, -vP_3 + P_2, -wP_3), \quad P_i = P_i(u/w, v/w, 1/w),$$

and now u and v are the coordinates of the tangent plane to the sphere $\mathbb{S}^2$ at the point $(0,0,1)$.

The following result is proved in [7].

Lemma 2.1. *Let $f(x,y,z) = 0$ be an algebraic surface of degree m in $\mathbb{R}^3$. The extension of this surface to the boundary of the Poincaré ball is contained in the surface defined by*

$$w^m f\left(\frac{x}{w}, \frac{y}{w}, \frac{z}{w}\right) = 0, \quad w = 0.$$

2.2 Invariant algebraic surfaces and Darboux invariants

We will use the following results (see Theorem 8.7 and Proposition 8.4 of [3], respectively, for a proof):

Proposition 2.2. *Assume that a system (1.1) admit p irreducible invariant algebraic surfaces $f_i = 0$ with cofactors K_i, for $i = 1, \cdots, p$, not all zero such that $\sum_{i=1}^{p} \lambda_i K_i = -s$ for some $s \in \mathbb{R} \setminus 0$, then the function*

$$f_1^{\lambda_1} \cdots f_p^{\lambda_p} e^{st}$$

is a Darboux invariant of that system.

Proposition 2.3. *Suppose $f \in \mathbb{R}[x,y,z]$ and let $f = f_1^{n_1} \cdots f_r^{n_r}$ be its factorization into irreducible factors over $\mathbb{R}[x,y,z]$. Then, for a polynomial system (1.1), $f = 0$ is an invariant algebraic curve with cofactor K_f if and only if $f_i = 0$ is an invariant algebraic curve for each $i = 1 \cdots, r$ with cofactor K_{f_i}. Moreover $K_f = n_1 K_{f_1} + \cdots + n_r K_{f_r}$.*

The following proposition is Proposition 5 of [8].

Proposition 2.4. *Let $\mathbb{S}^2$ be the infinity of the Poincaré ball and $I(x,y,z,t) = f(x,y,z)\ e^{st}$ be a Darboux invariant of a system (1.1). Let also $p \in \mathbb{R}^3$ and $\phi_p(t)$ be the solution of that system (1.1) with maximal interval (α_p, ω_p) such that $\phi_p(0) = p$. Then*

1. *Assume that $s > 0$. If $\omega_p = +\infty$, then $\omega(p)$ is contained in the closure $\overline{\{f(x,y,z) = 0\}}$ in the Poincaré ball, and if $\alpha_p = -\infty$ then $\alpha(p) \subset \overline{\{f(x,y,z) = 0\}} \cap \mathbb{S}^2$, being $\mathbb{S}^2$ the boundary of the Poincaré ball.*

2. *Assume that $s < 0$. If $\alpha_p = -\infty$, then $\alpha(p)$ is contained in $\overline{\{f(x,y,z) = 0\}}$, and if $\omega_p = +\infty$, then $\omega(p) \subset \overline{\{f(x,y,z) = 0\}} \cap \mathbb{S}^2$.*

The following definition and theorem is Definition 3.1 and Theorem 3.2 in [2] (based on the work in [5]).

Let ϕ_t be a smooth flow on a manifold M and suppose C is a submanifold of M consisting entirely of equilibrium points for the flow. C is said to be *normally hyperbolic* if the tangent bundle to M over C splits into three subbundles TC, E^s, and E^u that are invariant under $d\phi_t$

and satisfy: $d\phi_t$ contracts E^s exponentially, $d\phi_t$ expands E^u exponentially and TC is the tangent bundle of C.

For normally hyperbolic submanifolds one has the usual existence of smooth stable and unstable manifolds together with the persistence of these invariant manifolds under small perturbations. More precisely, we have the following theorem.

Theorem 2.5. *Let C be a normally hyperbolic submanifold of equilibrium points for ϕ_t. Then there exist smooth stable and unstable manifolds tangent along C to $E^s \oplus TC$ and $E^u \oplus TC$ respectively. Furthermore, both C and the stable and unstable manifolds are persistent under small perturbations of the flow.*

3 Proof of Propositions 1.1, 1.2, 1.3, 1.5 and Corollary 1.4

3.1 Proof of Proposition 1.1

Let $F(x,y,z) = a_0 + a_1x + a_2y + a_3z + a_4x^2 + a_5xy + a_6xz + a_7y^2 + a_8yz + a_9z^2$ with $a_i \in \mathbb{R}$ and $K = K(x,y,z) = k_0 + k_1x + k_2y + k_3z$ with $k_i \in \mathbb{R}$. If $F(x,y,z) = 0$ is an invariant algebraic surface of a system (1.1), with fixed $\alpha, \beta, \kappa, \lambda \in \mathbb{R}$, with cofactor K it must verify

$$\frac{\partial F}{\partial x}(x(y-1) - \beta z) + \frac{\partial F}{\partial y}(\alpha(1-x^2) - \kappa y) + \frac{\partial F}{\partial z}(x - \lambda z) = (k_0 + k_1x + k_2y + k_3z)F. \tag{3.1}$$

Equating the coefficients of the left-hand side polynomial of (3.1) with the right-hand side polynomial of (3.1) we get a system of 20 equations with 18 unknowns which are a_j for $j = 0, \ldots, 9$, k_i for $i = 0, \ldots, 3$ and α, β, λ and κ. Solving this system of equations with the help of an algebraic manipulator as Mathematica or Maple we obtain the 13 invariant algebraic surfaces F_k given in Table 1.1. This completes the proof of the proposition.

3.2 Proof of Proposition 1.2

We note that if H is a first integral then $H +$ constant is also a first integral. Without loss of generality we can assume that H has no constant term. Moreover, if H is a first integral then CH, where C is a constant, is also a first integral, so the first integrals in Table 1.2 are determined up to multiplication by a constant.

Since a polynomial first integral is an invariant algebraic surface with zero cofactor, from Proposition 1.1, Table 1.1 and Proposition 2.3, Proposition 1.2 is proved. In particular we need to take among the invariant algebraic surfaces in Table 1.1 with zero cofactor also all possible combinations of the invariant algebraic surfaces in Table 1.1 with the respectively non-zero cofactors such that the sum of the cofactors is zero. Thus we obtain the polynomial first integrals F_1, F_2, F_3 and F_6F_7 when $\alpha = \beta = \lambda = \kappa = 0$. Since the constants a, b, c are arbitrary and we look for simple polynomial first integrals, the first integral F_2 becomes the simple first integral $H_1 = y$, and the first integral F_1 is function of the simple first integrals H_1 and $H_2 = x + z - yz$. Moreover F_6F_7 when $\alpha = \beta = \lambda = \kappa = 0$ can be expressed as a function of H_1 and H_2. This completes the proof of the proposition.

3.3 Proof of Proposition 1.3

Since a rational first integral is the quotient of two invariant algebraic surfaces with the same cofactor, Table 1.3 follows from Proposition 1.1, Table 1.1 and Proposition 2.3, taking all possible combinations of the invariant algebraic surfaces in Table 1.1 with the respectively cofactors

and the resulting function is a non-polynomial rational function. To that end, it is taken into account that the sum of invariant surfaces is an invariant surface if the cofactors of both are the same, and also that the product of invariant surfaces is always an invariant surface, with its cofactor being the sum of the corresponding cofactors associated with each of them. Doing so, all possible rational first integrals are: F_{13}/F_4, F_6/F_5, F_{12}/F_8, F_{12}/F_{11}, F_9F_{10}/F_{12}, F_5F_6/F_8, F_5F_6/F_{12}, F_8/F_5^2, F_{12}/F_5^2, F_9F_{10}/F_5^2, F_8/F_6^2, F_{12}/F_6^2. However the unique real simple rational first integral of degree one or two are G_1 (which is obtained from F_8/F_5^2) and G_2 (which is obtained from F_6/F_5) because for the others, they are either polynomial first integrals or can be expressed as a function of G_1 and G_2.

3.4 Proof of Corollary 1.4

From Table 1.2 it follows that system (1.1) under the conditions $\alpha = \beta = \kappa = \lambda = 0$ have the two polynomial first integrals H_1 and H_2. They clearly are independent because H_1 does not depend on x or z while H_2 does depend on these variables. This proves Corollary 1.4.

3.5 Proof of Proposition 1.5

It follows from Propositions 2.2 and 2.3 that to obtain Table 1.4 we need to take all the invariant algebraic surfaces in Table 1.1 such that their cofactors are non-zero constants, or different invariant algebraic surfaces with nonzero constant cofactor such that the product of them to some power (either positive or negative) provide a polynomial or a rational function $f(x,y,z)$ with constant cofactor $-s$, and consequently a Darboux invariant $f(x,y,z)e^{st}$.

The Darboux invariants I_1, I_2, I_3, I_4 and I_6, of Table 1.4 are simple and are obtained from the invariant algebraic surfaces of Table 1.1 as $I_1 = F_5e^{\kappa t}$, $I_1 + I_2 = F_6e^{\kappa t}$, $I_3 = F_7e^{-\kappa t}$, $I_4 + I_1^2 = F_8e^{2\kappa t}$ and $I_6 = F_{12}e^{-\kappa t}$. Moreover, I_5 is a simple Darboux invariant: it is $I_5 = F_{11}e^{2\kappa t}$ if $\kappa(1-\kappa) > 0$, and it is $I_5 = F_9F_{10}e^{2\kappa t}$ if $\kappa(1-\kappa) < 0$.

4 Proof of Theorem 1.6

The family of systems (1.1) under conditions $\alpha = 0$, $\beta = \kappa = -\lambda$ has the first integral $H_2 = x + z - yz$, so on any level $H_2 = h$ we can reduce these systems to the planar polynomial family of systems

$$\dot{y} = -\kappa y, \quad \dot{z} = h + (\kappa - 1)z + yz. \tag{4.1}$$

In this section we study the dynamics of systems (4.1) in the Poincaré disc for any value of $h \in \mathbb{R}$.

Finite equilibrium points

If $\kappa \neq 1$ and $\kappa \neq 0$ systems (4.1) have the unique equilibrium point $(0, h/(1-\kappa))$ which is a stable hyperbolic node if $\kappa \in (0,1)$, an a hyperbolic saddle if $\kappa > 1$ or $\kappa < 0$.

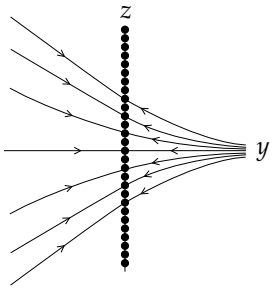
If $\kappa = 1$ and $h = 0$ then system (4.1) has the straight line $y = 0$ filled of equilibrium points. If $\kappa = 1$ and $h \neq 0$ there are no finite equilibrium points on systems (4.1).

If $\kappa = 0$ and $h \neq 0$ then systems (4.1) have the curve $z = h/(1-y)$ filled with equilibrium points. If $\kappa = 0$ and $h = 0$ then system (4.1) has two curves filled with equilibrium points: $z = 0$ and $y = 1$.

When $\kappa = 1$ and $h = 0$ system (4.1) becomes

$$\dot{y} = -y, \quad \dot{z} = yz,$$

and the orbits behave as in Figure 4.1, so the equilibrium points are all stable.



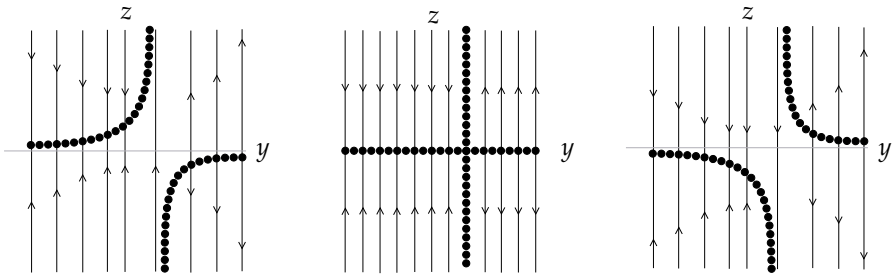


Figure 4.1: Phase portrait around the line $y = 0$ consisting of equilibrium points.

When $\kappa = 0$ systems (4.1) become

$$\dot{y} = 0, \quad \dot{z} = h - z + yz,$$

so all the orbits live in vertical straight lines: if $h > 0$ the orbits are as in Figure 4.2(a), if $h = 0$ then the phase portrait becomes as in Figure 4.2(b), and finally if $h < 0$ the orbits are as in Figure 4.2(c).

(a) $h > 0$ (b) $h = 0$ (c) $h < 0$

Figure 4.2: Finite phase portraits of systems (4.1) with $\kappa = 0$.

Infinite equilibrium points

In order to study the dynamics of systems (4.1) at infinity, we will use the Poincaré compactification introduced in subsection 2.1.1. We only consider the case $\kappa \neq 0$, as the phase portrait in the case $\kappa = 0$ can be totally determined with the finite phase portrait.

In the local chart U_1 systems (4.1) have the expression

$$\dot{u} = u + (2\kappa - 1)uv + hv^2, \quad \dot{v} = \kappa v^2. \tag{4.2}$$

If $\kappa \neq 0$, the only equilibrium point at infinity is the origin of the systems. This point is a semi-hyperbolic equilibrium point. Applying Theorem 2.19 of [3] it is a saddle-node for any $\kappa \neq 0$.

In the local chart U_2 systems(4.1) have the expression

$$\dot{u} = -u^2 - (2\kappa - 1)uv - huv^2, \quad \dot{v} = -uv - (\kappa - 1)v^2 - hv^3. \tag{4.3}$$

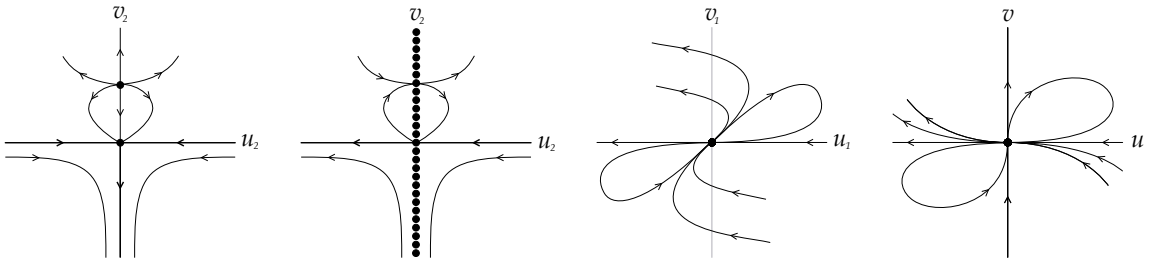
The only point we need to study in the local chart U_2 is the origin, and it is linearly zero.

We will study the local phase portrait at the origin of the chart U_2 doing vertical blow-ups. Since the characteristic directions at the origin of system (4.3) are given by the factors of the polynomial $\kappa u(v-2)v^2 = 0$ when $\kappa \neq 0$, we need to do a twist $(u, v) = (u_1 - v_1, v_1)$ because $u = 0$ is a characteristic direction. When $\kappa = 0$ all the directions are characteristic. In the new coordinates (u_1, v_1) system (4.3) becomes

$$\dot{u_1} = -u_1^2 + 2(1-\kappa)u_1v_1 + \kappa v_1^2 - hu_1v_1^2, \quad \dot{v_1} = -v_1(u_1 + (\kappa - 2)v_1 + hv_1^2). \tag{4.4}$$

Now we do the vertical blow up $(u_1, v_1) = (u_2, u_2v_2)$ and system (4.4) becomes

$$\dot{u_2} = -u_2^2(1 + 2(\kappa - 1)v_2 - \kappa v_2^2 + hu_2v_2^2), \quad \dot{v_2} = -\kappa u_2(v_2 - 1)v_2^2. \tag{4.5}$$

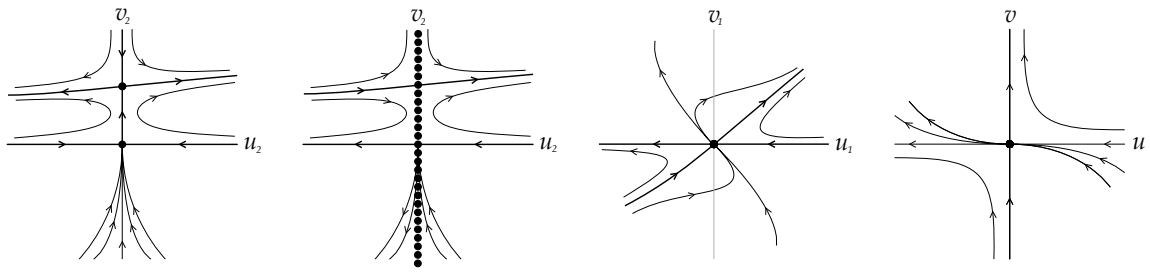


Since u_2 is a common factor of $\dot{u_2}$ and $\dot{v_2}$ we rescale the time and we get the differential system

$$\dot{u_2} = -u_2(1 + 2(\kappa - 1)v_2 - \kappa v_2^2 + hu_2v_2^2), \quad \dot{v_2} = -\kappa(v_2 - 1)v_2^2. \tag{4.6}$$

This system has on the straight line $u_2 = 0$ two equilibrium points: $(0, 0)$ and $(0, 1)$. As $\kappa \neq 0$ by Theorem 2.19 of [3] the point $(0, 0)$ is a saddle-node.

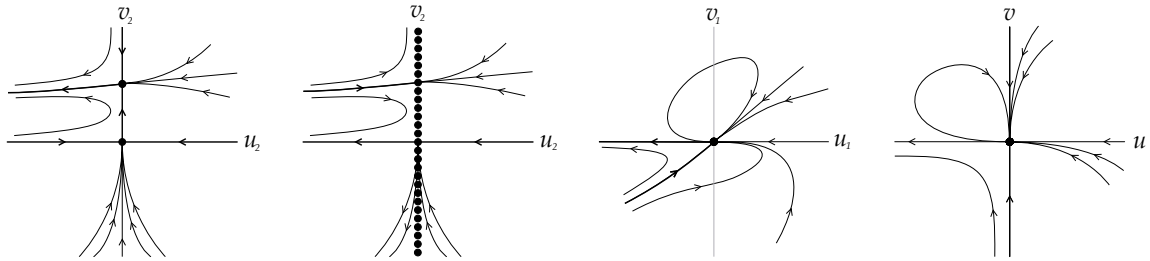
If $\kappa < 0$ the point $(0, 1)$ is a hyperbolic unstable node, and if $\kappa \in (0, 1)$ it is a hyperbolic saddle, if $\kappa = 1$ it is a semihyperbolic saddle node if $h \neq 0$ and it is not isolated if $h = 0$, and if $\kappa > 1$ it is a hyperbolic stable node.



Assume $\kappa < 0$. Then for system (4.6) the origin is a saddle-node and the point $(0, 1)$ is an unstable node, and in Figure 4.3(a) we include the local phase portrait of this system in a neighborhood of the straight line $u_2 = 0$. If we multiply by u_2 to return to system (4.5), then all points on the u_2-axis become equilibrium points, and the orientation of the orbits in the second and third quadrants are reversed. Thus we obtain the phase portrait of Figure 4.3(b) for system (4.5) around the straight line $u_2 = 0$. Now we undo the blow up to obtain the local phase portrait at the origin of system (4.4). We must take into account that for this system the u_1-axis is invariant and as $\dot{u_1}|_{u_1=0} = -u_1^2$, then over this axis the flow points in the negative direction. The v_1-axis is not invariant, and we have that $\dot{u_1}|_{u_1=0} = kv_1^2$ and $\dot{v_1}|_{u_1=0} = (2-k)v_1^2 - hv_1^3$, so in a neighborhood of the origin, over the v_1 axis, the flow points in the negative u_1-direction and in the positive v_1-direction. Then we obtain the local phase portrait in Figure 4.3(c) for system (4.4) . Finally, if we undo the twist, we obtain the local phase portrait at the origin of the local chart U_2, which is given in Figure 4.3(d).

(a) (b) (c) (d)

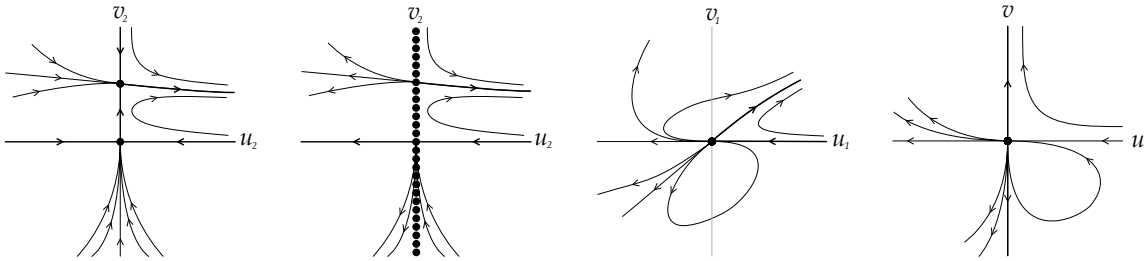
Figure 4.3: Blowing down of the origin of system (4.3) with $\kappa < 0$.



Assume now that $\kappa \in (0,1)$. In Figure 4.4(a) we plotted the local phase portrait of system (4.6) in a neighborhood of the straight line $u_2 = 0$. In Figure 4.4(b) there is the phase portrait of system (4.5) around the straight line $u_2 = 0$ and in Figure 4.4(c) at the origin of system (4.4). Finally in Figure 4.4(d) there is the local phase portrait at the origin of the local chart U_2.

(a) (b) (c) (d)

Figure 4.4: Blowing down of the origin of the system (4.3) with $\kappa \in (0,1)$.

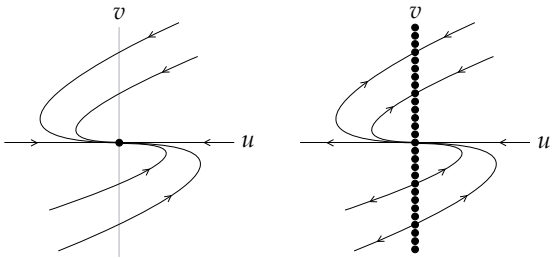


For $\kappa = 1$ and $h > 0$, in Figure 4.5(a) we plotted the local phase portrait of system (4.6) in a neighborhood of the straight line $u_2 = 0$. In Figure 4.5(b) there is the phase portrait of system (4.5) around the straight line $u_2 = 0$ and in Figure 4.5(c) at the origin of system (4.4). Finally in Figure 4.5(d) there is the local phase portrait at the origin of the local chart U_2.

(a) (b) (c) (d)

Figure 4.5: Blowing down of the origin of the system (4.3) with $\kappa = 1$ and $h > 0$.

Assume that $\kappa = 1$ and $h < 0$. In Figure 4.6(a) we plotted the local phase portrait of system (4.6) in a neighborhood of the straight line $u_2 = 0$. In Figure 4.6(b) there is the phase portrait of system (4.5) around the straight line $u_2 = 0$ and in Figure 4.6(c) at the origin of system (4.4). Finally in Figure 4.6(d) there is the local phase portrait at the origin of the local chart U_2.

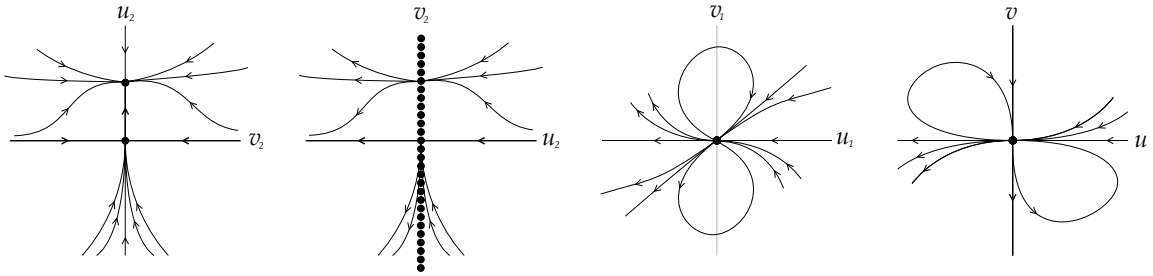


(a) (b) (c) (d)

Figure 4.6: Blowing down of the origin of the system (4.3) with $\kappa = 1$ and $h < 0$.

If $\kappa = 1$ and $h = 0$, the line $u = 0$ is filled of equilibrium points. We eliminate the common factor u rescaling the time and we get the differential system

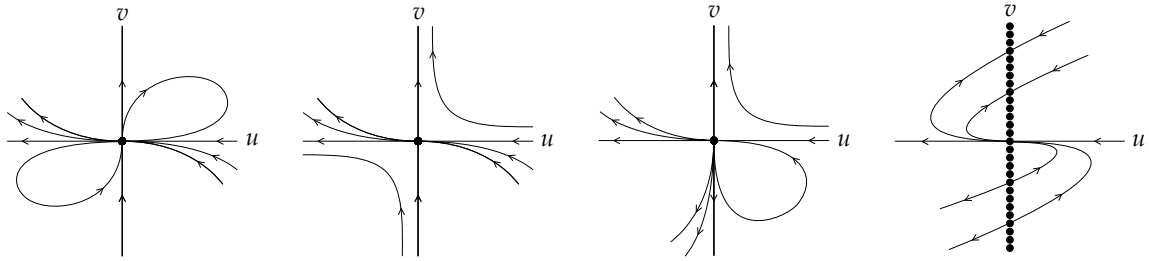
$$\dot{u} = -u - v, \qquad \dot{v} = -v. \tag{4.7}$$



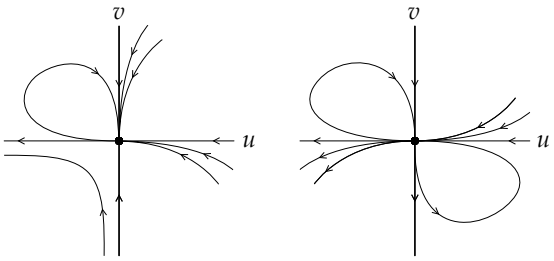
The local phase portrait of system (4.7) is shown in Figure 4.7(a), and the local phase portrait at the origin of U_2 is given in Figure 4.7(b).

(a) (b)

Figure 4.7: Phase portrait at the origin of the system (4.3) with $\kappa = 1$ and $h = 0$.



Finally, for $\kappa > 1$, in Figure 4.8(a) we plotted the local phase portrait of system (4.6) in a neighborhood of the straight line $u_2 = 0$. In Figure 4.8(b) there is the phase portrait of system (4.5) around the straight line $u_2 = 0$ and in Figure 4.8(c) at the origin of system (4.4). Finally in Figure 4.8(d) there is the local phase portrait at the origin of the local chart U_2.



(a) (b) (c) (d)

Figure 4.8: Blowing down of the origin of the system (4.3) with $\kappa \in (1, 2)$.

Summarizing, all the possible phase portraits at the origin of the local chart U_2 for $k \neq 0$, are given in Figure 4.9.

$L_1\ (\kappa < 0)$ $L_2\ (\kappa \in (0,1))$ $L_3\ (\kappa = 1,\ h < 0)$ $L_4\ (\kappa = 1,\ h = 0)$

$L_5\ (\kappa = 1,\ h > 0)$ $L_6\ (\kappa > 1)$

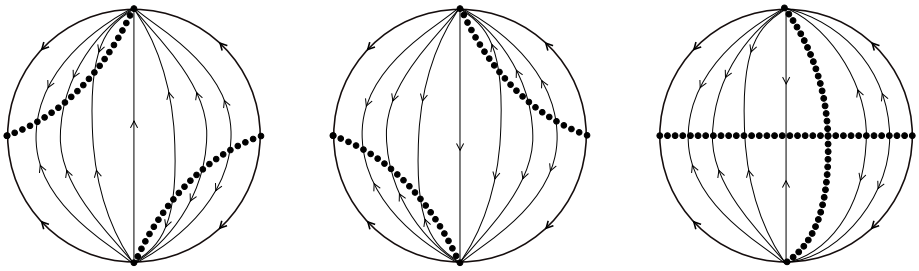


Figure 4.9: Phase portraits of the origin of U_2.

4.1 Phase portraits in the Poincaré disc

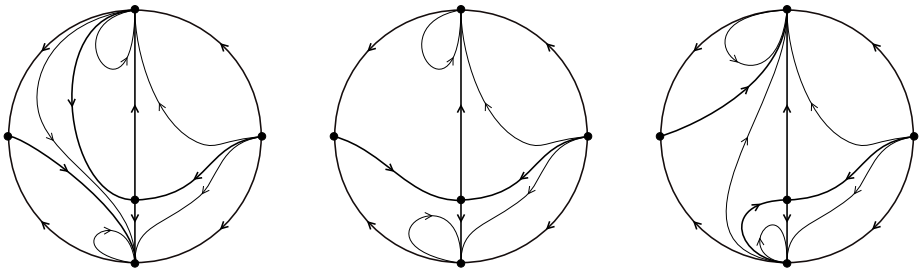
In this subsection we give the topological classification of all phase portraits of systems (4.1) stated in Theorem 1.6.

We bring together the local information previously obtained. In some cases the local information gives rise to only one phase portrait in the Poincaré disc, this occurs when the separatrices can be connected in only one way, but in other cases several phase portraits in the Poincaré disc are possible, and we shall prove which of them are feasible.

Case $\kappa = 0$. In this case there exists a continuum of equilibrium points given by the curve $z = h/(1-y)$, and the finite phase portrait completely defines the phase portrait in the Poincaré disc. The infinite equilibrium points are also contained in this continuum. All the orbits in the finite region are contained in vertical straight lines. We will have three different phase portraits depending on whether $h > 0$, $h = 0$ or $h < 0$, because the sign of h determines the position of the continuum of equilibria and the orientation of the orbits. In the case in which h is zero, the curve of equilibrium points previously mentioned becomes the y-axis, and we have another straight line filled of equilibrium points, which is $y = 1$. The three possibilities are given in Figure 4.10. Cases with $h > 0$ and $h < 0$ are topologically equivalent by doing a symmetry with respect to the y-axis, so in the classification it is enough to consider one of them, which is G1 in Figure 1.1. The case with $h = 0$ is G2 in Figure 1.1.

$h > 0$ $h < 0$ $h = 0$

Figure 4.10: Possible phase portraits of systems (4.1) with $\kappa = 0$.

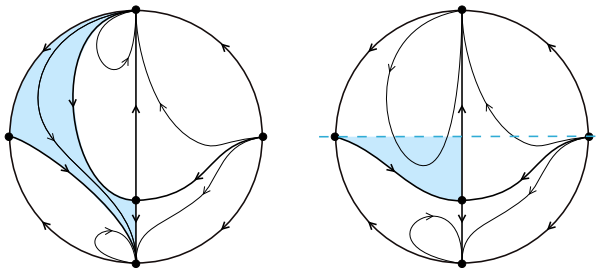


Case $\kappa \in (0,1)$. In this case there exist the finite equilibrium point P which is a stable node, the origin of U_1 is a saddle-node and the origin of U_2 has the local phase portrait L_2. We recall that the origin of the local charts V_1 and V_2 have the same phase portraits as the origin of the local charts U_1 and U_2, respectively, but reversing the orientation of the orbits. Then, we obtain only one possible phase portrait, which is G3 in Figure 1.1. Note that in the figure the point P is represented in the positive part of the z-axis, which corresponds to $h > 0$. For the case $h < 0$ the point is over the negative part of the z-axis, but these phase portraits are topologically equivalent.

Case $\kappa = 1$, $h \neq 0$. There are not finite equilibrium points, the origin of U_1 has the local phase portrait L_{11} and the origin of U_2 has the local phase portrait L_{24} if $h > 0$, and L_{25} if $h < 0$. In both cases there are only one way to connect the separatrices. In the case $h > 0$ we obtain the global phase portrait G4 in Figure 1.1, and in the case $h < 0$ we obtain a topologically equivalent phase portrait, obtained by a symmetry with respect to the y-axis.

Case $\kappa = 1$, $h = 0$. The z-axis is a continuum of equilibrium points, and then the origin of charts U_2 and V_2 are contained in this continuum, and the finite orbits are as in Figure 4.1. The origin of chart U_1 has the local phase portrait L_{11}. There is only one possible global configuration in this case, which is G5 in Figure 1.1.

Case $\kappa > 1$. In this case the finite equilibrium point P is a saddle, the origin of U_1 is a saddle-node and the origin of U_2 has the local phase portrait L_6.

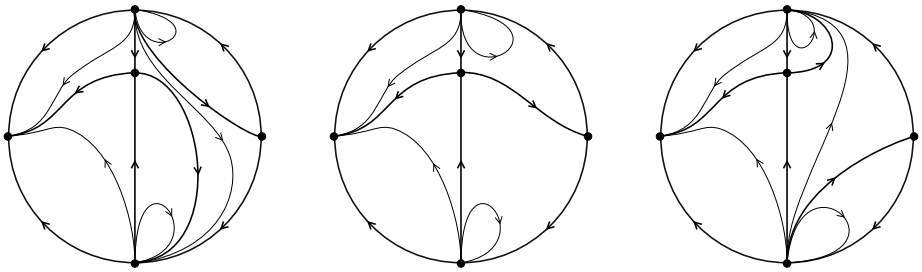


We first consider $h > 0$. The separatrices can be connected in three ways, giving rise to the three phase portraits given in Figure 4.11.

Case 1 Case 2 Case 3

Figure 4.11: Possible phase portraits of systems (4.1) with $\kappa > 1$, $h > 0$.

We can prove that the two first cases of Figure 4.11 are not possible. The flow over the horizontal axis points upward as $\dot{z}|_{z=0} = h > 0$. In Figure 4.12 we can see two shaded regions. In the shaded region of case 1 the flow points downwards over the horizontal axis, so that configuration is not possible. If we take any point in the shaded region of case 2, the orbit passing through that point starts and ends in the origin of the local chart U_2, so at some point of the z-axis the flow points downwards, so this case is also not possible. The only possible phase portrait is the one in case 3, which corresponds to G6 in Figure 1.1.



Case 1 Case 2

Figure 4.12: Regions that allow us to prove that the flow points downwards over the z-axis.

For the case with $h < 0$ an analogous reasoning can be done. The obtained phase portrait is topologically equivalent to G6 by doing a symmetry with respect to the y-axis.

Case $\kappa < 0$. As in the previous case, the finite equilibrium point P is a saddle, but the origin of U_1 is a saddle-node, and the origin of U_2 has the local phase portrait L_1.

We consider $h > 0$. We can connect the separatrices in three forms, giving rise to the three phase portraits given in Figure 4.13.

Case 1 Case 2 Case 3

Figure 4.13: Possible phase portraits of systems (4.1) with $\kappa < 0$.

Cases 1 and 2 are not possible and an analogous reasoning to the previous case works, as we find that the flow point downwards at some points of the y-axis, which contradicts the fact that $\dot{z}|_{z=0} = h > 0$. The only feasible phase portrait is case 3, which is topologically equivalent to G6 in Figure 1.1, by doing a symmetry with respect to the x-axis, a symmetry with respect to the z-axis and reversing the orientation.

For the case with $h < 0$ we obtain analogous results. The obtained phase portrait is topologically equivalent to case 3 by doing a symmetry with respect to the y-axis.

Summarizing the information in this section, we can conclude that systems (4.1) can present six topologically different phase portraits, given in Figure 1.1 and according to the classification given in Table 4.1.

Conditions	**Phase portrait**
$\kappa = 0,\ h \neq 0$	G1
$\kappa = 0,\ h = 0$	G2
$\kappa \in (0,1)$	G3
$\kappa = 1,\ h \neq 0$	G4
$\kappa = 1,\ h = 0$	G5
$\kappa > 1$	G6
$\kappa < 0$	

Table 4.1: Classification of phase portraits of systems (4.1).

5 Proof of Theorem 1.7

We consider systems (1.1) under conditions $\alpha = \kappa(1-\kappa) \neq 0$, $\beta = 0$, i.e.,

$$\dot{x} = x(y-1), \quad \dot{y} = \kappa(1-\kappa)(1-x^2) - \kappa y, \quad \dot{z} = x - \lambda z. \tag{5.1}$$

These systems have the Darboux invariant $I_5 = ((\kappa - 1 + y)^2 + \kappa(1-\kappa)x^2)e^{2\kappa t}$.

Finite equilibrium points

We study the finite equilibrium points of systems (5.1).

We first consider the case $\kappa(1-\kappa) > 0$ (i.e. $\kappa \in (0,1)$). If $\lambda \neq 0$, the unique equilibrium point is $P_1 = (0, 1-\kappa, 0)$ contained in $F_{11} = 0$. The Jacobian matrix of systems (5.1) at P_1 has eigenvalues $-\kappa$ with multiplicity two and $-\lambda$. Hence, if $\lambda > 0$ it is a local attractor, and if $\lambda < 0$ it has a 2-dimensional stable manifold and a 1-dimensional unstable manifold. If $\lambda = 0$ then the straight line $(0, 1-\kappa, z)$ with $z \in \mathbb{R}$ is filled of equilibria. The eigenvalues of the Jacobian matrix at any of these points are $-\kappa$ with multiplicity two and 0. All equilibrium points are normally hyperbolic and in view of Theorem 2.5 taking into account that in this case we have $\kappa \in (0,1)$ we get that to each equilibrium point arrives a 2-dimensional stable manifold.

Consider now the case $\kappa(1-\kappa) < 0$ (i.e. $\kappa < 0$ or $\kappa > 1$). If $\lambda \neq 0$ there are three equilibrium points which are

$$P_1 = (0, 1-\kappa, 0), \quad P_2 = \Big(\sqrt{\frac{\kappa}{\kappa-1}}, 1, \frac{1}{\lambda}\sqrt{\frac{\kappa}{\kappa-1}}\Big), \quad P_3 = -\Big(\sqrt{\frac{\kappa}{\kappa-1}}, -1, \frac{1}{\lambda}\sqrt{\frac{\kappa}{\kappa-1}}\Big).$$

All three equilibrium points are contained in $F_9 F_{10} = 0$. The eigenvalues of the Jacobian matrix at the equilibrium point P_1 are $-\kappa$ with multiplicity two and $-\lambda$. Hence, P_1 is a local attractor if $\kappa > 1$ and $\lambda > 0$; has a 2-dimensional stable manifold and a 1-dimensional unstable manifold if $\kappa > 1$ and $\lambda < 0$; it is a local repeller if $\kappa, \lambda < 0$, and it has a 2-dimensional

unstable manifold and a 1-dimensional stable manifold if $\kappa < 0$ and $\lambda > 0$. On the other hand the eigenvalues of the Jacobian matrix at the equilibrium points P_2 and P_3 are $-\lambda$, -2κ and κ. Therefore, both equilibrium points have a 2-dimensional stable manifold and a 1-dimensional unstable manifold if either $\kappa > 1$ and $\lambda > 0$, or $\kappa < 0$ and $\lambda > 0$; and they have a 2-dimensional unstable manifold and a 1-dimensional stable manifold if either $\kappa, \lambda < 0$, or $\kappa > 1$ and $\lambda < 0$.

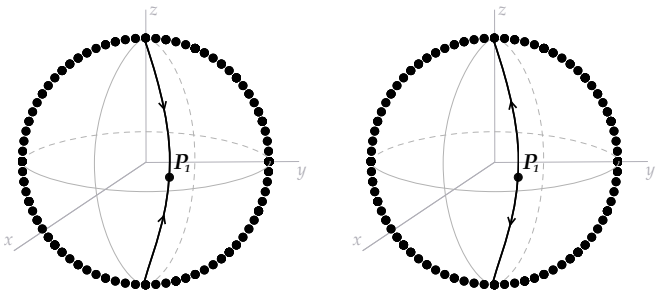
Conditions	**Finite equilibrium points**
$\kappa \in (0,1)$, $\lambda > 0$	P_1 stable node
$\kappa \in (0,1)$, $\lambda < 0$	P_1 saddle (stable manifold of dimension 2)
$\kappa > 1$, $\lambda > 0$	P_1 stable node, P_2 and P_3 saddles (stable manifold of dimension 2)
$\kappa > 1$, $\lambda < 0$	P_1 saddle (stable manifold of dimension 2), P_2 and P_3 saddles (unstable manifold of dimension 2)
$\kappa < 0$, $\lambda < 0$	P_1 unstable node, P_2 and P_3 saddles (unstable manifold of dimension 2)
$\kappa < 0$, $\lambda > 0$	P_1 saddle (unstable manifold of dimension 2), P_2 and P_3 saddles (stable manifold of dimension 2)

Table 5.1: Local behavior of the finite equilibrium points of systems (5.1) with $\lambda \neq 0$.

If $\lambda = 0$ the straight line $(0, 1-\kappa, z)$ with $z \in \mathbb{R}$ is filled of equilibria. The eigenvalues of the Jacobian matrix at any of these points are $-\kappa$ with multiplicity two and 0. All equilibrium points are normally hyperbolic and in view of Theorem 2.5 we have that if $\kappa > 1$ then to each equilibrium point arrives a 2-dimensional stable manifold, and if $\kappa < 0$ at each equilibrium point starts a 2-dimensional unstable manifold.

Dynamics on the invariant surfaces

We consider two different cases: $\kappa(1-\kappa) > 0$ and $\kappa(1-\kappa) < 0$.



Case $\kappa(1-\kappa) > 0$

In this case $F_{11} = 0$ corresponds to the straight line $(0, 1-\kappa, z)$ with $z \in \mathbb{R}$. The dynamics on this straight line is given by $\dot{z} = -\lambda z$.

If $\lambda > 0$ the points over this straight line have their α-limit at the endpoints of the z-axis in the sphere, and their ω-limit in P_1. If $\lambda < 0$ the points over this straight line have their α-limit at P_1 and their ω-limit at the endpoints of the z-axis in the sphere. This is represented in Figure 5.1. Note that if $\lambda = 0$ the straight line is filled with equilibria.

Case $\kappa(1-\kappa) < 0$

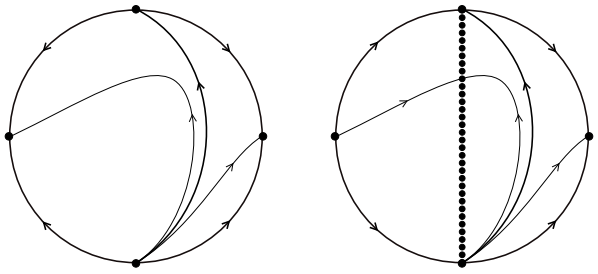
We will study the dynamics on $F_9 = 0$ and on $F_{10} = 0$.

$\lambda > 0$ $\lambda < 0$

Figure 5.1: Phase portraits in the Poincaré disc for systems (5.2) and (5.3).

Dynamics on $F_9 = 0$

We note that systems (5.1) restricted to $F_9 = \kappa - 1 - \sqrt{\kappa(\kappa-1)}x + y = 0$ by setting $y = 1 - \kappa + \sqrt{\kappa(\kappa-1)}x$ are



$$\dot{x} = x\left(\sqrt{\kappa(\kappa-1)}x - \kappa\right), \quad \dot{z} = x - \lambda z. \tag{5.2}$$

When $\lambda \neq 0$, there are two equilibrium points $Q_1 = (0,0)$ and $Q_2 = \frac{\sqrt{\kappa(\kappa-1)}}{\kappa-1}(1, 1/\lambda)$. The eigenvalues of the Jacobian matrix at Q_1 are $-\kappa$, $-\lambda$ and the eigenvalues of the Jacobian matrix at Q_2 are κ and $-\lambda$. Hence, Q_1 is a stable node when $\kappa, \lambda > 0$; an unstable node when $\kappa, \lambda < 0$, and a saddle when $\kappa\lambda < 0$. On the other hand Q_2 is a stable node when $\kappa < 0$ and $\lambda > 0$; an unstable node when $\kappa > 0$ and $\lambda < 0$, and a saddle when $\kappa\lambda > 0$.

If $\lambda = 0$ then $x = 0$ is filled with equilibrium points. Removing the common factor x between $\dot{x}$ and $\dot{z}$ with a rescaling of the time we get that system (5.2) when $\lambda = 0$ becomes

$$\dot{x} = \sqrt{\kappa(\kappa-1)}x - \kappa, \quad \dot{z} = 1. \tag{5.3}$$

This linear system has the phase portrait in Figure 5.2(a) for $k > 0$, and so system (5.2) with $\lambda = 0$ has the phase portrait in Figure 5.2(b) for $k > 0$. In the cases with $k < 0$ the phase portrait is the same but doing a symmetry with respect to the z-axis and changing the time t into $-t$.

(a) (b)

Figure 5.2: Phase portraits in the Poincaré disc for systems (5.2) and (5.3).

From now on we focus on the study of system (5.2) with $\lambda \neq 0$. Note that system (5.2) has the invariant straight lines $x = 0$ and $\sqrt{\kappa(\kappa-1)}x - \kappa = 0$ that contain the equilibrium points. Therefore there cannot be periodic orbits.

Now we study system (5.2) in the Poincaré disc. We first study it on the local chart U_1. On the local chart U_1 system (5.2) takes the form

$$\dot{u} = -\sqrt{\kappa(\kappa-1)}u + v + (\kappa-\lambda)uv, \quad \dot{v} = v(-\sqrt{\kappa(\kappa-1)} + \kappa v).$$

The unique equilibrium point on $v = 0$ is the origin $(0,0)$. The Jacobian matrix at that point has the eigenvalue $-\sqrt{\kappa(\kappa-1)}$ with multiplicity two and so the origin of the local chart U_1 is a stable node.

On the local chart U_2 system (5.2) takes the form

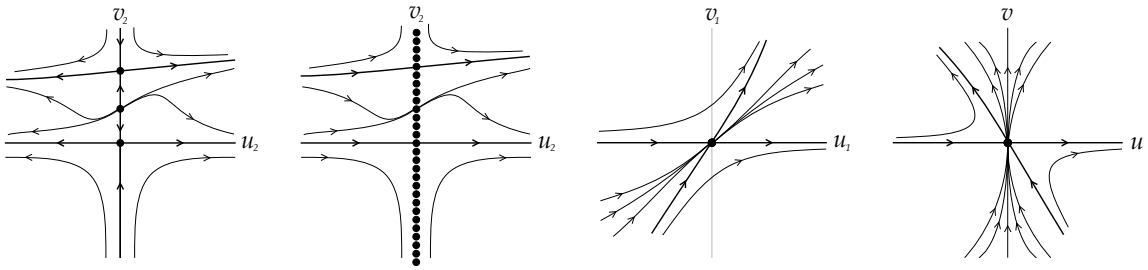
$$\dot{u} = u\left(\sqrt{\kappa(\kappa-1)}u + (\lambda-\kappa)v - uv\right), \quad \dot{v} = v^2(\lambda-u). \tag{5.4}$$

The origin is an equilibrium point. The Jacobian matrix at that point is the zero matrix, so in order to study its local phase portrait we need to do blow-ups. Since the characteristic directions at the origin of system (5.4) are given by the factors of the polynomial $uv(\sqrt{\kappa(\kappa-1)}u - \kappa v) = 0$, we need to do a twist $(u,v) = (u_1 - v_1, v_1)$ because $u = 0$ is a characteristic direction. In the new coordinates (u_1, v_1) system (5.4) becomes

$$\begin{aligned} \dot{u_1} &= \sqrt{\kappa(\kappa-1)}u_1^2 - \left(\kappa - \lambda + 2\sqrt{\kappa(\kappa-1)}\right)u_1v_1 + \left(\kappa + \sqrt{\kappa(\kappa-1)}\right)v_1^2 - u_1^2v_1 + u_1v_1^2, \\ \dot{v_1} &= v_1^2(\lambda - u_1 + v_1). \end{aligned} \tag{5.5}$$

Now we do the vertical blow up $(u_1, v_1) = (u_2, u_2v_2)$ and system (5.5) becomes

$$\begin{aligned} \dot{u_2} &= u_2^2\left(\sqrt{\kappa(\kappa-1)} - \left(\kappa - \lambda + 2\sqrt{\kappa(\kappa-1)}\right)v_2 - u_2v_2 + \left(\kappa + \sqrt{\kappa(\kappa-1)}\right)v_2^2 + u_2v_2^2\right), \\ \dot{v_2} &= u_2v_2(v_2-1)\left(\sqrt{\kappa(\kappa-1)} - \left(\kappa + \sqrt{\kappa(\kappa-1)}\right)v_2\right). \end{aligned} \tag{5.6}$$

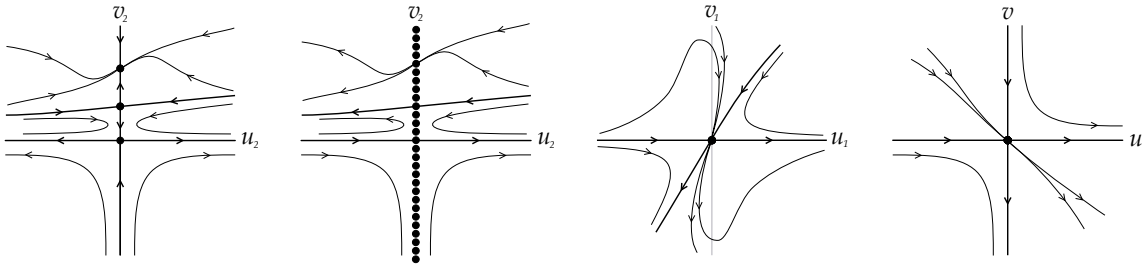


Since u_2 is a common factor of $\dot{u_2}$ and $\dot{v_2}$ we rescale the time and we get the differential system

$$\begin{aligned} \dot{u_2} &= u_2\left(\sqrt{\kappa(\kappa-1)} - \left(\kappa - \lambda + 2\sqrt{\kappa(\kappa-1)}\right)v_2 - u_2v_2 + \left(\kappa + \sqrt{\kappa(\kappa-1)}\right)v_2^2 + u_2v_2^2\right), \\ \dot{v_2} &= v_2(v_2-1)(\sqrt{\kappa(\kappa-1)} - (\kappa + \sqrt{\kappa(\kappa-1)})v_2). \end{aligned} \tag{5.7}$$

This system has on the straight line $u_2 = 0$ three equilibrium points: $(0,0)$, $(0,1)$ and $\left(0, \frac{\sqrt{\kappa(\kappa-1)}}{\kappa+\sqrt{\kappa(\kappa-1)}}\right)$. The equilibrium point $(0,0)$ is a hyperbolic saddle. The equilibrium point $(0,1)$ is a hyperbolic stable node if $\lambda < 0$ and $\kappa > 0$; a hyperbolic unstable node if $\lambda > 0$ and $\kappa < 0$, and a hyperbolic saddle if $\lambda\kappa > 0$. Finally the equilibrium point $\left(0, \frac{\sqrt{\kappa(\kappa-1)}}{\kappa+\sqrt{\kappa(\kappa-1)}}\right)$ is a hyperbolic saddle if $\lambda\kappa < 0$, a hyperbolic stable node if $\lambda, \kappa < 0$ and a hyperbolic unstable node if $\lambda, \kappa > 0$. The equilibrium point $\left(0, \frac{\sqrt{\kappa(\kappa-1)}}{\kappa+\sqrt{\kappa(\kappa-1)}}\right)$ is greater than the point $(0,1)$ if $\kappa < 0$ and is between the points $(0,0)$ and $(0,1)$ if $\kappa > 1$.

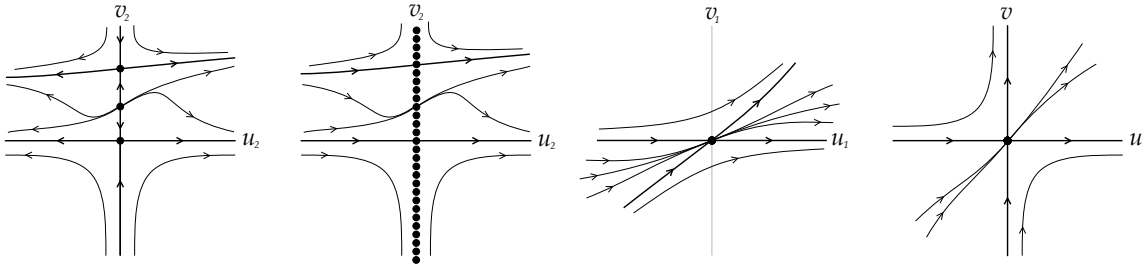
Assume $\kappa < 0$ and $\lambda > 0$, in Figure 5.3(a) we plotted the local phase portrait of system (5.7) in a neighborhood of the straight line $u_2 = 0$. In Figure 5.3(b) there is the phase portrait



of system (5.6) around the straight line $u_2 = 0$ and in Figure 5.3(c) at the origin of system (5.5). Finally in Figure 5.3(d) there is the local phase portrait at the origin of the local chart U_2.

(a) (b) (c) (d)

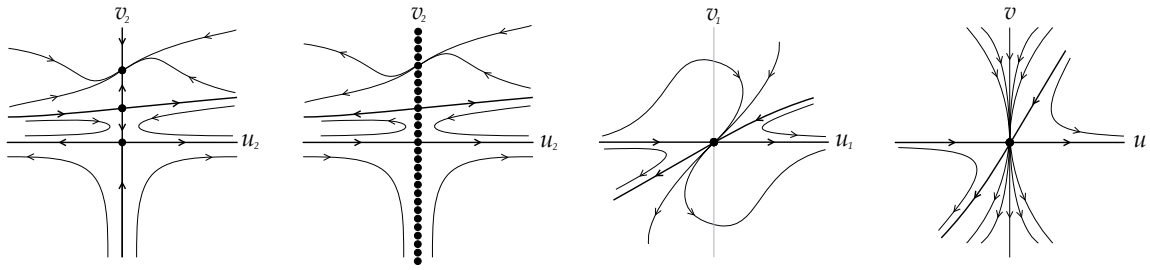
Figure 5.3: Blowing down of the origin of the system (5.4) with $\kappa < 0$ and $\lambda > 0$.



Now consider $\kappa < 0$ and $\lambda < 0$. In Figure 5.4(a) we plotted the local phase portrait of system (5.7) in a neighborhood of the straight line $u_2 = 0$. In Figure 5.4(b) there is the phase portrait of system (5.6) around the straight line $u_2 = 0$ and in Figure 5.4(c) at the origin of system (5.5). Finally in Figure 5.4(d) there is the local phase portrait at the origin of the local chart U_2.

(a) (b) (c) (d)

Figure 5.4: Blowing down of the origin of the system (5.4) with $\kappa < 0$ and $\lambda < 0$.



For $\kappa > 1$ and $\lambda > 0$, in Figure 5.5(a) we plotted the local phase portrait of system (5.7) in a neighborhood of the straight line $u_2 = 0$. In Figure 5.5(b) there is the phase portrait of system (5.6) around the straight line $u_2 = 0$ and in Figure 5.5(c) at the origin of system (5.5). Finally in Figure 5.5(d) there is the local phase portrait at the origin of the local chart U_2.

(a) (b) (c) (d)

Figure 5.5: Blowing down of the origin of the system (5.4) with $\kappa > 1$ and $\lambda > 0$.

Consider $\kappa > 1$ and $\lambda < 0$. In Figure 5.6(a) we plotted the local phase portrait of system (5.7) in a neighborhood of the straight line $u_2 = 0$. In Figure 5.6(b) there is the phase portrait of system (5.6) around the straight line $u_2 = 0$ and in Figure 5.6(c) at the origin of system (5.5). Finally in Figure 5.6(d) there is the local phase portrait at the origin of the local chart U_2.

(a) (b) (c) (d)

Figure 5.6: Blowing down of the origin of the system (5.4) with $\kappa > 1$ and $\lambda < 0$.

Phase portraits in the Poincaré disc

Taking into account the local information obtained for the finite and infinite equilibrium points, now we study the local phase portraits in the Poincaré disc. In all the cases the local information gives rise to only one phase portrait, as the separatrices can be connected only in one way.

Case $\lambda > 0$, $k > 0$. In this case the origin is a stable node and the equilibrium point Q_2 is a saddle and it is on the first quadrant. The origin of the local chart U_1 is a stable node and the origin of U_2 has the phase portrait in Figure 5.5(d). The equilibrium point Q_2 is contained in the invariant straight line $\sqrt{\kappa(\kappa-1)}x - \kappa = 0$, and over this line are the two stable separatrices of the saddle Q_2. The unstable separatrices have only one possible ω-limit for each of them: one goes to the origin and the other to the origin of the local chart U_2. Then we have the phase portrait given in Figure 1.2(a).

Case $\lambda > 0$, $k < 0$. In this case the origin is a saddle and the equilibrium point Q_2 is a stable node and it is on the third quadrant. The origin of the local chart U_1 is a stable node and the origin of U_2 has the phase portrait in Figure 5.3(d). The separatrix that leaves the origin in the half of the disc corresponding to the positive x-axis, goes to the origin of U_2. There are three separatrices in the half of the disc corresponding to the negative x-axis, and for the three of them the only possible ω-limit is the equilibrium point Q_2. Then we have a phase portrait which is topologically equivalent to the one in Figure 1.2(a) by moving the equilibrium point Q_2 into the origin and thus the origin into the first quadrant.

Case $\lambda < 0$, $k > 0$. In this case the origin is a saddle and the equilibrium point Q_2 is an unstable node and it is on the fourth quadrant. The origin of the local chart U_1 is a stable node and the origin of U_2 has the phase portrait in Figure 5.6(d). Similar to the previous case, there are three separatrices in the half of the disc corresponding to the positive x-axis whose only possible α-limit is the origin of U_2. The α-limit of the other stable separatrix of the origin is the origin of the local chart V_2. The phase portrait obtained is the one of Figure 1.2(b). It is topologically equivalent to the one of Figure 1.2(a) doing a symmetry with respect to the z-axis and changing t into $-t$, but we include it in order to study the $\alpha-$ and ω-limits.

Case $\lambda < 0$, $k < 0$. In this case the origin is an unstable node and the equilibrium point Q_2

is a saddle and it is on the second quadrant. The origin of the local chart U_1 is a stable node and the origin of U_2 has the phase portrait of Figure 5.4(d). The two unstable separatrices of Q_2 are over the invariant line $\sqrt{\kappa(\kappa-1)}x-\kappa=0$ and the stable separatrices have as α-limit the origin and the origin of the local chart V_2. The phase portrait in this case is topologically equivalent to the one of Figure 1.2(b) by moving the equilibrium point Q_2 into the origin.

Summarizing, we have included four phase portraits in Figure 1.2, attending to the orientations of the orbits, but note that phase portraits (a) and (b) of Figure 1.2 are topologically equivalent, and also phase portraits (c) and (d) are topologically equivalent.

Taking into account these phase portraits we analyze the α- and ω-limits of the orbits in the invariant plane $F_9=0$.

If $\lambda>0$ all the points in the invariant plane have their ω-limit at the point Q_9 or at a point at infinity, and their α-limit at an infinite point, except for the points of the two unstable separatrices of P_9 for which their α-limit is P_9.

If $\lambda<0$ all the points in the invariant plane have their ω-limit at an infinite point, except for the points of the two stable separatrices of Q_9 for which their ω-limit is Q_9. Moreover they have their α-limit at the point P_9 or in a point at infinity.

If $\lambda=0$ and $k>0$ all the points in the invariant plane have their ω-limit at an infinite point or at any point of the straight line filled of equilibria and have their α-limit in a point at infinity.

If $\lambda=0$ and $k<0$ all the points in the invariant plane have their ω-limit in a point at infinity and their α-limit at an infinite point or at any point of the straight line filled with equilibria.

Dynamics on $F_{10}=0$

We note that systems (5.1) restricted to $F_{10}=\kappa-1+\sqrt{\kappa(\kappa-1)}x+y=0$ by setting $y=1-\kappa-\sqrt{\kappa(\kappa-1)}x$ are

$$\dot{x}=-x\left(\sqrt{\kappa(\kappa-1)}x+\kappa\right),\quad \dot{z}=x-\lambda z. \tag{5.8}$$

Doing a study completely analogous to the one carried out to study $F_9=0$, we get that the phase portrait are those included in Figure 1.2.

Dynamics at infinity

Study of the infinity in the local charts U_1 and V_1

The expression of the Poincaré compactification of systems (5.1) in the local chart U_1 is given by

$$\begin{aligned}\dot{u}&=\kappa(\kappa-1)-u^2+(1-\kappa)uw+\kappa(1-\kappa)w^2,\\ \dot{v}&=w-uv+(1-\lambda)vw,\\ \dot{w}&=-w(u-w).\end{aligned}$$

At infinity, i.e. when $w=0$ this system writes as

$$\dot{u}=\kappa(\kappa-1)-u^2,\quad \dot{v}=-uv.$$

We have two different cases.

If $\kappa(1-\kappa) > 0$, there are no infinite equilibrium points in the local chart U_1.

If $\kappa(1-\kappa) < 0$, there are two infinite equilibrium points in the local chart U_1, which are $s_1 = (\sqrt{\kappa(\kappa-1)}, 0)$ and $s_4 = (-\sqrt{\kappa(\kappa-1)}, 0)$. The eigenvalues of the Jacobian matrix at these points are $-2\sqrt{\kappa(\kappa-1)}$ and $-\sqrt{\kappa(\kappa-1)}$ for s_1 and $2\sqrt{\kappa(\kappa-1)}$ and $\sqrt{\kappa(\kappa-1)}$ for s_4. Hence s_1 is a stable node and s_4 is an unstable node, as in Figure 5.7

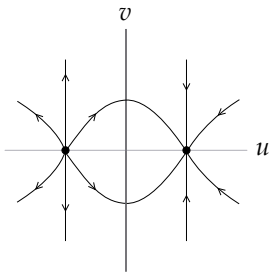


Figure 5.7: Phase portrait at the origin of the local chart U_1 with $\kappa(1-\kappa) < 0$.

Study of the infinity in the local charts U_2 and V_2

The expression of the Poincaré compactification of systems (5.1) in the local chart U_2 is given by

$$\begin{aligned}
\dot{u} &= u(1+\kappa(\kappa-1)w + \kappa(1-\kappa)u^2 + \kappa(\kappa-1)w^2),\\
\dot{v} &= uw + (\kappa-\lambda)vw + \kappa(1-\kappa)u^2v + \kappa(\kappa-1)vw^2,\\
\dot{w} &= \kappa w(w - (\kappa-1)u^2 - (1-\kappa)w^2).
\end{aligned}$$

At infinity, i.e. when $w = 0$ this system writes as

$$\dot{u} = u(1+\kappa(1-\kappa)u^2), \quad \dot{v} = \kappa(1-\kappa)u^3.$$

The line $u = 0$ if filled with equilibria. With a change of time we remove the common factor between $\dot{u}$ and $\dot{v}$ and we get

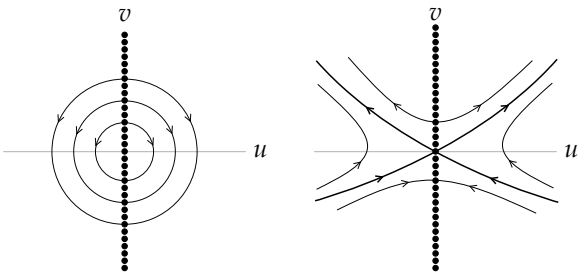
$$\dot{u} = 1+\kappa(1-\kappa)u^2, \quad \dot{v} = \kappa(1-\kappa)u^2.$$

If $\kappa(1-\kappa) > 0$ there are no equilibrium points and if $\kappa(1-\kappa) < 0$ there are two equilibrium points which are $(\pm 1/\sqrt{\kappa(1-\kappa)}, 0)$. Since we are interested in the equilibrium points with $u = 0$ (the ones with $u \neq 0$ are the same as the ones obtained in the local chart U_1) we do not consider these equilibrium points.

Study of the infinity in the local charts U_3 and V_3

The expression of the Poincaré compactification of systems (5.1) in the local chart U_2 is given by

$$\begin{aligned}
\dot{u} &= u(v + (\lambda-1)w - uw),\\
\dot{v} &= \kappa(\kappa-1)u^2 + (\lambda-\kappa)vw + \kappa(1-\kappa)w^2 - uvw,\\
\dot{w} &= w^2(\lambda-u).
\end{aligned}$$



At infinity, i.e. when $w = 0$ this system writes as

$$\dot{u} = uv, \quad \dot{v} = \kappa(\kappa - 1)u^2.$$

Again the line $u = 0$ if filled with equilibria. With a change of time we remove the common factor between $\dot{u}$ and $\dot{v}$ and we get

$$\dot{u} = v, \quad \dot{v} = \kappa(\kappa - 1)u.$$

We are only interested in the point $(0, 0)$. It is indeed an equilibrium point. Again we consider two cases. If $\kappa(1 - \kappa) > 0$ the origin is a center and if $\kappa(1 - \kappa) < 0$ the origin is a saddle. Going back with the rescaling of time we see that the local phase portraits at the origin of the local chart U_3 are the ones given in Figure 5.8.

$\kappa(\kappa - 1) < 0$ $\kappa(\kappa - 1) > 0$

Figure 5.8: Phase portraits at the origin of the local chart U_3.

The phase portrait of systems (1.1) under the conditions $\alpha = \kappa(1 - \kappa) \neq 0$ on the sphere at infinity is as shown in Figure 1.3, because the dynamics depend on the sign of $\kappa(1 - \kappa)$.

When $\kappa(\kappa - 1) < 0$ the infinity of the plane $x = 0$ is filled with equilibria. All the orbits are heteroclinic having their α-limit in one of the equilibria with $y > 0$, and their ω-limit in their symmetric equilibria with respect to the origin of coordinates.

When $\kappa(\kappa - 1) > 0$ the infinity of the plane $x = 0$ is again filled with equilibria. There are eight separatrices. The equilibrium points S_3 and S_4 are the α-limits of the two separatrices whose ω-limit is the endpoint of the positive z-axis and also of the two separatrices whose ω-limit is the endpoint of the negative z-axis. On the other hand, the points S_1 and S_2 are the ω-limits of the two separatrices whose α-limit is the endpoint of the positive z-axis and also of the two separatrices whose α-limit is the endpoint of the negative z-axis. The orbits inside the regions delimited by these separatrices have S_4 as α-limit and S_1 as ω-limit (respectively S_3 as α-limit and S_2 as ω-limit). For all the other orbits: the ones with $x, y > 0$ have their α-limit on the infinity of the plane $x = 0$ with $y > 0$ and their ω-limit is S_1; the ones with $x > 0$, $y < 0$ have their ω-limit on the infinity of the plane $x = 0$ with $y < 0$ and their α-limit is S_4; the ones with $x < 0$, $y > 0$ have their α-limit on the infinity of the plane $x = 0$ with $y > 0$ and their ω-limit is S_2; the ones with $x, y < 0$ have their ω-limit on the infinity of the plane $x = 0$ with $y < 0$ and their α-limit is S_3.

α- and ω-limits for the points in $\mathbb{R}^3$

Case $\kappa(\kappa - 1) < 0$

If $\lambda > 0$, all the points in $\mathbb{R}^3$ have their ω-limit in P_1 and their α-limit in a point at infinity.

If $\lambda < 0$ all the points in $\mathbb{R}^3$ have their ω-limit in the endpoints of the z-axis, and their α-limit is an infinite point except for the points at the straight line $(0, 1-k, z)$ with $z \in \mathbb{R}$, for which their α-limit is P_1.

If $\lambda = 0$ all the points in $\mathbb{R}^3$ have their ω-limit in one of the points of the straight line $(0, 1-k, z)$ with $z \in \mathbb{R}$, which is filled with equilibria. Moreover the α-limit is a point at infinity.

Case $\kappa(\kappa - 1) > 0$

If $\lambda > 0$ and $\kappa > 1$ there are three finite equilibrium points, P_1 which is a stable node and P_2 and P_3 which are saddles with a stable manifold of dimension two, one of them in $F_9 = 0$ and the other in $F_{10} = 0$. Taking into account the phase portrait over these invariant surfaces (see Figure 1.2), there are two stable manifolds of dimension one that enter in the invariant surface $F_9 = 0$ and another two that enter into $F_{10} = 0$. The possible α-limits are the negative endpoint of the x-axis in $F_9 = 0$ and the positive endpoint of the x-axis in $F_{10} = 0$, which correspond to the infinite points S_3 and S_4; the positive and negative endpoints of the z-axis in $\mathbb{R}^3$ (which correspond to the positive and negative endpoints of the z-axis in $F_9 = 0$ and $F_{10} = 0$).

The possible ω-limits are the points Q_9 on $F_9 = 0$, and the equivalent in $F_{10} = 0$, which both correspond with the equilibrium point P_1 in $\mathbb{R}^3$; the positive endpoint of the x-axis in $F_9 = 0$ and the negative endpoint of the x-axis in $F_{10} = 0$, which correspond to the infinite points S_1 and S_2; and also the positive and negative endpoints of the z-axis, but only for the orbits over the infinity in $F_9 = 0$ and $F_{10} = 0$, which are the separatrices in the region with $y < 0$ in $\mathbb{R}^3$.

With a similar reasoning we can analyze the following cases.

If $\lambda > 0$ and $\kappa < 0$ the possible α-limits for any point $p \in \mathbb{R}^3$ are the infinite points S_3 and S_4, and also the positive and negative endpoints of the z-axis. The possible ω-limits are the infinite points S_1 and S_2, and also the positive and negative endpoints of the z-axis in the case of the four separatrices in the region with $y < 0$.

If $\lambda = 0$ and $\kappa > 0$ the possible α-limits for any point $p \in \mathbb{R}^3$ are the infinite points S_3 and S_4, the positive endpoints of the z-axis and also the negative endpoint of the z-axis in the case of the four separatrices in the region with $y > 0$ and $z > 0$. The possible ω-limits are the finite points over the straight line $(0, 1-\kappa, z)$ with $z \in \mathbb{R}$, the infinite points S_1, S_2, the positive endpoints of the z-axis, and also the negative endpoints of the z-axis in the case of the separatrices in the region with $y < 0$ and $z < 0$.

If $\lambda = 0$ and $\kappa < 0$ the possible α-limits for any point $p \in \mathbb{R}^3$ are the finite points over the straight line $(0, 1-\kappa, z)$ with $z \in \mathbb{R}$, the infinite points S_3, S_4, the positive endpoint of the z-axis, and also the negative endpoint of the z-axis for the separatrices in the region with $y > 0$ and $z < 0$. The possible ω-limits are the points S_1, S_2, the negative endpoints of the z-axis, and also the positive endpoints of the z-axis for the separatrices in the region with $y < 0$ and $z > 0$.

If $\lambda < 0$ and $\kappa > 1$ the possible α-limits for any point $p \in \mathbb{R}^3$ are the infinite points S_3 and S_4, and also the positive and negative endpoints of the z-axis in the case of the four separatrices in the region with $y > 0$. The possible ω-limits are the infinite points S_1, S_2, and the positive and negative endpoints of the z-axis.

If $\lambda < 0$ and $\kappa < 0$ the possible α-limits for any point $p \in \mathbb{R}^3$ are the finite point P_1 and the infinite points S_3 and S_4, also the positive and negative endpoints of the z-axis in the case of the four separatrices in the region with $y > 0$. The possible ω-limits are the points S_1, S_2, and the positive and negative endpoints of the z-axis.

Abstract. We consider a nonlinear Dirichlet problem driven by a nonautonomous (p, q)-Laplacian and a Carathéodory reaction which is $(p-1)$-linear near $\pm\infty$. Using variational tools, comparison principles and critical groups, we prove two multiplicity theorems producing six nontrivial smooth solutions, all with sign information and ordered.

Keywords: comparison principles, nonlinear regularity theory, tangency principle, constant sign solutions, nodal solutions, critical groups.

2020 Mathematics Subject Classification: 35J20, 35J60

1 Introduction

Let $\Omega \subseteq \mathbb{R}^N$ be a bounded domain with a C^2-boundary $\partial\Omega$. In this paper we study the following nonhomogeneous Dirichlet (p, q)-equation:

$$\begin{cases} -\Delta_p^{a_1} u(z) - \Delta_q^{a_2} u(z) = f(z, u(z)) \text{ in } \Omega, \\ u|_{\partial\Omega} = 0, \ 1 < q < p. \end{cases} \tag{1.1}$$

If $a \in L^\infty(\Omega)$, $0 < \hat{c} \leq \operatorname{essinf}_\Omega a$ and $r \in (1, \infty)$, then by Δ_r^a we denote the weighted r-Laplace differential operator defined by

$$\Delta_r^a u = \operatorname{div}(a(z)|Du|^{r-2}|Du), \quad \text{for all } u \in W_0^{1,r}(\Omega).$$

✉Corresponding author. Email: zhhliu@hotmail.com

In (1.1) the equation is driven by the sum of two such operators with different exponents $(1 < q < p)$ and in general different weights $(a_1(\cdot), a_2(\cdot))$. So in (1.1) the differential operator is nonautonomous and nonhomogeneous. The reaction (right-hand side) $f(z,x)$ is a Carathéodory function (that is, for all $x \in \mathbb{R}$, $z \mapsto f(z,x)$ is measurable, and for a.a. $z \in \Omega$, $x \mapsto f(z,x)$ is continuous). Such a function is jointly measurable and so superpositionally measurable (that is, for every measurable function $u : \Omega \to \mathbb{R}$, the function $z \mapsto f(z,u(z))$ is measurable). We assume that $f(z,\cdot)$ exhibits $(p-1)$-linear growth as $x \to \pm\infty$.

Using variational tools from the critical point theory and the spectral properties of the nonhomogeneous p and q Laplacians (see Liu–Papageorgiou [9]), we prove the existence of at least six nontrivial smooth solutions, all with sign information and ordered. Our work here extends that of Liu–Papageorgiou [8,9] where the authors obtain three nontrivial smooth solutions. In the process of the proof, we prove two strong comparison theorems, which provide powerful tools for the analysis of nonautonomous equations.

2 Mathematical background – hypotheses

The main spaces in the analysis of problem (1.1) are the Sobolev spaces $W_0^{1,p}(\Omega)$ and the Banach space $C_0^1(\overline{\Omega}) = \{u \in C^1(\overline{\Omega}) : u|_{\partial\Omega} = 0\}$. On account of the Poincaré inequality, on $W_0^{1,p}(\Omega)$ we can use the norm

$$\|u\| = \|Du\|_p \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

The Banach space $C_0^1(\overline{\Omega})$ is an ordered Banach space with positive (order) cone

$$C_+ = \left\{u \in C_0^1(\overline{\Omega}) : u(z) \geq 0 \text{ for all } z \in \overline{\Omega}\right\}.$$

This cone has a nonempty interior given by

$$\operatorname{int} C_+ = \left\{u \in C_+ : u(z) > 0 \text{ for all } z \in \Omega,\ \frac{\partial u}{\partial n}\Big|_{\partial\Omega} < 0\right\},$$

where $\frac{\partial u}{\partial n} = (Du, n)_{\mathbb{R}^N}$ with $n(\cdot)$ being the outward unit normal on $\partial\Omega$.

Let $C^{0,1}(\overline{\Omega})$ be the space of all Lipschitz continuous functions on $\overline{\Omega}$. Suppose $a \in C^{0,1}(\overline{\Omega})$, $0 < \hat{c} \leq a(z)$ for all $z \in \overline{\Omega}$ and $1 < r < \infty$. We consider the following nonlinear eigenvalue problem

$$-\Delta_r^a u(z) = \hat{\lambda}|u(z)|^{r-2}u(z) \quad \text{in } \Omega,\ u|_{\partial\Omega} = 0. \tag{2.1}$$

From Liu–Papageorgiou [9], we know that

(a) Problem (2.1) has a smallest eigenvalue $\hat{\lambda}_1^a(r) > 0$ which has the following variational characterization

$$\hat{\lambda}_1^a(r) = \inf\left\{\frac{\int_\Omega a(z)|Du|^r\,dz}{\|u\|_r^r} : u \in W_0^{1,r}(\Omega), u \neq 0\right\}. \tag{2.2}$$

(b) $\hat{\lambda}_1^a(r) > 0$ is isolated, that is, if $\hat{\sigma}(r) > 0$ denotes the spectrum of (2.1), then there exists $\varepsilon > 0$ such that

$$\hat{\sigma}(r) \cap (\hat{\lambda}_1^a(r), \hat{\lambda}_1^a(r) + \varepsilon) = \emptyset.$$

(c) $\hat{\lambda}_1^a(r) > 0$ is simple, that is, if $\hat{u}, \hat{v} \in W_0^{1,p}(\Omega)$ are eigenfunctions corresponding to $\hat{\lambda}_1^a(r)$, then $\hat{u} = \theta\hat{v}$ for some $\theta \in \mathbb{R}\backslash\{0\}$.

(d) All eigenfunctions of (2.1) belong in $C_0^1(\bar{\Omega})$ (nonlinear regularity theory of Lieberman [7]), if $\lambda > \hat{\lambda}_1^a(r)$ is an eigenvalue of (2.1), then the eigenfunctions corresponding to λ are nodal (sign-changing) and the eigenfunctions of $\hat{\lambda}_1^a(r)$ have fixed sign (see (2.2)) and by $\hat{u}_1^a(r)$ we denote the positive, r-normalized (that is, $\|\hat{u}_1^a(r)\|_r = 1$) eigenfunction for $\hat{\lambda}_1^a(r)$. Using the nonlinear maximum principle (see Pacci–Serrin [16], p. 120), we have

$$\hat{u}_1^a(r) \in \operatorname{int} C_+.$$

(e) We do not have a full knowledge of $\hat{\sigma}(r)$, $r \neq 2$. Using the Ljusternik–Schnirelmann minimax scheme, we know that (2.1) has a sequence $\{\hat{\lambda}_k^a(r)\}_{k\in\mathbb{N}}$ of eigenvalues (known as variational eigenvalues) such that $\hat{\lambda}_k^a(r) \to +\infty$ as $k \to \infty$. We do not know if this sequence exhausts $\hat{\sigma}(r)$.

If $r = 2$ (linear eigenvalue problem), then using the spectral theorem for compact operators, we have a full description of the spectrum $\hat{\sigma}(2)$ which consists of a sequence $\{\hat{\lambda}_k(2)\}_{k\in\mathbb{N}}$ of distinct eigenvalues with $\hat{\lambda}_k(2) \to +\infty$. The eigenspaces $E(\hat{\lambda}_k(2))$ are finite dimensional linear spaces and we have $E(\hat{\lambda}_k(2)) \subseteq C_0^1(\bar{\Omega})$ for all $k \in \mathbb{N}$. We have variational characterizations for all the eigenvalues:

$$\hat{\lambda}_1^a(2) = \inf\left\{\frac{\int_\Omega a(z)|Du|^2dz}{\|u\|_2^2} : u \in H_0^1(\Omega), u \neq 0\right\}, \tag{2.3}$$

$$\begin{aligned} m \geq 2 \quad \hat{\lambda}_m^a(2) &= \inf\left\{\frac{\int_\Omega a(z)|Du|^2dz}{\|u\|_2^2} : u \in V = \overline{\bigoplus_{k\geq m} E(\hat{\lambda}_k(2))}, u \neq 0\right\} \\ &= \sup\left\{\frac{\int_\Omega a(z)|Du|^2dz}{\|u\|_2^2} : u \in V = \bigoplus_{k=1}^m E(\hat{\lambda}_k(2)), u \neq 0\right\}. \end{aligned} \tag{2.4}$$

The extrema in (2.3) and (2.4) are realized on the corresponding eigenspaces.

The next inequalities are easy consequences of the aforementioned properties (see Hu–Papageorgiou [5]).

Proposition 2.1. *If $\hat{\eta} \in L^\infty(\Omega)$, $\hat{\eta}(z) \leq \hat{\lambda}_1^a(r)$ for a.a. $z \in \Omega$ and $\hat{\eta} \not\equiv \hat{\lambda}_1^a(r)$, then there exists $c_1 > 0$ such that*

$$c_1\|u\|^r \leq \|Du\|_r^r - \int_\Omega \hat{\eta}(z)|u|^r dz \quad \text{for all } u \in W_0^{1,r}(\Omega).$$

Proposition 2.2.

(a) If $\hat{\eta} \in L^\infty(\Omega)$, $\hat{\eta}(z) \leq \hat{\lambda}_k^a(2)$ for a.a. $z \in \Omega$ and $\hat{\eta} \not\equiv \hat{\lambda}_k^a(2)$, then there exists $c_2 > 0$ such that

$$c_2\|u\|^2 \leq \|Du\|_2^2 - \int_\Omega \hat{\eta}(z)u^2dz \quad \text{for all } u \in V = \overline{\bigoplus_{m\geq k} E(\hat{\lambda}_m(2))}.$$

(b) If $\hat{\eta} \in L^\infty(\Omega)$, $\hat{\eta}(z) \geq \hat{\lambda}_k^a(2)$ for a.a. $z \in \Omega$ and $\hat{\eta} \not\equiv \hat{\lambda}_k^a(2)$, then there exists $c_3 > 0$ such that

$$\|Du\|_2^2 - \int_\Omega \hat{\eta}(z)u^2\,dz \leq -c_3\|u\|_2^2 \quad \text{for all } u \in V = \bigoplus_{m=1}^k E(\hat{\lambda}_m(2)).$$

Let $A_p^{a_1} : W_0^{1,p}(\Omega) \to W^{-1,p'}(\Omega) = W_0^{1,p}(\Omega)^* \left(p' = \frac{p}{p-1}\right)$ and $A_q^{a_2} : W_0^{1,q}(\Omega) \to W^{-1,q'}(\Omega) = W_0^{1,q}(\Omega)^*$ be defined by

$$\langle A_p^{a_1}(u), h\rangle = \int_\Omega a_1(z)|Du|^{p-2}(Du, Dh)_{\mathbb{R}^N}\, dz \quad \text{for all } u, h \in W_0^{1,p}(\Omega),$$
$$\langle A_q^{a_2}(u), h\rangle = \int_\Omega a_2(z)|Du|^{q-2}(Du, Dh)_{\mathbb{R}^N}\, dz \quad \text{for all } u, h \in W_0^{1,q}(\Omega).$$

We set $V = A_p^{a_1} + A_q^{a_2}$ (recall $W_0^{1,p}(\Omega) \hookrightarrow W_0^{1,q}(\Omega)$).

Proposition 2.3. *The operators $A_p^{a_1}$, $A_q^{a_2}$, V are bounded (map bounded sets to bounded ones), continuous, strictly monotone (thus maximal monotone too), coercive and of type $(S)_+$, that is,*

$$\text{if } u_n \to u \text{ in } X \quad (\text{with } X = W_0^{1,p}(\Omega) \text{ or } X = W_0^{1,q}(\Omega))$$

and $\limsup_{n\to\infty}\langle G(u_n), u_n - u\rangle \le 0$ *(with $G = A_p^{a_1}$ or $G = A_q^{a_2}$ or $G = V$), then $u_n \to u$ in X.*

Let X be a Banach space and $\varphi \in C^1(X)$. We say that $\varphi(\cdot)$ satisfies the "C-condition" if it has the following property:

"every sequence $\{u_n\}_{n\in\mathbb{N}} \subseteq X$ such that $|\varphi(u_n)| \le M$ for some $M > 0$, all $n \in \mathbb{N}$, $(1 + \|u_n\|_X)\varphi'(u_n) \to 0$ in X^* as $n \to \infty$, admits a strongly convergent subsequence".

We introduce the following sets:

$$K_\varphi = \{u \in X : \varphi'(u) = 0\} \quad \text{(critical set of } \varphi(\cdot)),$$
$$\varphi^c = \{u \in X : \varphi(u) \le c\} \quad \text{for every } c \in \mathbb{R}.$$

If $Y_2 \subseteq Y_1 \subseteq X$ and $k \in \mathbb{N}_0 = \mathbb{N} \cup \{0\}$, then by $H_k(Y_1, Y_2)$ we denote the kth-singular homology group with real coefficients (so the critical groups are vector spaces). Let $u \in K_\varphi$ be isolated and $c = \varphi(u)$. The critical groups of $\varphi(\cdot)$ at u are defined by

$$C_k(\varphi, u) = H_k(\varphi^c \cap U, \varphi^c \cap U \setminus \{u\}) \quad \text{for all } k \in \mathbb{N}_0,$$

where U is a neighborhood of u such that $K_\varphi \cap U \cap \varphi^c = \{u\}$. The excision property of singular homology implies that this definition is independent of the isolating neighborhood U.

If $u, v : \Omega \to \mathbb{R}$ are measurable functions such that $u(z) \le v(z)$ for a.a. $z \in \Omega$". We define

$$[u, v] = \{h \in W_0^{1,p}(\Omega) : u(z) \le h(z) \le v(z) \text{ for a.a. } z \in \Omega\}$$
$$\text{int}_{C_0^1(\overline{\Omega})}[u, v] = \text{ interior in } C_0^1(\overline{\Omega}) \text{ of } [u, v] \cap C_0^1(\overline{\Omega}).$$

Also given $u : \Omega \to \mathbb{R}$ measurable, we write $0 \prec u$ if for every $K \subseteq \Omega$ compact we have $0 < c_K \le u(z)$ for a.a $z \in K$. Also, we set $u^\pm = \max\{\pm u, 0\}$ and we have $u = u^+ - u^-$, $|u| = u^+ + u^-$ and if $u \in W_0^{1,p}(\Omega)$, then $u^\pm \in W_0^{1,p}(\Omega)$. By $|\cdot|_N$ we denote the Lebesgue measure on $\mathbb{R}^N$.

The hypotheses on the data of (1.1), are the following:

H_0 $a_1, a_2 \in C^{0,1}(\overline{\Omega})$, $0 < \hat{c} \le a_1(z), a_2(z)$ for all $z \in \overline{\Omega}$, $1 < q < p < N$.

H_1 $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function such that

(i) $|f(z, x)| \le \hat{a}(z)[1 + |x|^{p-1}]$ for a.a. $z \in \Omega$, all $x \in \mathbb{R}$, with $\hat{a} \in L^\infty(\Omega)$;

(ii) there exists $\hat{\eta} \in L^\infty(\Omega)$ such that

$$\hat{\lambda}_1^{a_1}(p) \leq \hat{\eta}(z) \text{ for a.a. } z \in \Omega, \quad \hat{\eta} \not\equiv \hat{\lambda}_1^{a_1}(p),$$

$$\hat{\eta}(z) \leq \liminf_{x \to \pm\infty} \frac{f(z,x)}{|x|^{p-2}x} \text{ uniformly for a.a. } z \in \Omega;$$

(iii) there exists $\eta \in L^\infty(\Omega)$ such that

$$\hat{\lambda}_1^{a_2}(q) \leq \eta(z) \text{ for a.a. } z \in \Omega, \quad \eta \not\equiv \hat{\lambda}_1^{a_2}(q),$$

$$\eta(z) \leq \liminf_{x \to 0} \frac{f(z,x)}{|x|^{q-2}x} \text{ uniformly for a.a. } z \in \Omega;$$

(iv) there exist real numbers $\theta_- < 0 < \theta_+$ such that

$$f(z,\theta_+) \leq -l < 0 < l \leq f(z,\theta_-) \text{ for a.a. } z \in \Omega;$$

(v) for every $\rho > 0$, there exists $\hat{\xi}_\rho > 0$ such that for a.a. $z \in \Omega$, the function $x \to f(z,x) + \hat{\xi}_\rho |x|^{p-2}x$ is nondecreasing on $[-\rho, \rho]$.

Remark 2.4. Hypotheses H_1(i),(ii) imply that $f(z,\cdot)$ is $(p-1)$-linear as $x \to \pm\infty$. We can have partial interaction with $\hat{\lambda}_1^{a_1}(p) > 0$ from the right (nonuniform nonresonance). Similarly as $x \to 0$ with respect to $\hat{\lambda}_1^{a_2}(q) > 0$, Hypothesis H_1(i),(iii) imply that $f(z,0) = 0$ for a.a. $z \in \Omega$. Hypothesis H_1(iv) implies that $f(z,\cdot)$ is necessarily sign changing (it exhibits an oscillatory behavior near zero). Later (see hypotheses H_2 in Section 4), we will see that by requiring that $q = 2$, we can relax hypothesis H_1(iii) and incorporate in our framework reactions which satisfy the sign condition (that is, $f(z,x)x \geq 0$ for a.a. $z \in \Omega$, all $x \in \mathbb{R}$).

In what follows, for notational economy, we write

$$\rho_{a_1,p}(Du) = \int_\Omega a_1(z)|Du|^p \, dz,$$
$$\rho_{a_2,q}(Du) = \int_\Omega a_2(z)|Du|^q \, dz \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

Let $\varphi : W_0^{1,p}(\Omega) \to \mathbb{R}$ be the energy functional for problem (1.1) defined by

$$\varphi(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega F(z,u) \, dz \quad \text{for all } u \in W_0^{1,p}(\Omega),$$

where $F(z,x) = \int_0^x f(z,s)ds$. Evidently $\varphi \in C^1(W_0^{1,p}(\Omega))$.

To produce solutions of constant sign, we introduce the positive and negative truncations of $\varphi(\cdot)$, namely the C^1-functionals $\varphi_\pm : W_0^{1,p}(\Omega) \to \mathbb{R}$ defined by

$$\varphi_\pm(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega F(z,\pm u^\pm)dz \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

3 Comparison theorems

In this section, we prove two strong comparison theorems which we will use in the sequel and which are of independent interest.

Given two measurable functions $u, v : \Omega \to \mathbb{R}$, we write

$$u \prec v \quad \text{if } 0 \prec u - v \quad \text{(see Section 2)}.$$

Proposition 3.1. *If hypotheses H_0 hold, $\hat{\xi} \geq 0$, $h_1, h_2 \in L^\infty(\Omega)$ and $h_1 \prec h_2$ and $u \in C_0^1(\overline{\Omega}) \setminus \{0\}$, $v \in \operatorname{int} C_+$ satisfy the equations*

$$\begin{aligned} -\Delta_p^{a_1} u - \Delta_q^{a_2} u + \hat{\xi}|u|^{p-2}u &= h_1 \quad \text{in } \Omega, \\ -\Delta_p^{a_1} v - \Delta_q^{a_2} v + \hat{\xi} v^{p-1} &= h_2 \quad \text{in } \Omega, \end{aligned}$$

then $v - u \in \operatorname{int} C_+$.

Proof. From Theorem 3.4.1, p. 61 of Pucci–Serrin [16] (the weak comparison principle), we have

$$u(z) \leq v(z) \quad \text{for all } z \in \overline{\Omega}. \tag{3.1}$$

We introduce the following closed subsets of Ω:

$$E_0 = \{z \in \Omega : u(z) = v(z)\}, \quad E_1 = \{z \in \Omega : Du(z) = Dv(z) = 0\}.$$

First we show that $E_0 \subseteq E_1$. To this end let $\hat{z} \in E_0$ and set $y = v - u$. Then $y \in C_+ \setminus \{0\}$ and $y(\hat{z}) = \min_{\overline{\Omega}} y$. Hence

$$\begin{aligned} &Dy(\hat{z}) = 0, \\ \Rightarrow\ &Dv(\hat{z}) = Du(\hat{z}). \end{aligned}$$

If $\hat{z} \notin E_1$, then $Dv(\hat{z}) = Du(\hat{z}) \neq 0$ and so we can find an open ball B centered at $\hat{z}$ such that $Dv(z) \neq 0$, $Du(z) \neq 0$ for all $z \in B$. As in the proof of Proposition 2.1 of Guedda–Véron [3], we show that there exists $K \in W^{1,\infty}(\Omega, \mathbb{R}^{N\times N})$ such that

$$-\operatorname{div}(K(z)Dy) = h_2(z) - h_1(z) - \hat{\xi}(v^{p-1} - |u|^{p-2}u) \text{ in } B. \tag{3.2}$$

By taking B even smaller if necessary, we can apply the strong maximum principle of Pucci–Serrin [16] (p. 111) and obtain

$$\begin{aligned} &y(z) > 0 \quad \text{for all } z \in B, \\ \Rightarrow\ &u(z) < v(z) \quad \text{for all } z \in B, \end{aligned}$$

a contradiction since $\hat{z} \in E_0 \cap B$. This proves that

$$E_0 \subseteq E_1. \tag{3.3}$$

Since $v \in \operatorname{int} C_+$, it follows that $E_1 \subseteq \Omega$ is compact. Hence E_0 is compact too (see (3.3)). So, we can find $\Omega' \subset \Omega$ open such that

$$E_0 \subseteq \Omega' \subseteq \overline{\Omega'} \subseteq \Omega. \tag{3.4}$$

From (3.4) and since $\overline{\Omega'}$ is compact, we can find $\varepsilon > 0$ such that

$$u(z) + \varepsilon \leq v(z) \quad \text{for all } z \in \partial\Omega', \tag{3.5}$$

$$h_1(z) + \varepsilon \leq h_2(z) \quad \text{for all } z \in \overline{\Omega'} \quad (\text{recall } h_1 \prec h_2). \tag{3.6}$$

We choose $\delta \in (0, \varepsilon)$ small such that

$$\hat{\xi}\,\big||s|^{p-2}s - |t|^{p-2}t\big| \leq \varepsilon \quad \text{for all } s, t \in [\min_{\overline{\Omega}} u, \|v\|_\infty],\ |t-s| \leq \delta. \tag{3.7}$$

Then we have

$$\begin{aligned}
&-\Delta_p^{a_1}(u+\delta) - \Delta_q^{a_2}(u+\delta) + \hat{\xi}|u+\delta|^{p-2}(u+\delta)\\
&\quad = -\Delta_p^{a_1}u - \Delta_q^{a_2}u + \hat{\xi}|u+\delta|^{p-2}(u+\delta)\\
&\quad = h_1 - \hat{\xi}|u|^{p-2}u + \hat{\xi}|u+\delta|^{p-2}(u+\delta)\\
&\quad \leq h_2 - \varepsilon + \varepsilon \quad (\text{see (3.6), (3.7)})\\
&\quad = -\Delta_p^{a_1}v - \Delta_q^{a_2}v + \hat{\xi}v^{p-1} \quad \text{in } \Omega',\\
&\Rightarrow u + \delta \leq v \quad \text{in } \Omega' \quad (\text{by the weak comparison principle, see [16], p. 61})\\
&\Rightarrow E_0 = \emptyset \quad (\text{see (2.4)}),\\
&\Rightarrow u(z) < v(z) \quad \text{for all } z \in \Omega.
\end{aligned}$$

Now let $z_0 \in \partial\Omega$ and let $z_1 = z_0 - 2rn$ with $n = n(z_0)$ the outward unit normal at $z_0 \in \partial\Omega$. For $r \in (0,1)$ small, we consider the annulus

$$R = \{z \in \Omega : r \leq |z - z_1| \leq 2r\}$$

and let $m = \min\{y(z) : z \in \partial B_r(z_1)\} > 0$. From the proof of Proposition 2.3 of Papageorgiou–Vetro–Vetro [13], we can find $\widetilde{w} \in C^1(\overline{R}) \cap C^2(R)$ satisfying

$$-\Delta_p^{a_1}\widetilde{w} - \Delta_q^{a_2}\widetilde{w} + \hat{\xi}|\widetilde{w}|^{p-2}\widetilde{w} \leq 0 \quad \text{in } R$$

with $\widetilde{w} \leq u$ on ∂R. Then by the weak comparison principle, we have

$$\widetilde{w} \leq u \quad \text{in } R.$$

Moreover, it follows $\widetilde{w}(z_0) = 0$, $\frac{\partial y}{\partial n}(z_0) \leq \frac{\partial \widetilde{w}}{\partial n}(z_0)$ and so $y \in \operatorname{int} C_+$,

$$\Longrightarrow\ v - u \in \operatorname{int} C_+. \qquad \square$$

In the second comparison result, we strengthen the relation between the two forcing terms h_1, h_2 but relax the conditions on u, v.

Proposition 3.2. *If hypothesis H_0 holds, $\hat{\xi} \geq 0$, $h_1, h_2 \in L^1(\Omega)$ satisfy*

$$\alpha \leq \hat{c}_0 \leq h_2(z) - h_1(z) \quad \textit{for a.a. } z \in \Omega$$

and $u, v \in C^1(\overline{\Omega}) \setminus \{0\}$ with $0 < v(z)$ for all $z \in \Omega$ satisfy

$$\begin{aligned}
&-\Delta_p^{a_1}u - \Delta_q^{a_2}u + \hat{\xi}|u|^{p-2}u = h_1 \quad \textit{in } \Omega,\\
&-\Delta_p^{a_1}v - \Delta_q^{a_2}v + \hat{\xi}|v|^{p-1} = h_2 \quad \textit{in } \Omega, \quad u \leq v \textit{ on } \partial\Omega,
\end{aligned}$$

then $u(z) < v(z)$ for all $z \in \Omega$.

Proof. Let $\eta(z,y) = a_1(z)|y|^{p-2}y + a_2(z)|y|^{q-2}y$ for all $z \in \Omega$, all $y \in \mathbb{R}^N$. We have

$$-\operatorname{div}(\eta(z,Dv) - \eta(z,Du)) = h_2 - h_1 - \hat{\xi}(v^{p-1} - |u|^{p-2}u) \quad \text{in } \Omega. \tag{3.8}$$

As before the weak comparison principle implies $u \leq v$. Let $y = v - u$. Then $y \in C^1(\overline{\Omega})$, $y(z) \geq 0$ for all $z \in \Omega$ and as in Guedda–Véron [3], we have

$$-\operatorname{div}(K(z)Dy(z)) = h_2 - h_1 - \hat{\xi}(v^{p-1} - |u|^{p-2}u) \quad \text{in } \Omega,$$

with $K \in W^{1,\infty}(\Omega, \mathbb{R}^{N\times N})$.

Suppose that for some $\hat{z} \in \Omega$, we have $y(\hat{z}) = 0$, hence $v(\hat{z}) = u(\hat{z})$. Then from (3.8) and the hypothesis on h_1, h_2 we can find $r \in (0,1)$ small such that

$$-\operatorname{div}(K(z)Dy(z)) \geq \hat{c}_1 > 0 \quad \text{in } B_r(\hat{z}) = \{z \in \mathbb{R}^N : |z - \hat{z}| \leq r\} \subseteq \Omega.$$

Invoking Theorem 4 of Vázquez [18], we obtain

$$0 < y(z) \quad \text{for all } z \in B_r(\hat{z}),$$

a contradiction since $y(\hat{z}) = 0$. It follows that

$$u(z) < v(z) \quad \text{for all } z \in \Omega. \qquad \square$$

In the next section we will use these comparison results to produce multiple constant sign solutions of (1.1).

4 Constant sign solutions

We start by obtaining constant sign solutions which are local minimizers of the energy functional $\varphi(\cdot)$.

Proposition 4.1. *If hypotheses H_0, H_1 (i), (iii), (iv), (v) hold, then problem (1.1) has two constant sign solutions*

$$u_0 \in \operatorname{int} C_+ \quad \textit{with} \quad u(z) < \theta_+ \quad \textit{for all } z \in \overline{\Omega},$$

$$v_0 \in -\operatorname{int} C_+ \quad \textit{with} \quad \theta_- < v(z) \quad \textit{for all } z \in \overline{\Omega}$$

and u_0 is a local minimizer of the functionals φ, φ_+, v_0 is a local minimizer of the functionals φ, φ_-.

Proof. First we produce the positive solution. To this end we introduce the Carathéodory function $\hat{f}_+ : \Omega \times \mathbb{R} \to \mathbb{R}$ defined by

$$\hat{f}_+(z,x) = \begin{cases} f(z,x^+) & \text{if } x \leq \theta_+, \\ f(z,\theta_+) & \text{if } \theta_+ < x. \end{cases} \tag{4.1}$$

We set $\hat{F}_+(z,x) = \int_0^x \hat{f}_+(z,s)ds$ and consider the C^1-functional $\hat{\varphi}_+ : W_0^{1,p}(\Omega) \to \mathbb{R}$ defined by

$$\hat{\varphi}_+(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega \hat{F}_+(z,u)\,dz \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

From (4.1) and hypotheses H_0, we see that $\hat{\varphi}_+(\cdot)$ is coercive. Also, using the Sobolev embedding theorem, we have that $\hat{\varphi}_+(\cdot)$ is sequentially weakly lower semicontinuous, so by the Weierstrass–Tonelli theorem, we can find $u_0 \in W_0^{1,p}(\Omega)$ such that

$$\hat{\varphi}_+(u_0) = \inf\left\{\hat{\varphi}_+(u) : u \in W_0^{1,p}(\Omega)\right\}. \tag{4.2}$$

On account of hypothesis H_1(iii), given $\varepsilon > 0$, we can find $\delta \in (0, \theta_+)$ such that

$$\frac{1}{q}[\eta(z) - \varepsilon]x^q \leq F(z,x) \quad \text{for a.a. } z \in \Omega, \text{ all } 0 \leq x \leq \delta. \tag{4.3}$$

From Section 2, we know that $\hat{u}_1^{a_2}(q) \in \operatorname{int} C_+$. So, we can find $t \in (0,1)$ small such that

$$0 \leq t\hat{u}_1^{a_2}(q)(z) \leq \delta \quad \text{for all } z \in \overline{\Omega}. \tag{4.4}$$

Using (4.3), (4.4) and (4.1), we have

$$\begin{aligned}\hat{\varphi}_+(t\hat{u}_1^{a_2}(q)) \leq{}& \frac{t^p}{p}\rho_{a_1,p}(D\hat{u}_1^{a_2}(q)) \\ &+ \frac{t^q}{q}\left[\int_\Omega (\hat{\lambda}_1^{a_2}(q) - \eta(z))(\hat{u}_1^{a_2}(q)^q)\,dz + \varepsilon\right] \text{ (recall that } \|\hat{u}_1^{a_2}(q)\|_q = 1).\end{aligned} \tag{4.5}$$

Since by hypothesis the inequality $\hat{\lambda}_1^{a_2}(q) \leq \eta(z)$ is strict on a set of positive Lebesgue measure, we have

$$\beta = \int_\Omega (\eta(z) - \hat{\lambda}_1^{a_2}(q))\hat{u}_1^{a_2}(q)^q\,dz > 0.$$

So, choosing $\varepsilon \in (0, \beta)$ small, from (4.5), we obtain

$$\hat{\varphi}_+(t\hat{u}_1^{a_2}(q)) \leq c_4 t^p - c_5 t^q \quad \text{for some } c_4, c_5 > 0.$$

Since $q < p$, choosing $t \in (0,1)$ even smaller if necessary, we have

$$\begin{aligned}&\hat{\varphi}_+(t\hat{u}_1^{a_2}(q)) < 0, \\ \Rightarrow\ &\hat{\varphi}_+(u_0) < 0 = \hat{\varphi}_+(0) \quad \text{(see (4.2))}, \\ \Rightarrow\ &u_0 \neq 0.\end{aligned}$$

From (4.2) we have

$$\begin{aligned}&\langle \hat{\varphi}_+'(u_0), h\rangle = 0 \quad \text{for all } h \in W_0^{1,p}(\Omega), \\ \Rightarrow\ &\langle V(u_0), h\rangle = \int_\Omega \hat{f}_+(z, u_0)h\,dz \quad \text{for all } h \in W_0^{1,p}(\Omega).\end{aligned} \tag{4.6}$$

In (4.6) first we choose the test function $h = -u_0^- \in W_0^{1,p}(\Omega)$. Then from (4.1) we have

$$\hat{c}\|Du_0^-\|_p^p \leq 0 \Rightarrow u_0 \geq 0, \quad u_0 \neq 0.$$

Next in (4.6) we choose the test function $(u_0 - \theta_+)^+ \in W_0^{1,p}(\Omega)$. Then

$$\begin{aligned}\langle V(u_0), (u_0 - \theta_+)^+\rangle &= \int_\Omega f(z, \theta_+)(u_0 - \theta_+)^+\,dz \quad \text{(see (4.1))} \\ &\leq 0 \quad \text{(see hypothesis } H_1\text{(iv))} \\ &= \langle V(\theta_+), (u_0 - \theta_+)^+\rangle \\ &\Rightarrow u_0 \leq \theta_+.\end{aligned}$$

So, we have proved that

$$u_0 \in [0, \theta_+], \quad u_0 \neq 0. \tag{4.7}$$

From (4.7), (4.1) and (4.6), we infer that u_0 is a nontrivial nonnegative solution of (1.1). Evidently $u_0 \in L^\infty(\Omega)$ and then the nonlinear regularity theory of Lieberman [7] implies $u_0 \in C_+ \setminus \{0\}$. Let $\rho = \|u_0\|_\infty$ and let $\hat{\xi}_\rho > 0$ be as postulated by hypothesis H_1(v). We have

$$\begin{aligned} &-\Delta_p^{a_1} u_0 - \Delta_q^{a_2} u_0 + \hat{\xi}_\rho u_0^{p-1} \geq 0 \quad \text{in } \Omega, \\ &\Rightarrow u_0 \in \operatorname{int} C_+ \quad \text{(see Pucci–Serrin [16], pp. 111, 120).} \end{aligned} \tag{4.8}$$

We have

$$\begin{aligned} -\Delta_p^{a_1} u_0 - \Delta_q^{a_2} u_0 + \hat{\xi}_\rho u_0^{p-1} &= f(z, u_0) + \hat{\xi}_\rho u_0^{p-1} \quad \text{(see (4.7), (4.1))} \\ &\leq f(z, \theta_+) + \hat{\xi}_\rho \theta_+^{p-1} \quad \text{(see (4.7) and hypothesis } H_1\text{(v))} \\ &\leq -l + \hat{\xi}_\rho \theta_+^{p-1} \quad \text{(see hypothesis } H_1\text{(iv))} \\ &\leq -\Delta_p^{a_1} \theta_+ - \Delta_q^{a_2} \theta_+ + \hat{\xi}_\rho \theta_+^{p-1} \quad \text{in } \Omega. \end{aligned}$$

Invoking Proposition 3.2, we infer that

$$u_0(z) < \theta_+ \quad \text{for all } z \in \overline{\Omega}. \tag{4.9}$$

Then (4.8) and (4.9) imply that

$$u_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})} [0, \theta_+]. \tag{4.10}$$

Note that

$$\hat{\varphi}_+\big|_{[0,\theta_+]} = \varphi_+\big|_{[0,\theta_+]} \quad \text{(see (4.1))}. \tag{4.11}$$

Recall that u_0 is a minimizer of $\hat{\varphi}_+(\cdot)$. So, from (4.10) and (4.11) it follows that

$$\begin{aligned} &u_0 \text{ is a local } C_0^1(\overline{\Omega})\text{-minimizer of } \varphi_+(\cdot), \\ &\Rightarrow u_0 \text{ is a local } W_0^{1,p}(\Omega)\text{-minimizer of } \varphi_+(\cdot). \\ &\qquad \text{(see Hu–Papageorgiou [5, p. 339]).} \end{aligned} \tag{4.12}$$

Let $W_+ = \{u \in W_0^{1,p}(\Omega) : u(z) \geq 0 \quad \text{for a.a. } z \in \Omega\}$. We have

$$\varphi\big|_{W_+} = \varphi_+\big|_{W_+}, \quad u_0 \in \operatorname{int} W_+. \tag{4.13}$$

So, from (4.12) and (4.13) it follows that

$$u_0 \text{ is a local } W_0^{1,p}(\Omega)\text{-minimizer of } \varphi(\cdot).$$

For the negative solution, we start with the Carathéodory function $\hat{f}_-(z, x)$ defined by

$$\hat{f}_-(z, x) = \begin{cases} f(z, \theta_-) & \text{if } x < \theta_-, \\ f(z, -x^-) & \text{if } \theta_- \leq x. \end{cases}$$

We set $\hat{F}_-(z, x) = \int_0^x \hat{f}_-(z, s)\, ds$ and consider the C^1-functional $\hat{\varphi}_- : W_0^{1,p}(\Omega) \to \mathbb{R}$ defined by

$$\hat{\varphi}_-(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega \hat{F}_-(z, u)\, dz \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

Working as above, this time with the functional $\hat{\varphi}_-(\cdot)$, we produce a negative solution $v_0 \in -\operatorname{int} C_+$, such that

$$v_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})}[\theta_-, 0],$$

and v_0 is a local $W_0^{1,p}(\Omega)$ minimizer of both $\varphi_-(\cdot)$, $\varphi(\cdot)$. □

As we already mentioned, hypothesis H_1(iv) forces $f(z,\cdot)$ to be sign-changing. We can modify hypothesis H_1(iv) so as to include in our framework reactions which satisfy the sign condition. We can do this if we restrict to $q = 2$. The new hypotheses on $f(z,x)$ are the following:

$H_2 : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function such that

(i) same as hypothesis H_1(i);

(ii) same as hypothesis H_1(ii);

(iii) same as hypothesis H_1(iii) with $q = 2$;

(iv) there exist $\theta_- < 0 < \theta_+$ such that $f(z,\theta_+) \leq 0 \leq f(z,\theta_-)$ for a.a. $z \in \Omega$;

(v) same as hypothesis H_1(v).

Remark 4.2. We see that this set of hypotheses includes also reactions which satisfy the sign condition, that is, $f(z,x)x \geq 0$ for a.a. $z \in \Omega$, all $x \in \mathbb{R}$. Such functions were excluded under hypotheses H_1.

Proposition 4.3. *If hypotheses H_0, H_2(i), (iii), (iv), (v) hold, then problem (1.1) has at least two constant sign solutions*

$$u_0 \in \operatorname{int} C_+ \quad \text{with} \quad u_0(z) < \theta_+ \quad \text{for all } z \in \overline{\Omega},$$

$$v_0 \in -\operatorname{int} C_+ \quad \text{with} \quad \theta_- < v_0(z) \quad \text{for all } z \in \overline{\Omega},$$

u_0 is a local minimizer of the functionals φ, φ_+, v_0 is a local minimizer of the functionals φ, φ_-.

Proof. The proof is the same as that of Proposition 4.1 and it differs only at the point where we show that $u_0(z) < \theta_+$ (resp. $\theta_- < v_0(z)$) for all $z \in \overline{\Omega}$. In this case we argue as follows: let $\eta(z,y) = a_1(z)|y|^{p-2}y + a_2(z)|y|^{q-2}y$ for all $z \in \Omega$, all $y \in \mathbb{R}^N$. Then

$$\operatorname{div} \eta(z, Du) = \Delta_p^{a_1} u + \Delta_q^{a_2} u \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

Since $2 < p$ (see hypothesis H_2(iii)), we see that $\eta(z,\cdot) \in C^1(\mathbb{R}^N, \mathbb{R}^N)$ and we have

$$\nabla_y \eta(z,y) = a_1(z)|y|^{p-2}\left[\mathrm{id} + (p-2)\frac{y \otimes y}{|y|^2}\right] + a_2(z)\mathrm{id}.$$

Therefore for any $h \in \mathbb{R}^N \setminus \{0\}$, we have

$$\begin{aligned} &(\nabla_y \eta(z,y)h, h)_{\mathbb{R}^N} \geq \hat{c}|h|^2, \\ \Rightarrow\ &\nabla_y \eta(z,\cdot) \text{ is positive definite.} \end{aligned} \tag{4.14}$$

Note that

$$\operatorname{div} \eta(z, Du_0) + f(z,u_0) \geq -\operatorname{div} \eta(z,\theta_+) + f(z,\theta_+) \quad \text{in } \Omega. \tag{4.15}$$

(see hypothesis H_2(iv)).

From (4.14), (4.15) and the tangency principle of Serrin [17] (see also Pucci–Serrin [16], p. 35), we have

$$u_0(z) < \theta_+ \quad \text{for all } z \in \overline{\Omega}.$$

Similarly, we show that $\theta_- < v_0(z)$ for all $z \in \overline{\Omega}$. □

Next we will show the existence of extremal constant sign solutions, that is, a minimal positive solution and a maximal negative solution. In Section 4 we will use these extremal constant sign solutions in order to produce a nodal (sign-changing) solutions.

On account of hypotheses H_1(i), (iii) (they are also valid when H_2 hold, with $q = 2$), given $\varepsilon > 0$, we can find $c_6 = c_6(\varepsilon) \geq 0$ such that

$$f(z,x)x \geq [\eta(z) - \varepsilon]|x|^q - c_6|x|^p \quad \text{for a.a. } z \in \Omega, \text{ all } x \in \mathbb{R}. \tag{4.16}$$

This unilateral growth condition suggests that we consider the following auxiliary Dirichlet problem

$$\begin{cases} -\Delta_p^{a_1} u(z) - \Delta_q^{a_2} u(z) = [\eta(z) - \varepsilon]|u(z)|^{q-2}u(z) - c_6|u(z)|^{p-2}u(z) & \text{in } \Omega, \\ u|_{\partial\Omega} = 0. \end{cases} \tag{4.17}$$

For this problem we have the following existence and uniqueness result.

Proposition 4.4. *If hypothesis H_0 holds, then for all $\varepsilon \in (0,1)$ small problem has a unique positive solution*

$$\bar{u} \in \operatorname{int} C_+,$$

and since the equation is odd $\bar{v} = -\bar{u} \in -\operatorname{int} C_+$ is the unique negative solution of (4.17).

Proof. Let $\sigma_+ : W_0^{1,p}(\Omega) \to \mathbb{R}$ be the C^1-functional defined by

$$\sigma_+(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \frac{1}{q}\int_\Omega [\eta(z) - \varepsilon](u^+)^q \, dz + \frac{c_6}{p}\|u^+\|_p^p$$

for all $u \in W_0^{1,p}(\Omega)$.

Since $q < p$, we see that $\sigma_+(\cdot)$ is coercive. Also using the Sobolev embedding theorem, we show that $\sigma_+(\cdot)$ is sequentially weakly lower semicontinuous. So, we can find $\bar{u} \in W_0^{1,p}(\Omega)$ such that

$$\sigma_+(\bar{u}) = \inf\left\{\sigma_+(u) : u \in W_0^{1,p}(\Omega)\right\}. \tag{4.18}$$

As in the proof of Proposition 4.1, for $t \in (0,1)$ small, we have

$$\begin{aligned} &\sigma_+(t\hat{u}_1^{a_2}(q)) < 0, \\ \Rightarrow\ &\sigma_+(\bar{u}) < 0 = \sigma_+(0) \quad \text{(see (4.18))}, \\ \Rightarrow\ &\bar{u} \neq 0. \end{aligned}$$

From (4.18) we have

$$\begin{aligned} &\langle \sigma_+'(\bar{u}), h\rangle = 0 \quad \text{for all } h \in W_0^{1,p}(\Omega), \\ \Rightarrow\ &\langle V(\bar{u}), h\rangle = \int_\Omega [\eta(z) - \varepsilon](\bar{u}^+)^{q-1}h \, dz - c_6 \int_\Omega (\bar{u}^+)^{p-1}h \, dz \end{aligned} \tag{4.19}$$

for all $h \in W_0^{1,p}(\Omega)$.

In (4.19) we choose the test function $h = \bar{u}^- \in W_0^{1,p}(\Omega)$ and obtain

$$\hat{c}\|D\bar{u}\|_p^p \leq 0, \quad \Rightarrow \quad \bar{u} \geq 0, \quad \bar{u} \neq 0.$$

Therefore $\bar{u}$ is a nontrivial positive solution of (4.17). Using Theorem 7.1, p. 286, of Ladyzhenskaya–Uraltseva [6], we have that $\bar{u} \in L^\infty(\Omega)$ and then the nonlinear regularity theory of Lieberman [7] implies that $\bar{u} \in C_+ \setminus \{0\}$. We have

$$\Delta_p^{a_1}\bar{u} + \Delta_q^{a_2}\bar{u} \leq c_6\bar{u}^{p-1} \quad \text{in } \Omega,$$

$$\Rightarrow \bar{u} \in \operatorname{int} C_+ \quad \text{(see Pucci–Serrin [16], p. 120)}.$$

Now we show the uniqueness of this positive solution of (4.17). To this end, we introduce the integral functional $j : L^1(\Omega) \to \overline{\mathbb{R}} = \mathbb{R} \cup \{+\infty\}$ defined by

$$j(u) = \begin{cases} \frac{1}{p}\rho_{a_1,p}(Du^{1/q}) + \frac{1}{q}\rho_{a_2,q}(Du^{1/q}) & \text{if } u \geq 0,\ u^{1/q} \in W_0^{1,p}(\Omega), \\ +\infty & \text{otherwise.} \end{cases}$$

From Diaz-Saa [2], we know that $j(\cdot)$ is convex. Suppose that $\bar{y}$ is another positive solution of (4.17). Again we have $\bar{y} \in \operatorname{int} C_+$. On account of Proposition 4.1.22, p. 274, of Papageorgiou–Rădulescu–Repovš [12], implies that

$$\frac{\bar{u}}{\bar{y}} \in L^\infty(\Omega), \quad \frac{\bar{y}}{\bar{u}} \in L^\infty(\Omega). \tag{4.20}$$

Set $h = \bar{u}^q - \bar{y}^q \in C_0^1(\overline{\Omega})$. Then (4.20) implies that for $t > 0$ small, we have

$$\bar{u} + th \in \operatorname{dom} j, \quad \bar{y} + th \in \operatorname{dom} j,$$

where $\operatorname{dom} j = \{u \in L^1(\Omega) : j(u) < \infty\}$ (effective domain of $j(\cdot)$). Then we can compute the directional derivatives of $j(\cdot)$ at $\bar{u}^q$ and at $\bar{y}^q$ in the direction h. A simple computation using the convexity of $j(\cdot)$ and the nonlinear Green's theorem (see [12], p. 35), we obtain

$$\begin{aligned} j'(\bar{u}^q)(h) &= \frac{1}{q}\int_\Omega \frac{-\Delta_p^{a_1}\bar{u} - \Delta_q^{a_2}\bar{u}}{\bar{u}^{q-1}}(\bar{u}^q - \bar{y}^q)\,dz \\ &= \frac{1}{q}\int_\Omega \left[(\eta(z) - \varepsilon) - c_4\bar{u}^{p-q}\right](\bar{u}^q - \bar{y}^q)\,dz, \\ j'(\bar{y}^q)(h) &= \frac{1}{q}\int_\Omega \frac{-\Delta_p^{a_1}\bar{y} - \Delta_q^{a_2}\bar{y}}{\bar{y}^{q-1}}(\bar{u}^q - \bar{y}^q)\,dz \\ &= \frac{1}{q}\int_\Omega \left[(\eta(z) - \varepsilon) - c_4\bar{y}^{p-q}\right](\bar{u}^q - \bar{y}^q)\,dz. \end{aligned}$$

The convexity of $j(\cdot)$ implies the monotonicity of $j'(\cdot)$. So, we have

$$0 \leq \frac{c_6}{q}\int_\Omega \left(\bar{y}^{p-q} - \bar{u}^{p-q}\right)(\bar{u}^q - \bar{y}^q)\,dz,$$

$$\Rightarrow \bar{u} = \bar{y} \quad (\text{since } q < p).$$

Therefore $\bar{u} \in \operatorname{int} C_+$ is the unique positive solution of (4.17). The equation is odd, so $\bar{v} = -\bar{u} \in -\operatorname{int} C_+$ is the unique negative solution of (4.17). □

Let S_+ (resp. S_-) be the set of positive (resp. negative) solutions of (1.1). From Propositions 4.1 and 4.3 and the nonlinear regularity theory, we have

$$\emptyset \neq S_+ \subseteq \operatorname{int} C_+ \quad \text{and} \quad \emptyset \neq S_- \subseteq -\operatorname{int} C_+.$$

Next we show that the solutions $\bar{u} \in \operatorname{int} C_+$ (resp. $\bar{v} \in -\operatorname{int} C_+$) from Proposition 4.4, is a lower bound (resp. upper bound) for the elements of S_+ (resp. of S_-).

Proposition 4.5. *If hypotheses H_0 and H_1 or H_2 ($q = 2$) hold, then $\bar{u} \leq u$ for all $u \in S_+$, and $v \leq \bar{v}$ for all $v \in S_-$.*

Proof. For $u \in S_+ \subseteq \operatorname{int} C_+$ and consider the Carathéodory function $k_+ : \Omega \times \mathbb{R} \to \mathbb{R}$ defined by

$$k_+(z,x) = \begin{cases} (\eta(z) - \varepsilon)(x^+)^{q-1} - c_6(x^+)^{p-1} & \text{if } x \leq u(z), \\ (\eta(z) - \varepsilon)(u(z))^{q-1} - c_6(u(z))^{p-1} & \text{if } u(z) < x. \end{cases} \tag{4.21}$$

We set $K_+(z,x) = \int_0^x k_+(z,s)\,ds$ and consider the C^1-functional $\gamma_+ : W_0^{1,p}(\Omega) \to \mathbb{R}$ defined by

$$\gamma_+(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega K_+(z,u)\,dz \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

Clearly $\gamma_+(\cdot)$ is coercive (see (4.21)). Also using the Sobolev embedding theorem, we see that $\gamma_+(\cdot)$ is sequentially weakly lower semicontinuous. So, we can find $\tilde{u} \in W_0^{1,p}(\Omega)$ such that

$$\gamma_+(\tilde{u}) = \inf\left\{\gamma_+(u) : u \in W_0^{1,p}(\Omega)\right\}. \tag{4.22}$$

As in the proof of Proposition 4.1, we choose $t \in (0,1)$ small so that $t\hat{u}_1^{a_2}(q) \leq u$ (recall $u \in \operatorname{int} C_+$ and use Proposition 4.1.22, p. 274 of [12]) and using (4.21) and since $q < p$, we have

$$\begin{aligned} &\gamma_+(t\hat{u}_1^{a_2}(q)) < 0 \ \text{ (choosing } t \in (0,1) \text{ even smaller if necessary)}, \\ &\Rightarrow \gamma_+(\tilde{u}) < 0 = \gamma_+(0) \quad \text{(see (4.22))}, \\ &\Rightarrow \tilde{u} \neq 0. \end{aligned}$$

From (4.22) we have

$$\begin{aligned} &\langle \gamma_+'(\tilde{u}), h\rangle = 0 \quad \text{for all } h \in W_0^{1,p}(\Omega), \\ &\Rightarrow \langle V(\tilde{u}), h\rangle = \int_\Omega k_+(z,\tilde{u})h\,dz \quad \text{for all } h \in W_0^{1,p}(\Omega). \end{aligned} \tag{4.23}$$

In (4.23) we choose the test function $h = -\tilde{u}^- \in W_0^{1,p}(\Omega)$ and obtain

$$\begin{aligned} &\hat{c}\|D\tilde{u}^-\|_p^p \leq 0 \quad \text{(see (4.21))}, \\ &\Rightarrow \tilde{u} \geq 0, \quad \tilde{u} \neq 0. \end{aligned}$$

Next in (4.23), we choose the test function $h = (\tilde{u} - u)^+ \in W_0^{1,p}(\Omega)$. Then

$$\begin{aligned} \langle V(\tilde{u}), (\tilde{u} - u)^+\rangle &= \int_\Omega \left[(\eta(z) - \varepsilon)u^{q-1} - c_6 u^{p-1}\right](\tilde{u} - u)^+\,dz \quad \text{(see (4.21))} \\ &\leq \int_\Omega f(z,u)(\tilde{u} - u)^+\,dz \quad \text{(see (4.16))} \\ &= \langle V(u), (\tilde{u} - u)^+\rangle \quad \text{(since } u \in S_+\text{)}. \\ &\Rightarrow \tilde{u} \leq u. \end{aligned}$$

So, we have proved that

$$\tilde{u} \in [0, u], \quad \tilde{u} \neq 0. \tag{4.24}$$

From (4.24), (4.21), (4.23) and Proposition 4.5, it follows that

$$\tilde{u} = \bar{u} \leq u \quad \text{for all } u \in S_+ \ (u \in S_+ \text{ was arbitrary}).$$

Similarly, we show that

$$v \leq \bar{v} \quad \text{for all } v \in S_-. \qquad \square$$

Using these bounds, we can produce the extremal constant sign solutions for problem (1.1).

Proposition 4.6. *If hypotheses H_0 and H_1 or H_2 $(q = 2)$ hold, then there exist $u^* \in S_+$ and $v^* \in S_-$ such that $u^* \leq u$ for all $u \in S_+$, $v \leq v^*$ for all $v \in S_-$.*

Proof. We know that S_+ is downward directed, that is, if $u_1, u_2 \in S_+$, then there exists $u \in S_+$ such that $u \leq u_1$, $u \leq u_2$ (see Papageorgiou–Rădulescu–Repovš [11]). Then using Theorem 5.109, p. 308, of Papageorgiou–Rădulescu [4], we can find $\{u_n\}_{n\in\mathbb{N}} \subseteq S_+$ decreasing such that

$$\inf S_+ = \inf_{n\in\mathbb{N}} u_n.$$

From Proposition 4.5, we have

$$\bar{u} \leq u_n \leq u_1 \quad \text{for all } n \in \mathbb{N}. \tag{4.25}$$

Also, since $u_n \in S_+$ for all $n \in \mathbb{N}$, we have

$$\langle V(u_n), h\rangle = \int_\Omega f(z, u_n)h\,dz \quad \text{for all } h \in W_0^{1,p}(\Omega). \tag{4.26}$$

In (4.26) we choose the test function $h = u_n \in W_0^{1,p}(\Omega)$. Then using (4.25) and hypothesis $H_1(\mathrm{i}) = H_2(\mathrm{i})$, we infer that

$$\{u_n\}_{n\in\mathbb{N}} \subseteq W_0^{1,p}(\Omega) \quad \text{is bounded.}$$

So, we may assume that

$$u_n \xrightarrow{w} u^* \quad \text{in } W_0^{1,p}(\Omega), \quad u_n \to u^* \quad \text{in } L^p(\Omega). \tag{4.27}$$

In (4.26) we choose the test function $h = u_n - u^* \in W_0^{1,p}(\Omega)$, pass to the limit as $n \to \infty$ and use (4.27). Then

$$\lim_{n\to\infty} \langle V(u_n), u_n - u^*\rangle = 0,$$

$$\Rightarrow u_n \to u^* \quad \text{in } W_0^{1,p}(\Omega) \quad (\text{see Proposition 2.3}).$$

Passing to the limit as $n \to \infty$ in (4.26), we obtain

$$\langle V(u^*), h\rangle = \int_\Omega f(z, u^*)h\,dz \quad \text{for all } h \in W_0^{1,p}(\Omega),$$
$$\bar{u} \leq u^* \ (\text{see (4.25)}).$$

Therefore, $u^* \in S_+$, $u^* = \inf S_+$.

To produce the maximal negative solution, we note that S_- is upward directed (that is, if $v_1, v_2 \in S_-$, there exists $v \in S_-$ such that $v_1 \leq v,\ v_2 \leq v$). Therefore, we can find $\{v_n\}_{n\in\mathbb{N}}$ increasing such that

$$\sup S_- = \sup_{n\in\mathbb{N}} v_n.$$

Reasoning as above, we produce $v^* \in S_-$ such that

$$v \leq v^* \quad \text{for all } v \in S_-. \qquad \square$$

In Proposition 4.1, to obtain the solutions $u_0 \in \operatorname{int} C_+$ and $v_0 \in -\operatorname{int} C_+$, we did not use the asymptotic condition as $x \to \pm\infty$ (hypothesis $H_1(\text{ii}) = H_2(\text{ii})$). If we bring this condition in the picture and strengthen hypotheses $H_1(\text{iii})$, $H_2(\text{iii})$, we can generate additional constant sign solutions.

The new hypotheses on $f(z,x)$ are the following:

H_1' : $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function such that $H_1'(\text{i})$, (ii), (iv), (v) are the same as the corresponding hypotheses $H_1(\text{i})$, (ii), (iv), (v) and

(iii) there exist $\tau \in (1,q)$, $\delta > 0$ and $c_0^* > 0$ such that

$$c_0^*|x|^\tau \leq f(z,x)x \leq \tau F(z,x) \quad \text{for a.a. } z \in \Omega, \text{ all } |x| \leq \delta.$$

H_2' : $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is a Carathéodory function such that $H_2'(\text{i})$, (ii), (iv), (v) are the same as the corresponding hypotheses $H_2(\text{i})$, (ii), (iv), (v) and

(iii) $q = 2$ and there exist $\eta_1, \eta_2 \in L^\infty(\Omega)$ and $k \geq 2$ such that

$$\begin{aligned}
&\hat{\lambda}_k^{a_2}(2) \leq \eta_1(z) \leq \eta_2(z) \leq \hat{\lambda}_{k+1}^{a_2}(2) \quad \text{for a.a. } z \in \Omega,\\
&\eta_1 \not\equiv \hat{\lambda}_k^{a_2}(2), \quad \eta_2 \not\equiv \hat{\lambda}_{k+1}^{a_2}(2),\\
&\eta_1(z) \leq \liminf_{x\to 0} \frac{f(z,x)}{x} \leq \limsup_{x\to 0} \frac{f(z,x)}{x} \leq \eta_2(z)\\
&\qquad\qquad \text{uniformly for a.a. } z \in \Omega.
\end{aligned}$$

Proposition 4.7. *If hypotheses H_0 and H_1' or H_2' ($q = 2$) hold, then we can find two more constant sign solutions:*

$$\hat{u} \in \operatorname{int} C_+, \quad u_0 \leq \hat{u}, \quad \hat{u} \neq u_0,$$
$$\hat{v} \in -\operatorname{int} C_+, \quad \hat{v} \leq v_0, \quad \hat{v} \neq v_0.$$

Proof. From Proposition 4.1, we know that there is a positive solution $u_0 \in \operatorname{int} C_+$ such that

$$u_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})}[0, \theta_+]$$

and u_0 is a local minimizer of $\varphi_+(\cdot)$. We assume that K_{φ_+} is finite, otherwise we already have an infinite number of positive smooth solutions and so we are done.

Claim: $\varphi_+(\cdot)$ satisfies the C-condition.

Consider a sequence $\{u_n\}_{n\in\mathbb{N}} \subseteq W_0^{1,p}(\Omega)$ such that $\{\varphi_+(u_n)\}_{n\in\mathbb{N}} \subseteq \mathbb{R}$ is bounded and

$$\left| \langle V(u_n), h\rangle - \int_\Omega f(z, u_n^+)h\, dz \right| \leq \frac{\varepsilon_n \|h\|}{1 + \|u_n\|} \tag{4.28}$$

for all $h \in W_0^{1,p}(\Omega)$, all $n \in \mathbb{N}$ with $\varepsilon_n \to 0$.

In (4.28), we choose the test function $h = -u_n^- \in W_0^{1,p}(\Omega)$ and obtain

$$\hat{c}\|Du_n^-\|_p^p \leq \varepsilon_n \quad \text{for all } n \in \mathbb{N},$$

$$\Rightarrow u_n^- \to 0 \quad \text{in } W_0^{1,p}(\Omega). \tag{4.29}$$

Suppose that $\|u_n^+\| \to \infty$ and let $y_n = \frac{u_n^+}{\|u_n^+\|}$, $n \in \mathbb{N}$. Then

$$\|y_n\| = 1, \ y_n \geq 0 \quad \text{for all } n \in \mathbb{N}.$$

So, we may assume that

$$y_n \xrightarrow{w} y \quad \text{in } W_0^{1,p}(\Omega), \quad y_n \to y \quad \text{in } L^p(\Omega), \quad y \geq 0. \tag{4.30}$$

From (4.28) and (4.29) it follows that

$$|\langle V(u_n^+), h\rangle| \leq \varepsilon_n'\|h\| + \int_\Omega f(z, u_n^+)h\,dz \tag{4.31}$$

$$\text{for all } h \in W_0^{1,p}(\Omega), \text{ all } n \in \mathbb{N}, \text{ with } \varepsilon_n' \to 0^+.$$

$$\Rightarrow \int_\Omega a_1(z)|Dy_n|^{p-2}(Dy_n, Dh)_{\mathbb{R}^N}dz + \frac{1}{\|u_n\|^{p-q}}\int_\Omega a_2|Dy_n|^{q-2}(Dy_n, Dh)_{\mathbb{R}^N}\,dz$$

$$\leq \frac{\varepsilon_n'}{\|u_n^+\|^{p-1}}\|h\| + \int_\Omega \frac{f(z, u_n^+)}{\|u_n^+\|^{p-1}}h\,dz \quad \text{for all } h \in W_0^{1,p}(\Omega), \text{ all } n \in \mathbb{N}. \tag{4.32}$$

On account of hypothesis H_1(i)=H_2(i), we have that

$$\left\{\frac{f(\cdot, u_n^+(\cdot))}{\|u_n^+\|^{p-1}}\right\}_{n\in\mathbb{N}} \subseteq L^{p'}(\Omega) \text{ is bounded.} \tag{4.33}$$

So using hypothesis $H_1(\text{ii}) = H_2(\text{ii})$, we may assume that

$$\frac{f(\cdot, u_n^+(\cdot))}{\|u_n^+\|^{p-1}} \xrightarrow{w} \hat{\eta}_0(\cdot)y^{p-1} \tag{4.34}$$

with $\hat{\eta}_0 \in L^\infty(\Omega)$, $\hat{\eta}(z) \leq \hat{\eta}_0(z)$ for a.a. $z \in \Omega$. (see Aizicovici–Papageorgiou–Staicu [1], proof of Proposition 16). In (4.32), we choose the test function $h = y_n - y \in W_0^{1,p}(\Omega)$, pass to the limit as $n \to \infty$ and use (4.30) and (4.33). Then

$$\limsup_{n\to\infty}\int_\Omega a_1(z)|Dy_n|^{p-2}(Dy_n, Dy_n - Dy)_{\mathbb{R}^N}\,dz \leq 0,$$

$$\Rightarrow y_n \to y \quad \text{in } W_0^{1,p}(\Omega), \quad \|y\| = 1, \quad y \geq 0 \tag{4.35}$$

(see Papageorgiou–Winkert [14], p. 665).

If in (4.32), we pass to the limit as $n \to \infty$ and use (4.34), (4.35), we obtain

$$\int_\Omega a_1(z)|Dy|^{p-2}(Dy, Dh)_{\mathbb{R}^N}\,dz = \int_\Omega \hat{\eta}_0(z)y^{p-1}h\,dz \quad \text{for all } h \in W_0^{1,p}(\Omega),$$

$$\Rightarrow -\Delta_p^{a_1}y = \hat{\eta}_0(z)y^{p-1} \quad \text{in } \Omega, \quad y|_{\partial\Omega} = 0. \tag{4.36}$$

Recall that $\hat{\lambda}_1^{a_1}(p) \leq \hat{\eta}(z) \leq \hat{\eta}_0(z)$ for a.a. $z \in \Omega$. Let $\tilde{\lambda}_1^{a_1}(p, \hat{\eta}_0)$ be the principal eigenvalue of $-\Delta_p^{a_1} y = \tilde{\lambda}\hat{\eta}_0(z)|y|^{p-2}y$ in Ω, $y|_{\partial\Omega} = 0$ (weighted version of the eigenvalue problem (2.1). From Proposition 4.133, p. 271, of Hu–Papageorgiou [5] we have

$$\tilde{\lambda}_1^{a_1}(p, \hat{\eta}_0) < \tilde{\lambda}_1^{a_1}(p, \hat{\lambda}_1^{a_1}(p)) = 1.$$

Then from (4.36) it follows that

$$y(\cdot) \text{ is nodal or zero (see Hu–Papageorgiou [5, Proposition 4.127, p. 268]).}$$

Both possibilities contradict (4.35). Therefore

$$\begin{aligned} &\{u_n^+\}_{n\in\mathbb{N}} \subseteq W_0^{1,p}(\Omega) \text{ is bounded,} \\ \Rightarrow\ &\{u_n\}_{n\in\mathbb{N}} \subseteq W_0^{1,p}(\Omega) \text{ is bounded (see (4.29)).} \end{aligned}$$

So, we may assume that

$$u_n \xrightarrow{w} u \quad \text{in } W_0^{1,p}(\Omega), \quad u_n \to u \quad \text{in } L^p(\Omega). \tag{4.37}$$

In (4.28) we choose the test function $h = u_n - u \in W_0^{1,p}(\Omega)$, pass to the limit as $n \to \infty$ and use (4.37). Then

$$\begin{aligned} &\lim_{n\to\infty} \langle V(u_n), u_n - u\rangle = 0 \\ \Rightarrow\ &u_n \to u \quad \text{in } W_0^{1,p}(\Omega) \quad \text{(see Proposition 2.3)}, \\ \Rightarrow\ &\varphi_+(\cdot) \text{ satisfies the C-condition.} \end{aligned}$$

This proves the claim.

Recall that u_0 is a local minimizer of $\varphi_+(\cdot)$ and that K_{φ_+} is finite (see the beginning of the proof). These facts and Proposition 3.132, p. 179, of Hu–Papageorgiou [5], imply that we can find $\rho \in (0,1)$ small such that

$$\varphi_+(u_0) < \inf\{\varphi_+(u) : \|u - u_0\| = \rho\} = m_+. \tag{4.38}$$

Hypotheses H_1(i),(ii) $= H_2$(i),(ii) imply that given $\varepsilon > 0$, we can find $\delta = \delta(\varepsilon) > 0$ such that

$$F(z,x) \geq \frac{1}{p}[\hat{\eta}(z) - \varepsilon]|x|^p \quad \text{for a.a. } z \in \Omega, \text{ all } |x| \leq \delta.$$

For $t \in (0,1)$, we have

$$\begin{aligned} \varphi_+(t\hat{u}_1^{a_1}(p)) &\leq \frac{t^p}{p}\int_\Omega [\hat{\lambda}_1^{a_1}(p) - \eta(z)]\hat{u}_1^{a_1}(p)^p\, dz + \frac{\varepsilon t^p}{p} + \frac{t^q}{t^q}\rho_{a_2,q}(D\hat{u}_1^{a_1}(p)) \\ &\quad \text{(since } \rho_{a_1,p}(D\hat{u}_1^{a_1}(p)) = \hat{\lambda}_1^{a_1}(p)\|\hat{u}_1^{a_1}(p)\|_p^p,\ \|\hat{u}_1^{a_1}(p)\|_p = 1). \end{aligned}$$

Since $\hat{u}_1^{a_1} \in \operatorname{int} C_+$ and the inequality $\hat{\lambda}_1^{a_1}(p) \leq \eta(z)$ for a.a. $z \in \Omega$ is strict on a set of positive Lebesgue measure, it follows that

$$\hat{\beta} = \int_\Omega [\hat{\eta}(z) - \hat{\lambda}_1^{a_1}(p)]\hat{u}_1(p)^p\, dz > 0.$$

Choosing $\varepsilon \in (0, \hat{\beta})$ small, we obtain

$$\varphi_+(t\hat{u}_1^{a_1}(p)) \leq c_7 t^q - c_8 t^p \quad \text{for some } c_7, c_8 > 0.$$

Since $q < p$, we infer that

$$\varphi_+(t\hat{u}_1(p)) \to -\infty \quad \text{as } t \to +\infty. \tag{4.39}$$

Then (4.38), (4.39) and the Claim, permit the use of the mountain pass theorem and obtain $\hat{u} \in W_0^{1,p}(\Omega)$ such that

$$\begin{aligned} &\hat{u} \in K_{\varphi_+} \subseteq \operatorname{int} C_+ \cup \{0\}, \quad m_+ \leq \varphi_+(\hat{u}), \\ \Rightarrow\ &\hat{u} \neq u_0. \end{aligned}$$

If we show that $\hat{u} \neq 0$, then $\hat{u} \in \operatorname{int} C_+$ is the second positive solution of (1.1). First assume that hypotheses H_1' hold. On account of hypothesis H_1'(iii) and of Lemma 5.125, p. 459, of Hu–Papageorgiou [5] we have

$$C_k(\varphi_+, 0) = 0 \quad \text{for all } k \in \mathbb{N}_0. \tag{4.40}$$

On the other hand since $\hat{u} \in K_{\varphi_+}$ is a critical point of mountain pass type, using Corollary 3.125, p. 178, of Hu–Papageorgiou [5], we have

$$C_1(\varphi_+, \hat{u}) \neq 0. \tag{4.41}$$

Comparing (4.40) and (4.41), we conclude that $\hat{u} \neq 0$. So $\hat{u} \in \operatorname{int} C_+$ is the second positive solution of (1.1).

Similarly working this time with the functional $\varphi_-(\cdot)$, we produce a second negative solution $\hat{v} \in -\operatorname{int} C_+$, $\hat{v} \neq v_0$. □

5 Nodal solutions

In this section we prove the existence of nodal solutions (sign-changing solutions) for problem (1.1) and state the complete multiplicity theorem.

First we consider the case where hypotheses H_1' hold.

Proposition 5.1. *If hypotheses H_0, H_1' hold, then problem (1.1) admits at least two nodal solutions*

$$y_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})}[v_0, u_0], \ \hat{y} \in [v_0, u_0] \cap C_0^1(\overline{\Omega}), \ \hat{y} \neq y_0.$$

Proof. Let $u_* \in \operatorname{int} C_+$, $v_* \in -\operatorname{int} C_+$ be the two extremal constant sign solutions produced in Proposition 4.6. We introduce the Carathéodory function defined by

$$\gamma(z,x) = \begin{cases} f(z, v^*(z)) & \text{if } x < v^*(z), \\ f(z,x) & \text{if } v^*(z) \leq x \leq u^*(z), \\ f(z, u^*(z)) & \text{if } u^*(z) < x. \end{cases} \tag{5.1}$$

In addition, we introduce the positive and negative truncations of $\gamma_*(z,\cdot)$, namely the Carathéodory functions

$$\gamma_\pm(z,x) = \gamma(z, \pm x^\pm) \quad \text{for all } z \in \Omega, \text{ all } x \in \mathbb{R}. \tag{5.2}$$

We set $\Gamma(z,x) = \int_0^x \gamma(z,s)\,ds$, $\Gamma_\pm(z,x) = \int_0^x \gamma_\pm(z,s)\,ds$ and consider the C^1-functionals $\mu, \mu_\pm : W_0^{1,p}(\Omega) \to \mathbb{R}$ defined by

$$\mu(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega \Gamma(z,u)\,dz,$$
$$\mu_\pm(u) = \frac{1}{p}\rho_{a_1,p}(Du) + \frac{1}{q}\rho_{a_2,q}(Du) - \int_\Omega \Gamma_\pm(z,u)\,dz \quad \text{for all } u \in W_0^{1,p}(\Omega).$$

Using (5.1) and (5.2), we can check easily that

$$K_\mu \subseteq [v_*, u_*] \cap C_0^1(\overline{\Omega}), \qquad K_{\mu_+} \subseteq [0, u_*] \cap C_+, \qquad K_{\mu_-} \subseteq [v_*, 0] \cap (-C_+).$$

The extremality of u^*, v^* implies that

$$K_\mu \subseteq [v_*, u_*] \cap C_0^1(\overline{\Omega}), \qquad K_{\mu_+} = \{0, u^*\}, \qquad K_{\mu_-} = \{0, v_*\}. \tag{5.3}$$

From (5.1) and (5.2) it is clear that $\mu_+(\cdot)$ is coercive. Also, it is sequentially weakly lower semicontinuous. So, we can find $\hat{u}^* \in W_0^{1,p}(\Omega)$ such that

$$\mu_+(\hat{u}^*) = \inf\left\{\mu_+(u) : u \in W_0^{1,p}(\Omega)\right\} < 0 = \mu_+(0),$$
$$\text{(since } \tau < q \text{ and } u^* \in \operatorname{int} C_+)$$
$$\Rightarrow \hat{u}^* \neq 0 \quad \text{and so } \hat{u}^* = u^* \quad \text{(see (5.3))}.$$

From (5.1) and (5.2) it is clear that

$$\mu_+\big|_{C_+} = \mu\big|_{C_+}.$$

Therefore, we have that

$$u^* \in \operatorname{int} C_+ \text{ is a local } C_0^1(\overline{\Omega})\text{-minimizer of } \varphi(\cdot),$$
$$\Rightarrow u^* \in \operatorname{int} C_+ \text{ is a local } W_0^{1,p}(\Omega)\text{-minimizer of } \mu(\cdot).$$

In a similar fashion, using this time the functional $\mu_-(\cdot)$, we show that

$$v^* \in -\operatorname{int} C_+ \text{ is a local } W_0^{1,p}(\Omega)\text{-minimizer of } \mu(\cdot).$$

We may assume that

$$\mu(v^*) \leq \mu(u^*) \quad \text{and} \quad K_\mu \text{ is finite} \tag{5.4}$$

(see (5.3) and note that any solution $y \notin \{0, u^*, v^*\}$ of (1.1) is necessarily nodal). The functional $\mu(\cdot)$ being coercive, satisfies the C-condition (see Hu–Papageorgiou [5], Proposition 3.19, p. 123). So, using Proposition 3.132, p. 179, of Hu–Papageorgiou [5], we can find $\rho \in (0,1)$ small such that

$$\rho < \|u^* - v^*\|, \ \mu(u^*) < \inf\{\mu(u) : \|u - u^*\| = \rho\} = m^*. \tag{5.5}$$

Then (5.4),(5.5) and the C-condition of $\mu(\cdot)$, permit the use of the mountain pass theorem. So, we can find $y_0 \in W_0^{1,p}(\Omega)$ such that

$$y_0 \in K_\mu \in [v^*, u^*] \cap C_0^1(\overline{\Omega}) \text{ (see(5.3))}, \quad m^* \leq \mu(y_0) \text{ (see (5.5))}. \tag{5.6}$$

We know that

$$C_1(\mu, y_0) \neq 0 \quad \text{(see [5, Corollary 3.123, p. 176])}. \tag{5.7}$$

Using the homotopy invariance property of critical groups (see [5, p. 179]) and the nonlinear regularity theory, we obtain

$$C_k(\mu, 0) = C_k(\varphi, 0) \quad \text{for all } k \in \mathbb{N}_0. \tag{5.8}$$

From hypothesis H_1'(iii) and Hu–Papageorgiou [5, Lemma 5.126, p. 462], we have

$$\begin{aligned} & C_k(\varphi, 0) = 0 \quad \text{for all } k \in \mathbb{N}_0, \\ \Rightarrow\ & C_k(\mu, 0) = 0 \quad \text{for all } k \in \mathbb{N}_0 \quad \text{(see (5.8))}. \end{aligned} \tag{5.9}$$

From (5.7) and (5.9), we infer that

$$y_0 \neq 0.$$

Also, $y_0 \notin \{u^*, v^*\}$ (see (5.5), (5.6)). Therefore

$$y_0 \in [v^*, u^*] \cap C_0^1(\overline{\Omega}) \text{ is a nodal solution of (1.1)}.$$

By Theorem 1.3 of Lucia–Prashanth [10] (see also Pucci–Serrin [15, p. 6]), we have

$$y_0(z) < u^*(z) \quad \text{for all } z \in \Omega. \tag{5.10}$$

Let $\rho = \max\{\|v^*\|_\infty, \|u^*\|_\infty\}$ and let $\hat{\xi}_\rho > 0$ be as postulated by hypothesis H_1(v). We take $\hat{\xi}^* > \hat{\xi}_\rho$ and have

$$\begin{aligned} -\Delta_p^{a_1} y_0 - \Delta_q^{a_2} y_0 + \hat{\xi}^* |y_0|^{p-2} y_0 &= f(z, y_0) + \hat{\xi}^* |y_0|^{p-2} y_0 \\ &\leq f(z, u^*) + \hat{\xi}^* (u^*)^{p-1} \\ &= -\Delta_p^{a_1} u^* - \Delta_q^{a_2} u^* + \hat{\xi}^* (u^*)^{p-1} \quad \text{in } \Omega. \end{aligned}$$

Note that

$$\begin{aligned} f(z, u^*) + \hat{\xi}^* (u^*)^{p-1} &= f(z, u^*) + \hat{\xi}_\rho (u^*) + (\hat{\xi}^* - \hat{\xi}_\rho)(u^*)^{p-1} \\ &\geq f(z, y_0) + \hat{\xi}_\rho |y_0|^{p-2} y_0 + (\hat{\xi}^* - \hat{\xi}_\rho)|y_0|^{p-2} y_0 \\ &= f(z, y_0) + \hat{\xi}^* |y_0|^{p-2} y_0 \quad \text{in } \Omega. \end{aligned} \tag{5.11}$$

From hypothesis H_1(v) and (5.10), we see that

$$f(\cdot, y_0(\cdot)) + \hat{\xi}^* |y_0(\cdot)|^{p-2} y_0(\cdot) \prec f(\cdot, u^*(\cdot)) + \hat{\xi}^* (u^*(\cdot))^{p-1}.$$

So, using Preccosition 3.1, from (5.11) we infer that

$$u^* - y_0 \in \operatorname{int} C_+.$$

Similarly we show that

$$y_0 - v^* \in \operatorname{int} C_+.$$

It follows that

$$y_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})} [v^*, u^*]. \tag{5.12}$$

Moreover, using the flow invariance argument from the proof of Proposition 5.1 of Liu–Papageorgiou [8], we generate another solution

$$\hat{y} \in [v^*, u^*] \cap C_0^1(\overline{\Omega}) \setminus \operatorname{int}_{C_0^1(\overline{\Omega})} [v^*, u^*]. \tag{5.13}$$

From (5.12) and (5.13) it follows that

$$\hat{y} \in C_0^1(\overline{\Omega}) \text{ is a nodal solution of (1.1)}, \quad \hat{y} \neq y_0. \qquad \square$$

When hypotheses $H_2'(q=2)$ hold, since the behavior of $f(z,\cdot)$ near zero is different, we need to strengthen the hypotheses on the reaction $f(z,x)$ in order to have nodal solutions.

H_2'': $f:\Omega\times\mathbb{R}\to\mathbb{R}$ is a measurable function such that $f(z,\cdot)\in C^1(\mathbb{R})$ for a.a. $z\in\Omega$, hypotheses H_2''(i), (ii), (iv), (v) are the same as the corresponding hypotheses H_2(i), (ii), (iv), (v) and

(iii) there exists $k\geq 2$ such that

$$f_x'(z,0)\in\left[\hat{\lambda}_k^{a_2}(2),\hat{\lambda}_{k+1}^{a_2}(2)\right] \quad \text{for a.a. } z\in\Omega,$$
$$f_x'(\cdot,0)\not\equiv\hat{\lambda}_k^{a_2}(2),\ f_x'(\cdot,0)\not\equiv\hat{\lambda}_{k+1}^{a_2}(2).$$

Proposition 5.2. *If hypotheses H_0 and $H_2''(q\neq 2)$ hold, then problem (1.1) $(q=2)$ admits at least two nodal solutions*

$$y_0\in \operatorname{int}_{C_0^1(\overline{\Omega})}[v^*,u^*]$$
$$\hat{y}\in[v^*,u^*]\cap C_0^1(\overline{\Omega}),\quad \hat{y}\neq y_0.$$

Proof. The proof is similar to that of Proposition 5.1.

In this case (5.10) follows from the tangency principle (see Pucci–Serrin [16, p. 35]). Since $f(z,\cdot)$ exhibits a linear behavior near zero (see hypothesis H_2''(iii)) and so there is no resonance, we can not claim that $C_k(\mu,0)=0$ for all $k\in\mathbb{N}_0$. So, to prove the nontriviality of y_0, we have to use a different argument.

Let $\hat{l}:H_0^1(\Omega)\to\mathbb{R}$ be the C^2-functional defined by

$$\hat{l}(u)=\frac{1}{2}\rho_{a_2,2}(Du)-\int_\Omega F(z,u)\,dz \quad \text{for all } u\in H_0^1(\Omega).$$

We consider the following orthogonal direct sum decomposition

$$H_0^1(\Omega)=Y\oplus V$$

with $Y=\bigoplus_{i=1}^k E(\hat{\lambda}_i^{a_2}(2))$, $V=\overline{\bigoplus_{i\geq k}E(\hat{\lambda}_i^{a_2}(2))}$.

Hypotheses H_2''(i), (iii), imply that given $\varepsilon>0$, we can find $c_{10}=c_{10}(\varepsilon)>0$ such that

$$F(z,x)\leq\frac{1}{2}[f_x'(z,0)+\varepsilon]x^2+c_{10}|x|^p \tag{5.14}$$

If $u\in V$, then using (5.14), we have

$$\begin{aligned}\hat{l}(u)&\geq\frac{1}{2}\rho_{a_2,2}(Du)-\frac{1}{2}\int_\Omega f_x'(z,0)u^2\,dz-\frac{\varepsilon}{2\hat{\lambda}_1^{a_2}(2)}\rho_{a_2,2}(Du)-c_{11}\|u\|^p \quad \text{for some } c_{11}>0\\ &\geq\frac{1}{2}\left[c_{12}-\varepsilon\right]\|u\|^2-c_{11}\|u\|^p \quad \text{for some } c_{12}>0 \text{ (see Proposition 2.2)}\end{aligned}$$

Choosing $\varepsilon\in(0,c_{12})$, we obtain

$$\hat{l}(u)\geq c_{13}\|u\|^2-c_{11}\|u\|^p \quad \text{for some } c_{13}>0.$$

Since $2<p$, for $\rho\in(0,1)$ small we can say that

$$\hat{l}(u)\geq 0 \quad \text{for all } u\in V, \text{ with } \|u\|\leq\rho. \tag{5.15}$$

On the other hand, again from hypothesis H_2''(iii), we see that given $\varepsilon > 0$, we can find $\delta = \delta(\varepsilon) > 0$ such that

$$F(z,x) \geq \frac{1}{2}[f_x'(z,0) - \varepsilon]x^2 \quad \text{for a.a. } z \in \Omega, \text{ all } |x| \leq \delta. \tag{5.16}$$

The space Y is finite dimensional and so all norms are equivalent (see Papageorgiou–Winkert [14], p. 183). Therefore we can find $\hat{\rho} > 0$ such that

$$u \in Y,\ \|u\| \leq \hat{\rho} \Rightarrow |u(z)| \leq \delta \quad \text{for all } z \in \Omega. \tag{5.17}$$

Therefore if $u \in Y$ with $\|u\| \leq \hat{\rho}$, then

$$\begin{aligned}\hat{l}(u) &\leq \frac{1}{2}\rho_{a_2,2}(Du) - \frac{1}{2}\int_\Omega [f_x'(z,0) - \varepsilon]u^2\,dz \quad \text{(see (5.16), (5.17))}\\ &\leq \frac{1}{2}\left[\varepsilon - c_{14}\right]\|u\|^2 \quad \text{for some } c_{14} > 0 \quad \text{(see Proposition 2.2)}\end{aligned}$$

Choosing $\varepsilon \in (0, c_{14})$, we conclude that

$$\hat{l}(u) \leq 0 \quad \text{for all } u \in Y,\ \|u\| \leq \hat{\rho}. \tag{5.18}$$

From (5.15) and (5.18), we infer that $\hat{l}(\cdot)$ has a local linking at the origin with respect to the orthogonal decomposition (Y, V) (see [5, p. 145]). If $d_k = \dim Y \geq 2$ (recall $k \geq 2$), then

$$C_m(\hat{l}, 0) = \delta_{m,d_k}\mathbb{R} \quad \text{for all } m \in \mathbb{N}_0 \quad \text{(see [12], p. 539)}. \tag{5.19}$$

Let $l = \hat{l}|_{W_0^{1,p}(\Omega)}$ (recall $W_0^{1,p}(\Omega) \hookrightarrow H_0^1(\Omega)$ densely since $p > 2$). So by Proposition 3.128, p. 178, of Hu–Papageorgiou [5], we have

$$\begin{aligned}&C_m(l,0) = C_m(\hat{l},0) \quad \text{for all } m \in \mathbb{N}_0,\\ \Rightarrow\ &C_m(l,0) = \delta_{m,d_k}\mathbb{R} \quad \text{for all } m \in \mathbb{N}_0 \quad \text{(see (5.17))}.\end{aligned} \tag{5.20}$$

From the C^1-continuity property of critical groups (see Theorem 3.129, p. 179, of Hu–Papageorgiou [5]), we have

$$\begin{aligned}&C_m(\psi,0) = C_m(l,0) \quad \text{for all } m \in \mathbb{N}_0.\\ \Rightarrow\ &C_m(\psi,0) = \delta_{m,d_k}\mathbb{R} \quad \text{for all } m \in \mathbb{N}_0 \quad \text{(see (5.20))}.\end{aligned}$$

Recall via the homotopy invariance property of critical groups (see [5, p. 179]), we have

$$\begin{aligned}&C_m(\mu,0) = C_m(\psi,0)\mathbb{R} \quad \text{for all } m \in \mathbb{N}_0,\\ \Rightarrow\ &C_m(\mu,0) = \delta_{m,d_k}\mathbb{R} \quad \text{for all } m \in \mathbb{N}_0\ (d_k \geq 2).\end{aligned} \tag{5.21}$$

We know that $C_1(\mu, y_0) \neq 0$. Comparing with (5.21) we deduce that

$$\begin{aligned}&y_0 \neq 0,\\ \Rightarrow\ &y_0 \in C_0^1(\overline{\Omega}) \text{ is a nodal solution of (1.1) } (q = 2).\end{aligned}$$

Since $y_0(z) < u^*(z)$ for all $z \in \Omega$, as in the proof of Proposition 5.1, we show that

$$y_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})}[v^*, u^*].$$

Finally, the flow invariance argument of Liu–Papageorgiou [8], generates $\hat{y} \in [v^*, u^*] \cap C_0^1(\overline{\Omega})$ another nodal solution of problem (1.1) ($q = 2$), $\hat{y} \neq y_0$. □

We conclude with the following two multiplicity theorems for

Theorem 5.3. *If hypotheses H_0 and H_1' hold, then problem (1.1) admits at least six nontrivial smooth solutions:*

$$\begin{aligned} &u_0, \hat{u} \in \operatorname{int} C_+, \quad u_0 \leq \hat{u}, \quad u_0(z) < \theta_+ \quad \text{for all } z \in \overline{\Omega}, \\ &v_0, \hat{v} \in -\operatorname{int} C_+, \quad \hat{v} \leq v_0, \quad \theta_- < v_0(z) \quad \text{for all } z \in \overline{\Omega}, \\ &y_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})}[v_0, u_0], \quad \hat{y} \in [v_0, u_0] \cap C_0^1(\overline{\Omega}), \quad y_0 \neq \hat{y} \text{ both nodal.} \end{aligned}$$

Theorem 5.4. *If hypotheses H_0 and H_2' ($q = 2$) hold, then problem (1.1) ($q = 2$) admits at least six nontrivial smooth solutions*

$$\begin{aligned} &u_0, \hat{u} \in \operatorname{int} C_+, \quad u_0 \leq \hat{u}, \quad u_0(z) < \theta_+ \quad \text{for all } z \in \overline{\Omega}, \\ &v_0, \hat{v} \in -\operatorname{int} C_+, \quad \hat{v} \leq v_0, \quad \theta_- < v_0(z) \quad \text{for all } z \in \overline{\Omega}, \\ &y_0 \in \operatorname{int}_{C_0^1(\overline{\Omega})}[v_0, u_0], \quad \hat{y} \in [v_0, u_0] \cap C_0^1(\overline{\Omega}), \quad y_0 \neq \hat{y} \text{ both nodal.} \end{aligned}$$

Remark 5.5. We point out that in the above multiplicity theorems, we provide sign information for all the solutions produced. Moreover, the solutions $\{u_0, \hat{u}, v_0, \hat{v}, y_0\}$ and $\{u_0, \hat{u}, v_0, \hat{v}, y_0\}$ are ordered.

Abstract. In this article, we prove the existence of a weak solution to the sub-elliptic problem

$$-\Delta_{\mathbb{H}} u + V(\xi)u = \left(\int_{\mathbb{H}^N} \frac{|u(\eta)|^{Q_\alpha^*} + K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right)\left(Q_\alpha^*|u|^{Q_\alpha^*-2}u + pK(\xi)|u|^{p-2}u\right)$$

in the Heisenberg group $\mathbb{H}^N$, where $0<\alpha<4$, $Q=2N+2$, $Q_\alpha^*=\frac{2Q-\alpha}{Q-2}$, $p\in(2,Q_\alpha^*)$, V is a non-negative continuous function that can vanish at infinity and K is continuous non-negative bounded function. We establish the existence of a weak solution by employing the penalization method in conjunction with the mountain pass theorem.

Keywords: vanishing potential, critical Choquard type non-linearity, Heisenberg group, penalization method.

2020 Mathematics Subject Classification: 35R03, 35A15, 35H20.

1 Introduction

In this paper, we study the existence of a weak solution to the problem:

$$-\Delta_{\mathbb{H}} u + V(\xi)u = \left(\int_{\mathbb{H}^N} \frac{|u(\eta)|^{Q_\alpha^*} + K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right)\left(Q_\alpha^*|u|^{Q_\alpha^*-2}u + pK(\xi)|u|^{p-2}u\right) \tag{1.1}$$

in the Heisenberg group $\mathbb{H}^N$, where $0<\alpha<4$, $Q=2N+2$, $Q_\alpha^*=\frac{2Q-\alpha}{Q-2}$, $p\in(2,Q_\alpha^*)$, V is a non-negative continuous function that can vanish at infinity and K is continuous non-negative bounded function.

The Heisenberg group has found significant attraction due to its rich geometry, leading to various applications in the field of partial differential equations. In one of the pioneering works, Garofalo and Lanconelli [20] obtained the existence of a solution for a semilinear

✉Corresponding author. Emails: vikramnaik154@gmail.com (V. Y. Naik), gaurav.dwivedi@pilani.bits-pilani.ac.in (G. Dwivedi)

subelliptic PDE in the Heisenberg group via a variational technique. Since then, a wide range of results have been obtained, see [7,8,13,21,25,36,39] and references therein.

The equation (1.1) is analogous to the well-known steady state Schrödinger equation

$$\Delta\Psi + V(x)\Psi = (Z(x) * |\Psi|^q)|\Psi|^{q-2}\Psi \quad \text{in } \mathbb{R}^N, \tag{1.2}$$

where V is the potential, and Z is the response function describing the mutual interaction between the bosons. When $Z(x) = |x|^{-1}$, (1.2) reduces to the Choquard equation. A typical model, corresponding to $q = 2$, is

$$-\Delta\Psi + \Psi = \left(\frac{1}{|x|} * |\Psi|^2\right)\Psi \quad \text{in } \mathbb{R}^N,$$

which was originally introduced in the context of polaron models [19,33]. For a comprehensive overview of Choquard-type problems in $\mathbb{R}^N$, see [31].

On setting the response function $Z(x)$ to be the Dirac-delta function in (1.2), we obtain the Schrödinger equation in the following form:

$$-\Delta u + V(x)u = f(x,u) \quad \text{in } \mathbb{R}^N, \tag{1.3}$$

where $u > 0, V$ is a continuous function and f is a non-linear function. The function V is commonly referred to as the potential function. Equation (1.3) has been extensively studied under various assumptions on V and f. For bounded, coercive potentials V, see [15,30,34,36]. For vanishing potentials ($V(x) \to 0$ as $|x| \to \infty$), notable contributions include [3–5,24,29]. Other situations such as constant, periodic, asymptotically constant, asymptotically periodic, and radial potentials have also been addressed (see [1,2,10,32,40]). For the vanishing potential case Alves–Souto [4], Alves–Figueiredo-Yang [3] employed a penalization technique inspired by Del Pino–Felmer [16].

In recent years, considerable progress has been made on critical Choquard-type problems in the Heisenberg group. Goel and Sreenadh [21] established a Brezis–Nirenberg type result for Choquard equations in $\Omega \subset \mathbb{H}^N$. Sun et al. [36] developed a concentration-compactness lemma for the Choquard equation and applied it to obtain weak solutions of a Kirchhoff–Choquard problem with the critical Hardy–Littlewood–Sobolev exponent. Subsequent works extended and refined these results: Bai et al. [7] proved existence of weak solutions to Kirchhoff–Choquard equations with the same critical exponent in bounded domains, recovering compactness through suitable conditions on the Kirchhoff term, while Sun et al. [36] investigated Kirchhoff-–Choquard systems in bounded domains of $\mathbb{H}^N$. Yang et al. [38] studied (p,q)-type Choquard equations in $\mathbb{H}^N$, focusing on cases where the Choquard term is subcritical. Liang et al. [26] extended the concentration-compactness approach of [36] to the p-sub-Laplacian framework. Further contributions include Bai et al. [6], who considered critical Choquard-type problems with lower-order perturbation terms that may be sublinear or superlinear. Bai et al. [9], who established results for fractional p-sub-Laplacian equations with critical Choquard non-linearities. Most recently, Liang et al. [27] proved the existence of normalized solutions for critical Choquard-type equations with logarithmic perturbations in bounded domains of $\mathbb{H}^N$.

From the above survey, we conclude, to the best of our knowledge, that there are no existing works addressing problems involving vanishing potentials in the Heisenberg group. Moreover, we are not aware of any research in the Heisenberg group that employs the penalization technique. Although Li et al. [24] studied a problem similar to (1.1) in $\mathbb{R}^N$ for the

Laplacian, their approach did not involve the penalization method. Furthermore, to the best of our knowledge, Choquard-type problems have not been investigated via the penalization technique either in $\mathbb{R}^N$ or in $\mathbb{H}^N$. In this article, we obtain an existence result for (1.1) by employing the penalization method, inspired by the works of Alves et al. [3,4].

Before stating our main result, we specify our assumptions on V and K :

(Σ_1) $V : \mathbb{H}^N \to \mathbb{R}$, is continuous, non-negative, $V \in L^\infty(\mathbb{H}^N) \cap L^{\frac{Q}{2}}(\mathbb{H}^N)$ and there exists $\mu > 0, \Lambda > 0$ and $R > 0$ such that

$$\inf_{|\xi| \geq R} |\xi|^\mu V(\xi) \geq \Lambda.$$

(Σ_2) $K : \mathbb{H}^N \to \mathbb{R}$ is continuous, non-negative, bounded and $K \in L^{\frac{Q^*}{Q^*_\alpha - p}}$, where $Q^* = \frac{2Q}{Q-2}$.

From (Σ_1), we have $V \in L^{\frac{2Q}{4-\alpha}}(\mathbb{H}^N)$ by interpolation of the Lebesgue spaces $L^\infty(\mathbb{H}^N)$ and $L^{\frac{Q}{2}}(\mathbb{H}^N)$.

Next, we present and example of V and K satisfying (Σ_1) and (Σ_2), respectively.

Example 1.1. Let $R = 1$. Define

$$V_1(\xi) = \begin{cases} \dfrac{1}{|\xi|^a}, & \xi \in \mathbb{H}^N \setminus B_1(0),\ a > 2, \\ 1, & \xi \in B_1(0). \end{cases}$$

Then V_1 satisfies (Σ_1) for any $\mu > a$ with $\Lambda = 1$.

Examples for K.

(i) Define

$$K_1(\xi) = \begin{cases} \dfrac{1}{|\xi|^a}, & \xi \in \mathbb{H}^N \setminus B_1(0),\ a > \dfrac{Q(Q^*_\alpha - p)}{Q^*}, \\ 1, & \xi \in B_1(0), \end{cases}$$

where

$$p \in \left(2, \frac{2Q-\alpha}{Q-2}\right).$$

Then, K_1 satisfies (Σ_2).

(ii) As a different example, consider

$$K_2(\xi) = e^{-|\xi|^4}.$$

Then K_2 also satisfies (Σ_2).

Now, we state the main result of this paper:

Theorem 1.2. *Let the conditions (Σ_1), (Σ_2) hold. Then, there exists a constant γ such that (1.1) admits a positive weak solution $u \in E$ (see Section 2 for the definition of E) for any $\Lambda \geq \gamma R^\mu$.*

We have organized the paper as follows. Section 2 gives the preliminaries for the Heisenberg group and some primary results on the Heisenberg group. Further, Section 3 converts the main problem into an auxiliary problem and describes its variational framework. In the last section, we prove Theorem 1.2.

2 Preliminaries

We recall some terminologies and definitions related to the Heisenberg group $\mathbb{H}^N = \left(\mathbb{R}^{2N+1}, \circ\right)$, where '$\circ$' denotes the group operation defined as

$$\xi \circ \xi' = (x + x', y + y', t + t' + 2(x' \cdot y - y' \cdot x)), \quad \text{for every } \xi = (x, y, t), \xi' = (x', y', t') \in \mathbb{H}^N,$$

where $x, y, x', y' \in \mathbb{R}^N, t, t' \in \mathbb{R}$. $\xi^{-1} = -\xi$ is the inverse, and therefore $(\xi')^{-1} \circ \xi^{-1} = (\xi \circ \xi')^{-1}$.

The natural group of dilations on $\mathbb{H}^N$ is defined as $\delta_s(\xi) = (sx, sy, s^2 t)$, for every $s > 0$. Hence, $\delta_s(\xi' \circ \xi) = \delta_s(\xi') \circ \delta_s(\xi)$ and $\delta_s(\delta_{s'}(\xi)) = \delta_{ss'}(\xi)$, for $s, s' > 0$. It can be easily proved that the Jacobian determinant of dilations $\delta_s : \mathbb{H}^N \to \mathbb{H}^N$ is constant and equal to s^Q, for every $\xi = (x, y, t) \in \mathbb{H}^N$. The natural number $Q = 2N + 2$ is called the homogeneous dimension of $\mathbb{H}^N$. The homogeneous norm on $\mathbb{H}^N$ is defined as follows

$$|\xi| = |\xi|_{\mathbb{H}} = \left[(|x|^2 + |y|^2)^2 + t^2\right]^{\frac{1}{4}}, \quad \text{for every } \xi \in \mathbb{H}^N.$$

By definition, the homogeneous degree of the norm is 1, in terms of dilations. The following vector fields

$$T = \frac{\partial}{\partial t}, \quad X_j = \frac{\partial}{\partial x_j} + 2y_j \frac{\partial}{\partial t}, \quad Y_j = \frac{\partial}{\partial y_j} - 2x_j \frac{\partial}{\partial t}, \quad j = 1, \ldots, N,$$

generate the real Lie algebra of left-invariant vector fields. The vector fields, T, X_j, Y_j satisfy the following relations:

$$[X_j, Y_k] = -4\delta_{jk} T, \qquad [Y_j, Y_k] = [X_j, X_k] = [Y_j, T] = [X_j, T] = 0.$$

The Heisenberg gradient on $\mathbb{H}^N$ is given by

$$\nabla_{\mathbb{H}} = (X_1, X_2, \cdots, X_N, Y_1, Y_2, \cdots, Y_N),$$

and the Kohn-Laplacian on $\mathbb{H}^N$ is given by

$$\Delta_{\mathbb{H}} = \sum_{j=1}^{N} X_j^2 + Y_j^2 = \sum_{j=1}^{N} \frac{\partial^2}{\partial x_j^2} + \frac{\partial^2}{\partial y_j^2} + 4y_j \frac{\partial^2}{\partial x_j \partial t} - 4x_j \frac{\partial^2}{\partial x_j \partial t} + 4(x_j^2 + y_j^2) \frac{\partial^2}{\partial t^2}.$$

The Haar measure on $\mathbb{H}^N$ coincides with the Lebesgue measure and is Q-homogeneous with respect to dilations. More precisely, it is consistent with the $(2N+1)$-dimensional Lebesgue measure. Consequently, the topological dimension of $\mathbb{H}^N$ is $2N + 1$, which is strictly smaller than its Hausdorff dimension $Q = 2N + 2$.

For a measurable set $\Omega \subseteq \mathbb{H}^N$, we denote by $|\Omega|$ its $(2N+1)$-dimensional Lebesgue measure. Then, for every $s > 0$, we have

$$|\delta_s(\Omega)| = s^Q |\Omega|, \quad d(\delta_s(\xi)) = s^Q \, d\xi, \quad \text{and} \quad |B_r(\xi)| = \alpha_Q r^Q,$$

where $\alpha_Q = |B_1(0)|$. Here, $B_r(\xi)$ denotes the ball in $\mathbb{H}^N$ centered at ξ with radius r.

The horizontal Sobolev space is defined as

$$HW^{1,2}(\mathbb{H}^N) = \left\{ u \in L^2(\mathbb{H}^N) \ : \ X_j u, \, Y_j u \in L^2(\mathbb{H}^N), \ j = 1, \ldots, N \right\}.$$

It is a Hilbert space equipped with the inner product

$$\langle u, v \rangle = \int_{\mathbb{H}^N} \nabla_{\mathbb{H}} u(\xi) \cdot \nabla_{\mathbb{H}} v(\xi) \, d\xi + \int_{\mathbb{H}^N} u(\xi) \, v(\xi) \, d\xi,$$

which induces the norm

$$\|u\|_{HW^{1,2}(\mathbb{H}^N)} = \left(\int_{\mathbb{H}^N} \left| \nabla_{\mathbb{H}} u(\xi) \right|^2 d\xi + \int_{\mathbb{H}^N} |u(\xi)|^2 \, d\xi \right)^{\frac{1}{2}}.$$

We define

$$E = \left\{ u \in S^{1,2}(\mathbb{H}^N) : \int_{\mathbb{H}^N} V(\xi) \, |u(\xi)|^2 \, d\xi < \infty \right\},$$

where $S^{1,2}(\mathbb{H}^N)$ denotes the completion of $C_0^\infty(\mathbb{H}^N)$ with respect to the norm

$$\|u\|_{S^{1,2}(\mathbb{H}^N)} = \left(\int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} u(\xi)|^2 \, d\xi \right)^{\frac{1}{2}}.$$

The space E is a Hilbert space endowed with the inner product

$$\langle u, v \rangle = \int_{\mathbb{H}^N} \left(\nabla_{\mathbb{H}} u(\xi) \cdot \nabla_{\mathbb{H}} v(\xi) + V(\xi) \, u(\xi) \, v(\xi) \right) d\xi,$$

which induces the norm

$$\|u\| = \left(\int_{\mathbb{H}^N} \left(|\nabla_{\mathbb{H}} u(\xi)|^2 + V(\xi) |u(\xi)|^2 \right) d\xi \right)^{1/2}.$$

The continuous embedding

$$E \subset S^{1,2}(\mathbb{H}^N) \hookrightarrow L^{Q^*}(\mathbb{H}^N)$$

holds (see [22]); that is,

$$\|u\|_{L^{Q^*}(\mathbb{H}^N)} \leq C \|u\|, \quad u \in E.$$

Since $S^{1,2}(\mathbb{H}^N) \hookrightarrow L^{Q^*}(\mathbb{H}^N)$, we have

$$S \, \|u\|^2_{L^{Q^*}(\mathbb{H}^N)} \leq \int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} u(\xi)|^2 \, d\xi,$$

where S is the best Sobolev constant, defined by

$$S = \inf_{S^{1,2}(\mathbb{H}^N) \setminus \{0\}} \frac{\int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} u(\xi)|^2 \, d\xi}{\left(\int_{\mathbb{H}^N} |u|^{Q^*} \, d\xi \right)^{\frac{2}{Q^*}}}.$$

It was proved by Jerison and Lee [23] that S is attained by the function

$$U(\xi) = U(x, y, t) = \frac{C}{\left(t^2 + \left(1 + |x|^2 + |y|^2 \right)^2 \right)^{\frac{Q-2}{4}}}, \tag{2.1}$$

(up to dilation and translation), where $C > 0$ is a suitable constant.

Now, we state the Hardy–Littlewood–Sobolev inequality.

Lemma 2.1. *Let $r, s > 1$ and $0 < \alpha < Q$ satisfy*

$$\frac{1}{r} + \frac{\alpha}{Q} + \frac{1}{s} = 2.$$

If $f \in L^r(\mathbb{H}^N)$ and $h \in L^s(\mathbb{H}^N)$, then there exists a sharp constant $C(r,s,\alpha,Q) > 0$, independent of f and h, such that

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N} \frac{f(\xi)\,h(\eta)}{|\eta^{-1}\circ\xi|^{\alpha}}\,d\eta\,d\xi \;\leq\; C(r,s,\alpha,Q)\,\|f\|_{L^r(\mathbb{H}^N)}\,\|h\|_{L^s(\mathbb{H}^N)}. \tag{2.2}$$

In particular, if $r = s = \frac{2Q}{2Q-\alpha}$, then the sharp constant is given by

$$C(r,s,\alpha,Q) = C(Q,\alpha) = \left(\frac{\pi^{N+1}}{2^{N-1}N!}\right)^{\frac{\alpha}{Q}} \frac{N!\,\Gamma\left(\frac{Q-\alpha}{2}\right)}{\Gamma^2\left(\frac{2Q-\alpha}{2}\right)}, \tag{2.3}$$

where Γ denotes the Gamma function.

Frank and Lieb [18] proved that the equality holds in (2.2) if and only if $f, h \in L^{\frac{2Q}{2Q-\alpha}}(\mathbb{H}^N)$ defined as $f(\xi) = cW\left(\delta_\theta\left(\eta^{-1}\circ\xi\right)\right)$, $h(\xi) = c'W\left(\delta_\theta\left(\eta^{-1}\circ\xi\right)\right)$, where $c \in \mathbb{C}, \theta > 0$, and $\eta \in \mathbb{H}^N$(unless $f \equiv 0$ or $g \equiv 0$) and

$$W(\xi) = W(x,y,t) = \left(t^2 + \left(1+|x|^2+|y|^2\right)^2\right)^{-\frac{2Q-\alpha}{4}}, \quad \text{for all } \xi = (x,y,t) \in \mathbb{H}^N.$$

S_{HG} is defined as

$$S_{HG} = \inf_{S^{1,2}(\mathbb{H}^N)\setminus\{0\}} \frac{\int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} u(\xi)|^2 d\xi}{\left(\int_{\mathbb{H}^N}\int_{\mathbb{H}^N} \frac{|u(\eta)|^{Q_\alpha^*}|u(\xi)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^{\alpha}} d\eta d\xi\right)^{\frac{1}{Q_\alpha^*}}}.$$

Goel and Sreenadh [21] proved that S_{HG} is attained by the function U (defined in (2.1)), up to the translation and dilation.(cf [21, Lemma 2.1]) and

$$S_{HG} = S\left(C(Q,\alpha)^{-\frac{1}{Q_\alpha^*}}\right),$$

where $C(Q,\alpha)$ is defined in (2.3).

To deal with the lack of compactness caused by the term with critical exponent, we use the Concentration-Compactness Principle, which was given by Lions [28] in the Euclidean framework and by Ivanov et al. [22] in the Carnot groups setting. We state the lemma in the Heisenberg group setting.

Lemma 2.2 ([22, Lemma 1.4.5]). *Let $\{u_n\}$ be a bounded sequence in $S^{1,2}(\mathbb{H}^N)$ converging weakly and a.e. to some $u \in S^{1,2}(\mathbb{H}^N)$. $|\nabla_{\mathbb{H}} u_n|^2 \rightharpoonup \omega$, $|u_n|^{Q^*} \rightharpoonup \zeta$ weakly in the sense of measures where ω and ζ are bounded non-negative measures on $\mathbb{H}^N$. Then we have:*

(1) there exists some at most countable set I, a family $\{z_i : i \in I\}$ of distinct points in $\mathbb{H}^N$, and a family $\{\zeta_i : i \in I\}$ of positive numbers such that

$$\zeta = |u|^{Q^*} + \sum_{i\in I} \zeta_i \delta_{z_i},$$

where $\delta_{\tilde{\xi}}$ is the Dirac-mass of mass 1 concentrated at $\xi \in \mathbb{H}^N$.

(2) In addition, we have

$$\omega \geq |\nabla_{\mathbb{H}} u|^2 + \sum_{i\in I} \omega_i \delta_{z_i}$$

for some family $\{\omega_i : i \in I\}$, $\omega_i > 0$ *satisfying*

$$S\zeta_i^{\frac{2}{Q^*}} \leq \omega_i, \quad \text{for all } i \in I.$$

In particular, $\sum_{i\in I} \zeta_i^{\frac{2}{Q^*}} < \infty$.

We next recall the Concentration–Compactness Principle to handle Choquard-type problems in the Heisenberg group:

Lemma 2.3 ([36, Theorem 3.1]). *Let* $\{u_n\}$ *be a bounded sequence in* $S^{1,2}(\mathbb{H}^N)$ *converging weakly and a.e. to some* u *and* ω, ζ *be the bounded nonnegative measures in Lemma 2.2. Assume that*

$$\int_{\mathbb{H}^N} \left(\frac{|u_n(\eta)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha} d\eta \right) |u_n(\xi)|^{Q_\alpha^*} \rightharpoonup \nu$$

weakly in the sense of measure where ν *is a bounded positive measure on* $\mathbb{H}^N$. *Then, there exists a countable sequence of points* $\{z_i\}_{i\in I} \subset \mathbb{H}^N$ *and families of positive numbers* $\{\nu_i : i \in I\}$, $\{\zeta_i : i \in I\}$ *and* $\{\omega_i : i \in I\}$ *such that*

$$\nu = \left(\int_{\mathbb{R}^N} \frac{|u(\eta)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha} d\eta \right) |u(\xi)|^{Q_\alpha^*} + \sum_{i\in I} \nu_i \delta_{z_i}, \qquad \sum_{i\in I} \nu_i^{\frac{1}{Q_\alpha^*}} < \infty,$$

$$\omega \geq |\nabla_{\mathbb{H}} u|^2 + \sum_{i\in I} \omega_i \delta_{z_i},$$

$$\zeta \geq |u|^{Q^*} + \sum_{i\in I} \zeta_i \delta_{z_i},$$

and

$$S_{HG}\nu_i^{\frac{1}{Q_\alpha^*}} \leq \omega_i, \quad \nu_i^{\frac{Q}{2Q-\alpha}} \leq C(Q,\alpha)^{\frac{Q}{2Q-\alpha}} \zeta_i,$$

where $\delta_{\bar{\xi}}$ *is the Dirac-mass of mass 1 concentrated at* $\bar{\xi} \in \mathbb{H}^N$.

Lemma 2.4 ([21, Lemma 2.5]). *Let* $0 < \alpha < Q$. *If* $\{u_n\}$ *is a bounded sequence in* $L^{\frac{2Q}{Q-2}}(\mathbb{H}^N)$ *such that* $u_n \to u$ *a.e. in* $\mathbb{H}^N$ *as* $n \to \infty$. *Then as* $n \to \infty$, *the following holds:*

$$\int_{\mathbb{H}^N} \left(|\xi|^{-\alpha} * |u_n|^{Q_\alpha^*} \right) |u_n|^{Q_\alpha^*} d\xi - \int_{\mathbb{H}^N} \left(|\xi|^{-\alpha} * |u_n - u|^{Q_\alpha^*} \right) |u_n - u|^{Q_\alpha^*} d\xi \\ \to \int_{\mathbb{H}^N} \left(|\xi|^{-\alpha} * |u|^{Q_\alpha^*} \right) |u|^{Q_\alpha^*} d\xi.$$

By following the proof of [11, Proposition 2.2], we get the following embedding result:

Lemma 2.5. *Let* $g \in L^m(\mathbb{H}^N)$, *where* $m = \frac{Q^*}{Q^*-q}, q \in [1, Q^*)$. *Then* $S^{1,2}(\mathbb{H}^N) \hookrightarrow L^q(\mathbb{H}^N, |g|)$ *compactly, where* $L^q(\mathbb{H}^N, |g|) = \{u \text{ is a measurable function} \mid \int_{\mathbb{H}^N} g|u(\xi)|^q d\xi < \infty\}$.

3 Auxiliary problem and variational framework

In this section, adapting the arguments in [3, 29], we study the existence of a weak solution to an auxiliary problem associated with (1.1). Throughout this and the following sections, we use C to denote a generic constant, whose value may change from line to line.

Let $f(\xi,u) = Q_\alpha^*|u(\xi)|^{Q_\alpha^*-2}u(\xi) + pK(\xi)|u(\xi)|^{p-2}u(\xi)$. We penalize the left hand side of (1.1)

Define, for $\ell > 1$ and $R > 1$,

$$\tilde{f}(\xi,t) = \begin{cases} f(\xi,t) & \text{if } \ell f(\xi,t) \le V(\xi)t, \\ \frac{V(\xi)}{\ell}t & \text{if } \ell f(\xi,t) > V(\xi)t, \end{cases} \tag{3.1}$$

and

$$g(\xi,t) = \begin{cases} f(\xi,t) & \text{if } |\xi| \le R, \\ \tilde{f}(\xi,t) & \text{if } |\xi| > R. \end{cases} \tag{3.2}$$

From (3.1) and (3.2), it follows that

$$\begin{aligned} &\tilde{f}(\xi,t) \le f(\xi,t), && \forall\, \xi \in \mathbb{H}^N, \\ &g(\xi,t) \le \frac{V(\xi)}{\ell}\,t, && |\xi| \ge R, \\ &G(\xi,t) = F(\xi,t), && |\xi| \le R, \\ &G(\xi,t) \le \frac{V(\xi)}{2\ell}\,t^2, && |\xi| \ge R, \end{aligned} \tag{3.3}$$

where $F(\xi,t) = \int_0^t f(\xi,s)ds$, and $G(\xi,t) = \int_0^t g(\xi,s)ds$.

We consider the following auxiliary problem associated with (1.1):

$$-\Delta_{\mathbb{H}}u(\xi) + V(\xi)u(\xi) = \left(\int_{\mathbb{H}^N} \frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right) g(\xi,u(\xi)) \quad \text{in } \mathbb{H}^N. \tag{3.4}$$

The energy functional $J : E \to \mathbb{R}$ associated with (3.4) is given by

$$J(u) = \frac{1}{2}\|u\|^2 - \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N} \frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right) G(\xi,u(\xi))d\xi. \tag{3.5}$$

One can verify that J is a C^1-functional and its derivative is given by

$$\begin{aligned} \langle J'(u), v\rangle = &\int_{\mathbb{H}^N} \left(\nabla_{\mathbb{H}}u(\xi)\cdot\nabla_{\mathbb{H}}v(\xi) + V(\xi)u(\xi)v(\xi)\right) d\xi \\ &- \int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N} \frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right) g(\xi,u(\xi))v(\xi)d\xi. \end{aligned}$$

We now present the result that constitutes the core of this paper.

Theorem 3.1. *Let the conditions (Σ_1), (Σ_2) hold. Then, (3.4) admits a positive weak solution $u \in E$.*

To prove Theorem 3.1, we first prove a series of lemmas.

Lemma 3.2. *The functional J satisfies the following properties:*

(i) there exist $\beta, r > 0$ such that $J(u) \geq \beta$ whenever $\|u\| = r$;

(ii) there exists $e \in E$ with $\|e\| > \rho$ (for some $\rho > 0$) such that $J(e) < \beta$.

Proof. Consider,

$$\begin{aligned}
J(u) &= \frac{1}{2}\|u\|^2 - \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)G(\xi,u(\xi))d\xi \\
&\geq \frac{1}{2}\|u\|^2 - \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{F(\eta,u)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)F(\xi,u)d\xi \\
&\geq \frac{1}{2}\|u\|^2 - \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{|u(\eta)|^{Q^*_\alpha}+K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)\left(|u(\xi)|^{Q^*_\alpha}+K(\xi)|u(\xi)|^p\right)d\xi \\
&= \frac{1}{2}\|u\|^2 - \frac{1}{2}\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u(\eta)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}|u(\xi)|^{Q^*_\alpha}d\eta d\xi - \frac{1}{2}\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u(\eta)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}K(\xi)|u(\xi)|^p d\eta d\xi \\
&- \frac{1}{2}\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}K(\xi)|u(\xi)|^p d\eta d\xi - \frac{1}{2}\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}|u(\xi)|^{Q^*_\alpha}d\eta d\xi.
\end{aligned}$$

Using (2.2), we get

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}K(\xi)|u(\xi)|^p d\eta d\xi \leq C\left(\int_{\mathbb{H}^N}|K(\xi)|^{\frac{2Q}{2Q-\alpha}}|u(\xi)|^{\frac{2Qp}{2Q-\alpha}}d\xi\right)^{\frac{2Q-\alpha}{Q}}. \tag{3.6}$$

By using Hölder's inequality and (Σ_2), we get

$$\begin{aligned}
\int_{\mathbb{H}^N}|K(\xi)|^{\frac{2Q}{2Q-\alpha}}|u(\xi)|^{\frac{2Qp}{2Q-\alpha}}d\xi &\leq \left(\int_{\mathbb{H}^N}|K(\xi)|^{\frac{Q^*}{Q^*_\alpha-p}}d\xi\right)^{\frac{Q^*_\alpha-p}{Q^*_\alpha}}\left(\int_{\mathbb{H}^N}|u(\xi)|^{Q^*}d\xi\right)^{\frac{p}{Q^*_\alpha}} \\
&\leq C\left(\int_{\mathbb{H}^N}|u(\xi)|^{Q^*}d\xi\right)^{\frac{p}{Q^*_\alpha}}.
\end{aligned}$$

On using this in (3.6), we get

$$\begin{aligned}
\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}K(\xi)|u(\xi)|^p d\eta d\xi &\leq C\left(\int_{\mathbb{H}^N}|u(\xi)|^{Q*}d\xi\right)^{\frac{p}{Q^*}}\left(\int_{\mathbb{H}^N}|u(\xi)|^{Q^*}d\xi\right)^{\frac{p}{Q^*}} \\
&= C\|u\|^{2p}_{L^{Q^*}}(\mathbb{H}^N).
\end{aligned}$$

Similarly, we have

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u(\eta)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}K(\xi)|u(\xi)|^p d\eta d\xi \leq C\|u\|^{p+Q^*_\alpha}_{L^{Q^*}}$$

and

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u(\eta)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}|u(\xi)|^{Q^*_\alpha}d\eta d\xi \leq C\|u\|^{2Q^*_\alpha}_{L^{Q^*}}.$$

Hence,

$$\begin{aligned}
J(u) &\geq \frac{1}{2}\|u\|^2 - \frac{1}{2}C\left(\|u\|^{p+Q^*_\alpha}_{L^{Q^*}} + \|u\|^{2Q^*_\alpha}_{L^{Q^*}} + \|u\|^{2p}_{L^{Q^*}}\right) \\
&\geq \frac{1}{2}\|u\|^2 - \frac{1}{2}C\left(\|u\|^{p+Q^*_\alpha} + \|u\|^{2Q^*_\alpha} + \|u\|^{2p}\right).
\end{aligned}$$

Thus for sufficiently small $\|u\| = r$, $J(u) \geq \beta$.

(ii) For $u \in C_0^\infty(B_R \setminus \{0\})$,

$$J(tu) \leq \frac{t^2}{2}\int_{|\xi|\leq R} |\nabla_{\mathbb{H}} u|^2 + V(\xi)u^2 d\xi - \frac{t^{2p}}{2}\int_{|\eta|\leq R}\left(\int_{|\xi|\leq R}\frac{|u(\eta)|^{Q_\alpha^*} + K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(|u(\xi)|^{Q_\alpha^*} + K(\xi)|u(\xi)|^p d\xi\right).$$

Thus, we conclude that $J(tu) \to -\infty$ as $t \to \infty$. Hence for some $e \in E$ with $\|e\| > \rho$ such that $J(e) < \beta$. This completes the proof.

□

Lemma 3.3. *Let $\{u_n\}$ be a $(PS)_c$ sequence associated to the functional J in $E \subset S^{1,2}(\mathbb{H}^N)$. Then $\{u_n\}$ is bounded.*

Proof. Let $\{u_n\}$ be a $(PS)_c$ sequence associated to the functional J in $E \subset S^{1,2}(\mathbb{H}^N)$. Then

$$J(u_n) \to c,\ J'(u_n) \to 0. \tag{3.7}$$

Let $\Psi(u) = \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)G(\xi,u(\xi))d\xi$.
We prove $\langle\Psi'(u),u\rangle \geq 2\theta\Psi(u) > 0$, for some $\theta \in (1,2)$.
Consider,

$$\begin{aligned}\frac{1}{2\theta}\langle\Psi'(u),u\rangle - \Psi(u) &= \int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}g(\xi,u(\xi))u - \frac{1}{2}G(\xi,u(\xi))\right)d\xi\\ &= \int_{|\xi|\leq R}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}f(\xi,u)u - \frac{1}{2}F(\xi,u)\right)d\xi\\ &\quad + \int_{|\xi|>R}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}g(\xi,u(\xi))u - \frac{1}{2}G(\xi,u(\xi))\right)d\xi\end{aligned}$$

Let,

$$\begin{aligned}A &= \{\sigma \in \mathbb{H}^N : |\sigma| > R \text{ and } \ell f(\sigma,u) \leq V(\sigma)u(\sigma)\},\\ B &= \{\sigma \in \mathbb{H}^N : |\sigma| > R \text{ and } \ell f(\sigma,u) > V(\sigma)u(\sigma)\}.\end{aligned} \tag{3.8}$$

We have, $uf(\xi,u) \geq \theta F(\xi,u)$. Now for $|\xi| > R$,

$$\begin{aligned}\frac{1}{2\theta}\langle\Psi'(u),u\rangle - \Psi(u) &= \int_{|\xi|>R}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}g(\xi,u(\xi))u - \frac{1}{2}G(\xi,u(\xi))\right)d\xi\\ &\geq \int_A\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}g(\xi,u(\xi))u - \frac{1}{2}G(\xi,u(\xi))\right)d\xi\\ &\quad + \int_B\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}g(\xi,u(\xi))u - \frac{1}{2}G(\xi,u(\xi))\right)d\xi\\ &\geq \int_A\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta}f(\xi,u)u - \frac{1}{2}F(\xi,u)\right)d\xi\\ &\quad + \int_B\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\left(\frac{1}{2\theta\ell} - \frac{1}{4\ell}\right)V(\xi)u^2 d\xi\\ &\geq 0.\end{aligned}$$

Consider,

$$\begin{aligned} c + \|u_n\| o(1) &= J(u_n) - \frac{1}{2\theta}\langle J'(u_n), u_n\rangle \\ &= \left(\frac{1}{2} - \frac{1}{2\theta}\right)\|u_n\|^2 + \frac{1}{2\theta}\langle \Psi'(u_n), u_n\rangle - \Psi(u_n) \\ &\geq \left(\frac{1}{2} - \frac{1}{2\theta}\right)\|u_n\|^2. \end{aligned}$$

Thus, $\{u_n\}$ is bounded. □

Lemma 3.4. *Let V and K satisfy (Σ_1), (Σ_2) and let $\{u_n\}$ be as $(PS)_c$ sequence of J. Then, there exists a positive number $c_1 > 0$ such that for $c < c_1$,*

$$\lim_{n\to\infty} \int_{\overline{B_R}} \int_{\mathbb{H}^N} \frac{|(u_n - u)(\xi)|^{Q^*_\alpha} |(u_n - u)(\eta)|^{Q^*_\alpha}}{|\eta^{-1} \circ \xi|^\alpha} \, d\eta \, d\xi = 0$$

Proof. Let $\{u_n\}$ be a $(PS)_c$ sequence. By Lemma 3.3, the sequence $\{u_n\}$ is bounded in E. Since E is reflexive, there exists $u \in E$ such that, up to a subsequence, $u_n \rightharpoonup u$ weakly in E. Consequently, $u_n \to u$ strongly in $L^q_{\text{loc}}(\mathbb{H}^N)$ for every $q \in [2, Q^*)$, and $u_n(\xi) \to u(\xi)$ a.e. in $\mathbb{H}^N$. Moreover, $u_n \rightharpoonup u$ in $S^{1,2}(\mathbb{H}^N)$, and hence, by Sobolev embedding, $u_n \rightharpoonup u$ in $L^{Q^*}(\mathbb{H}^N)$. Therefore, there exist bounded nonnegative measures ω, ζ, and ν such that, as $n \to \infty$,

$$|\nabla_{\mathbb{H}} u_n|^2 \rightharpoonup \omega, \qquad |u_n|^{Q^*} \rightharpoonup \zeta, \qquad \int_{\mathbb{H}^N} \frac{|u_n(\eta)|^{Q^*_\alpha}}{|\eta^{-1} \circ \xi|^\alpha} \, d\eta \, |u_n(\xi)|^{Q^*_\alpha} \rightharpoonup \nu.$$

Therefore by Lemma 2.3, there exists a countable sequence of points $\{z_i\}_{i\in I} \subset \mathbb{H}^N$ and families of positive numbers $\{\nu_i : i \in I\}$, $\{\zeta_i : i \in I\}$ and $\{\omega_i : i \in I\}$ such that

$$\begin{gathered} \nu = \left(\int_{\mathbb{R}^N} \frac{|u(\eta)|^{Q^*_\alpha}}{|\eta^{-1} \circ \xi|^\alpha} dy \right) |u(x)|^{Q^*_\alpha} + \Sigma_{i\in I} \nu_i \delta_{z_i}, \qquad \Sigma_{i\in I} \nu_i^{\frac{1}{Q^*_\alpha}} < \infty, \\ \omega \geq |\nabla_{\mathbb{H}} u|^2 + \sum_{i\in I} \omega_i \delta_{z_i}, \\ \zeta \geq |u|^{Q^*} + \sum_{i\in I} \zeta_i \delta_{z_i}, \end{gathered}$$

and

$$S_{HG} \nu_i^{\frac{1}{Q^*_\alpha}} \leq \omega_i, \qquad \nu_i^{\frac{Q}{2Q-\alpha}} \leq C(Q, \alpha)^{\frac{Q}{2Q-\alpha}} \zeta_i,$$

where $\delta_{\bar{\xi}}$ is the Dirac-mass of mass 1 concentrated at $\bar{\xi} \in \mathbb{H}^N$.

Let $\phi \in C_0^\infty(\mathbb{H}^n)$ be such that $0 \leq \phi \leq 1$,

$$\phi(\xi) = \begin{cases} 1 & \text{if } \xi \in B_1(0), \\ 0 & \text{if } \xi \in \mathbb{H}^N \setminus B_2(0). \end{cases} \tag{3.9}$$

Let $\varepsilon > 0$. For fixed $i \in I$, define

$$\phi_{\varepsilon,i}(\xi) = \phi\left(\delta_{\frac{2}{\varepsilon}}(z_i^{-1} \circ \xi)\right).$$

From (3.7), we have $J'(u_n) \to 0$ as $n \to \infty$. Therefore, $\langle J'(u_n), \phi_{\varepsilon,i} u_n\rangle \to 0$ as $n \to \infty$. Hence,

$$\begin{aligned} \lim_{n\to\infty} \int_{\mathbb{H}^N} &\left(\nabla_{\mathbb{H}} u_n \cdot \nabla_{\mathbb{H}} \left(u_n \cdot \phi_{\varepsilon,i}(\xi) u_n + V(\xi)|u_n|^2 \phi_{\varepsilon,i}\right) d\xi \right. \\ &\left. - \int_{\mathbb{H}^N} \left(\int_{\mathbb{H}^N} \frac{G(\eta, u_n)}{|\eta^{-1} \circ \xi|^\alpha} d\eta \right) g(\xi, u_n) u_n(\xi) \phi_{\varepsilon,i}(\xi) d\xi = 0. \right. \end{aligned} \tag{3.10}$$

Next, we claim that

$$\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{H}^N} u_n\nabla_{\mathbb{H}}u_n\nabla_{\mathbb{H}}\phi_{\varepsilon,i}=0. \tag{3.11}$$

Indeed, the boundedness of $\{u_n\}$, combined with Hölder's inequality and the Sobolev embedding theorem, yields

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\lim_{n\to\infty}\left|\int_{\mathbb{H}^N} u_n(\xi)\nabla_{\mathbb{H}}u_n(\xi)\cdot\nabla_{\mathbb{H}}\phi_{\varepsilon,i}(\xi)\,d\xi\right|\\
&\quad\le \lim_{\varepsilon\to 0}\lim_{n\to\infty}\left(\int_{\mathbb{H}^N}|\nabla_{\mathbb{H}}u_n(\xi)|^2\,d\xi\right)^{\frac{1}{2}}\left(\int_{\mathbb{H}^N}|u_n(\xi)\nabla_{\mathbb{H}}\phi_{\varepsilon,i}(\xi)|^2\,d\xi\right)^{\frac{1}{2}}\\
&\quad\le \lim_{\varepsilon\to 0}\lim_{n\to\infty} C\left(\int_{B_\varepsilon(z_i)}|u_n(\xi)|^2|\nabla_{\mathbb{H}}\phi_{\varepsilon,i}(\xi)|^2\,d\xi\right)^{\frac{1}{2}}\\
&\quad\le \lim_{\varepsilon\to 0} C\left(\int_{B_\varepsilon(z_i)}|u(\xi)|^2|\nabla_{\mathbb{H}}\phi_{\varepsilon,i}(\xi)|^2\,d\xi\right)^{\frac{1}{2}}\\
&\quad\le \lim_{\varepsilon\to 0} C\left(\int_{B_\varepsilon(z_i)}|\nabla_{\mathbb{H}}\phi_{\varepsilon,i}(\xi)|^Q\,d\xi\right)^{\frac{1}{Q}}\left(\int_{B_\varepsilon(z_i)}|u(\xi)|^{Q^*}\,d\xi\right)^{\frac{1}{Q^*}}.
\end{aligned}$$

One can see that using change of variables, $\int_{B_\varepsilon(z_i)}|\nabla_{\mathbb{H}}\phi_{\varepsilon,i}(\xi)|^Q\,d\xi$ is bounded as $\varepsilon\to 0$. Thus, (3.11) holds. Further, by using (Σ_2) and Lemma 2.5, with $m=2$, we have

$$\lim_{n\to\infty}\int_{\mathbb{H}^N}V(\xi)|u_n(\xi)|^2d\xi=\lim_{n\to\infty}\int_{\mathbb{H}^N}V(\xi)|u(\xi)|^2d\xi.$$

So by Hölder's inequality,

$$\begin{aligned}
\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{H}^N}V(\xi)|u_n(\xi)|^2\phi_{\varepsilon,i}(\xi)d\xi&=\lim_{\varepsilon\to 0}\int_{\mathbb{H}^N}V(\xi)|u(\xi)|^2\phi_{\varepsilon,i}(\xi)d\xi\\
&\le\lim_{\varepsilon\to 0}\left(\int_{B_\varepsilon(z_i)}|V(\xi)|^{\frac{Q}{2}}\right)\left(\int_{B_\varepsilon(z_i)}|u(\xi)|^{Q^*}d\xi\right)^{\frac{1}{Q^*}}.
\end{aligned}$$

Hence,

$$\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{H}^N}V(\xi)|u_n(\xi)|^2\phi_{\varepsilon,i}(\xi)d\xi=0. \tag{3.12}$$

Therefore, using Lemma 2.3, (3.11) and (3.12), we get

$$\omega_i\le\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{H}^N}|\nabla_{\mathbb{H}}u_n|^2\phi_{\varepsilon,i}(\xi)d\xi=\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{H}^N}\nabla_{\mathbb{H}}u_n\cdot\nabla_{\mathbb{H}}\left(\phi_{\varepsilon,i}(\xi)u_n(\xi)\right)d\xi. \tag{3.13}$$

Suppose that there exists $i\in I$ such that $z_i\in\overline{B_R(0)}$. Hence for small $\varepsilon>0$,

$$\begin{aligned}
&\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)g(\xi,u_n)u_n(\xi)\phi_{\varepsilon,i}(\xi)d\xi\\
&\quad=\int_{|\xi|\le R}\left(\int_{|\eta|\le R}\frac{|u_n(\eta)|^{Q^*_\alpha}+K(\eta)|u_n(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)(Q^*_\alpha|u_n(\xi)|^{Q^*_\alpha}+pK(\xi)|u_n(\xi)|^p)\phi_{\varepsilon,i}(\xi)d\xi\\
&\qquad+\int_{|\xi|\le R}\left(\int_{A}\frac{|u_n(\eta)|^{Q^*_\alpha}+K(\eta)|u_n(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)(Q^*_\alpha|u_n(\xi)|^{Q^*_\alpha}+pK(\xi)|u_n(\xi)|^p)\phi_{\varepsilon,i}(\xi)d\xi\\
&\qquad+\int_{|\xi|\le R}\left(\int_{B}\frac{V(\eta)|u_n(\eta)|^2}{2\ell|\eta^{-1}\circ\xi|^\alpha}d\eta\right)(Q^*_\alpha|u_n(\xi)|^{Q^*_\alpha}+pK(\xi)|u_n(\xi)|^p)\phi_{\varepsilon,i}(\xi)d\xi.
\end{aligned} \tag{3.14}$$

We now claim

$$\lim_{n\to\infty}\int_{|\xi|\le R}\int_{|\eta|\ge R}\frac{V(\eta)|u_n(\eta)|^2|u_n(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\to 0\quad\text{as }\varepsilon\to 0. \tag{3.15}$$

By the Hardy–Littlewood–Sobolev inequality,

$$\int_{|\xi|\le R}\int_{|\eta|\ge R}\frac{V(\eta)|u_n(\eta)|^2|u_n(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\le C\|V|u_n|^2\|_{L^{\frac{2Q}{2Q-\alpha}}(\mathbb{H}^N)}\|u_n\|^p_{L^{\frac{2Qp}{2Q-\alpha}}(B_\varepsilon(z_i))}.$$

On using Hölder's inequality, Sobolev embedding and (Σ_1), we get

$$\int_{|\xi|\le R}\int_{|\eta|\ge R}\frac{V(\eta)|u_n(\eta)|^2|u_n(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\le C\|u\|^p_{L^{\frac{2Qp}{2Q-\alpha}}(B_\varepsilon(z_i))}.$$

Letting $\varepsilon\to 0$, we prove the claim. Similarly, by the Hardy–Littlewood–Sobolev inequality and (Σ_2), we have

$$\lim_{n\to\infty}\int_{|\xi|\le R}\int_{|\eta|\le R}\frac{K(\eta)|u_n(\eta)|^pK(\xi)|u_n(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\to 0\quad\text{as }\varepsilon\to 0, \tag{3.16}$$

$$\lim_{n\to\infty}\int_{|\xi|\le R}\int_{|\eta|\le R}\frac{|u_n(\eta)|^{Q^*_\alpha}K(\xi)|u_n(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\to 0,\quad\text{as }\varepsilon\to 0. \tag{3.17}$$

Next, we claim that

$$\lim_{n\to\infty}\int_{|\xi|\le R}\int_{A}\frac{K(\eta)|u_n(\eta)|^p|u_n(\xi)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\to 0\quad\text{as }\varepsilon\to 0.$$

We have $p\in\left(2,\frac{2Q-\alpha}{Q-2}\right)$, $K\in L^{\frac{Q^*}{Q^*_\alpha-p}}(\mathbb{H}^N)$. Hence, $K^{\frac{2Q}{2Q-\alpha}}\in L^{\frac{Q^*}{Q^*-\frac{2Qp}{2Q-\alpha}}}(\mathbb{H}^N)$. By Lemma 2.5,

$$\int_A(K(\eta)|u_n(\eta)-u(\eta)|^p)^{\frac{2Q}{2Q-\alpha}}\to 0$$

as $n\to\infty$, i.e $K|u_n|^p\to K|u|^p$ in $L^{\frac{2Q}{2Q-\alpha}}(\mathbb{H}^N)$. By the Hardy–Littlewood–Sobolev inequality, we have

$$\int_A\frac{K(\eta)|u_n(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta\to\int_A\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta$$

in $L^{\frac{2Q}{\alpha}}(\mathbb{H}^N)$. Now since u_n is a bounded sequence in E, we have $\int_{|\xi|\le R}(|u_n(\xi)|^{Q^*_\alpha}\phi_{\varepsilon,i})^{\frac{2Q}{2Q-\alpha}}d\xi\le C$. Since $u_n\rightharpoonup u$ in E, as $n\to\infty$, $|u_n(\xi)|^{Q^*_\alpha}\phi_{\varepsilon,i}(\xi)\rightharpoonup|u(\xi)|^{Q^*_\alpha}\phi_{\varepsilon,i}(\xi)$ in $L^{\frac{2Q}{2Q-\alpha}}(|\xi|\le R)$. Thus,

$$\int_{|\xi|\le R}\int_A\frac{K(\eta)|u_n(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta|u_n(\xi)|^{Q^*_\alpha}\phi_{\varepsilon,i}(\xi)d\xi\to\int_{|\xi|\le R}\int_A\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta|u(\xi)|^{Q^*_\alpha}\phi_{\varepsilon,i}(\xi)d\xi,$$

as $n\to\infty$. Now using the Hardy–Littlewood–Sobolev inequality,

$$\int_{|\xi|<R}\int_A\frac{K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta|u(\xi)|^{Q^*_\alpha}\phi_{\varepsilon,i}(\xi)d\xi\le C\|K|u|^p\|_{L^{\frac{2Q}{2Q-\alpha}}(|\xi|\le R)}\|u\|^{Q^*_\alpha}_{L^{Q^*}(B_\varepsilon(z_i))}$$

and taking limit as $\varepsilon\to 0$, we prove the claim. Thus, we have

$$\lim_{n\to\infty}\int_{|\xi|}\int_A\frac{K(\eta)|u_n(\eta)|^p|u_n(\xi)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi\to 0\quad\text{as }\varepsilon\to 0.$$

Similarly, we can prove

$$\lim_{n\to\infty}\int_{|\xi|\le R}\int_B \frac{V(\eta)|u_n(\eta)|^2|u_n(\xi)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha}\phi_{\varepsilon,i}(\xi)d\eta d\xi \to 0 \quad \text{as } \varepsilon\to 0.$$

Hence, taking limit as $\varepsilon\to 0$ and $n\to\infty$ in (3.14) and using Lemma 2.3 we get

$$\begin{aligned}
&\lim_{\varepsilon\to\infty}\lim_{n\to\infty}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)g(\xi,u_n)u_n(\xi)\phi_{\varepsilon,i}(\xi)d\xi\\
&\quad\le \lim_{\varepsilon\to\infty}\lim_{n\to\infty} Q_\alpha^*\int_{|\xi|\le R}\left(\int_{|\eta|\le R}\frac{|u_n(\eta)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)|u_n(\xi)|^{Q_\alpha^*}\phi_{\varepsilon,i}(\xi)d\xi\\
&\qquad + Q_\alpha^*\int_{|\xi|\le R}\left(\int_A\frac{|u_n(\eta)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)|u_n(\xi)|^{Q_\alpha^*}\phi_{\varepsilon,i}(\xi)d\xi\\
&\quad\le Q_\alpha^*\nu_i
\end{aligned}$$

where we have used (2.2) and Hölder's inequality. Hence, from (3.10) and (3.12)

$$\begin{aligned}
\omega_i &\le Q_\alpha^*\nu_i\,,\\
S_{HG}\nu_i^{\frac{Q-2}{2Q-\alpha}} &\le Q_\alpha^*\nu_i\,,\\
S_{HG} &\le Q_\alpha^*\nu_i^{\frac{Q-\alpha+2}{2Q-\alpha}}.
\end{aligned}$$

Hence, we conclude that $\nu_i > \delta > 0$, for some fixed δ. Now by Lemma 2.3, we have $\sum_{i\in I}\nu_i^{\frac{2}{Q_\alpha^*}} < \infty$. Hence, I is finite.

Consider,

$$\begin{aligned}
c+o(1) &= J(u_n) - \frac{1}{2}\langle J'(u_n),u_n\rangle\\
&\ge \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)(g(\xi,u_n)u_n - 2G(\xi,u_n))d\xi\\
&= \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_{|\eta|\le R}\frac{|u_n|^{Q_\alpha^*}+K(\eta)|u_n|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)((Q_\alpha^*-2)|u_n|^{Q_\alpha^*}+(p-2)K(\xi)|u_n|^p)d\xi\\
&\quad + \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_A\frac{|u_n|^{Q_\alpha^*}+K(\eta)|u_n|^p}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)((Q_\alpha^*-2)|u_n|^{Q_\alpha^*}+(p-2)K(\xi)|u_n|^p)d\xi\\
&\quad + \frac{1}{2}\int_{\mathbb{H}^N}\left(\int_B\frac{V(\eta)|u_n|^2}{2\ell|\eta^{-1}\circ\xi|^\alpha}d\eta\right)((Q_\alpha^*-2)|u_n|^{Q_\alpha^*}+(p-2)K(\xi)|u_n|^p)d\xi\\
&\ge \left(\frac{Q_\alpha^*-2}{2}\right)\int_{\mathbb{H}^N}\left(\int_{|\eta|\le R}\frac{|u_n(\eta)|^{Q_\alpha^*}|u_n(\xi)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\phi_{\varepsilon,i}(\xi)d\xi\\
&\quad + \left(\frac{Q_\alpha^*-2}{2}\right)\int_{\mathbb{H}^N}\left(\int_A\frac{|u_n(\eta)|^{Q_\alpha^*}|u_n(\xi)|^{Q_\alpha^*}}{|\eta^{-1}\circ\xi|^\alpha}d\eta\right)\phi_{\varepsilon,i}(\xi)d\xi\\
&\ge \left(\frac{Q_\alpha^*-2}{2Q_\alpha^*}\right)\omega_i\\
&\ge \left(\frac{Q_\alpha^*-2}{2Q_\alpha^*}\right)S_{HG}\nu_i^{\frac{Q-2}{2Q-\alpha}}\\
&\ge \left(\frac{Q_\alpha^*-2}{2}\right)\left(\frac{S_{HG}}{Q_\alpha^*}\right)^{\frac{2Q-\alpha}{Q-\alpha+2}}
\end{aligned}$$

as $\varepsilon \to 0$. Therefore,

$$c \geq \left(\frac{Q_\alpha^* - 2}{2}\right)\left(\frac{S_{HG}}{Q_\alpha^*}\right)^{\frac{2Q-\alpha}{Q-2+\alpha}}.$$

Hence for level less than $c_1 = \left(\frac{Q_\alpha^*-2}{2}\right)\left(\frac{S_{HG}}{Q_\alpha^*}\right)^{\frac{2Q-\alpha}{Q-2+\alpha}}$, I is empty or $\nu_i = 0$ for all $z_i \in B_R(0)$ and using Lemma 2.4 we get the desired result. □

Lemma 3.5. *Let V and K satisfy (Σ_1), (Σ_2) and $\{u_n\}$ be a $(PS)_c$ sequence for J. Then, at least for a subsequence and for any $\varepsilon > 0$ there exists $r \geq R$ such that, for all r*

$$\limsup_{n\to\infty} \int_{|\xi|\geq 2r} (|\nabla_{\mathbb{H}} u_n(\xi)|^2 + V(\xi)u_n(\xi)^2)d\xi < \varepsilon.$$

Proof. For $r > R$, let $\psi_r \in C^\infty(\mathbb{H}^n)$ be such that $0 \leq \psi_r \leq 1$,

$$\psi_r(\xi) = \begin{cases} 0 & \text{if } \xi \in B_r(0), \\ 1 & \text{if } \xi \in \mathbb{H}^N \setminus B_{2r}(0), \end{cases} \tag{3.18}$$

and $|\nabla_{\mathbb{H}}\psi_r(\xi)| \leq \frac{2}{r}$. Since $J'(u_n) \to 0$ as $n \to \infty$, $\langle J'(u_n), \psi_r u_n\rangle \to 0$ as $n \to \infty$. Thus,

$$\begin{aligned} &\lim_{n\to\infty} \int_{\mathbb{H}^N} \nabla_{\mathbb{H}} u_n(\xi) \cdot \nabla_{\mathbb{H}}(u_n(\xi)\psi_r(\xi))d\xi + \lim_{n\to\infty} \int_{\mathbb{H}^N} V(\xi)|u_n(\xi)|^2\psi_r(\xi)d\xi \\ &\quad = \lim_{n\to\infty} \int_{\mathbb{H}^N} \left(\int_{\mathbb{H}^N} \frac{G(\eta, u_n)}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right) g(\xi, u_n)u_n\psi_r(\xi)d\xi, \end{aligned}$$

$$\begin{aligned} &\lim_{n\to\infty} \int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} u_n(\xi)|^2\psi_r(\xi)d\xi + \lim_{n\to\infty} \int_{\mathbb{H}^N} V(\xi)|u_n(\xi)|^2\psi_r(\xi)d\xi \\ &\qquad + \lim_{n\to\infty} \int_{\mathbb{H}^N} u_n(\xi)\nabla_{\mathbb{H}} u_n(\xi) \cdot \nabla_{\mathbb{H}}\psi_r(\xi)d\xi \\ &\quad = \lim_{n\to\infty} \int_{\mathbb{H}^N} \left(\int_{\mathbb{H}^N} \frac{G(\eta, u_n)}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right) g(\xi, u_n)u_n\psi_r(\xi)d\xi. \end{aligned}$$

Next, we claim that

$$\lim_{r\to\infty}\lim_{n\to\infty} \int_{\mathbb{H}^N} u_n(\xi)\nabla_{\mathbb{H}} u_n(\xi) \cdot \nabla_{\mathbb{H}}\psi_r(\xi)d\xi = 0. \tag{3.19}$$

Since $\nabla_{\mathbb{H}}\psi_r(\xi) = 0$ for $|\xi| \leq r$ and $|\xi| \geq 2r$, it follows from Hölder's inequality, boundedness of $\{u_n\}$ and compact embedding $S^{1,2}(\mathbb{H}^N) \hookrightarrow L^2_{\text{loc}}(\mathbb{H}^N)$ that

$$\begin{aligned} \int_{\mathbb{H}^N} u_n(\xi)\nabla_{\mathbb{H}} u_n(\xi) \cdot \nabla_{\mathbb{H}}\psi_r(\xi)d\xi &\leq \frac{2}{r}\int_{r\leq|\xi|\leq 2r} |u_n(\xi)||\nabla_{\mathbb{H}} u_n(\xi)|d\xi \\ &\leq \frac{2}{r}\left(\int_{r\leq|\xi|\leq 2r} |u_n|^2 d\xi\right)^{\frac{1}{2}}\left(\int_{r\leq|\xi|\leq 2r} |\nabla u_n|^2 d\xi\right)^{\frac{1}{2}} \\ &\leq \frac{C}{r}\left(\int_{r\leq|\xi|\leq 2r} |u_n|^2 d\xi\right)^{\frac{1}{2}}. \\ &\to \frac{C}{r}\left(\int_{r\leq|\xi|\leq 2r} |u(\xi)|^2 d\xi\right)^{\frac{1}{2}} \quad \text{as } n \to \infty. \end{aligned}$$

Thus, we have

$$\begin{aligned}\lim_{n\to\infty}\int_{\mathbb{H}^N} u_n(\xi)\nabla_{\mathbb{H}}u_n(\xi)\cdot\nabla_{\mathbb{H}}\psi_r(\xi)d\xi &\le \frac{C}{r}\left(\int_{r\le|\xi|\le 2r}|u(\xi)|^2 d\xi\right)^{\frac{1}{2}}\\ &\le \frac{C}{r}\left(\int_{r\le|\xi|\le 2r} d\xi\right)^{\frac{1}{Q}}\left(\int_{r\le|\xi|\le 2r}|u(\xi)|^{Q^*}d\xi\right)^{\frac{1}{Q^*}}\\ &\le C\left(\int_{r\le|\xi|}|u(\xi)|^{Q^*}d\xi\right)^{\frac{1}{Q^*}},\end{aligned}$$

which shows that

$$\lim_{r\to\infty}\lim_{n\to\infty}\int_{\mathbb{H}^N} u_n(\xi)\nabla_{\mathbb{H}}u_n(\xi)\cdot\nabla_{\mathbb{H}}\psi_r(\xi)d\xi = 0.$$

This proves (3.19). Next, we see that

$$\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u_n)u_n\psi_r(\xi)d\xi \le \int_{|\xi|\ge r}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u_n)u_n\psi_r(\xi)d\xi.$$

Since $r > R$, using (3.3), boundedness of $\{u_n\}$, (Σ_1), and (Σ_2), we have

$$\begin{aligned}&\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u_n)u_n\psi_r(\xi)d\xi\\ &\le \int_{|\xi|\ge r}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)\frac{V(\xi)|u_n(\xi)|^2}{\ell}d\xi\\ &\le \int_{|\xi|\ge r}\left(\int_{\mathbb{H}^N}\frac{|u_n(\eta)|^{Q^*_\alpha}+K(\eta)|u_n(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)\frac{V(\xi)|u_n(\xi)|^2}{\ell}d\xi\\ &\quad+\int_{|\xi|\ge r}\left(\int_{\mathbb{H}^N}\frac{V(\eta)|u_n(\eta)|^2}{2\ell|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)\frac{V(\xi)|u_n(\xi)|^2}{\ell}d\xi\\ &\le C\left(\int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi\right)^{\frac{2Q-\alpha}{2Q}}\left(\int_{\mathbb{H}^N}\left(|u_n(\eta)|^{Q^*}+|K(\eta)|^{\frac{2Q}{2Q-\alpha}}|u_n(\eta)|^{\frac{2Qp}{2Q-\alpha}}\right)d\eta\right)^{\frac{2Q-\alpha}{2Q}}\\ &\quad+C\left(\int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi\right)^{\frac{2Q-\alpha}{2Q}}\left(\int_{\mathbb{H}^N}|V(\eta)|^{\frac{2Q}{2Q-\alpha}}|u_n(\eta)|^{\frac{4Q}{2Q-\alpha}}d\eta\right)^{\frac{2Q-\alpha}{2Q}}\\ &\le C\left(\int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi\right)^{\frac{2Q-\alpha}{2Q}}\left(\int_{\mathbb{H}^N}\left(|u_n(\eta)|^{Q^*}+|K(\eta)|^{\frac{2Q}{2Q-\alpha}}|u_n(\eta)|^{\frac{2Qp}{2Q-\alpha}}\right)d\eta\right)^{\frac{2Q-\alpha}{2Q}}\\ &\quad+C\left(\int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi\right)^{\frac{2Q-\alpha}{2Q}}\left(\int_{\mathbb{H}^N}|V(\eta)|^{\frac{2Q}{4-\alpha}}d\eta\right)^{\frac{4-\alpha}{2Q}}\left(\int_{\mathbb{H}^N}|u_n(\eta)|^{Q^*}d\eta\right)^{\frac{2Q-4}{2Q}}\\ &\le C\left(\int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi\right)^{\frac{2Q-\alpha}{2Q}}.\end{aligned}\tag{3.20}$$

Since $\alpha\in(0,4)$, it follows that $\frac{4Q}{2Q-\alpha}\in(2,Q^*)$. Moreover, as $V\in L^{\frac{2Q}{4-\alpha}}(\mathbb{H}^N)$, we have

$$V^{\frac{2Q}{2Q-\alpha}}\in L^{\frac{Q^*}{Q^*-\frac{4Q}{2Q-\alpha}}}(\mathbb{H}^N).$$

Therefore, by applying Lemma 2.5, we deduce that

$$\lim_{n\to\infty}\int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi = \int_{|\xi|\ge r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi.$$

Hence,

$$\lim_{r\to\infty}\lim_{n\to\infty}\int_{|\xi|\geq r}|V(\xi)|^{\frac{2Q}{2Q-\alpha}}|u_n(\xi)|^{\frac{4Q}{2Q-\alpha}}d\xi=0.$$

Substituting this into (3.20), we obtain

$$\lim_{r\to\infty}\lim_{n\to\infty}\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u_n)u_n\psi_r(\xi)d\xi=0.$$

This completes the proof. □

We now find the upper bound for the functional J. Before that, we state some asymptotic estimates which can be proved similar to [21, Lemma 3.1] and [14, Lemma 1.1]. The minimizer for the Sobolev inequality

$$S\,\|u\|^2_{L^{Q^*}(\mathbb{H}^N)}\leq\int_{\mathbb{H}^N}|\nabla_{\mathbb{H}}u(\xi)|^2\,d\xi,$$

is attained by

$$U(\xi)=U(x,y,t)=\frac{C}{((t^2+(1+|x|^2+|y^2|)^2))^{\frac{Q-2}{4}}},$$

where C is a suitable positive constant. Let,

$$U_\varepsilon(\xi)=\frac{C}{((t^2+(\varepsilon+|x|^2+|y^2|)^2))^{\frac{Q-2}{4}}},\tag{3.21}$$

where C is a suitable constant. Hence

$$U_\varepsilon(\xi)=\varepsilon^{-\frac{Q-2}{2}}U(\delta_{\frac{1}{\sqrt{\varepsilon}}}(\xi)).$$

Define,

$$\phi(\xi)=\begin{cases}1 & \text{if } \xi\in B_{\frac{R}{2}}(0),\\ 0 & \text{if } \xi\in B^c_R(0),\end{cases}$$

$$u_\varepsilon(\xi)=U_\varepsilon(\xi)\phi(\xi),$$

$$v_\varepsilon(\xi)=\frac{u_\varepsilon(\xi)}{\left(\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u_\varepsilon(\eta)|^{Q^*_\alpha}|u_\varepsilon(\xi)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta d\xi\right)^{\frac{1}{2Q^*_\alpha}}}.\tag{3.22}$$

Since $S^{1,2}(\mathbb{H}^N)\hookrightarrow L^2_{\mathrm{loc}}(\mathbb{H}^N)$ and $\phi\in C^\infty_c(\mathbb{H}^N)$, we have $u_\varepsilon\in L^2_{\mathrm{loc}}(\mathbb{H}^N)$. Consequently, $v_\varepsilon\in E$. Further, we have

$$\int_{\mathbb{H}^N}|\nabla_{\mathbb{H}}u_\varepsilon(\xi)|^2d\xi=\varepsilon^{-\frac{Q-2}{2}}\int_{\mathbb{H}^N}|\nabla_{\mathbb{H}}U(\xi)|^2d\xi+O(1).\tag{3.23}$$

$$\int_{\mathbb{H}^N}|u_\varepsilon(\xi)|^{Q^*}d\xi=\varepsilon^{-\frac{Q}{2}}\int_{\mathbb{H}^N}|U(\xi)|^{Q^*}d\xi+O(1).\tag{3.24}$$

Using the Hardy–Littlewood–Sobolev inequality, we get

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u_\varepsilon(\eta)|^{Q^*_\alpha}|u_\varepsilon(\xi)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta d\xi\leq C(Q,\alpha)\varepsilon^{-\frac{2Q-\alpha}{2}}\left(\int_{\mathbb{H}^N}|U(\xi)|^{Q^*}d\xi\right)^{\frac{2Q-\alpha}{Q}}+O(1)\tag{3.25}$$

Following the calculations in [21, Lemma 3.1], we obtain

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|u_\varepsilon(\eta)|^{Q^*_\alpha}|u_\varepsilon(\xi)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta d\xi\geq\varepsilon^{-\frac{2Q-\alpha}{2}}\int_{\mathbb{H}^N}\int_{\mathbb{H}^N}\frac{|U(\eta)|^{Q^*_\alpha}|U(\xi)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta d\xi-O(1).\tag{3.26}$$

Lemma 3.6.

$$\int_{\mathbb{H}^N} |u_\varepsilon(\xi)|^q d\xi \leq \begin{cases} C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} + O(1), & q \in (2, Q^*), \\ 1 + \log \frac{R}{\sqrt{\varepsilon}}, & q = 2, Q = 4, \\ C\varepsilon^{-\frac{Q-4}{2}} + O(1), & q = 2, Q > 4. \end{cases}$$

Proof. If $q \in (2, Q^*)$, then

$$\begin{aligned} \int_{\mathbb{H}^N} |u_\varepsilon(\xi)|^q d\xi &\leq \int_{|\xi|\leq R} |U_\varepsilon(\xi)|^q d\xi \\ &\leq \varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} \int_{|\xi|\leq \frac{R}{\sqrt{\varepsilon}}} |U(\xi)|^q d\xi \\ &= C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} \int_{|\xi|\leq \frac{R}{\sqrt{\varepsilon}}} \frac{1}{(t^2 + (1+|x|^2+|y|^2)^2)^{\frac{Q-2}{4}q}} d\xi \\ &\leq C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} \int_{|\xi|\leq \frac{R}{\sqrt{\varepsilon}}} \frac{1}{(1+|\xi|^4)^{\frac{Q-2}{4}q}} d\xi \\ &\leq C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} \left(\int_{1\leq|\xi|\leq \frac{R}{\sqrt{\varepsilon}}} \frac{1}{|\xi|^{(Q-2)q}} d\xi + \int_{|\xi|\leq 1} 1 d\xi \right) \\ &\leq C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} \left(1 + \int_1^{\frac{R}{\sqrt{\varepsilon}}} \frac{1}{s^{(Q-2)q-Q+1}} ds \right) \\ &\leq C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} \left(1 + \frac{1}{\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q}} \right), \end{aligned}$$

that is,

$$\int_{\mathbb{H}^N} |u_\varepsilon(\xi)|^q d\xi \leq C\varepsilon^{\frac{Q}{2}-\frac{Q-2}{2}q} + O(1).$$

For $q = 2$, $Q = 4$, we have

$$\begin{aligned} \int_{\mathbb{H}^N} |u_\varepsilon(\xi)|^2 d\xi &\leq \int_{|\xi|\leq R} |U_\varepsilon(\xi)|^2 d\xi \\ &\leq C \int_{|\xi|\leq \frac{R}{\sqrt{\varepsilon}}} \frac{C}{1+|\xi|^4} d\xi \\ &\leq C \left(1 + \int_1^{\frac{R}{\sqrt{\varepsilon}}} \frac{1}{s} ds \right) \\ &\leq 1 + \log \frac{R}{\sqrt{\varepsilon}}. \end{aligned}$$

For $q = 2$, $Q > 4$, we have

$$\begin{aligned} \int_{\mathbb{H}^N} |u_\varepsilon(\xi)|^2 d\xi &\leq \varepsilon^{-\frac{Q-4}{2}} \int_{|\xi|\leq R} |U_\varepsilon(\xi)|^2 d\xi \\ &\leq C\varepsilon^{-\frac{Q-4}{2}} \left(1 + \int_1^{\frac{R}{\sqrt{\varepsilon}}} \frac{1}{s^{Q-3}} ds \right) \\ &\leq C\varepsilon^{-\frac{Q-4}{2}} + O(1). \end{aligned}$$

□

Using these estimates and following the calculations as in [14, Lemma 1.1] we obtain the following: Using (3.23), (3.25) and (3.26) we get,

$$\int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} v_\varepsilon(\xi)|^2 d\xi = S_{HG} + O(\varepsilon^{\frac{Q-2}{2}}), \tag{3.27}$$

Using Lemma 3.6, (3.26) and the Hardy–Littlewood–Sobolev inequality,

$$\int_{\mathbb{H}^N}\int_{\mathbb{H}^N} \frac{|v_\varepsilon(\eta)|^p |v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi \le O\left(\varepsilon^{\frac{2Q-\alpha}{2}-\frac{Q-2}{2}p}\right) + O\left(\varepsilon^{\frac{Q-2}{2}p}\right). \tag{3.28}$$

Using Lemma 3.6 and (3.26),

$$\int_{\mathbb{H}^N} |v_\varepsilon(\xi)|^2 d\xi \le \begin{cases} C\varepsilon\left(1+\log\left(\frac{R}{\sqrt{\varepsilon}}\right)\right), \text{ if } Q=4, \\ O(\varepsilon^2), \text{ if } Q>4. \end{cases} \tag{3.29}$$

Thus, from (3.28) and (3.29), we conclude

$$\lim_{\varepsilon\to 0}\int_{\mathbb{H}^N}\int_{\mathbb{H}^N} \frac{|v_\varepsilon(\eta)|^p |v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi = 0$$

and

$$\lim_{\varepsilon\to 0}\int_{\mathbb{H}^N} |v_\varepsilon(\xi)|^2 d\xi = 0.$$

Now, we prove a bound for the energy functional J.

Lemma 3.7. *There exists $v \in E, v > 0$, such that* $\sup_{t>0} J(tv) < \frac{1}{2}\left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}}\left(1-\left(\frac{1}{Q_\alpha^*}\right)^{Q_\alpha^*}\right) S_{HG}^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}$.

Proof. Let $v_\varepsilon \in E$ be defined as in (3.22). Define

$$h(t) = \frac{t^2}{2}\|v_\varepsilon\|^2 - \frac{t^{2p}}{2}\int_{|\xi|\le R}\int_{|\eta|\le R} \frac{K(\eta)|v_\varepsilon(\eta)|^p K(\xi)|v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi - \frac{t^{2Q_\alpha^*}}{2}. \tag{3.30}$$

We observe that $h(t) \ge J(tv_\varepsilon)$, with $h(t) \to 0$ as $t \to 0$ and $h(t) \to -\infty$ as $t \to \infty$. Since $2 < 2p < 2Q_\alpha^*$, we have $h(t) > 0$ for small $t > 0$. Therefore, h attains a global maximum. Let t_ε denote a point at which h achieves its global maximum. Then

$$\|v_\varepsilon\|^2 = p t_\varepsilon^{2(p-1)} \int_{|\xi|\le R}\int_{|\eta|\le R} \frac{K(\eta)|v_\varepsilon(\eta)|^p K(\xi)|v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi + Q_\alpha^* t_\varepsilon^{2(Q_\alpha^*-1)}. \tag{3.31}$$

Hence,

$$Q_\alpha^* t_\varepsilon^{2(Q_\alpha^*-1)} \le \|v_\varepsilon\|^2,$$
$$t_\varepsilon \le \left(\frac{1}{Q_\alpha^*}\|v_\varepsilon\|^2\right)^{\frac{1}{2(Q_\alpha^*-1)}}.$$

Therefore, using this preceding inequality in (3.30),

$$\int_{|\xi|\le R} |\nabla_{\mathbb{H}} v_\varepsilon(\xi)|^2 d\xi \le p\left(\frac{1}{Q_\alpha^*}\|v_\varepsilon\|^2\right)^{\frac{2(p-1)}{2(Q_\alpha^*-1)}} \int_{|\xi|\le R}\int_{|\eta|\le R} \frac{K(\eta)|v_\varepsilon(\eta)|^p K(\xi)|v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi + Q_\alpha^* t_\varepsilon^{2(Q_\alpha^*-1)}.$$

From (3.27) for sufficiently small ε,

$$Q_\alpha^* t_\varepsilon^{2(Q_\alpha^*-1)} \geq \frac{S_{HG}}{2}.$$

Hence,

$$h(t_\varepsilon) \leq \frac{t_\varepsilon^2}{2}\int_{|\xi|\leq R}|\nabla_{\mathbb{H}} v_\varepsilon(\xi)|^2 d\xi + C\int_{|\xi|\leq R}|v_\varepsilon(\xi)|^2 d\xi$$
$$- C\int_{|\xi|\leq R}\int_{|\eta|\leq R}\frac{K(\eta)|v_\varepsilon(\eta)|^p K(\xi)|v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi - \frac{t_\varepsilon^{2Q_\alpha^*}}{2}.$$

Let $\rho(\tau) = \frac{\tau^2}{2}\|v_\varepsilon\|^2 - \frac{\tau^{2Q_\alpha^*}}{2}$. By an argument similar to that used for h, the function ρ attains a global maximum. Let $\tau' = \left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}}\|v_\varepsilon\|^{\frac{1}{Q_\alpha^*-1}}$ be the point at which ρ attains its maximum. Hence,

$$\rho(\tau') = \frac{1}{2}\left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}}\|v_\varepsilon\|^{\frac{2Q_\alpha^*}{Q_\alpha^*-1}} - \frac{1}{2}\left(\frac{1}{Q_\alpha^*}\right)^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}\|v_\varepsilon\|^{\frac{2Q_\alpha^*}{Q_\alpha^*-1}}$$
$$= \frac{1}{2}\|v_\varepsilon\|^{\frac{2Q_\alpha^*}{Q_\alpha^*-1}}\left(\left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}} - \left(\frac{1}{Q_\alpha^*}\right)^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}\right).$$

Therefore using (3.27), (3.28) and (3.29),

$$h(t) \leq \frac{1}{2}\left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}}\|v_\varepsilon\|^{\frac{2Q_\alpha^*}{Q_\alpha^*-1}}\left(1-\left(\frac{1}{Q_\alpha^*}\right)^{Q_\alpha^*}\right) + C\int_{|\xi|\leq R}|v_\varepsilon(\xi)|^2 d\xi$$
$$- C\int_{|\xi|\leq R}\int_{|\eta|\leq R}\frac{K(\eta)|v_\varepsilon(\eta)|^p K(\xi)|v_\varepsilon(\xi)|^p}{|\eta^{-1}\circ\xi|^\alpha} d\eta d\xi$$
$$\leq \frac{1}{2}\left(\left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}} - \left(\frac{1}{Q_\alpha^*}\right)^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}\right) S_{HG}^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}.$$

□

Proof of Theorem 3.1. Let,

$$c_0 = \min\left\{\left(\frac{Q_\alpha^*-2}{2}\right)\left(\frac{S_{HG}}{Q_\alpha^*}\right)^{\frac{2Q-\alpha}{Q-2+\alpha}}, \frac{1}{2}\left(\left(\frac{1}{Q_\alpha^*}\right)^{\frac{1}{Q_\alpha^*-1}} - \left(\frac{1}{Q_\alpha^*}\right)^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}\right) S_{HG}^{\frac{Q_\alpha^*}{Q_\alpha^*-1}}\right\}.$$

$c_0 > 0$. We conclude that from Lemma 3.4, Lemma 3.5 and Lemma 3.6, if $c \leq c_0$, then $I = \emptyset$. To conclude the result, it is enough to prove that the $(PS)_c-$sequence $\{u_n\}$ is convergent in E. From (3.7) we have $\langle J'(u_n), u_n - u\rangle \to 0$ and so $\langle J'(u_n - u), u_n - u\rangle \to 0$. Hence,

$$\int_{\mathbb{H}^N}|\nabla_{\mathbb{H}}(u_n-u)(\xi)|^2 + V(\xi)|(u_n-u)(\xi)|^2 d\xi$$
$$- \int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta, u_n-u)}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right) g(\xi, u_n-u)(u_n-u) d\xi \to 0.$$

We claim that $\int_{\mathbb{H}^N}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n-u)}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right) g(\xi, u_n-u)(u_n-u) \to 0$ as $n \to \infty$.

Using Lemma 3.5, for given $\varepsilon > 0$, if $r > R$ is sufficiently large then for all $n \geq n_0$,

$$\int_{|\xi|\geq 2r}\left(\int_{\mathbb{H}^N}\frac{G(\eta, u_n-u)}{|\eta^{-1}\circ\xi|^\alpha} d\eta\right) g(\xi, u_n-u)(u_n-u) d\xi \leq \frac{\varepsilon}{2}.$$

Consider

$$\begin{aligned}
&\int_{|\xi|\le R}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n-u)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u_n-u)(u_n-u)d\xi\\
&=\int_{|\xi|\le R}\left(\int_{|\eta|\le R}\frac{|(u_n-u)(\eta)|^{Q_\alpha^*}+K(\eta)|(u_n-u)(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)(Q_\alpha^*|(u_n-u)(\xi)|^{Q_\alpha^*}+pK(\xi)|(u_n-u)(\xi)|^p)d\xi\\
&\quad+\int_{|\xi|\le R}\left(\int_{A}\frac{|(u_n-u)(\eta)|^{Q_\alpha^*}+K(\eta)|(u_n-u)(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)(Q_\alpha^*|(u_n-u)(\xi)|^{Q_\alpha^*}+pK(\xi)|(u_n-u)(\xi)|^p)d\xi\\
&\quad+\int_{|\xi|\le R}\left(\int_{B}\frac{V(\eta)|(u_n-u)(\eta)|^2}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)(Q_\alpha^*|(u_n-u)(\xi)|^{Q_\alpha^*}+pK(\xi)|(u_n-u)(\xi)|^p)d\xi.
\end{aligned}\tag{3.32}$$

Now by virtue of Lemma 3.4, Lemma 2.5 and compact embedding in bounded domain,

$$\int_{|\xi|\le 2r}\left(\int_{\mathbb{H}^N}\frac{G(\eta,u_n-u)}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u_n-u)(u_n-u)d\xi\le\varepsilon.$$

Hence combining the results, we get $\|u_n-u\|\to 0$ in E, as $n\to\infty$. Therefore, by the Mountain Pass Theorem [37, Theorem 1.17], equation (3.4) admits a weak solution. Moreover, the positivity of the solution follows from the strong maximum principle [12]. □

4 Proof of Theorem 1.2

In this section, we prove the main result of this paper. The following theorem provides the L^∞-regularity of the weak solution to (3.4). The proof is based on an argument of Brezis–Kato type, as carried out in $\mathbb{R}^N$ in [4, Lemma 2.10]. For the adaptation of the Brezis–Kato argument to the Heisenberg group, we refer to [20, Theorem 4.2]. We omit the details.

Theorem 4.1. *Let u be the solution obtained for the equation (3.4). Then, there exists a constant M_0, such that*

$$\|u\|_{L^\infty(\mathbb{H}^N)}\le M_0.$$

Before presenting the proof of Theorem 1.2, we prove the following lemma:

Lemma 4.2. *Let u be a solution of (3.4). Then, there exists $\ell_0>0$ such that*

$$\sup_{u\in E}\frac{H(u)(\xi)}{\ell_0}\le\frac{1}{2},$$

where $H(u)(\xi)=\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta$

Proof. Consider,

$$-\Delta_{\mathbb{H}}u+V(\xi)u=\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)g(\xi,u(\xi))$$

and

$$-\Delta_{\mathbb{H}}u=\left(-V(\xi)+\left(\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)\frac{g(\xi,u(\xi))}{u}\right)u.$$

One can verify that $\int_{\mathbb{H}^N}\left(\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right)\frac{g(\xi,u(\xi))}{u}\in L^{\frac{Q}{2}}(\mathbb{H}^N)$. Hence by Brezis–Kato argument [35, Lemma B.3], $u\in L^t_{\mathrm{loc}}(\mathbb{H}^N)$ for all $t<\infty$. Consider,

$$\begin{aligned}
|H(u)(\xi)| &= \left|\int_{\mathbb{H}^N}\frac{G(\eta,u(\eta))}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta\right| \\
&\le \int_{\mathbb{H}^N}\frac{|u(\eta)|^{Q^*_\alpha}+K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta \\
&\le \int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}\frac{|u(\eta)|^{Q^*_\alpha}+K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta+\int_{|\eta^{-1}\circ\xi|^{\alpha}>1}\frac{|u(\eta)|^{Q^*_\alpha}+K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta \\
&\le \int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}\frac{|u(\eta)|^{Q^*_\alpha}+K(\eta)|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta+C \\
&\le \int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}\frac{|u(\eta)|^{Q^*_\alpha}}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta+C\int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}\frac{|u(\eta)|^p}{|\eta^{-1}\circ\xi|^{\alpha}}d\eta+C \\
&\le \left(\int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}|u(\eta)|^{Q^*_\alpha t}d\eta\right)^{\frac{1}{t}}\left(\int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}\frac{1}{|\eta^{-1}\circ\xi|^{\alpha t'}}d\eta\right)^{\frac{1}{t'}} \\
&\quad + C\left(\int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}|u(\eta)|^{ps}d\eta\right)^{\frac{1}{s}}\left(\int_{|\eta^{-1}\circ\xi|^{\alpha}\le 1}\frac{1}{|\eta^{-1}\circ\xi|^{\alpha s'}}d\eta\right)^{\frac{1}{s'}}+C
\end{aligned}$$

where $s',t'\in\left[1,\frac{Q}{\alpha}\right)$ and $\frac{1}{s'}+\frac{1}{s}=1$, $\frac{1}{t'}+\frac{1}{t}=1$. Hence, by using the Hardy–Littlewood–Sobolev inequality, we have

$$|H(u)(\xi)|\le C.$$

Thus, we may choose $\ell_0>0$ such that

$$\sup_{u\in E}\frac{H(u)(\xi)}{\ell_0}\le\frac{1}{2}.$$ □

We take $\ell\ge\ell_0>0$ and consider the penalized problem.

In order to prove the existence of solution for (1.1), we show that there exists $R>1$ such that u satisfies the inequality

$$f(\xi,u)\le\frac{V(\xi)}{\ell}u$$

for $|\xi|\ge R$.

Proof of Theorem 1.2. Let

$$v(\xi)=\frac{R^{Q-2}\|u\|_{L^\infty(\mathbb{H}^N)}}{|\xi|^{Q-2}}.$$

One can verify that $v\in C^\infty(\mathbb{H}^N)\setminus\{0\}$. Observe that $u\le v$ for $|\xi|=R$. Define

$$w=\begin{cases}(u-v)_+ & \text{if } |\xi|\ge R,\\ 0 & \text{if } |\xi|<R.\end{cases}$$

We see that $w=0$ on $\partial B_R(0)$, $w\ge 0$ and $\Delta_{\mathbb{H}}v=0$ in $\mathbb{H}^N\setminus B_R(0)$, since $\frac{C}{|\xi|^{Q-2}}$ is a fundamental

solution where C is suitable constant[17, Theorem 2.1]. Therefore,

$$\begin{aligned}\int_{\mathbb{H}^N} |\nabla_{\mathbb{H}} w(\xi)|^2 d\xi &= \int_{\mathbb{H}^N} \nabla_{\mathbb{H}}(u-v)(\xi)\cdot\nabla_{\mathbb{H}} w(\xi) d\xi \\ &= \int_{|\xi|\geq R} H(\xi)g(\xi,u(\xi))w(\xi) - V(\xi)u(\xi)w(\xi)d\xi \\ &\leq \int_{|\xi|\geq R}\left(\frac{H(\xi)}{\ell_0}-1\right)V(\xi)u(\xi)w(\xi)d\xi \\ &\leq 0.\end{aligned}$$

Thus $w \equiv 0$ and hence, $u \leq v \leq \frac{R^{Q-2}M}{|\xi|^{Q-2}}$ if $|\xi| \geq R$. Consider,

$$\begin{aligned}\frac{f(\xi,u)}{u}p &\leq K(\xi)|u|^{p-2} + Q_\alpha^*|u|^{Q_\alpha^*-2} \\ &\leq pM^{p-2}K(\xi)\left(\frac{R}{|\xi|}\right)^{(p-2)(Q-2)} + Q_\alpha^* M^{Q_\alpha^*-2}\left(\frac{R}{|\xi|}\right)^{(Q_\alpha^*-2)(Q-2)} \\ &\leq C\left(\frac{R}{|\xi|}\right)^{(p-2)(Q-2)} \\ &\leq \frac{C\ell R^{(p-2)(Q-2)}}{\ell|\xi|^{(p-2)(Q-2)}}.\end{aligned}$$

Let $\gamma = C\ell, \Lambda \geq \gamma R^\mu$ and $\mu = (p-2)(Q-2)$. Then, from (Σ_1), we have

$$\frac{f(\xi,u)}{u} \leq \frac{1}{\ell}\frac{\Lambda}{|\xi|^\mu} \leq \frac{V(\xi)}{\ell}.$$

This completes the proof. □

Abstract. In this paper, we study a class of partial functional differential equations with infinite delay within an abstract phase space framework. By employing the α-norm, we establish the existence and uniqueness of mild solutions under a more general condition on the nonlinear term, which is weaker than the classical Lipschitz condition. The linear part is governed by an unbounded operator that generates an analytic semigroup. Furthermore, an averaging principle is established in this case. To illustrate the applicability of the theoretical results, a concrete example is provided.

Keywords: analytic semigroup, infinite delay, alpha-norm, non-Lipschitz condition.

2020 Mathematics Subject Classification: 35A01, 35A02, 35B40.

1 Introduction

This work is concerned with the uniqueness existence of mild solutions and an averaging principle in the case of finite interval, especially $t \in [0, a]$, of the following partial functional differential equations with infinite delay of the form,

$$\begin{cases} x'(t) = -Ax(t) + f\left(\frac{t}{\varepsilon}, x_t\right), \quad t \geq 0, \\ x_0 = \varphi \in \mathcal{B}_\alpha, \end{cases} \tag{P_ε}$$

where $\varepsilon > 0$ and $-A$ generates an analytic semigroup $(T(t))_{t\geq 0}$ on a Banach space $(X, \|\cdot\|)$. The space $\mathcal{B}$ is a Banach space of functions mapping $(-\infty, 0]$ to X defined axiomatically. For $0 < \alpha < 1$, A^α denotes the fractional power of A. We assume that f is defined on $\mathbb{R}^+ \times \mathcal{B}_\alpha$ with values in X, where $\mathcal{B}_\alpha$ is defined by

$$\mathcal{B}_\alpha = \{\varphi \in \mathcal{B} : \varphi(\theta) \in D(A^\alpha) \text{ for } \theta \leq 0 \text{ and } A^\alpha \varphi \in \mathcal{B}\},$$

✉Corresponding author. Email: elhafianezakaria@gmail.com

and the function $A^{\alpha}\varphi$ is defined by

$$(A^{\alpha}\varphi)(\theta) = A^{\alpha}(\varphi(\theta)) \quad \text{for } \theta \leq 0.$$

For for every $t \geq 0$, the history function $x_t \in \mathcal{B}_{\alpha}$ is defined by

$$x_t(\theta) = x(t+\theta) \quad \text{for } \theta \leq 0.$$

The delay phenomenon is ubiquitous and extremely important in various engineering and dynamic systems, playing a significant role in their evolution. Mathematical models with delays are typically more suitable for practical problems than those without, and they have a stronger application background. The development was initiated for equations with finite delay by Travis and Webb in [23] and [24] and a book of Wu [25]. Concerning the case of infinite delay, an extensive theory has been developed by many authors, including Hino et al. [11], Hale and Kato [9], and Ezzinbi et al. [1] and [2].

However in many practical cases, the source function f may implicitly include spatial derivatives, then the above established results become invalid. In this case, the problem becomes more complicated, and to tackle this difficulty, Ezzinbi et al. in [6] examined the following equation:

$$\begin{cases} x'(t) = -Ax(t) + f(t, x_t), & t \geq 0, \\ x_0 = \varphi \in \mathcal{B}_{\alpha}. \end{cases}$$

In their work, they proved the existence of a mild solution without proving uniqueness, under the assumption that $-A$ generates an analytic semigroup and that the function f is continuous with respect to both its time variable and its history function. As far as we know, no research has been published on the unique existence of mild solutions and the averaging principle for the problem (P_{ε}), when the source function involves implicit spatial derivatives, and the the function f satisfies a condition weaker than the ordinary Lipschitz one as we can see in the sequel.

The initial studies on the averaging principle originate from the problem of celestial mechanic, we refer the reader to [4,12,17], for more details about this topic. The authors provide a justification of the averaging principle in the context of finite-dimensional differential equations. Subsequently, in [5,7,8,10,13–15,20,21], the authors extended the averaging principle to both finite- and infinite-dimensional equations as well as to functional differential equations with finite delay.

The approach here is to consider the following partial functional differential equations with infinite delay in X and a small positive parameter ε of the (normal) form

$$\begin{cases} z'(\tau) = \varepsilon[-Az(\tau) + f(\tau, z_{\tau})], & \tau \geq 0, \\ z_0 = \psi. \end{cases} \tag{1.1}$$

Under the same hypotheses on the operator $-A$ and the function f, and adding the following condition on the phase space $\mathcal{B}$,

$$\psi\left(\frac{\cdot}{\varepsilon}\right) \in \mathcal{B}, \quad \text{for all } \varepsilon > 0, \tag{C_1}$$

we can prove that problem (1.1) can be equivalently rewritten as (P_{ε}).

The averaging principle is based on the replacement of the nonautonomous part of a partial differential equation with small parameter $\varepsilon > 0$ by its time average $f_0 : \mathcal{B} \to E$ defined by

$$f_0(v) = \lim_{t \to +\infty} \frac{1}{t} \int_0^t f(s, v)ds, \quad \text{for } v \in \mathcal{B},$$

and which figure in the parallel problem of (1.1) given by

$$\begin{cases} z'(\tau) = \varepsilon[-Az(\tau) + f_0(z_\tau)], \quad \tau \geq 0, \\ z_0 = \psi. \end{cases} \tag{1.2}$$

Therefore, we conclude that under the additional condition (C_1) on the phase space $\mathcal{B}$ and in order to establish the averaging principle for problem (1.1) in the case of finite time interval, it is necessary to show that, for any fixed time $a > 0$, the (unique) solution of the problem (P_ε) can be approximated (in a certain sense) by the (unique) solution of the parallel problem

$$\begin{cases} x'(t) = -Ax(t) + f_0(x_t), \quad t \in [0, a], \\ x_0 = \varphi, \end{cases} \tag{P_0}$$

as $\varepsilon \to 0^+$.

The paper is organized as follows: In Section 2, we recall some necessary preliminaries. In Section 3, we establish a uniqueness existence result of mild solutions in a Banach space with infinite delay in an abstract phase space $\mathcal{B}$, where the linear part $-A$ generates an analytic semigroup which will be denoted by $(T(t))_{t\geq 0}$ on a Banach space X, and the nonlinear part f satisfies a condition with respect to the second argument, which is weaker than the ordinary Lipschitz condition. In Section 4, we consider the problem (P_ε) and its corresponding parallel problem (P_0). we establish the averaging principle result for the problem (P_ε). Finally we illustrate our results in the third and the last section by showing how they can be applied to a parabolic partial differential equation with infinite delay.

2 Preliminaries

Consider the following partial functional differential equation in X of the form:

$$\begin{cases} x'(t) = -Ax(t) + f(t, x_t), \quad t \in [0, a], \\ x_0 = \varphi \in \mathcal{B}_\alpha, \end{cases} \tag{2.1}$$

In the whole of this work, we assume that

($\mathbf{H}_0$) $-A$ is the infinitesimal generator of a compact analytic semigroup $(T(t))_{t\geq 0}$ on a Banach space X and $0 \in \rho(A)$, where $\rho(A)$ is the resolvent set of A.

Then, there exist constants $M \geq 1$ and $\omega \in \mathbb{R}$ such that $\|T(t)\| \leq Me^{\omega t}$ for $t \geq 0$. Without loss of generality, we assume that $\omega > 0$. If the assumption $0 \in \rho(A)$ is not satisfied, one can substitute the operator A by the operator $(A - \sigma I)$ with σ large enough such that $0 \in \rho(A - \sigma I)$ and so we can always assume that $0 \in \rho(A)$.

For the fractional power $(A^\alpha, D(A^\alpha))$, for $0 < \alpha < 1$, and its inverse $A^{-\alpha}$. One has the following known result.

Theorem 2.1 ([16, Theorems 6.8–6.13, pp. 72–74]]). *Let $0 < \alpha < 1$ and assume that ($\mathbf{H}_0$) holds. Then*

(i) $D(A^\alpha)$ is a Banach space with the norm $|x|_\alpha = |A^\alpha x|$ for $x \in D(A^\alpha)$,

(ii) $T(t) : X \to D(A^\alpha)$ for $t > 0$,

(iii) $A^{\alpha}T(t)x = T(t)A^{\alpha}x$ *for* $x \in D(A^{\alpha})$ *and* $t \geq 0$,

(iv) for every $t > 0$, $A^{\alpha}T(t)$ *is bounded on* X *and there exists* $M_{\alpha} > 0$ *such that*

$$|A^{\alpha}T(t)| \leq M_{\alpha}\frac{e^{\omega t}}{t^{\alpha}} \text{ for } t > 0, \tag{2.2}$$

(v) $A^{-\alpha}$ *is a bounded linear operator on* X *with* $D(A^{\alpha}) = \mathrm{Im}(A^{-\alpha})$,

(vi) if $0 < \alpha < \beta < 1$, *then* $D(A^{\beta}) \hookrightarrow D(A^{\alpha})$,

(vii) there exists $N_{\alpha} > 0$ *such that*

$$\left|(T(t) - I)A^{-\alpha}\right| \leq N_{\alpha}t^{\alpha} \quad \text{for } t > 0. \tag{2.3}$$

In the sequel, we denote by X_{α} *the Banach space* $(D(A^{\alpha}), |\cdot|_{\alpha})$. *Recall that* $A^{-\alpha}$ *is given by the following formulas*

$$A^{-\alpha} = \frac{\sin(\pi\alpha)}{\alpha}\int_0^{\infty} t^{-\alpha}(t + A)^{-1}dt,$$

or

$$A^{-\alpha} = \frac{1}{\Gamma(\alpha)}\int_0^{\infty} t^{\alpha-1}T(t)\mathrm{d}t.$$

We denote by $C_{\alpha} := C_B((-\infty, 0]; X_{\alpha})$ the space of continuous bounded functions from $(-\infty, 0]$ into X_{α} endowed with the norm

$$\|\varphi\|_{\alpha} := \sup_{\theta \leq 0} |\varphi(\theta)|_{\alpha}, \quad \varphi \in C_{\alpha}.$$

Remark that $(C_{\alpha}, \|\cdot\|_{\alpha})$ is also a Banach space.

From now on, we adopt the axiomatic definition of the phase space $\mathcal{B}$, originally introduced by Hale and Kato in [9]. We denote its norm by $\|\cdot\|_{\mathcal{B}}$. The space $\mathcal{B}$ consists of all functions mapping $(-\infty, 0]$ into X and satisfying the following fundamental axioms:

(A) there exist a positive constant N, a locally bounded function $M(\cdot)$ on $[0, +\infty)$ and a continuous function $K(\cdot)$ on $[0, +\infty)$, such that if $x : (-\infty, a] \to X$ is continuous on $[\sigma, a]$ with $x_{\sigma} \in \mathcal{B}$, for some $\sigma < a$, then for all $t \in [\sigma, a]$,

(i) $x_t \in \mathcal{B}$,

(ii) $t \mapsto x_t$ is continuous with respect to $\|\cdot\|$ on $[\sigma, a]$,

(iii) $N|x(t)| \leq \|x_t\| \leq K(t - \sigma)\sup_{\sigma \leq s \leq t}|x(s)| + M(t - \sigma)\|x_{\sigma}\|$.

(B) $\mathcal{B}$ is a Banach space.

We suppose that

$(\mathbf{H}_1)$ $A^{-\alpha}\varphi \in \mathcal{B}$ for $\varphi \in \mathcal{B}$, where the function $A^{-\alpha}\varphi$ is defined by

$$\left(A^{-\alpha}\varphi\right)(\theta) = A^{-\alpha}(\varphi(\theta)) \text{ for } \theta \leq 0.$$

Consequently, we get the following result.

Proposition 2.2 ([6]). *Assume that* $(\mathbf{H}_0)$ *and* $(\mathbf{H}_1)$ *hold. If* $\mathcal{B}$ *satisfies axioms* (**A**) *and* (**B**). *Then* $\mathcal{B}_{\alpha}$ *satisfies axioms* (**A**) *and* (**B**).

(**A**) *if* $x : (-\infty, a] \to X_\alpha$ *is continuous on* $[\sigma, a]$ *with* $x_\sigma \in \mathcal{B}$, *for some* $\sigma < a$, *then for all* $t \in [\sigma, a]$,

(i) $x_t \in \mathcal{B}$,

(ii) $t \mapsto x_t$ *is continuous with respect to* $\|\cdot\|_\alpha$ *on* $[\sigma, a]$,

(iii) $N|x(t)|_\alpha \leq \|x_t\|_\alpha \leq K(t-\sigma)\sup_{\sigma\leq s\leq t}|x(s)|_\alpha + M(t-\sigma)\|x_\sigma\|_\alpha$.

(**B**) $\mathcal{B}_\alpha$ *is a Banach space.*

We have the following definition.

Definition 2.3. Let $\varphi \in \mathcal{B}_\oslash$. We say that $x \in \mathcal{C}(]-\infty, a]; X_\alpha)$ is a mild solution to problem (2.1) if $x_0 = \varphi$ and,

$$x(t) = T(t)\varphi(0) + \int_0^t T(t-s)f(s, x_s)ds \quad \text{for } 0 \leq t \leq a.$$

3 Existence results

In the whole of this work we suppose that $\mathcal{B}$ satisfies (**A**) and (**B**).

For the existence result we suppose that the function $f : (t, u) \mapsto f(t, u)$ acts from $[0, a] \times \mathcal{B}_\alpha$ into X and continuous with respect to t and u. Then we have the following theorem,

Theorem 3.1 ([6]). *Assume that* $(\mathbf{H}_0)$ *and* $(\mathbf{H}_1)$ *hold. Then for* $\varphi \in \mathcal{B}_\alpha$ *problem* (2.1) *has a mild solution on* $[0, a]$, *for a small enough.*

In order to prove a uniqueness result, we suppose that the function f satisfies a condition weaker than the ordinary Lipschitz condition, which is given as follows

$(\mathbf{H}_2)$ For all $(u, v) \in \mathcal{B}_\alpha \times \mathcal{B}_\alpha$, and $t \geq 0$

$$\|f(t, u) - f(t, v)\| \leq L(t, \|u - v\|_\alpha),$$

where $L : [0, a] \times [0, +\infty[\to [0, +\infty[$ satisfies:

(i) continuous, nondecreasing with respect to the first and the second argument, and $L(t, 0) = 0$, for all $t \in [0, a]$,

(ii) for any $\zeta > 0$ and for all continuous mapping $h : [0, a] \to [0, +\infty[$, such that:

$$h(t) \leq \zeta \int_0^t (t-s)^{-\alpha} L(s, h(s))ds, \quad \text{for all } t \in [0, a],$$

then $h(t) = 0$ for all $t \in [0, a]$.

We have the following theorem.

Theorem 3.2. *Assume that* $(\mathbf{H}_0)$–$(\mathbf{H}_2)$ *are satisfied, then problem* (2.1) *has a unique mild solution.*

Proof. The existence is ensured by Theorem 3.1. To attend for a uniqueness result we suppose that problem (2.1) has two solutions x_1 and x_2 in X_α. Let $s \in [0, t]$, by using the fact that the mapping L is nondecreasing with respect to the second argument and **A**-(iii), we get

$$\begin{aligned}
|x_1(s) - x_2(s)|_\alpha &= \left| \int_0^s T(s-\tau)\Big(f\Big(\tau, x_\tau^1\Big) - f\big(\tau, x_\tau^2\big)\Big)d\tau \right|_\alpha \\
&\leq M_\alpha e^{\omega a} \int_0^s (s-\tau)^{-\alpha} \Big\| f\Big(\tau, x_\tau^1\Big) - f\big(\tau, x_\tau^2\big) \Big\| d\tau \\
&\leq M_\alpha e^{\omega a} \int_0^s (s-\tau)^{-\alpha} L\left(\tau, K_a \sup_{0\leq\theta\leq\tau} |x_1(\theta) - x_2(\theta)|_\alpha\right) d\tau.
\end{aligned}$$

We claim that the function $s \mapsto \int_0^s (s-\tau)^{-\alpha} L(\tau, K_a \sup_{0\le\theta\le\tau} |x_1(\theta) - x_2(\theta)|_\alpha) d\tau$ is nondecreasing on $[0,t]$. In fact let us denote $g(\tau) = L(\tau, K_a \sup_{0\le\theta\le\tau} |x_1(\theta) - x_2(\theta)|_\alpha)$, which is a nondecreasing function by $(\mathbf{H}_2)$-(i). Then for $s, s' \in [0,t]$ be such that $s < s'$ we have

$$\int_0^s (s-\tau)^{-\alpha} g(\tau) d\tau = \int_0^s \tau^{-\alpha} g(s-\tau) d\tau \le \int_0^{s'} \tau^{-\alpha} g(s'-\tau) d\tau = \int_0^{s'} (s'-\tau)^{-\alpha} g(\tau) d\tau.$$

Then $\sup_{s\in[0,t]} \int_0^s (s-\tau)^{-\alpha} g(\tau) d\tau = \int_0^t (t-\tau)^{-\alpha} g(\tau) d\tau$. Thus,

$$\sup_{0\le s\le t} |x_1(s) - x_2(s)|_\alpha \le M_\alpha e^{\omega a} \int_0^t (t-\tau)^{-\alpha} L\left(\tau, K_a \sup_{0\le\theta\le\tau} |x_1(\theta) - x_2(\theta)|_\alpha\right) d\tau.$$

Consequently,

$$K_a \sup_{0\le s\le t} |x_1(s) - x_2(s)|_\alpha \le \zeta_{\alpha,a} \int_0^t (t-\tau)^{-\alpha} L\left(\tau, K_a \sup_{0\le\theta\le\tau} |x_1(\theta) - x_2(\theta)|_\alpha\right) d\tau.$$

Using $(\mathbf{H}_2)$-(ii), we get

$$\sup_{0\le s\le t} |x_1(s) - x_2(s)|_\alpha = 0 \quad \text{for all } t \in [0,a].$$

Thus, problem (2.1) has a unique mild solution. □

Corollary 3.3. Let k a positive constant. If the mapping $L(t,u) = ku$ for all $t \ge 0$, then our assumption $(\mathbf{H}_2)$ becomes the ordinary Lipschitz condition and $(\mathbf{H}_2)$-(ii) still hold.

Proof. Let $h : [0,a] \to [0,+\infty[$ a continuous function then by taking $L(t,u) = ku$, for all $t \ge 0$, we can see that

$$h(t) \le \zeta \int_0^t (t-s)^{-\alpha} L(s, h(s)) ds, \quad \text{for all } t \in [0,a],$$

becomes

$$h(t) \le \zeta' \int_0^t \frac{h(s)}{(t-s)^\alpha} ds, \quad \text{for all } t \in [0,a], \tag{3.1}$$

for $\zeta' > 0$. To complete to proof we need the following lemma.

Lemma 3.4 ([16, Lemma 6.7, p. 159])**.** *Let $\varphi : [0,a] \to [0,\infty[$ be continuous. If there are positive constants A, B and $0 < \alpha < 1$ such that*

$$\varphi(t) \le A + B \int_0^t \frac{\varphi(s)}{(t-s)^\alpha} ds, \quad \text{for } 0 \le t \le a,$$

then there exist $A' > 0, B' > 0$, such that

$$\varphi(t) \le A' + B' \int_0^t \varphi(s) ds,$$

where $A' = A \sum_{j=0}^{n-1} \left(\frac{Ba^{1-\alpha}}{1-\alpha}\right)^j$, and $B' = \frac{(B\Gamma(1-\alpha))^n}{\Gamma(n(1-\alpha))} a^{n(1-\alpha)-1}$. In particular there exists $C' \ge 0$ such that $\varphi(t) \le C'$, for all $t \ge 0$.

Proof. By taking $A = 0$, $B = \zeta'$ in (3.1), we can deduce that

$$h(t) \le B' \int_0^t h(s) ds.$$

Gronwall's inequality leads to $h(t) = 0$ for all $t \ge 0$. □

Another example of a mapping with the Assumption $(\mathbf{H}_2)$, we give the following:

Example 3.5. [22] We take $L(t,u) = q(t)r(u)$, for all $t \in [0,a]$ and $u \in [0,+\infty[$, where $q : [0,a] \to [0,+\infty[$ is a continuous function, and $r : [0,+\infty[\to [0,+\infty[$, is a continuous nondecreasing function with $r(0) = 0$, such that

$$\int_{0^+} \frac{1}{r(u)} du = \infty.$$

Remark 3.6. To establish the existence of global solutions, we assume the same conditions on f as in Theorem 3.2, and we introduce the following additional assumption:

$(\mathbf{H}_3)$ There exists a continuous function g defined on $\mathbb{R}^+$ such that,

$$\|f(t,u)\| \leq g(t)(1 + \|u\|_\alpha) \quad \text{for all } t \in \mathbb{R}^+, \ \ u \in \mathcal{B}_\alpha.$$

The proof is similar to that of Corollary 6 in [6].

4 Averaging result

In order to prove an averaging principle result, we choose the phase space $\mathcal{B} = \mathcal{C}_\infty$ (see [11]). The space $\mathcal{C}_\infty$ is formed by all the continuous functions $\varphi : \mathbb{R}^- \to X$, such that $\lim_{\theta \to -\infty} \varphi(\theta)$ exists in X. Endowed with the following norm

$$\|\varphi\|_{\mathcal{B}} = \sup_{\theta \in]-\infty,0]} |\varphi(\theta)|.$$

Consider the partial functional differential equation in X with a small positive parameter ε of the form

$$\begin{cases} x'(t) = Ax(t) + f\left(\frac{t}{\varepsilon}, x_t\right), \quad t \in [0,a], \\ x_0 = \varphi. \end{cases} \tag{P_ε}$$

Further, parallel to the problem (P_ε), $\varepsilon > 0$, we consider the averaged problem

$$\begin{cases} x'(t) = Ax(t) + f_0(x_t), \\ x_0 = \varphi. \end{cases} \tag{P_0}$$

Remark 4.1. When the delay is infinite the choice of the phase space is crucial to establish the averaging principle result associate to problem (P_ε). To guarantee the equivalence between

$$\begin{cases} w'(\tau) = \varepsilon[Aw(\tau) + f(\tau, w_\tau)], \quad \tau \in \left[0, \frac{a}{\varepsilon}\right], \\ w_0 = \psi \end{cases} \tag{4.1}$$

and (P_ε). Also between

$$\begin{cases} w'(t) = \varepsilon[Aw(t) + f_0(w_t)] \\ w_0 = \psi \end{cases} \tag{4.2}$$

and (P_0), we have to suppose that the condition (C_1) is satisfied. Clearly, this condition is not satisfied for any choice of the space $\mathcal{B}$ introduced by Hale and Kato [9], as shown by the following phase space examples:

Let $E = \mathcal{C}([0,1];\mathbb{R})$ be the space of continuous functions endowed with the uniform norm topology. Let $\gamma > 0$ and $\mathcal{L}_\gamma$ be the space of measurable functions $\varphi : (-\infty, 0] \to X$ such that $e^{\gamma\theta}\varphi(\theta)$ is integrable on $(-\infty, 0\ ]$. We consider the phase space $\mathcal{B} = E \times \mathcal{L}_\gamma$. The space of functions $\varphi \in \mathcal{L}_\gamma$ which is uniquely defined at 0 and endowed with the following norm

$$\|\varphi\| = |\varphi(0)| + \int_{-\infty}^{0} e^{\gamma\theta}|\varphi(\theta)|d\theta \quad \text{for } \varphi \in \mathcal{B}.$$

Let the function φ be defined on $(-\infty, 0]$ by $\varphi(\theta) = e^{-\frac{\gamma}{2}\theta}$.
Since, for $\theta = 0$, we have $\varphi(0) = 1$, and

$$\int_{-\infty}^{0} e^{\gamma\theta}|\varphi(\theta)|d\theta = \int_{-\infty}^{0} e^{\gamma\theta}e^{-\frac{\gamma}{2}\theta}d\theta = \int_{-\infty}^{0} e^{\frac{\gamma}{2}\theta}d\theta = \frac{2}{\gamma},$$

it follows, $\varphi \in \mathcal{B}$.
Now, for $0 < \varepsilon < 1$, we consider the scaled function $\varphi\left(\frac{\cdot}{\varepsilon}\right)$, given by:

$$\varphi\left(\frac{\theta}{\varepsilon}\right) = e^{-\frac{\gamma}{2\varepsilon}\theta} \text{ for all } \theta \leq 0.$$

We can easily check that the integral condition is not satisfied.

In fact, we have

$$\int_{-\infty}^{0} e^{\gamma\theta}\left|\varphi\left(\frac{\theta}{\varepsilon}\right)\right|d\theta = \int_{-\infty}^{0} e^{\gamma\theta}e^{-\frac{\gamma}{2\varepsilon}\theta}d\theta = \int_{-\infty}^{0} e^{\left(1-\frac{1}{2\varepsilon}\right)\gamma\theta}d\theta.$$

For $\varepsilon \leq \frac{1}{2}$, the integral diverges, and $\varphi\left(\frac{\cdot}{\varepsilon}\right)$ does not belong to $\mathcal{B}$.

Another example of phase space given in [9], where the condition (C_1) fails, is the phase space $\mathcal{B} = C_\gamma$, where C_γ is the space of continuous functions $\psi : \mathbb{R}^- \to \mathbb{R}$ such $e^{\gamma\theta}\psi(\theta)$ has the limit in $\mathbb{R}$ as $\theta \to -\infty$ endowed with the following norm:

$$\|\psi\|_{\mathcal{B}} = \sup\left\{e^{\gamma\theta}|\psi(\theta)| : \theta \in \right] -\infty, 0\left]\right\}.$$

It is clear that the function $\psi(\theta) = e^{-\gamma\theta}$ belongs to $\mathcal{B}$ but, for every $0 < \varepsilon < 1$,

$$\left\|\psi\left(\frac{\cdot}{\varepsilon}\right)\right\|_{\mathcal{B}} = \sup_{\theta\in]-\infty,0]} e^{\gamma\theta}e^{-\gamma(\theta/\varepsilon)} = \sup_{\theta\in]-\infty,0]} e^{\gamma\theta(1-1/\varepsilon)} = +\infty.$$

Now, in problem (4.1), we consider the change of variables

$$\begin{cases} \theta = \dfrac{\theta'}{\varepsilon}, & \tau = \dfrac{t}{\varepsilon}, \quad \theta \leq 0, \quad \tau \geq 0, \\ \psi\left(\dfrac{\theta'}{\varepsilon}\right) = \varphi(\theta), & w\left(\dfrac{t}{\varepsilon}\right) = x(t). \end{cases}$$

Then we have the following proposition.

Proposition 4.2 ([7]). *For the choice $\mathcal{B} = C_\infty$, the condition (C_1) is satisfied and the problems (4.1) and (4.2) can be equivalently rewritten as (P_ε) and (P_0), respectively.*

We suppose the following hypotheses:
Hypotheses. Suppose that the unbounded linear operator A satisfies the condition $(\mathbf{H}_0)$, $(\mathbf{H}_1)$ and the function f acts from $[0, a] \times \mathcal{B}_\alpha$ into X. We consider the following hypotheses:

(f_1) f is continuous with respect to the first and the second argument,

(f_2) for all $(u,v) \in \mathcal{B}_\alpha \times \mathcal{B}_\alpha$,

$$\|f(t,u) - f(t,v)\| \leq \mathbb{L}(\|u-v\|_\alpha) \quad \text{for all} \quad t \in [0,a],$$

where $\mathbb{L} : [0,+\infty[\to [0,+\infty[$ is such that:
(i) $\mathbb{L}(\cdot)$ is continuous, nondecreasing, and $\mathbb{L}(0) = 0$,
(ii) for every nonnegative continuous mapping $h : [0,a] \to [0,+\infty[$ and every constant ζ, we have,

$$h(t) \leq \zeta \int_0^t (t-s)^{-\alpha} \mathbb{L}(h(s))ds \quad \text{for all } t \in [0,a],$$

then $h(t) = 0$.

(f_3) there exists a constant $C > 0$ such that,

$$\|f(t,u)\| \leq C(1 + \|u\|_\alpha) \quad \text{for all } t \in \mathbb{R}^+, \text{ and } u \in \mathcal{B}_\alpha$$

(Af) there exist $\Delta_0 > 0$ and a function $f_0 : \mathcal{B}_\alpha \to X$ satisfying (f_2) and (f_3) and, for all $u \in \mathcal{B}_\alpha$ and $t_1, t_2 \in [0,a]$ with $0 \leq t_1 \leq t_2 \leq t_1 + \Delta_0 \leq a$, we have

$$\lim_{\varepsilon \to 0^+} \int_{t_1}^{t_2} T(t_2 - \theta) \left[f\left(\frac{\theta}{\varepsilon}, u\right) - f_0(u) \right] d\theta = 0.$$

The function $f_0 : u \mapsto \lim_{T\to\infty} \frac{1}{T} \int_0^T f(t,u)dt$ satisfies a condition similar to (f_2) and (f_3), which is

(f_1') for all $(u,v) \in \mathcal{B}_\alpha \times \mathcal{B}_\alpha$,

$$\|f_0(u) - f_0(v)\| \leq \mathbb{L}(\|u-v\|_\alpha),$$

(f_2') there exists a constant $C > 0$ such that, for all $u \in \mathcal{B}_\alpha$,

$$\|f_0(u)\| \leq C(1 + \|u\|_\alpha).$$

In fact, for $(u,v) \in \mathcal{B}^2$ we have

$$\begin{aligned}
\|f_0(u)\| &= \left\| \lim_{T\to\infty} \frac{1}{T} \int_0^T f(t,u)dt \right\| \\
&\leq \lim_{T\to\infty} \frac{1}{T} \int_0^T \|f(t,u)\|dt \\
&\leq \lim_{T\to\infty} \frac{1}{T} \int_0^T C(|1 + \|u\|_\alpha)dt \\
&\leq C(\|1 + \|u\|_\alpha)
\end{aligned}$$

and

$$\begin{aligned}
\|f_0(x) - f_0(y)\| &= \left\| \lim_{T\to\infty} \frac{1}{T} \int_0^T f(t,u) - f(t,v)dt \right\| \\
&\leq \lim_{T\to\infty} \frac{1}{T} \int_0^T \|f(t,u) - f(t,v)\|dt \\
&\leq \lim_{T\to\infty} \frac{1}{T} \int_0^T \mathbb{L}(\|u-v\|_\alpha)dt \\
&\leq \mathbb{L}(\|u-v\|_\alpha).
\end{aligned}$$

By (f_1') we can easily deduce the continuity of the function f_0.

Theorem 4.3. *Assume that the hypotheses* $(\mathbf{H}_0)$, $(\mathbf{H}_1)$, (f_1)–(f_3), *and* (Af) *are satisfied. For* $\varphi \in \mathcal{B}_\alpha$, *the unique mild solution of the problem* (P_ε), *converges uniformly in each set* $[0,a]$ *to the mild solution* x^∞ *of the problem* (P_0), *as* $\varepsilon \to 0^+$.

Proof. According to Theorem 3.2 , for each $\varepsilon > 0$ there exists a unique mild solution x^ε of the problem (P_ε) and there exists a unique mild solution x^∞ of the problem (P_0). Moreover, for each $\varepsilon > 0$, x^ε is defined by

$$x^\varepsilon(t) = T(t)\varphi(0) + \int_0^t T(t-s) f\Big(\frac{s}{\varepsilon}, x_s^\varepsilon\Big) ds, \quad 0 \le t \le a,$$

and x^∞ is defined by

$$x^\infty(t) = T(t)\varphi(0) + \int_0^t T(t-s) f_0(x_s^\infty) ds, \quad 0 \le t \le a.$$

By axiom $(\mathbf{A})$-(iii) if $x^\varepsilon \to x^\infty$ in $\mathcal{C}([0,a]; X_\alpha)$, then $x_t^\varepsilon \to x_t^\infty$ in $\mathcal{C}(]-\infty, a]; \mathcal{B}_\alpha)$ as $\varepsilon \to 0^+$. Therefore, in order to prove Theorem 4.3, it remains to show that

$$\lim_{\varepsilon \to 0^+} \sup_{t \in [0,a]} |x^\varepsilon(t) - x^\infty(t)|_\alpha = 0.$$

First, we prove that the sequence $(x^\varepsilon)_{\varepsilon>0}$ is bounded. Let $\varepsilon > 0$, by using (f_3) and Axiom $(\mathbf{A})$-(iii) and let $M := \sup_{0 \le t \le a} \|T(t)\|$. Then for every $t \in [0,a]$, we have

$$\begin{aligned}
|x^\varepsilon(t)|_\alpha &= \left| T(t)\varphi(0) + \int_0^t T(t-s) f\Big(\frac{s}{\varepsilon}, x_s\Big) ds \right|_\alpha \\
&\le \|T(t)A^\alpha \varphi(0)\| + \left\| \int_0^t A^\alpha T(t-s) f\Big(\frac{s}{\varepsilon}, x_s^\varepsilon\Big) ds \right\| \\
&\le M|\varphi(0)|_\alpha + M_\alpha \int_0^t \frac{e^{\omega(t-s)}}{(t-s)^\alpha} C(1 + \|x_s^\varepsilon\|_\alpha) ds. \\
&\le MH\|\varphi\|_\alpha + M_\alpha \int_0^t \frac{e^{\omega(t-s)}}{(t-s)^\alpha} C\left(1 + K_a \sup_{0 \le \theta \le s} |x^\varepsilon(\theta)|_\alpha + N_a \|\varphi\|_\alpha\right) ds.
\end{aligned}$$

Therefore,

$$|x^\varepsilon(t)|_\alpha \le A + B \int_0^t \frac{1}{(t-s)^\alpha} \sup_{0 \le \theta \le s} |x^\varepsilon(\theta)|_\alpha ds, \tag{4.3}$$

where

$$A = MH\|\varphi\|_\alpha + M_\alpha [C(1 + N_a \|\varphi\|_\alpha)] \int_0^a \frac{e^{\omega s}}{s^\alpha} ds,$$

and

$$B = M_\alpha C K_a e^{\omega a}.$$

Let $z(\sigma) = \sup_{0 \le \tau \le \sigma} |x^\varepsilon(\tau)|_\alpha$. We claim that the function $s \mapsto \int_0^s \frac{1}{(s-\sigma)^\alpha} z(\sigma) d\sigma$ is nondecreasing on $[0,t]$.

In fact let $s, s' \in [0,t]$ be such that $s < s'$. Then

$$\int_0^s \frac{1}{(s-\sigma)^\alpha} z(\sigma) d\sigma = \int_0^s \frac{1}{\sigma^\alpha} z(s-\sigma) d\sigma \le \int_0^{s'} \frac{1}{\sigma^\alpha} z(s'-\sigma) d\sigma \le \int_0^{s'} \frac{1}{(s'-\sigma)^\alpha} z(\sigma) d\sigma.$$

Then we obtain

$$\sup_{0 \le s \le t} |x^\varepsilon(s)|_\alpha \le A + B \int_0^t \frac{1}{(t-s)^\alpha} \sup_{0 \le \sigma \le s} |x^\varepsilon(\sigma)|_\alpha ds.$$

Thus, by Lemma 3.4 there is a constant C' such that

$$\sup_{0\le s\le t}|x^\varepsilon(s)|_\alpha \le C', \quad \text{for all } \varepsilon>0,$$

Which proves that the sequence $(x^\varepsilon)_{\varepsilon>0}$ is bounded.

Now by Axiom $(\mathbf{A})$-(iii), the function $t\mapsto x_t^\infty$ is continuous on $[0,a]$. Let $\delta>0$, then we can find a partition $0=t_0<t_1<\ldots<t_m=a$ of $[0,a]$ such that, if $\max_{1\le i\le m}(t_i-t_{i-1})\le \min\{\delta,\Delta_0\}$, then

$$\left\|x_t^\infty - x_{t_i}^\infty\right\| \le \delta \quad \text{for all } t\in[t_{i-1},t_i], \quad i=1,\ldots,m, \tag{4.4}$$

where Δ_0 is from (Af).

We define a function $t\mapsto \bar{x}_t^\infty$by

$$\bar{x}_t^\infty = x_{t_{i-1}}^\infty \quad \text{for } t\in[t_{i-1},t_i[, \quad i=1,\ldots,m. \tag{4.5}$$

Setting $\tau(t)=\max\{i,t_i\le t\}$ and $t'=t_{\o(t)}$, for every $t\in[0,a]$, we get

$$\begin{aligned}
x^\varepsilon(t)-x^\infty(t) &= \int_{t'}^t T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},x_\theta^\varepsilon\right)-f_0(x_\theta^\infty)\right]d\theta\\
&\quad+\int_0^{t'} T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},x_\theta^\varepsilon\right)-f\left(\frac{\theta}{\varepsilon},x_\theta^\infty\right)\right]d\theta\\
&\quad+\int_0^{t'} T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},x_\theta^\infty\right)-f\left(\frac{\theta}{\varepsilon},\bar{x}_\theta^\infty\right)\right]d\theta\\
&\quad+\int_0^{t'} T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},\bar{x}_\theta^\infty\right)-f_0(\bar{x}_\theta^\infty)\right]d\theta\\
&\quad+\int_0^{t'} T(t-\theta)[f_0(\bar{x}_\theta^\infty)-f_0(x_\theta^\infty)]d\theta\\
&= I_1+I_2+I_3+I_4+I_5.
\end{aligned}$$

Since the sequence $(x^\varepsilon)_{\varepsilon>0}$ is bounded, by Axiom $(\mathbf{A})$-(iii), the sequence $(x_t^\varepsilon)_{\varepsilon>0}$ is also bounded in $\mathcal{C}([0,a];\mathcal{B}_\alpha)$, for all $t\in[0,a]$. Thus,

$$\begin{aligned}
|I_1|_\alpha &= \left|\int_{t'}^t T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},x_\theta^\varepsilon\right)-f_0(x_\theta^\infty)\right]d\theta\right|_\alpha\\
&\le M_\alpha\int_{t'}^t \frac{e^{\omega(t-\theta)}}{(t-\theta)^\alpha}\left\|f\left(\frac{\theta}{\varepsilon},x_\theta^\varepsilon\right)-f_0(x_\theta^\infty)\right\|d\theta\\
&\le M_\alpha\int_{t'}^t \frac{e^{\omega(t-\theta)}}{(t-\theta)^\alpha}\left[C\left(1+\sup_{\varepsilon>0}\left\|x_{(.)}^\varepsilon\right\|_{\mathcal{C}([0,a];\mathcal{B}_\alpha)}\right)+C\left(1+\max_{t\in[0,a]}\|x_t^\infty\|_\alpha\right)\right]d\theta\\
&\le M_\alpha\left[C\left(1+\sup_{\varepsilon>0}\left\|x_{(.)}^\varepsilon\right\|_{\mathcal{C}([0,a];\mathcal{B}_\alpha)}\right)+C\left(1+\max_{t\in[0,a]}\|x_t^\infty\|_\alpha\right)\right]e^{\omega a}\int_{t'}^t\frac{1}{(t-\theta)^\alpha}d\theta.
\end{aligned}$$

Then by a simple change of variable, we get to

$$\int_{t'}^t\frac{1}{(t-\theta)^\alpha}d\theta=\frac{1}{1-\alpha}(t-t')^{1-\alpha}\le\frac{1}{1-\alpha}\delta^{1-\alpha}.$$

This leads to

$$|I_1|_\alpha\le\tilde{\mu}\delta^{1-\alpha},$$

where

$$\tilde{\mu} = M_\alpha C \frac{e^{\omega a}}{1-\alpha}\left[\left(1+\sup_{\varepsilon>0}\left\|x^\varepsilon_{(.)}\right\|_{\mathcal{C}([0,a];\mathcal{B}_\alpha)}\right)+\left(1+\max_{t\in[0,a]}\|x^\infty_t\|_\alpha\right)\right].$$

By axiom $(\mathbf{A})$, and hypothesis (f_2), we get

$$\begin{aligned}|I_2|_\alpha &\leq \left|\int_0^t T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},x^\varepsilon_\theta\right)-f\left(\frac{\theta}{\varepsilon},x^\infty_\theta\right)\right]d\theta\right|_\alpha\\ &\leq M_\alpha e^{\omega a}\int_0^t (t-\theta)^{-\alpha}\mathbb{L}\left(K(\theta)\sup_{0\leq s\leq\theta}|x^\varepsilon(s)-x^\infty(s)|_\alpha\right)d\theta.\end{aligned}$$

Further, let $q=\frac{2-\alpha}{1-\alpha}$, $p=2-\alpha$. By using (f_2), (4.4), (4.5) and Hölder's inequality we obtain

$$\begin{aligned}|I_3|_\alpha &\leq M_\alpha\int_0^t \frac{e^{\omega(t-\theta)}}{(t-\theta)^\alpha}\left\|f\left(\frac{\theta}{\varepsilon},x^\infty_\theta\right)-f\left(\frac{\theta}{\varepsilon},\bar{x}^\infty_\theta\right)\right\|d\theta\\ &\leq M_\alpha\left(\int_0^t\frac{e^{\omega p\theta)}}{\theta^{p\alpha}}d\theta\right)^{\frac{1}{p}}\left(\int_0^t\left\|f\left(\frac{\theta}{\varepsilon},x^\infty_\theta\right)-f\left(\frac{\theta}{\varepsilon},\bar{x}^\infty_\theta\right)\right\|^q d\theta\right)^{\frac{1}{q}}\\ &\leq C''\left(\sum_{i=1}^m\int_{t_{i-1}}^{t_i}\left\|f\left(\frac{\theta}{\varepsilon},x^\infty_\theta\right)-f\left(\frac{\theta}{\varepsilon},\bar{x}^\infty_\theta\right)\right\|^q d\theta\right)^{\frac{1}{q}}\\ &\leq C''\left(\sum_{i=1}^m\int_{t_{i-1}}^{t_i}\left\|f\left(\frac{\theta}{\varepsilon},x^\infty_\theta\right)-f\left(\frac{\theta}{\varepsilon},x^\infty_{t_{i-1}}\right)\right\|^q d\theta\right)^{\frac{1}{q}}\\ &\leq C''\mathbb{L}(\delta)a^{\frac{1}{q}},\end{aligned}$$

where $C''=M_\alpha\left(\int_0^t\frac{e^{\omega p\theta)}}{\theta^{p\alpha}}d\theta\right)^{\frac{1}{p}}$.

For the term I_4, we have

$$\begin{aligned}|I_4|_\alpha &= \left|\int_0^{t'}T(t-\theta)\left[f\left(\frac{\theta}{\varepsilon},\bar{x}^\infty_\theta\right)-f_0(\bar{x}^\infty_\theta)\right]d\theta\right|_\alpha\\ &= \left|\sum_{i=1}^{\tau(t)}\int_{t_{i-1}}^{t_i}T(t-t_i)T(t_i-\theta)\left[f\left(\frac{\theta}{\varepsilon},x^\infty_{t_{i-1}}\right)-f_0\left(x^\infty_{t_{i-1}}\right)\right]d\theta\right|_\alpha\\ &\leq M\sum_{i=1}^{\tau(t)}\left|\int_{t_{i-1}}^{t_i}T(t_i-\theta)\left[f\left(\frac{\theta}{\varepsilon},x^\infty_{t_{i-1}}\right)-f_0\left(x^\infty_{t_{i-1}}\right)\right]d\theta\right|_\alpha,\end{aligned}$$

where $M=\sup_{t\in[0,a]}\|T(t)\|$.

Bearing in mind hypothesis (Af), we can see

$$\max_{1\leq i\leq m}\lim_{\varepsilon\to0^+}\int_{t_{i-1}}^{t_i}T(t_i-\theta)\left[f\left(\frac{\theta}{\varepsilon},x^\infty_{t_{i-1}}\right)-f_0\left(x^\infty_{t_{i-1}}\right)\right]d\theta=0.$$

Thus,

$$\max_{1\leq i\leq m}\left|\int_{t_{i-1}}^{t_i}T(t_i-\theta)\left[f\left(\frac{\theta}{\varepsilon},x^\infty_{t_i-1}\right)-f_0\left(x^\infty_{t_{i-1}}\right)\right]d\theta\right|_\alpha\leq\frac{\delta}{m}\quad\text{as }\varepsilon\to0^+.$$

Therefore,

$$|I_4|_\alpha\leq M\frac{\tau(t)}{m}\delta\leq M\delta\quad\text{as }\varepsilon\to0^+.$$

Since the function f_0 satisfies a condition similar to (f_2), the term I_5 can be estimated as I_3, thus,

$$|I_5|_\alpha \leq C''\mathbb{L}(\delta)a^{\frac{1}{q}}.$$

From the estimates obtained for the terms I_1 to I_5, for every $t \in [0,a]$, we get

$$\begin{aligned}|x^\varepsilon(t) - x^\infty(t)|_\alpha &\leq \tilde{\mu}\delta^{1-\alpha} + M\delta + 2C''\mathbb{L}(\delta)a^{\frac{1}{q}} \\ &\quad + M_\alpha e^{\omega a}\int_0^t (t-\theta)^\alpha \mathbb{L}\left(K(\theta)\sup_{0\leq s\leq\theta}|x^\varepsilon(s) - x^\infty(s)|_\alpha\right)d\theta, \quad \text{as } \varepsilon \to 0^+.\end{aligned}$$

By the same way as in the proof of Theorem 3.2, the last expression does not decrease, and if we set

$$r(\delta) = \tilde{\mu}\delta^{1-\alpha} + M\delta + 2C''\mathbb{L}(\delta)a^{\frac{1}{q}}, \quad \text{for every } t \in [0,a],$$

we get

$$\begin{aligned}&K_a \sup_{0\leq s\leq t}|x^\varepsilon(s) - x^\infty(s)|_\alpha \\ &\quad \leq K_a r(\delta) + K_a M_\alpha e^{\omega a}\int_0^t (t-\theta)^\alpha \mathbb{L}\left(K_a \sup_{0\leq s\leq\theta}|x^\varepsilon(s) - x^\infty(s)|_\alpha\right)d\theta \quad \text{as } \varepsilon \to 0^+.\end{aligned}$$

In view of (f_2), the function $\delta \to K_a r(\delta)$ is continuous on $[0,+\infty[$ and $K_a r(0) = 0$. Thus, in view of the arbitrariness of δ, we necessarily conclude that

$$K_a \sup_{0\leq s\leq t}|x^\varepsilon(s) - x^\infty(s)|_\alpha \leq M_\alpha e^{\omega a}\int_0^t (t-\theta)^\alpha \mathbb{L}\left(K_a \sup_{0\leq s\leq\theta}|x^\varepsilon(s) - x^\infty(s)|_\alpha\right)d\theta$$

as $\varepsilon \to 0^+$.

By using (f_2) once again, for every $t \in [0,a]$, we can write

$$K_a \sup_{0\leq s\leq t}|x^\varepsilon(s) - x^\infty(s)|_\alpha = 0 \quad \text{as } \varepsilon \to 0^+.$$

Since K_a is a positive constant, we conclude

$$\sup_{0\leq s\leq t}|x^\varepsilon(s) - x^\infty(s)|_\alpha = 0 \quad \text{as } \varepsilon \to 0^+.$$

This completes the proof. □

Now we give the averaging principle with a more general form.

We denote by $(Af)'$ the following hypothesis :

$$\lim_{T\to+\infty}\frac{1}{T}\int_0^T f(s,u)ds = f_0(u), \quad \text{for all } u \in \mathcal{B}_\alpha.$$

We have the following lemma.

Lemma 4.4 ([19]). *Assume that the hypotheses* ($\mathbf{H}_0$), (f_1)-(f_3) *and* $(Af)'$ *are satisfied. Moreover, suppose that* X *is reflexive. Then*

$$\lim_{\varepsilon\to0^+}\int_{t_1}^{t_2} T(t_2-\theta)\left[f\left(\frac{\theta}{\varepsilon},u\right) - f_0(u)\right]d\theta = 0.$$

Corollary 4.5. *Assume that the hypotheses* $(\mathbf{H}_0)$, $(\mathbf{H}_1)$, (f_1)–(f_3) *and* $(Af)'$ *are satisfied. Moreover, suppose that* X *is reflexive. Then the unique mild solution* x^ε *of the problem* (P_ε) *converges to the unique mild solution* x^∞ *of the problem* (P_0)*, i.e.,*

$$\lim_{\varepsilon\to 0^+} \|x^\varepsilon - x^\infty\|_{\mathcal{C}(]-\infty,a],X_\alpha)} = 0.$$

Proof. According to Lemma 4.4 all the hypotheses of Theorem 4.3 are satisfieded then the result. □

5 Application

Example 5.1 (Existence result)**.** We consider the following partial differential equation:

$$\begin{cases} \dfrac{\partial}{\partial t}v(t,\xi) = \dfrac{\partial^2}{\partial \xi^2}v(t,\xi) + F\left(t, \displaystyle\int_{-\infty}^{0} a_1(\theta)\int_0^\xi \frac{\partial}{\partial\sigma}v(t-r,\sigma)d\sigma d\theta, \int_{-\infty}^{t}\int_0^\xi a_2(\theta-t)v(\theta,\sigma)d\sigma d\theta\right) \\ v(t,0) = v(t,1) = 0, \quad t \geq 0, \\ v(\theta,\xi) = v_0(\theta,\xi), \quad \theta \leq 0, \quad \xi \in [0,1], \end{cases} \tag{5.1}$$

where $F : \mathbb{R}^+ \times \mathbb{R} \times \mathbb{R} \to \mathbb{R}$. The function $v_0 : (-\infty, 0] \times [0,1] \to \mathbb{R}$ is continuous and it will be described below.

In order to rewrite equation (5.1) in the abstract form, we choose $X = L^2([0,1];\mathbb{R})$ and we define the operator A on X by

$$\begin{cases} D(A) = H^2(0,1) \cap H_0^1(0,1), \\ Ay = -y''. \end{cases}$$

Then, by Theorem 2.7, page 211 in [16], we get that $-A$ generates an analytic compact semigroup $(T(t))_{t\geq 0}$ on X. From [24], the semigroup $T(t)$ is explicitly given by

$$T(t)y = \sum_{n=1}^{\infty} e^{-n^2 t}\langle y, e_n\rangle e_n \quad \text{for } y \in X.$$

If we choose $\alpha = \frac{1}{2}$, then

$$\begin{cases} A^{\frac{1}{2}}T(t)y = \sum_{n=1}^{\infty} n e^{-n^2 t}\langle y, e_n\rangle e_n & \text{for } y \in X, \\ A^{-\frac{1}{2}}y = \sum_{n=1}^{\infty} \frac{1}{n}\langle y, e_n\rangle e_n & \text{for } y \in X, \\ A^{\frac{1}{2}}y = \sum_{n=1}^{\infty} n\langle y, e_n\rangle e_n & \text{for } y \in D\left(A^{\frac{1}{2}}\right). \end{cases} \tag{5.2}$$

Lemma 5.2 ([24])**.** *If* $y \in D\left(A^{\frac{1}{2}}\right)$*, then* y *is absolutely continuous,* $y' \in X$ *and*

$$\|y'\| = \left\|A^{\frac{1}{2}}y\right\|.$$

Let $\gamma > 0$, we consider the following phase space introduced in [9], which satisfies all the axioms given in the first section

$$\mathcal{B} = \left\{\varphi \in C((-\infty,0];X) : \lim_{\theta\to-\infty} e^{\gamma\theta}\varphi(\theta) \text{ exists in } X\right\}.$$

We equip it with the following norm

$$\|\varphi\|_{\mathcal{B}} = \sup_{\theta\leq 0} e^{\gamma\theta}\|\varphi(\theta)\| \quad \text{for } \varphi \in \mathcal{B}.$$

The norm in $\mathcal{B}_{\frac{1}{2}}$ is given by

$$\|\varphi\|_{\frac{1}{2}} = \sup_{\theta\leq 0} e^{\gamma\theta}\left\|A^{\frac{1}{2}}\varphi(\theta)\right\| = \sup_{\theta\leq 0} e^{\gamma\theta}\sqrt{\int_0^\pi \left(\frac{\partial}{\partial\xi}(\varphi)(\theta)(\xi)\right)^2 d\xi}.$$

Assume that

$(\mathbf{H}_4)$ $e^{-2\gamma\cdot}a_i(\cdot) \in L^2(\mathbb{R}^-)$, for $i \in \{1,2\}$.

Since

$$\begin{aligned}\int_{-\infty}^t a_2(\theta-t)\int_0^\xi v(\theta,\sigma)\mathrm{d}\sigma\mathrm{d}\theta &= \int_{-\infty}^0 a_2(\theta)\int_0^\xi v(t+\theta,\sigma)\mathrm{d}\sigma\mathrm{d}\theta\\ &= \int_{-\infty}^0 a_2(\theta)\int_0^\xi v_t(\theta,\sigma)\mathrm{d}\sigma\mathrm{d}\theta.\end{aligned}$$

We introduce

$$x(t)(\xi) = v(t,\xi), \quad t \geq 0, 0 \leq \xi \leq 1,$$

$$\varphi(\theta)(\xi) = v_0(\theta,\xi), \quad -\infty < \theta \leq 0, 0 \leq \xi \leq 1,$$

$$f(t,\varphi)(\xi) = F\left(t, \int_{-\infty}^0 a_1(\theta)\int_0^\xi \frac{\partial}{\partial\sigma}(\varphi)(-r)(\sigma)d\sigma d\theta, \int_{-\infty}^0 a_2(\theta)\int_0^\xi \varphi(\theta)(\sigma)d\sigma d\theta\right).$$

Then the problem (5.1) can be rewritten as follows

$$\begin{cases} x'(t) = Ax(t) + f(t,x_t) & \text{for } t \geq 0,\\ x_0 = \varphi \in \mathcal{B}_\alpha. \end{cases} \tag{5.3}$$

Let us consider the following hypotheses on the function F.

(a) $F : [0,1]\times\mathbb{R}\times\mathbb{R} \to \mathbb{R}$ is continuous.

(b) There exists a constant $C > 0$, such that $|F(t,\mu,y) - F(t,\mu',y')| \leq C\lambda(|\mu-\mu'| + |y-y'|)$, where $\lambda(\cdot) : [0,+\infty[\to [0,+\infty[$ is a continuous, nondecreasing function with $\lambda(0) = 0$.

As example of such function $\lambda, +\infty[\to [0,+\infty[$, one can write

$$\lambda(z) = \begin{cases} 0, & z = 0\\ -z\ln z, & 0 < z < 1/e,\\ 1/e, & z > 1/e. \end{cases}$$

The function λ is continuous nondecreasing. For more example one can see [22].

Theorem 5.3. *Assume that the hypotheses (a), (b) and* $(\mathbf{H}_4)$ *are satisfied. Then the problem* (5.3) *has a unique mild solution in X.*

Proof. According to Theorem 3.2, we have to prove that f satisfies the hypotheses $(\mathbf{H}_2)$. Define in the space $\mathcal{B}_{\frac{1}{2}}$, an equivalent norm $|||\cdot|||_{\frac{1}{2}}$ by

$$|||\varphi|||_{\frac{1}{2}} = 2v\|\psi\|_{\frac{1}{2}},$$

with v is a positive constant chosen, such that

$$v \geq \frac{1}{\sqrt{2\gamma}} \max\Big(\|e^{-2\gamma(\cdot)}a_1(\cdot)\|_{L^2(\mathbb{R}^-)}; \|e^{-2\gamma(\cdot)}a_2(\cdot)\|_{L^2(\mathbb{R}^-)}\Big).$$

Using hypothesis (b) and the fact that the function $\lambda(\cdot)$ is nondecreasing, for $\psi_1, \psi_2 \in \mathcal{B}_{\frac{1}{2}}$, and for $\xi \in [0,1]$, we have

$$\begin{aligned}
&|\, f(t,\psi_1)(\xi) - f(t,\psi_2)(\xi)|^2 \\
&\leq C^2\Bigg[\lambda\Bigg(\Big(\int_{-\infty}^0 e^{-4\gamma\theta}a_1(\theta)^2 d\theta\Big)^{\frac{1}{2}}\Big(\int_{-\infty}^0 e^{4\gamma\theta}\int_0^\xi \frac{\partial}{\partial\sigma}(\psi_1(r)-\psi_2)^2(-r)(\sigma)d\sigma d\theta\Big)^{\frac{1}{2}} \\
&\quad +\Big(\int_{-\infty}^0 e^{-4\gamma\theta}a_2(\theta)^2 d\theta\Big)^{\frac{1}{2}}\Big(\int_{-\infty}^0 e^{4\gamma\theta}\Big(\int_0^\xi \Big(\psi_1(\theta)(\sigma)-\psi_2(\theta)(\sigma)\Big)\Big)^2 \mathrm{d}\sigma \mathrm{d}\theta\Big)^{\frac{1}{2}}\Bigg)\Bigg]^2 \\
&\leq C^2\Bigg[\lambda\Bigg(\Big(\int_{-\infty}^0 e^{-4\gamma\theta}a_1(\theta)^2 d\theta\Big)^{\frac{1}{2}}\frac{1}{\sqrt{2\gamma}}\sup_{\theta\leq 0}e^{\gamma\theta}\Big(\int_0^1 \frac{\partial}{\partial\sigma}(\psi_1-\psi_2)^2(-r)(\sigma)d\sigma\Big)^{\frac{1}{2}} \\
&\quad +\Big(\int_{-\infty}^0 e^{-4\gamma\theta}a_2(\theta)^2 d\theta\Big)^{\frac{1}{2}}\frac{1}{\sqrt{2\gamma}}\sup_{\theta\leq 0}e^{\gamma\theta}\Big(\int_0^1 \Big(\psi_1(\theta)(\sigma)-\psi_2(\theta)(\sigma)\Big)\Big)^2 \mathrm{d}\sigma\Big)^{\frac{1}{2}}\Bigg)\Bigg]^2 \\
&\leq C^2\Bigg[\lambda\Bigg(v\sup_{\theta\leq 0}e^{\gamma\theta}\Big(\|A^{\frac{1}{2}}(\psi_1-\psi_2)(\theta)\|+\Big(\int_0^1 \big(\psi_1(\theta)(\sigma)-\psi_2(\theta)(\sigma)\big)^2 \mathrm{d}\sigma\Big)^{\frac{1}{2}}\Big)\Bigg)\Bigg]^2.
\end{aligned}$$

Using formulas (5.2), one has

$$\begin{aligned}
\int_0^1 \Big(\psi_1(\theta)(\sigma)-\psi_2(\theta)(\sigma)\Big)^2 d\xi &\leq \int_0^1 \Big(\frac{\partial}{\partial\sigma}\Big(\psi_1(\theta)(\sigma)-\psi_2(\theta)(\sigma)\Big)\Big)^2 d\sigma \\
&= \Big\|A^{\frac{1}{2}}\Big(\psi_1(\theta)-\psi_2(\theta)\Big)\Big\|^2.
\end{aligned}$$

Then we get

$$|\, f(t,\psi_1)(\xi) - f(t,\psi_2)(\xi)|^2 \leq C^2\Bigg[\lambda\Big(2v\sup_{\theta\leq 0}e^{\gamma\theta}\|\psi_1-\psi_2\|_{\frac{1}{2}}\Big)\Bigg]^2,$$

which implies that for all $\psi_1,\ \psi_2 \in \mathcal{B}_{\frac{1}{2}}$, we have

$$\|f(t,\psi_1)-f(t,\psi_2)\|_{L^2(0,1)} \leq C\lambda(|||\psi_1-\psi_2|||_{\frac{1}{2}}).$$ □

Example 5.4 (Averaging principle)**.** Now, we present an example about the averaging principle result.

Consider the following partial differential equation

$$\begin{cases} x'(t) = -Ax(t) + f\big(\frac{t}{\varepsilon}, x_t\big), \\ x_0 = \varphi \in \mathcal{B}_\alpha, \end{cases} \tag{5.4}$$

such that, $-A$ generates an analytic semigroup compact on a reflexive space X (as example we can take A and X given in Example 5.1.

Concerning the phase space $\mathcal{B}$ is identically the phase space $\mathcal{C}_\infty$ described in Section 4, and which satisfies the condition (C_1) (for more examples we refer the reader to a book by Hino, Murakami and Naito [11]).

The function $f : \mathbb{R}^+ \times \mathcal{B}_\alpha \to \mathbb{R}$ is defined as follows

$$f\left(\frac{t}{\varepsilon}, u\right) = \frac{\sin\left(\frac{t}{\varepsilon} + u\right)}{e^{\frac{t}{\varepsilon}}} + 1, \quad \text{for all } t > 0,\ \varepsilon > 0 \ \text{ and } u \in \mathcal{B}_\alpha.$$

Since $-A$ generates an analytic semigroup compact, then $(\mathbf{H}_0)$ is satisfied.

Due to the boundedness of f we can easily show that f meets all the conditions (f_1)–(f_3).

Taking $f_0(u) = 1$, then we can verify that the averaging result condition is satisfied, in fact:

$$\begin{aligned}
\left|\frac{1}{T}\int_0^T f(t,u)dt - f_0(u)\right| &= \left|\frac{1}{T}\int_0^T \frac{\sin(t+u)}{e^t} + 1dt\ - 1\right| \\
&= \left|\frac{1}{T}\int_0^T \frac{\sin(t+u)}{e^t} + 1dt\ - \frac{1}{T}\int_0^T dt\right| \\
&\leq \frac{1}{T}\int_0^T \left|\frac{\sin(t+u)}{e^t}\right| dt \\
&\leq \frac{1}{T}\int_0^T e^{-t}dt \\
&= \frac{1-e^{-T}}{T} \to 0, \quad \text{as } T \to \infty.
\end{aligned}$$

Based on the above discussion and the result in Corollary 4.5, we can deduce that the solution of Equation (5.4) can be approximated as $\varepsilon \to 0$, by the solution of the following autonomous partial differential equation,

$$\begin{cases} x'(t) = -Ax(t) + f_0(x_t), \\ x_0 = \varphi \in \mathcal{B}_\alpha. \end{cases} \tag{5.5}$$

Nonexistence and existence of solutions for a Choquard–Kirchhoff type equation involving mixed local and nonlocal operators

Wenjing Chen ✉ and **Jingran Feng**

School of Mathematics and Statistics, Southwest University, Chongqing, 400715, P.R. China

Received 23 June 2025, appeared 28 December 2025
Communicated by Patrizia Pucci

Abstract. In this paper, we study the following Choquard–Kirchhoff type equation

$$\left(a+b\|u\|^{p(\theta-1)}\right)\left(-\Delta_p u+(-\Delta)_p^s u\right)=\left(\int_{\mathbb{R}^N}\frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu}dy\right)|u|^{p_\mu^*-2}u+\lambda f(x)\ \text{ in } \mathbb{R}^N,$$

where $a,b>0$, $\theta>1$, $\lambda\geq 0$, $0<s<1<p<N$, and $0<\mu<N$. Here $p_\mu^*=\frac{p(2N-\mu)}{2(N-p)}$ denotes the critical exponent associated with the Hardy–Littlewood–Sobolev inequality, and the norm

$$\|u\|=\left(\int_{\mathbb{R}^N}|\nabla u|^p\,dx+\iint_{\mathbb{R}^{2N}}\frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{1}{p}}.$$

The function $f\in L^{\frac{p^*}{p^*-1}}(\mathbb{R}^N)\setminus\{0\}$ is nonnegative, with $p^*=\frac{Np}{N-p}$ being the Sobolev critical exponent. For $\lambda=0$, we establish the nonexistence of nontrivial solutions. For $\lambda>0$, by developing a concentration compactness principle suited to the local-nonlocal setting and combining it with Ekeland's variational principle and the mountain pass theorem, we obtain the existence of multiple nonnegative solutions.

Keywords: Kirchhoff-type equation, local-nonlocal operators, critical equation, Choquard nonlinearity, concentration compactness principle.

2020 Mathematics Subject Classification: 35A15, 35M10, 35J92, 35R11.

1 Introduction

In this paper, we investigate the following Choquard–Kirchhoff type problem that combines mixed local and non-local operators

$$\begin{cases}\left(a+b\|u\|^{p(\theta-1)}\right)\left(-\Delta_p u+(-\Delta)_p^s u\right)=\left(\int_{\mathbb{R}^N}\frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\right)|u|^{p_\mu^*-2}u+\lambda f(x)\ \text{ in } \mathbb{R}^N,\\ u\in X^{1,p}(\mathbb{R}^N),\end{cases}\tag{1.1}$$

✉ Corresponding author. Email: wjchen@swu.edu.cn

where $a > 0$, $b > 0$, $\theta > 1$, $\lambda \geq 0$ is a parameter. Here, $0 < s < 1 < p < N$, $0 < \mu < N$, and $p_\mu^* = \frac{p(2N-\mu)}{2(N-p)}$ is the critical exponent in the sense of the Hardy–Littlewood–Sobolev inequality. The left hand side of (1.1) involves the classical p-Laplace operator $\Delta_p u = \operatorname{div}(|\nabla u|^{p-2}\nabla u)$, and $(-\Delta)_p^s$ is the fractional p-Laplacian operator. Up to normalization factors, for any $x \in \mathbb{R}^N$ and $u \in C_0^\infty(\mathbb{R}^N)$, it can be defined as

$$(-\Delta)_p^s u(x) = \lim_{\varepsilon \to 0^+} \int_{\mathbb{R}^N \setminus B_\varepsilon(x)} \frac{|u(y) - u(x)|^{p-2}(u(y) - u(x))}{|x-y|^{N+ps}}\, dy,$$

where $B_\varepsilon(x)$ denotes the ball in $\mathbb{R}^N$ centered at x with radius ε. For $s \in (0,1)$ and a measurable function $u : \mathbb{R}^{\mathbb{N}} \longrightarrow \mathbb{R}$, we define the Gagliardo seminorm as

$$[u]_{s,p} = \left(\iint_{\mathbb{R}^{2N}} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dx\, dy \right)^{\frac{1}{p}}.$$

Moreover, the space $X^{1,p}(\mathbb{R}^N)$ is defined as the completion of $C_0^\infty(\mathbb{R}^N)$ with respect to the norm

$$\|u\| = \left(\int_{\mathbb{R}^N} |\nabla u|^p\, dx + \iint_{\mathbb{R}^{2N}} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dx\, dy \right)^{\frac{1}{p}}.$$

In recent years, the research on partial differential equations incorporating a blend of local and non-local operators has witnessed substantial advancements in both theoretical exploration and practical implementations. These hybrid operators, constructed through the superposition of the p-Laplacian $(-\Delta)_p$ and the fractional p-Laplacian $(-\Delta)_p^s$, have emerged as significant mathematical models in diverse disciplines. For instance, they play a crucial role in population dynamics, where they can describe the movement and distribution of species, in biomathematics for modeling biological processes, and in optimal foraging strategies to understand how organisms search for food (see [19, 20, 37] and the references therein). Concurrently, these operators have spurred novel developments within the realm of mathematical analysis. This includes the generalization of classical inequalities such as the Hong–Krahn–Szegő inequality [10] and the Faber–Krahn inequality [9], as well as the in-depth investigation of non-local evolution equations, exemplified by the Cahn–Hilliard equation [14] and the porous medium equation [18].

The interplay between local and non-local diffusions has become a focal point of interest for numerous mathematicians. In the specific case of the fractional Laplacian ($p = 2$), variational techniques were employed in [5, 39, 40] to prove the existence and multiplicity of solutions for elliptic equations. When $p \neq 2$, the Brézis–Nirenberg problem associated with fractional p-Laplacian operators was explored in [35]. Moreover, in [30], Morse theory was applied to study the existence of solutions under general reaction terms. Fiscella and Pucci [23] delved into stationary Kirchhoff problems involving fractional operators, Hardy potentials, and critical nonlinearities, deriving results regarding the asymptotic behavior of solutions. The ground state solutions for fractional Choquard equations with sub-critical nonlinearities were also investigated in [7].

Kirchhoff-type equations that combine fractional Laplacians and critical Sobolev exponents have attracted considerable attention from the academic community. These studies cover both bounded domains [22, 36, 42] and the entire space [24, 29, 33], involving Kirchhoff models with critical-growth nonlinearities. Recent contributions in this area include fractional p-Laplacian Choquard–Kirchhoff equations [38], fractional Kirchhoff problems with a

combination of Choquard and singular terms [41], and Choquard–Kirchhoff equations featuring Hardy–Littlewood–Sobolev critical exponents [31]. In [43], nonhomogeneous p-Kirchhoff problems with convex-concave nonlinearities were analyzed. Additionally, Xiang et al. [44] studied the following fractional p-Kirchhoff problem:

$$\begin{cases} \left(a + b[u]_{s,p}^{p(\theta-1)}\right)(-\Delta)_p^s u = |u|^{p_s^*-2}u + \lambda f(x) \ \text{ in } \mathbb{R}^N, \\ u \in D^{s,p}(\mathbb{R}^N), \end{cases} \tag{1.2}$$

where $a \geq 0, b > 0, \theta > 1, 1 < p < N/s$, $p_s^* = \frac{Np}{N-ps}$, $\lambda \geq 0$ is a parameter, $f \in L^{\frac{p_s^*}{p_s^*-1}}(\mathbb{R}^N) \setminus \{0\}$, and $D^{s,p}(\mathbb{R}^N)$ is defined as the completion of $C_0^\infty(\mathbb{R}^N)$ with respect to the Gagliardo seminorm $[u]_{s,p}$. For the case of $\lambda = 0$, Xiang et al. demonstrated that the non - existence of non-trivial solutions to (1.2) depends on the parameters N, θ, s, p, a and b. When $\lambda > 0$, they utilized Ekeland's variational principle and the mountain pass theorem to prove the existence of at least two non-negative solutions.

Driven by the extensive applications of mixed local-nonlocal operators, considerable research efforts have been devoted to the existence and qualitative analysis of solutions to equations of the form

$$-\Delta_p u + (-\Delta)_p^s u = f(x,u) \quad \text{in } \Omega,$$

where $\Omega \subset \mathbb{R}^N$ is a domain, $p \in (1,\infty)$, $s \in (0,1)$ and f is a given function. For $p = 2$, symmetry properties of solutions to semilinear equations involving such hybrid operators were established in [11]. Fundamental contributions to existence theory, local boundedness, the strong maximum principle, Lipschitz regularity, and interior Sobolev regularity can be found in [1,6,8]. By combining variational techniques with a Pohožaev identity, Anthal et al. [4] derived existence and nonexistence results for Choquard-type equations with subcritical perturbations.

When $p \neq 2$, Garain and Kinnunen [27] investigated regularity properties-including local boundedness, Harnack estimates, local Hölder continuity, and semicontinuity-for weak solutions in the homogeneous case $f = 0$. In the nonhomogeneous case $f \neq 0$, Da Silva et al. [17] recently proved the existence and multiplicity of nontrivial solutions by integrating variational methods with topological tools such as the Krasnoselskii genus and Lusternik–Schnirelman category theories.

Define the optimal constants

$$S_{H,C} = \inf_{u \in C_0^\infty(\mathbb{R}^N)\setminus\{0\}} \frac{\int_{\mathbb{R}^N} |\nabla u|^p \, dx}{\left(\iint_{\mathbb{R}^{2N}} \frac{|u(x)|^{p_\mu^*} |u(y)|^{p_\mu^*}}{|x-y|^\mu} \, dx \, dy \right)^{\frac{p}{2p_\mu^*}}}, \tag{1.3}$$

and

$$S_{H,M} = \inf_{u \in C_0^\infty(\mathbb{R}^N)\setminus\{0\}} \frac{\int_{\mathbb{R}^N} |\nabla u|^p \, dx + \iint_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}} \, dx \, dy}{\left(\iint_{\mathbb{R}^{2N}} \frac{|u(x)|^{p_\mu^*} |u(y)|^{p_\mu^*}}{|x-y|^\mu} \, dx \, dy \right)^{\frac{p}{2p_\mu^*}}}, \tag{1.4}$$

well-posed via the classical Hardy–Littlewood–Sobolev inequality (cf. Proposition 2.1). Leveraging these definitions, we establish the following nonexistence result for trivial solutions when $\lambda = 0$.

Theorem 1.1. *Assume $\lambda = 0$ and $\theta > 1$. Then problem (1.1) admits no nontrivial solution.*

For the case $\lambda \neq 0$, we analyze problem (1.1). Owing to the lack of explicit expressions and asymptotic estimates for minimizers of $S_{H,M}$, we cannot directly characterize the threshold for nontrivial solutions as in [12, 26, 35]. To address the compactness deficit, we develop a specialized concentration-compactness principle for mixed local-nonlocal operators (see Section 4).

Henceforth, unless stated otherwise, we assume f satisfies

(f) $f \geq 0$, $f \not\equiv 0$ and $f \in L^{\frac{p^*}{p^*-1}}(\mathbb{R}^N)$.

Theorem 1.2. *Suppose $a > 0$, $b > 0$, and either $\theta = \frac{3N-\mu-p}{2(N-p)}$ or $a > 0$, $0 < b < S_{H,M}^{-\frac{2p_\mu^*}{p}}$, $\theta = \frac{2N-\mu}{N-p}$. Under assumption (f), there exists $\lambda^* > 0$ such that for all $\lambda \in (0, \lambda^*)$, problem (1.1) possesses a nonnegative weak solution $u_1 \in X^{1,p}(\mathbb{R}^N)$ satisfying $I_\lambda(u_1) < 0$. Moreover, there exists $\lambda^{**} \in (0, \lambda^*]$ such that for all $\lambda \in (0, \lambda^{**})$, problem (1.1) admits another nonnegative weak solution $u_2 \in X^{1,p}(\mathbb{R}^N)$ with $I_\lambda(u_2) > 0$.*

The paper is organized as follows. Section 2 reviews essential preliminaries. In Section 3, we analyze the optimal constant $S_{H,M}$ and prove Theorem 1.1. Section 4 extends Lions' concentration-compactness principle [32] to the mixed operator framework. Finally, Section 5 employs Ekeland's variational principle and the mountain pass theorem to establish the existence of two nonnegative solutions for (1.1) within a suitable parameter range of λ.

Notations

- The standard norm on $L^q(\mathbb{R}^N)$ denotes by $|\cdot|_q$ for $q \in [1, \infty)$.
- We shall also use the notation $\|u\|_{HL}^p = \big(\iint_{\mathbb{R}^{2N}} \frac{|u(x)|^{p_\mu^*}|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dx\,dy\big)^{\frac{p}{2p_\mu^*}}$ for $u \in X^{1,p}(\mathbb{R}^N)$.
- C denotes positive constant possibly different from line to line.

2 Preliminaries

Proposition 2.1 (Hardy–Littlewood–Sobolev inequality)**.** *Let $r, q > 1$ and $0 < \mu < N$ satisfy $\frac{1}{r} + \frac{1}{q} + \frac{\mu}{N} = 2$. For $g \in L^r(\mathbb{R}^N)$ and $h \in L^q(\mathbb{R}^N)$, there exists a constant $C(r, q, n, \mu)$ independent of g and h such that*

$$\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} \frac{g(x)h(x)}{|x-y|^\mu}\,dx\,dy \leq C(r, q, N, \mu)|g|_r|h|_q.$$

In particular, setting $g = h = |u|^t$, the Hardy–Littlewood–Sobolev inequality ensures the integral

$$\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} \frac{|u(x)|^t|u(y)|^t}{|x-y|^\mu}\,dx\,dy$$

is well defined provided $|u|^t \in L^v(\mathbb{R}^N)$ with $v = \frac{2N}{2N-\mu}$. By the Sobolev embedding $X^{1,p}(\mathbb{R}^N) \hookrightarrow L^{p^*}(\mathbb{R}^N)$, we deduce $t = \frac{p(2N-\mu)}{2(N-p)} := p_\mu^*$. Moreover, for $u \in X^{1,p}(\mathbb{R}^N)$, it holds that

$$\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} \frac{|u(x)|^{p_\mu^*}|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dx\,dy \leq C(N, \mu)|u|_{p^*}^{2p_\mu^*}.$$

Next, we introduce the concept of weak solutions for problem (1.1).

Definition 2.2. A function $u \in X^{1,p}(\mathbb{R}^N)$ is a weak solution of (1.1) if for all $\varphi \in X^{1,p}(\mathbb{R}^N)$, it satisfies

$$\begin{aligned}
&\Big(a + b\|u\|^{(\theta-1)p}\Big) \\
&\quad \times \left(\int_{\mathbb{R}^N} |\nabla u|^{p-2}\nabla u \nabla \varphi \, dx + \iint_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps}} \, dx\, dy \right) \\
&= \iint_{\mathbb{R}^{2N}} \frac{|u(y)|^{p_\mu^*}|u(x)|^{p_\mu^*-2}u(x)\varphi(x)}{|x-y|^{\mu}} \, dx\, dy + \lambda \int_{\mathbb{R}^N} f(x)\varphi(x)\, dx
\end{aligned} \tag{2.1}$$

We define the energy functional

$$I_\lambda(u) = \frac{a}{p}\|u\|^p + \frac{b}{\theta p}\|u\|^{\theta p} - \frac{1}{2p_\mu^*}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} \frac{|u^+(y)|^{p_\mu^*}|u^+(x)|^{p_\mu^*}}{|x-y|^{\mu}} \, dx\, dy - \lambda \int_{\mathbb{R}^N} f(x)u \, dx \tag{2.2}$$

for $u \in X^{1,p}(\mathbb{R}^N)$, where $u^+ = \max\{u, 0\}$. Since $f \in (X^{1,p}(\mathbb{R}^N))'$, the functional I_λ belongs to $C^1(X^{1,p}(\mathbb{R}^N))$. For all $u, \varphi \in X^{1,p}(\mathbb{R}^N)$, its derivative is given by

$$\begin{aligned}
&\langle I_\lambda'(u), \varphi\rangle \\
&\quad = \Big(a + b\|u\|^{(\theta-1)p}\Big) \\
&\qquad \times \left(\int_{\mathbb{R}^N} |\nabla u|^{p-2}\nabla u \nabla \varphi \, dx + \iint_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps}} \, dx\, dy \right) \\
&\qquad - \iint_{\mathbb{R}^{2N}} \frac{|u^+(y)|^{p_\mu^*}|u^+(x)|^{p_\mu^*-2}u^+(x)\varphi(x)}{|x-y|^{\mu}} \, dx\, dy - \lambda \int_{\mathbb{R}^N} f(x)\varphi(x)\, dx.
\end{aligned}$$

Consequently, u is a weak solution of (1.1) if and only if u is a critical point of the functional I_λ.

Remark 2.3. To verify the well-definedness of (2.2), we confirm the finiteness of all integrals in (2.1). For $u, \varphi \in X^{1,p}(\mathbb{R}^N)$, Hölder's inequality yields

$$\begin{aligned}
&\int_{\mathbb{R}^N} |\nabla u|^{p-2}\nabla u \nabla \varphi \, dx + \iint_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^{p-2}(u(x)-u(y))(\varphi(x)-\varphi(y))}{|x-y|^{N+ps}} \, dx\, dy \\
&\qquad \le |\nabla u|_p^{p-1}|\nabla \varphi|_p + [u]_{s,p}^{p-1}[\varphi]_{s,p} < \infty.
\end{aligned}$$

Additionally, leveraging the Sobolev embedding $X^{1,p}(\mathbb{R}^N) \hookrightarrow L^{p^*}(\mathbb{R}^N)$ and the Hardy–Littlewood–Sobolev inequality, we estimate

$$\begin{aligned}
&\iint_{\mathbb{R}^{2N}} \frac{|u(y)|^{p_\mu^*}|u(x)|^{p_\mu^*-2}u(x)\varphi(x)}{|x-y|^{\mu}} \, dx\, dy + \lambda \int_{\mathbb{R}^N} f(x)\varphi(x)\, dx \\
&\qquad \le C(N,\mu)|u|_{p^*}^{\frac{p(2N-\mu)+2Np}{2(N-p)}-\frac{2N}{2N-\mu}}|\varphi|_{p^*}^{\frac{2N}{2N-\mu}} + \lambda|f|_{(p^*)'}|\varphi|_{p^*} < \infty.
\end{aligned}$$

3 Proof of Theorem 1.1

We dedicate this section to prove Theorem 1.1 in the case $\lambda = 0$.

Lemma 3.1. *Let $s \in (0,1)$. For $S_{H,C}$ and $S_{H,M}$ defined in (1.3) and (1.4), it holds that $S_{H,M} = S_{H,C}$.*

Proof. From the definitions of $S_{H,C}$ and $S_{H,M}$, the inequality $S_{H,M} \geq S_{H,C}$ is immediate. To prove the reverse inequality, consider any $u \in C_0^\infty(\mathbb{R}^N)$. There exists $k_0(u) \in \mathbb{N}$ such that

$$\text{supp}(u) \subseteq B_{kr}(0), \quad \text{for all } k \geq k_0.$$

Define the scaled function $u_k := k^{\frac{N-p}{p}} u(kx)$ for $k \geq k_0$, which satisfies $supp(u_k) \subseteq B_r(0)$. By the definition of $S_{H,M}$, we have for every $k \geq k_0$,

$$S_{H,M} \leq \frac{\|u_k\|^p}{\|u_k\|_{HL}^p} = \frac{|\nabla u|_p^p}{\|u\|_{HL}^p} + k^{ps-p} \frac{[u]_{s,p}^p}{\|u\|_{HL}^p}.$$

Letting $k \to \infty$ and using $0 < s < 1$, the second term vanishes, yielding

$$S_{H,M} \leq \frac{|\nabla u|_p^p}{\|u\|_{HL}^p}.$$

By the arbitrariness of $u \in C_0^\infty(\mathbb{R}^N)$, we conclude

$$S_{H,M} \leq S_{H,C}.$$

Thus $S_{H,M} = S_{H,C}$. □

Lemma 3.2. *The optimal constant $S_{H,M}$ is never achieved.*

Proof. Assume for contradiction that there exists a nonzero function $v \in X^{1,p}(\mathbb{R}^N)$ such that $\|v\|_{HL} = 1$ and $\|v\|^p = S_{H,M} = S_{H,L}$, then

$$S_{H,L} \leq |\nabla v|_p^p \leq |\nabla v|_p^p + [v]_{s,p}^p = S_{H,L}.$$

This implies $[v]_{s,p} = 0$, meaning v is a constant in $\mathbb{R}^N$. However, a constant function v satisfies $\|v\| = 0$, contradicting $\|v\|_{HL} = 1$. Therefore, $S_{H,M}$ can not be achieved. □

Lemma 3.3. *Let $\alpha > 0$. The problem*

$$\begin{cases} -\Delta_p u + (-\Delta)_p^s u = \alpha \left(\displaystyle\int_{\mathbb{R}^N} \frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu} \, dy \right) |u|^{p_\mu^* - 2} u \quad \text{in } \mathbb{R}^N, \\ u \in X^{1,p}(\mathbb{R}^N), \end{cases} \tag{3.1}$$

admits no nontrivial solutions.

Proof. Suppose u is a solution to (3.1). Then u satisfies

$$\|u\|^p = \alpha \left(\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{|u(x)|^{p_\mu^*} |u(y)|^{p_\mu^*}}{|x-y|^\mu} \, dx \, dy \right).$$

Define $w = lu$ for some $l > 0$. Substituting into the equation gives

$$\frac{\|w\|^p}{l^p} = \alpha \cdot \frac{\int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{|w(x)|^{p_\mu^*} |w(y)|^{p_\mu^*}}{|x-y|^\mu} \, dx \, dy}{l^{2p_\mu^*}}.$$

Setting $S_{H,M} = \alpha l^{p - 2p_\mu^*}$, we obtain

$$\|w\|^p = S_{H,M} \int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{|w(x)|^{p_\mu^*} |w(y)|^{p_\mu^*}}{|x-y|^\mu} \, dx \, dy.$$

This implies w achieves $S_{H,M}$, contradicting Lemma 3.2. Hence, no nontrivial solutions exist. □

Proof of Theorem 1.1. Assume for contradiction that there exists a nonzero solution v to (1.1) with $\lambda = 0$. Then v satisfies

$$\left(a + b\|v\|^{p(\theta-1)}\right)\left(-\Delta_p v + (-\Delta)_p^s v\right) = \left(\int_{\mathbb{R}^N} \frac{|v(y)|^{p_\mu^*}}{|x-y|^\mu} dy\right)|v|^{p_\mu^*-2}v.$$

For any $\psi \in X^{1,p}(\mathbb{R}^N)$, testing the equation with ψ yields

$$\begin{aligned}\int_{\mathbb{R}^N} |\nabla v|^{p-2}\nabla v \nabla \psi \, dx + \iint_{\mathbb{R}^{2N}} \frac{|v(x)-v(y)|^{p-2}(v(x)-v(y))(\psi(x)-\psi(y))}{|x-y|^{N+ps}} \, dx\, dy \\ = \frac{1}{a + b\|v\|^{(\theta-1)p}} \iint_{\mathbb{R}^{2N}} \frac{|v(y)|^{p_\mu^*}|v(x)|^{p_\mu^*-2}v(x)\psi(x)}{|x-y|^\mu} \, dx\, dy.\end{aligned}$$

Let $\alpha = \frac{1}{a+b\|v\|^{(\theta-1)p}} > 0$. The equation then reduces to

$$-\Delta_p v + (-\Delta)_p^s v = \alpha\left(\int_{\mathbb{R}^N} \frac{|v(y)|^{p_\mu^*}}{|x-y|^\mu} \, dy\right)|v|^{p_\mu^*-2}v,$$

which contradicts Lemma 3.3. Therefore, no nontrivial solutions exist when $\lambda = 0$. □

4 The principle of concentration compactness

In [32], Lions established the celebrated concentration compactness principle in classical Sobolev spaces, which has since been widely applied to solve elliptic problems involving critical exponents. Xiang et al. [44] later extended this principle to fractional Sobolev spaces $D^{s,p}(\mathbb{R}^N)$, while Gao et al. [25] developed a concentration compactness framework for convolution nonlinearities to study critical Choquard equations. However, to the best of our knowledge, no existing results have formulated the concentration compactness principle for mixed local-nonlocal operators with Choquard-type nonlinearities. Motivated by these contributions, we establish such a principle in $X^{1,p}(\mathbb{R}^N)$, which will be pivotal in Section 5. Define

$$C_c(\mathbb{R}^N) = \{u \in C(\mathbb{R}^N) : \operatorname{supp}(u) \text{ is a compact subset of } \mathbb{R}^N\}$$

and denote by $C_0(\mathbb{R}^N)$ the closure of $C_c(\mathbb{R}^N)$ with respect to the supremum norm $|\eta|_\infty = \sup_{x\in\mathbb{R}^N} |\eta(x)|$. Recall that a finite measure on $\mathbb{R}^N$ corresponds to a continuous linear functional on $C_0(\mathbb{R}^N)$. For a measure ξ, its total variation norm is given by:

$$\|\xi\| = \sup_{\eta\in C_0(\mathbb{R}^N), |\eta|_\infty = 1} |(\xi, \eta)|,$$

where $(\xi, \eta) = \int_{\mathbb{R}^N} \eta \, d\xi$.

Definition 4.1. Let $\mathcal{M}(\mathbb{R}^N)$ denote the space of finite nonnegative Borel measure space on $\mathbb{R}^N$. For $\xi \in \mathcal{M}(\mathbb{R}^N)$, we have $\xi(\mathbb{R}^N) = \|\xi\|$. A sequence $\{\xi_n\} \subset \mathcal{M}(\mathbb{R}^N)$ converges weak-$*$ to $\xi \in \mathcal{M}(\mathbb{R}^N)$ (denoted $\xi_n \rightharpoonup \xi$) if $(\xi_n, \eta) \to (\xi, \eta)$ for all $\eta \in C_0(\mathbb{R}^N)$ as $n \to \infty$.

Theorem 4.2. *Let $\{u_n\}_n \subset X^{1,p}(\mathbb{R}^N)$ be a sequence with $\|u_n\| \le C$ for some constant $C > 0$, and suppose*

$$\begin{cases} u_n \rightharpoonup u & \text{weakly in } X^{1,p}(\mathbb{R}^N), \\ |\nabla u_n|^p + \displaystyle\int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}} \, dy \rightharpoonup \xi & \text{weak-}* \text{ in } \mathcal{M}(\mathbb{R}^N), \\ \displaystyle\int_{\mathbb{R}^N} \frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu} \, dy |u_n(x)|^{p_\mu^*} \rightharpoonup \nu & \text{weak-}* \text{ in } \mathcal{M}(\mathbb{R}^N). \end{cases}$$

Then the following hold

$$\xi(\mathbb{R}^N) \le C^p, \qquad \nu(\mathbb{R}^N) \le S_{H,M}^{-\frac{2p_\mu^*}{p}} C^{2p_\mu^*}, \tag{4.1}$$

$$\xi = |\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\, dy + \sum_{j\in J} \xi_j \delta_{x_j} + \tilde{\xi}, \tag{4.2}$$

$$\nu = \int_{\mathbb{R}^N} \frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu}\, dy |u(x)|^{p_\mu^*} + \sum_{j\in J} \nu_j \delta_{x_j}. \tag{4.3}$$

where J is at most countable, sequence $\{\xi_j\}_j$, $\{\nu_j\}_j \subset \mathbb{R}_0^+$, $\{x_j\}_j \subset \mathbb{R}^N$, δ_{x_j} is the Dirac mass centered at x_j, $\tilde{\xi}$ is a nonnegative non-atomic measure. Moreover, we have

$$\nu(\mathbb{R}^N) \le S_{H,M}^{-\frac{2p_\mu^*}{p}} \xi(\mathbb{R}^N)^{\frac{2p_\mu^*}{p}}, \qquad \nu_j \le S_{H,M}^{-\frac{2p_\mu^*}{p}} \xi_j^{\frac{2p_\mu^*}{p}}, \quad \text{for all } j \in J, \tag{4.4}$$

where $S_{H,M}$ is the optimal constant defined in (1.4).

Lemma 4.3. *Let $\{u_n\}_n \subset X^{1,p}(\mathbb{R}^N)$ be the sequence given by Theorem 4.2. Fix $x_0 \in \mathbb{R}^N$ and let $\varphi \in C_0^\infty(\mathbb{R}^N)$ satisfy $0 \le \varphi \le 1$, $\varphi \equiv 1$ on $B_1(0)$, $\varphi \equiv 0$ in $\mathbb{R}^N \setminus B_2(0)$, and $|\nabla \varphi| \le 2$. Define $\varphi_\varepsilon = \varphi((x-x_0)/\varepsilon)$ for all $x \in \mathbb{R}^N$. Then the following hold*

$$\lim_{\varepsilon\to 0} \lim_{n\to\infty} \int_{\mathbb{R}^N} |u_n|^p |\nabla \varphi_\varepsilon|^p\, dx = 0, \tag{4.5}$$

$$\lim_{\varepsilon\to 0} \limsup_{n\to\infty} \iint_{\mathbb{R}^{2N}} \frac{|u_n(y)|^p |\varphi_\varepsilon(x)-\varphi_\varepsilon(y)|^p}{|x-y|^{N+ps}}\, dx\, dy = 0. \tag{4.6}$$

Proof. We first prove (4.5). By the definition of φ_ε, we have:

$$\int_{\mathbb{R}^N} |u_n|^p |\nabla \varphi_\varepsilon|^p\, dx \le \int_{B_{2\varepsilon}(x_0)\setminus B_\varepsilon(x_0)} \frac{2^p}{\varepsilon^p} |u_n|^p\, dx.$$

Scaling the variable $z = \frac{x-x_0}{\varepsilon}$, this becomes

$$\int_{B_2(0)\setminus B_1(0)} 2^p \varepsilon^{N-p} |u_n(x_0+\varepsilon z)|^p\, dz.$$

For the bounded domain $\Omega = B_2(0) \setminus B_1(0)$, the Sobolev embedding $X^{1,p}(\Omega) \hookrightarrow L^p(\Omega)$ holds (cf. [13, Lemma 2.1]), where $X^{1,p}(\Omega)$ is the completion of $C_0^\infty(\Omega)$ with respect to the norm

$$\|u\|_{X^{1,p}(\Omega)} = \left(\int_\Omega |\nabla u|^p\, dx + \iint_{\Omega\times\Omega} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\, dx\, dy \right)^{\frac{1}{p}}.$$

Using the boundedness of $\{u_n\}$ in $X^{1,p}(\mathbb{R}^N)$ and $N > p$, we estimate

$$\int_{\mathbb{R}^N} |u_n|^p |\nabla \varphi_\varepsilon|^p\, dx \le C\varepsilon^{N-p} \|u_n\|_{X^{1,p}(\Omega)}^p \le C\varepsilon^{N-p} \|u_n\|^p \to 0$$

as $n \to \infty$ and $\varepsilon \to 0$, establishing (4.5). For (4.6), the proof follows similarly to [44, Lemma 2.3] by leveraging the fractional Sobolev seminorm properties and the decay of u_n at infinity. Details are omitted here for brevity. □

Proof of Theorem 4.2. We divide the proof into four steps.

Step 1. Proof of (4.1).
Fix $R > 0$ and let $\eta \in C_0^\infty(B_{2R}(0))$ satisfy $0 \le \eta \le 1$ and $\eta \equiv 1$ on $B_R(0)$. By weak-$*$ convergence,

$$\int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x) - u_n(y)|^p}{|x-y|^{N+ps}}\, dy \right) \eta(x)\, dx \to \int_{\mathbb{R}^N} \eta(x)\, d\xi$$

as $n \to \infty$. Since $\|u_n\| \le C$, we have

$$\begin{aligned} &\int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x) - u_n(y)|^p}{|x-y|^{N+ps}}\, dy \right) \eta(x)\, dx \\ &\quad \le \int_{\mathbb{R}^N} |\nabla u_n|^p\, dx + \iint_{\mathbb{R}^{2N}} \frac{|u_n(x) - u_n(y)|^p}{|x-y|^{N+ps}}\, dy\, dx \le C^p. \end{aligned}$$

Taking $R \to \infty$, we conclude $\xi(\mathbb{R}^N) \le C^p$. For $\nu(\mathbb{R}^N)$, by the definition of $S_{H,M}$ and $\|u_n\| \le C$,

$$\iint_{\mathbb{R}^{2N}} \frac{|u_n(x)|^{p_\mu^*} |u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\, dx\, dy \le S_{H,M}^{-\frac{2p_\mu^*}{p}} \|u_n\|^{2p_\mu^*} \le S_{H,M}^{-\frac{2p_\mu^*}{p}} C^{2p_\mu^*},$$

yielding $\nu(\mathbb{R}^N) \le S_{H,M}^{-\frac{2p_\mu^*}{p}} C^{2p_\mu^*}$.

Step 2. Proof of (4.2).
Define the functional

$$K(u) = \int_{\mathbb{R}^N} \left(|\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dy \right) \eta(x)\, dx$$

for $\eta \in C_0(\mathbb{R}^N)$. Since K is continuously differentiable and convex on $X^{1,p}(\mathbb{R}^N)$, it is weakly lower semicontinuous. Thus,

$$\begin{aligned} &\liminf_{n\to\infty} \int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x) - u_n(y)|^p}{|x-y|^{N+ps}}\, dy \right) \eta(x)\, dx \\ &\quad \ge \int_{\mathbb{R}^N} \left(|\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dy \right) \eta(x)\, dx. \end{aligned}$$

By weak-$*$ convergence, the left-hand side equals $\int_{\mathbb{R}^N} \eta\, d\xi$. Therefore,

$$\int_{\mathbb{R}^N} \eta\, d\xi \ge \int_{\mathbb{R}^N} \left(|\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dy \right) \eta(x)\, dx.$$

By the arbitrariness of $\eta \ge 0$ in $C_0(\mathbb{R}^N)$, we deduce

$$\xi \ge |\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dy.$$

The decomposition

$$\xi = |\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x) - u(y)|^p}{|x-y|^{N+ps}}\, dy + \sum_{j\in J} \xi_j \delta_{x_j} + \tilde{\xi}$$

follows from the structure of nonnegative Radon measures.

Step 3. Proof of (4.3).

For $\eta \in C_0(\mathbb{R}^N)$, using [34, Equation (3.6)], we have

$$\lim_{n\to\infty}\int_{\mathbb{R}^N}\left(\int_{\mathbb{R}^N}\frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}-\int_{\mathbb{R}^N}\frac{|\bar{u}_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|\bar{u}_n(x)|^{p_\mu^*}\right)\eta(x)\,dx$$
$$=\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u(x)|^{p_\mu^*}\eta(x)\,dx,$$

where $\bar{u}_n = u_n - u$. Define $\bar{\nu} = \nu - \int_{\mathbb{R}^N}\frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u(x)|^{p_\mu^*}$. By weak-$*$ convergence,

$$\int_{\mathbb{R}^N}\eta\,d\bar{\nu}=\lim_{n\to\infty}\iint_{\mathbb{R}^{2N}}\frac{|\bar{u}_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|\bar{u}_n(x)|^{p_\mu^*}\eta(x)\,dx.$$

To analyze the atomic part, fix $x_0 \in \mathbb{R}^N$ and let $\varphi \in C_0^\infty(\mathbb{R}^N)$ satisfy $0 \le \varphi \le 1$, $\varphi \equiv 1$ on $B_1(0)$, $\varphi \equiv 0$ outside $B_2(0)$, and $|\nabla\varphi| \le 2$. Define $\varphi_\varepsilon(x) = \varphi((x-x_0)/\varepsilon)$. Using [25, Equation (2.8)], we derive

$$\lim_{\varepsilon\to 0}\lim_{n\to\infty}\iint_{\mathbb{R}^{2N}}\frac{|\varphi_\varepsilon u_n(y)|^{p_\mu^*}|\varphi_\varepsilon u_n(x)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,dx=\nu(\{x_0\})$$

and

$$\lim_{\varepsilon\to 0}\lim_{n\to\infty}\left(\int_{\mathbb{R}^N}|\nabla u_n|^p\varphi_\varepsilon^p\,dx+\iint_{\mathbb{R}^{2N}}\frac{|\varphi_\varepsilon u_n(x)-\varphi_\varepsilon u_n(y)|^p}{|x-y|^{N+ps}}\,dy\,dx\right)=\xi(\{x_0\}).$$

Recall the following Young inequality

$$|\zeta_1+\zeta_2|^p \le (1+\beta)^{p-1}|\zeta_1|^p+(1+1/\beta)^{p-1}|\zeta_2|^p, \tag{4.7}$$

where $\zeta_1, \zeta_2 \in \mathbb{R}$ and $\beta > 0$. Applying (4.7) and Lemma 4.3, we find

$$\nu(\{x_0\}) \le S_{H,M}^{-\frac{2p_\mu^*}{p}}\xi(\{x_0\})^{\frac{2p_\mu^*}{p}}.$$

Thus, the atoms of ν are contained in those of ξ. For the non-atomic part, we use the Radon–Nikodym theorem and Lebesgue's differentiation theorem to show $\tilde{\nu} = 0$.

Step 4. Proof of (4.4).

Fix $\eta \in C_0^\infty(B_{2R}(0))$ with $0 \le \eta \le 1$, $\eta \equiv 1$ on $B_R(0)$, and $|\nabla\eta| \le 2/R$. By Young's inequality and Lemma 4.3,

$$\iint_{\mathbb{R}^{2N}}\frac{|\eta u_n(y)|^{p_\mu^*}|\eta u_n(x)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,dx$$
$$\le S_{H,M}^{-\frac{2p_\mu^*}{p}}\left((1+\beta)^{p-1}\int_{\mathbb{R}^N}|u_n\nabla\eta|^p\,dx+(1+\beta^{-1})^{p-1}\int_{\mathbb{R}^N}\eta^p\,d\xi\right)^{\frac{2p_\mu^*}{p}}.$$

Letting $R \to \infty$ and $\beta \to \infty$, we obtain

$$\int_{\mathbb{R}^N}\eta^{2p_\mu^*}\,d\nu \le S_{H,M}^{-\frac{2p_\mu^*}{p}}\left(\int_{\mathbb{R}^N}\eta^p\,d\xi\right)^{\frac{2p_\mu^*}{p}}.$$

Taking $R \to \infty$ and using the atomic decomposition, we conclude

$$\nu(\mathbb{R}^N) \le S_{H,M}^{-\frac{2p_\mu^*}{p}}\xi(\mathbb{R}^N)^{\frac{2p_\mu^*}{p}} \quad\text{and}\quad \nu_j \le S_{H,M}^{-\frac{2p_\mu^*}{p}}\xi_j^{\frac{2p_\mu^*}{p}} \quad \text{for all } j \in J.$$

This completes the proof. □

Theorem 4.4. *Let $\{u_n\}_n \subset X^{1,p}(\mathbb{R}^N)$ be a bounded sequence such that*

$$\begin{cases} |\nabla u_n|^p + \displaystyle\int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy \rightharpoonup \xi & \text{weak-}* \text{ in } \mathcal{M}(\mathbb{R}^N), \\ \displaystyle\int_{\mathbb{R}^N} \frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy |u_n(x)|^{p_\mu^*} \rightharpoonup \nu & \text{weak-}* \text{ in } \mathcal{M}(\mathbb{R}^N), \end{cases}$$

and set

$$\xi_\infty = \lim_{R\to\infty} \limsup_{n\to\infty} \int_{\{x\in\mathbb{R}^N:|x|>R\}} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}} dy \right) dx,$$

$$\nu_\infty = \lim_{R\to\infty} \limsup_{n\to\infty} \int_{\{x\in\mathbb{R}^N:|x|>R\}} \int_{\mathbb{R}^N} \frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}\,dx,$$

where the quantities ξ_∞ and ν_∞ are well defined. Then the following hold

$$\limsup_{n\to\infty} \int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}} dy \right) dx = \xi(\mathbb{R}^N) + \xi_\infty,$$

$$\limsup_{n\to\infty} \int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}\,dx = \nu(\mathbb{R}^N) + \nu_\infty,$$

$$\nu_\infty \le S_{H,M}^{-\frac{2p_\mu^*}{p}} \xi_\infty^{\frac{2p_\mu^*}{p}}.$$

Proof. Fix $\chi \in C^\infty(\mathbb{R}^N)$ with $0 \le \chi \le 1$, $\chi = 0$ in $B_1(0)$, $\chi = 1$ in $\mathbb{R}^N \setminus B_2(0)$, and $|\nabla\chi| \le 2$. Define $\chi_R(x) = \chi(x/R)$ for all $x \in \mathbb{R}^N$ and $R > 0$. Then

$$\begin{aligned} &\int_{\{x\in\mathbb{R}^N:|x|>2R\}} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy \right) dx \\ &\quad\le \int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy \right) \chi_R^p\,dx \\ &\quad\le \int_{\{x\in\mathbb{R}^N:|x|>R\}} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy \right) dx, \end{aligned}$$

which means

$$\xi_\infty = \lim_{R\to\infty} \limsup_{n\to\infty} \int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}} dy \right) \chi_R^p\,dx.$$

Similarly,

$$\nu_\infty = \lim_{R\to\infty} \limsup_{n\to\infty} \int_{\mathbb{R}^N} \int_{\mathbb{R}^N} \frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*} \chi_R^{2p_\mu^*}\,dx.$$

By the definition of weak-$*$ convergence, we have

$$\int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}} dy \right) (1-\chi_R^p)\,dx \to \int_{\mathbb{R}^N} (1-\chi_R^p)\,d\xi$$

as $n \to \infty$. So we get

$$\xi(\mathbb{R}^N) = \lim_{R\to\infty} \lim_{n\to\infty} \int_{\mathbb{R}^N} \left(|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}} dy \right) (1-\chi_R^p)\,dx.$$

Then the following decomposition

$$\begin{aligned}
&\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}dy\right)dx\\
&\quad=\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}dy\right)\chi_R^p\,dx\\
&\quad\quad+\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}dy\right)(1-\chi_R^p)\,dx
\end{aligned}$$

gives that

$$\limsup_{n\to\infty}\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}dy\right)dx=\xi_\infty+\xi(\mathbb{R}^N).$$

Similarly, we can conclude that

$$\limsup_{n\to\infty}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}\,dx=\nu(\mathbb{R}^N)+\nu_\infty.$$

To prove the last inequality

$$\nu_\infty\le S_{H,M}^{-\frac{2p_\mu^*}{p}}\xi_\infty^{\frac{2p_\mu^*}{p}},$$

we first claim that

$$\lim_{R\to\infty}\lim_{n\to\infty}\int_{\mathbb{R}^N}|u_n|^p|\nabla\chi_R|^p\,dx=0, \tag{4.8}$$

$$\lim_{R\to\infty}\limsup_{n\to\infty}\iint_{\mathbb{R}^{2N}}\frac{|u_n(y)|^p|\chi_R(x)-\chi_R(y)|^p}{|x-y|^{N+ps}}\,dx\,dy=0. \tag{4.9}$$

By the same argument as equation (4.5) in Lemma 4.3, we can derive (4.8). For (4.9), the proof follows similarly to [44, Equation (2.15)]. Details are omitted here for brevity.

By Young's inequality, (4.8) and (4.9), we deduce

$$\begin{aligned}
&\lim_{n\to\infty}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}|\chi_R|^{2p_\mu^*}\,dx\\
&=\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\frac{|u_n(y)\chi_R|^{p_\mu^*}}{|x-y|^\mu}dy\,|u_n(x)\chi_R|^{p_\mu^*}\,dx\\
&\le S_{H,M}^{-\frac{2p_\mu^*}{p}}\left((1+\beta^{-1})^{p-1}\int_{\mathbb{R}^N}|\nabla u_n\chi_R|^p\,dx+(1+\beta^{-1})^{p-1}\iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)|^p|\chi_R(x)|^p}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{2p_\mu^*}{p}}
\end{aligned}$$

Letting $R\to\infty$ and $\beta\to\infty$, we conclude

$$\nu_\infty\le S_{H,M}^{-\frac{2p_\mu^*}{p}}\xi_\infty^{\frac{2p_\mu^*}{p}}.$$

Therefore, the proof is complete. □

5 Proof of Theorem 1.2

Throughout this section, we consistently assume that $1<\theta\le\frac{2N-\mu}{N-p}$, without additional mention.

Definition 5.1. Let $c \in \mathbb{R}$, suppose $X^{1,p}(\mathbb{R}^N)$ is a Banach space and $I_\lambda \in C^1(X^{1,p}(\mathbb{R}^N), \mathbb{R})$. We say $\{u_n\}_n$ is a $(PS)_c$ sequence in $X^{1,p}(\mathbb{R}^N)$ if $I_\lambda(u_n) \to c$ and $I'_\lambda(u_n) \to 0$.

Lemma 5.2. *If $\{u_n\}_n$ is a $(PS)_c$ sequence, then $\{u_n\}_n$ is bounded in $X^{1,p}(\mathbb{R}^N)$ and $\{u_n^+\}_n$ is also a $(PS)_c$ sequence.*

Proof. Since $\{u_n\}_n$ is a $(PS)_c$ sequence, there exists $C > 0$ such that

$$|I_\lambda(u_n)| \le C, \ \left| \left\langle I'_\lambda(u_n), \frac{u_n}{\|u_n\|} \right\rangle \right| \le C.$$

Then we obtain

$$I_\lambda(u_n) - \frac{1}{2p_\mu^*}\langle I'_\lambda(u_n), u_n\rangle \le C + C\|u_n\|. \tag{5.1}$$

When $\theta < \frac{2N-\mu}{N-p}$ and $a > 0, \ b > 0$, we have

$$\begin{aligned} I_\lambda(u_n) - \frac{1}{2p_\mu^*}\langle I'_\lambda(u_n), u_n\rangle &= a\left(\frac{1}{p} - \frac{1}{2p_\mu^*}\right)\|u_n\|^p + b\left(\frac{1}{\theta p} - \frac{1}{2p_\mu^*}\right)\|u_n\|^{\theta p} \\ &\quad + \lambda\left(\frac{1}{2p_\mu^*} - 1\right)\int_{\mathbb{R}^N} f(x)u_n\,dx \\ &\ge b\left(\frac{1}{\theta p} - \frac{1}{2p_\mu^*}\right)\|u_n\|^{\theta p} - \lambda\left(1 - \frac{1}{2p_\mu^*}\right)S^{-\frac{1}{p}}|f|_{(p^*)'}\|u_n\|. \end{aligned}$$

When $\theta = \frac{2N-\mu}{N-p}$ and $a > 0, \ b > 0$, we have

$$\begin{aligned} I_\lambda(u_n) - \frac{1}{2p_\mu^*}\langle I'_\lambda(u_n), u_n\rangle &= a\left(\frac{1}{p} - \frac{1}{2p_\mu^*}\right)\|u_n\|^p + b\left(\frac{1}{\theta p} - \frac{1}{2p_\mu^*}\right)\|u_n\|^{\theta p} \\ &\quad + \lambda\left(\frac{1}{2p_\mu^*} - 1\right)\int_{\mathbb{R}^N} f(x)u_n\,dx \\ &\ge a\left(\frac{1}{p} - \frac{1}{2p_\mu^*}\right)\|u_n\|^p - \lambda\left(1 - \frac{1}{2p_\mu^*}\right)S^{-\frac{1}{p}}|f|_{(p^*)'}\|u_n\|. \end{aligned}$$

By invoking $1 < p < \theta p$ and (5.1), we conclude that $\{u_n\}_n$ is bounded in $X^{1,p}(\mathbb{R}^N)$.
Next, we aim to demonstrate that $\{u_n^+\}_n$ is also a $(PS)_c$ sequence, the proof is divided into two steps.

Step 1. We prove $I_\lambda(u_n^+) \to c$.
Since $\{u_n\}_n$ is a $(PS)_c$ sequence, we have $I_\lambda(u_n) \to c$ and $\langle I'_\lambda(u_n), u_n\rangle \to 0$. So $\langle I'_\lambda(u_n), u_n^+\rangle \to 0$. From the definition of I_λ, we have

$$\begin{aligned} &\langle I'_\lambda(u_n), u_n\rangle - \langle I'_\lambda(u_n), u_n^+\rangle \\ &= \left(a + b\|u_n\|^{p(\theta-1)}\right)\left(\int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\nabla u_n(-\nabla u_n^-)\,dx\right. \\ &\quad \left. + \iint\limits_{\mathbb{R}^N} \frac{|u_n(x) - u_n(y)|^{p-2}(u_n(x) - u_n(y))(-u_n^-(x) + u_n^-(y))}{|x-y|^{N+ps}}\,dx\,dy\right) \\ &\quad - \lambda\int_{\mathbb{R}^N} f(x)u_n\,dx + \lambda\int_{\mathbb{R}^N} f(x)u_n^+\,dx \to 0 \end{aligned} \tag{5.2}$$

as $n \to \infty$. Based on the fact that

$$|\xi^- - \eta^-|^p \le |\xi - \eta|^{p-2}(\xi - \eta)(-\xi^- + \eta^-),$$

we obtain

$$|u_n(x) - u_n(y)|^{p-2}\,(u_n(x) - u_n(y))\,\left(-u_n^-(x) + u_n^-(y)\right) \ge |u_n^-(x) - u_n^-(y)|^p \ge 0. \tag{5.3}$$

Besides,

$$\begin{aligned}&\int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\nabla u_n\left(-\nabla u_n^-\right)\,dx\\ &\quad= \int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\left(\nabla u_n^+ - \nabla u_n^-\right)\left(-\nabla u_n^-\right)\,dx = \int_{\mathbb{R}^N} |\nabla u_n^-|^p\,dx \ge 0.\end{aligned} \tag{5.4}$$

Moreover, $f \ge 0$ and $\lambda \ge 0$ implies

$$\lambda \int_{\mathbb{R}^N} f(x)\left(u_n^+ - u_n\right)\,dx = \lambda \int_{\mathbb{R}^N} f(x)u_n^-\,dx \ge 0. \tag{5.5}$$

By (5.2)–(5.5), we derive

$$[u_n^-]_{s,p}^p \to 0, \qquad \int_{\mathbb{R}^N} |\nabla u_n^-|^p\,dx \to 0, \qquad \int_{\mathbb{R}^N} f u_n^-\,dx \to 0 \tag{5.6}$$

as $n \to \infty$. By

$$[u_n^+]_{s,p} - [u_n^-]_{s,p} \le [u_n]_{s,p} = [u_n^+ - u_n^-]_{s,p} \le [u_n^+]_{s,p} + [u_n^-]_{s,p},$$

we eventually obtain $[u_n^+]_{s,p}^p \to [u_n]_{s,p}^p$. Similarly, we can get $\int_{\mathbb{R}^N} |\nabla u_n^+|^p\,dx \to \int_{\mathbb{R}^N} |\nabla u_n|^p\,dx$. It is also easy to deduce $\int_{\mathbb{R}^N} f u_n^+\,dx \to \int_{\mathbb{R}^N} f u_n\,dx$. Hence we conclude $I_\lambda(u_n^+) \to c$ since $I_\lambda(u_n) \to c$.

Step 2. We prove $\langle I_\lambda'(u_n^+), v\rangle \to 0$ for all $v \in X^{1,p}(\mathbb{R}^N)$.

Note that

$$\langle I_\lambda'(u_n), v\rangle - \langle I_\lambda'(u_n^+), v\rangle = \left(a + b\|u_n\|^{p(\theta-1)}\right)(\mathrm{I}_1 + \mathrm{I}_2) + o(1), \tag{5.7}$$

where

$$\mathrm{I}_1 = \int_{\mathbb{R}^N} \left(|\nabla u_n|^{p-2}\nabla u_n - |\nabla u_n^+|^{p-2}\nabla u_n^+\right) v\,dx$$

and

$$\mathrm{I}_2 = \iint_{\mathbb{R}^N} \frac{\left(|u_n(x)-u_n(y)|^{p-2}(u_n(x)-u_n(y)) - |u_n^+(x)-u_n^+(y)|^{p-2}(u_n^+(x)-u_n^+(y))\right)(v(x)-v(y))}{|x-y|^{N+ps}}\,dx\,dy.$$

Next we are going to estimate I_1 and I_2.

For I_1:

Case 1. When $u_n \ge 0$, we have $\mathrm{I}_1 = 0$.

Case 2. When $u_n < 0$,

$$\mathrm{I}_1 = \int_{\{x:\ u_n(x)<0\}} |\nabla u_n|^{p-2}\nabla u_n v\,dx \le \int_{\mathbb{R}^N} |\nabla u_n^-|^p\,dx \int_{\mathbb{R}^N} |v|^p\,dx \to 0$$

as $n \to \infty$ by (5.6).

For I_2:

Case 1. When $u_n(x) \geq 0,\ u_n(y) \geq 0$, it's obvious that $\mathrm{I}_2 = 0$.

Case 2. When $u_n(x) \geq 0,\ u_n(y) < 0$,

$$\begin{aligned}
\mathrm{I}_2 &= \int_{\{x:\ u_n(x)\geq 0\}} \int_{\{y:\ u_n(y)<0\}} \frac{\left[(u_n(x)-u_n(y))^{p-1} - (u_n(x))^{p-1}\right](v(x)-v(y))}{|x-y|^{N+ps}}\,dx\,dy. \\
&= \int_{\{x:\ u_n(x)\geq 0\}} \int_{\{y:\ u_n(y)<0\}} \frac{\left(\sum_{i,j\in Z^+,\ i+j=p-1,\ j\geq 1} (u_n(x))^i(-u_n(y))^j\right)(v(x)-v(y))}{|x-y|^{N+ps}}\,dx\,dy \\
&= \sum_{\substack{i,j\in Z^+\\ i+j=p-1\\ j\geq 1}} \int_{\{x:\ u_n(x)\geq 0\}} \int_{\{y:\ u_n(y)<0\}} \frac{(u_n(x))^i (v(x)-v(y))^{\frac{i}{p-1}} (-u_n(y))^j (v(x)-v(y))^{\frac{j}{p-1}}}{|x-y|^{N+ps}}\,dx\,dy \\
&\leq \sum_{\substack{i,j\in Z^+\\ i+j=p-1\\ j\geq 1}} \iint_{\mathbb{R}^{2N}} \frac{|u_n^+(x)-u_n^+(y)|^i |v(x)-v(y)|^{\frac{i}{p-1}}}{|x-y|^{(N+ps)\cdot\frac{i}{p-1}}} \cdot \frac{|u_n^-(x)-u_n^-(y)|^j |v(x)-v(y)|^{\frac{j}{p-1}}}{|x-y|^{(N+ps)\cdot\frac{j}{p-1}}}\,dx\,dy \\
&\leq \sum_{\substack{i,j\in Z^+\\ i+j=p-1\\ j\geq 1}} \left(\iint_{\mathbb{R}^{2N}} \frac{|u_n^+(x)-u_n^+(y)|^{p-1}|v(x)-v(y)|}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{i}{p-1}} \\
&\quad \left(\iint_{\mathbb{R}^{2N}} \frac{|u_n^-(x)-u_n^-(y)|^{p-1}|v(x)-v(y)|}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{j}{p-1}} \\
&\leq \sum_{\substack{i,j\in Z^+\\ i+j=p-1\\ j\geq 1}} \left(\iint_{\mathbb{R}^{2N}} \frac{|u_n^+(x)-u_n^+(y)|^{p}}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{p-1}{p}} \left(\iint_{\mathbb{R}^{2N}} \frac{|v(x)-v(y)|^{p}}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{1}{p}} \\
&\quad \left(\iint_{\mathbb{R}^{2N}} \frac{|u_n^-(x)-u_n^-(y)|^{p}}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{p-1}{p}} \left(\iint_{\mathbb{R}^{2N}} \frac{|v(x)-v(y)|^{p}}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{1}{p}} \\
&\leq \sum_{\substack{j\in Z^+\\ 1\leq j\leq p-1}} C\|u_n^-\|^{\frac{j}{p}} \to 0
\end{aligned}$$

as $n \to \infty$ by (5.6).

Case 3. When $u_n(x) < 0,\ u_n(y) \geq 0$, we can obtain $\mathrm{I}_2 \to 0$ as $n \to \infty$ through a discussion similar to Case 2.

Case 4. When $u_n(x) < 0,\ u_n(y) < 0$, we have

$$\begin{aligned}
\mathrm{I}_2 &= \int_{\{x:\ u_n(x)<0\}} \int_{\{y:\ u_n(y)<0\}} \frac{|u_n(x)-u_n(y)|^{p-2}(u_n(x)-u_n(y))(v(x)-v(y))}{|x-y|^{N+ps}}\,dx\,dy \\
&\leq \iint_{\mathbb{R}^{2N}} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\,dx\,dy \iint_{\mathbb{R}^{2N}} \frac{|v(x)-v(y)|^p}{|x-y|^{N+ps}}\,dx\,dy \\
&\leq C\|u_n^-\| \to 0
\end{aligned}$$

as $n \to \infty$ by (5.6).

By virtue of (5.7) and the fact that $\langle I'_\lambda(u_n), v\rangle \to 0$, we derive that $\langle I'_\lambda(u_n^+), v\rangle \to 0$ for all $v \in X^{1,p}(\mathbb{R}^N)$. Consequently, we conclude that $\{u_n^+\}_n$ is a $(PS)_c$ sequence. □

Lemma 5.3. *Suppose $a > 0,\ b > 0$ and either $\theta < \frac{2N-\mu}{N-p}$, or $a > 0,\ 0 < b < S_{H,M}^{-\frac{2p_\mu^*}{p}}$, $\theta = \frac{2N-\mu}{N-p}$. Then there exist $\lambda_0 > 0$, $\rho > 0$ and $\alpha > 0$ such that for any $\lambda \in (0, \lambda_0)$, $I_\lambda(u) \geq \alpha$ holds for every $u \in X^{1,p}(\mathbb{R}^N)$ satisfying $\|u\| = \rho$.*

Proof. For any $u \in X^{1,p}(\mathbb{R}^N)$, by the Sobolev inequality, we have

$$\begin{aligned} I_\lambda(u) &= \frac{a}{p}\|u\|^p + \frac{b}{\theta p}\|u\|^{\theta p} - \frac{1}{2p_\mu^*}\iint_{\mathbb{R}^{2N}} \frac{|u^+(x)|^{p_\mu^*}|u^+(y)|^{p_\mu^*}}{|x-y|^\mu}\,dx\,dy - \lambda\int_{\mathbb{R}^N} f(x)u\,dx \\ &\geq \frac{a}{p}\|u\|^p + \frac{b}{\theta p}\|u\|^{\theta p} - \frac{1}{2p_\mu^*}S_{H,M}^{-\frac{2p_\mu^*}{p}}\|u\|^{2p_\mu^*} - \lambda S^{-\frac{1}{p}}|f|_{(p^*)'}\|u\|, \end{aligned}$$

where S is the optimal constant for the Sobolev embedding $X^{1,p}(\mathbb{R}^N) \hookrightarrow L^{p^*}(\mathbb{R}^N)$.

Case 1. $a > 0,\ b > 0$ and $\theta < \frac{2N-\mu}{N-p}$. We have

$$I_\lambda(u) \geq \left(\frac{b}{\theta p}\|u\|^{\theta p-1} - \frac{1}{2p_\mu^*}S_{H,M}^{-\frac{2p_\mu^*}{p}}\|u\|^{2p_\mu^*-1} - \lambda S^{-\frac{1}{p}}|f|_{(p^*)'}\right)\|u\|.$$

Define

$$k(t) := \frac{b}{\theta p}t^{\theta p-1} - \frac{1}{2p_\mu^*}S_{H,M}^{-\frac{2p_\mu^*}{p}}t^{2p_\mu^*-1}$$

for all $t \geq 0$. Since $2p_\mu^* > \theta p$ by $\theta < \frac{2N-\mu}{N-p}$, we obtain that $\max_{t\geq 0} k(t) = k(\rho) > 0$, where

$$\rho = \left(\frac{2bp_\mu^*(\theta p-1)S_{H,M}^{\frac{2p_\mu^*}{p}}}{\theta p(2p_\mu^*-1)}\right)^{\frac{1}{2p_\mu^*-\theta p}}.$$

Set

$$\lambda_0 = \frac{k(\rho)}{S^{-\frac{1}{p}}|f|_{(p^*)'}},$$

then for any $\lambda \in (0, \lambda_0)$ we have

$$I_\lambda(u) \geq \left(k(\rho) - \lambda S^{-\frac{1}{p}}|f|_{(p^*)'}\right)\rho =: \alpha > 0 \quad \text{for all } \|u\| = \rho.$$

Case 2. $a > 0,\ 0 < b < S_{H,M}^{-\frac{2p_\mu^*}{p}}$ and $\theta = \frac{2N-\mu}{N-p}$. We have

$$I_\lambda(u) \geq \left[\frac{a}{p}\|u\|^{p-1} - \left(\frac{1}{2p_\mu^*}S_{H,M}^{-\frac{2p_\mu^*}{p}} - \frac{b}{\theta p}\right)\|u\|^{\theta p-1} - \lambda S^{-\frac{1}{p}}|f|_{(p^*)'}\right]\|u\|$$

with $2p_\mu^* = \theta p$. Define

$$l(t) := \frac{a}{p}t^{p-1} - \left(\frac{1}{2p_\mu^*}S_{H,M}^{-\frac{2p_\mu^*}{p}} - \frac{b}{\theta p}\right)t^{\theta p-1}$$

for all $t \geq 0$. Then $\max_{t\geq 0} l(t) = l(\rho) > 0$, where

$$\rho = \left(\frac{2a(p-1)p_\mu^*}{p(2p_\mu^*-1)(S_{H,M}^{-\frac{2p_\mu^*}{p}} - b)}\right)^{\frac{1}{2p_\mu^*-p}}.$$

Set

$$\lambda_0 = \frac{l(\rho)}{S^{-\frac{1}{p}}|f|_{(p^*)'}},$$

then for all $\lambda \in (0, \lambda_0)$ we deduce

$$I_\lambda(u) \geq \left(l(\rho) - \lambda S^{-\frac{1}{p}}|f|_{(p^*)'}\right)\rho =: \alpha > 0 \text{ for all } \|u\| = \rho.$$

Thus, the proof is completed. □

Lemma 5.4. *Suppose $a > 0$, $b > 0$, and either $\theta < \frac{2N-\mu}{N-p}$ or $a > 0$, $0 < b < S_{H,M}^{-\frac{2p_\mu^*}{p}}$, $\theta = \frac{2N-\mu}{N-p}$. Then for any $\lambda > 0$, there exists $e \in X^{1,p}(\mathbb{R}^N)$ such that $\|e\| \geq \rho$ and $I_\lambda(e) < 0$, where ρ is the number given in Lemma 5.3.*

Proof. By the definition of $S_{H,M}$ as given in (1.4), for all $\varepsilon > 0$, there exists $u \in X^{1,p}(\mathbb{R}^N) \setminus \{0\}$ such that

$$\frac{\|u\|^p}{\left(\iint_{\mathbb{R}^{2N}} \frac{|u(x)|^{p_\mu^*}|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dx\,dy\right)^{\frac{p}{2p_\mu^*}}} \leq S_{H,M} + \varepsilon.$$

Then there exists a positive U satisfying $\|U\|_{HL} = 1$ such that

$$\|U\|^p = S_{H,M} + h(\varepsilon), \tag{5.8}$$

where $h(\varepsilon)$ is a nonnegative constant associated with ε and $h(\varepsilon) \leq \varepsilon$. Then for any $t > 0$, we have

$$\begin{aligned} I_\lambda(tU) &= \frac{a\|U\|^p}{p}t^p + \frac{b\|U\|^{\theta p}}{\theta p}t^{\theta p} - \frac{t^{2p_\mu^*}}{2p_\mu^*} - \lambda t\int_{\mathbb{R}^N} f(x)U\,dx \\ &\leq \frac{a\|U\|^p}{p}t^p + \frac{b\|U\|^{\theta p}}{\theta p}t^{\theta p} - \frac{t^{2p_\mu^*}}{2p_\mu^*}. \end{aligned}$$

When $\theta < \frac{2N-\mu}{N-p}$(i.e. $\theta p < 2p_\mu^*$), there exists a sufficiently large $t > 0$ such that $\|tU\| \geq \rho$ and $I_\lambda(tU) < 0$.

When $\theta = \frac{2N-\mu}{N-p}$(i.e. $\theta p = 2p_\mu^*$), we derive

$$I_\lambda(tU) \leq \frac{a\|U\|^p}{p}t^p - \left(\frac{1}{2p_\mu^*} - \frac{b\|U\|^{\theta p}}{\theta p}\right)t^{2p_\mu^*}.$$

Given $0 < b < S_{H,M}^{-\theta}$, there exists $t > 0$ such that $\|tU\| \geq \rho$ and $I_\lambda(tU) < 0$. Setting $e = tU$ completes the proof. □

From Lemma 5.2, we have that any $(PS)_c$ sequence can be regarded as a sequence of nonnegative functions. Thus, we may assume without loss of generality that all $(PS)_c$ sequences are nonnegative in the subsequent analysis.

Define

$$\Lambda = \begin{cases} \left(\frac{1}{p} - \frac{1}{\theta p}\right)(aS_{H,M})^{\frac{\theta}{\theta-1}} \left(\frac{1}{1-bS_{H,M}^{\theta}}\right)^{\frac{1}{\theta-1}}, & \text{if } \theta = \frac{2N-\mu}{N-p},\ a>0,\ 0<b<S_{H,M}^{-\theta}, \\ \left(\frac{a}{p} - \frac{a}{\theta p}\right) S_{H,M} \left(\frac{bS_{H,M}^{\theta} + \sqrt{b^2 S_{H,M}^{2\theta} + 4aS_{H,M}}}{2}\right)^{\frac{2\theta-1}{\theta-1}\cdot\frac{p}{2p_{\mu}^*}} \\ \quad + \left(\frac{1}{\theta p} - \frac{1}{2p_{\mu}^*}\right) \left(\frac{bS_{H,M}^{\theta} + \sqrt{b^2 S_{H,M}^{2\theta} + 4aS_{H,M}}}{2}\right)^{\frac{2\theta-1}{\theta-1}}, & \text{if } \theta = \frac{3N-\mu-p}{2(N-p)},\ a>0,\ b>0, \end{cases}$$

and

$$\Theta(\lambda) = \frac{p-1}{p}\left[\left(a - \frac{a}{\theta}\right)S\right]^{-\frac{1}{p-1}} \left(1 - \frac{1}{\theta p}\right)^{\frac{p}{p-1}} \lambda^{\frac{p}{p-1}} |f|_{(p^*)'}^{\frac{p}{p-1}},$$

where $(p^*)' = \frac{p^*}{p^*-1}$.

Lemma 5.5. *Assume that $a>0,\ b>0$ and $\theta = \frac{3N-\mu-p}{2(N-p)}$, or $a>0,\ 0<b<S_{H,M}^{-\frac{2\cdot p_{\mu}^*}{p}}$ and $\theta = \frac{2N-\mu}{N-p}$, if $\{u_n\}_n \in X^{1,p}(\mathbb{R}^N)$ is a bounded and nonnegative sequence satisfying $I_\lambda(u_n) \to c < \Lambda - \Theta(\lambda)$ and $I'_\lambda(u_n) \to 0$ in $(X^{1,p}(\mathbb{R}^N))'$ as $n \to \infty$, then there exists a nonnegative function $u \in X^{1,p}(\mathbb{R}^N)$ such that, up to a subsequence, $u_n \to u$ in $X^{1,p}(\mathbb{R}^N)$ as $n \to \infty$.*

Proof. As $\{u_n\}_n$ is bounded and nonnegative, then there exists a subsequence, still noted $\{u_n\}_n$, and a nonnegative function $u \in X^{1,p}(\mathbb{R}^N)$ such that $u_n \rightharpoonup u$ in $X^{1,p}(\mathbb{R}^N)$, $u_n \to u$ in L^r_{loc} for $r \in [1, p^*)$ and $u_n \to u$ *a.e* in $\mathbb{R}^N$. Applying Theorem 4.2, up to a further subsequence, there exists a (at most) countable set J, a non-atomic measure $\tilde{\xi}$ and points $\{x_j\}_{j\in J} \subset \mathbb{R}^N$ and $\{\xi_j\}_{j\in J},\ \{\nu_j\}_{j\in J} \subset \mathbb{R}^+$ such that as $n \to \infty$ we have

$$|\nabla u_n|^p + \int_{\mathbb{R}^N} \frac{|u_n(x) - u_n(y)|^p}{|x-y|^{N+ps}}\, dy \rightharpoonup \xi = |\nabla u|^p + \int_{\mathbb{R}^N} \frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\, dy + \sum_{j\in J} \xi_j \delta_{x_j} + \tilde{\xi}, \quad (5.9)$$

$$\int_{\mathbb{R}^N} \frac{|u_n(y)|^{p_{\mu}^*}}{|x-y|^{\mu}}\, dy\, |u_n(x)|^{p_{\mu}^*} \rightharpoonup \nu = \int_{\mathbb{R}^N} \frac{|u(y)|^{p_{\mu}^*}}{|x-y|^{\mu}}\, dy\, |u(x)|^{p_{\mu}^*} + \sum_{j\in J} \nu_j \delta_{x_j} \quad (5.10)$$

in the measure sense, where δ_{x_j} is the Dirac measure concentrated at x_j. Moreover,

$$\nu_j \le S_{H,M}^{-\frac{2p_{\mu}^*}{p}} \xi_j^{\frac{2p_{\mu}^*}{p}} \quad (5.11)$$

for all $j \in J$, where $S_{H,M}$ is the optimal constant defined in (1.4). We now proceed with the proof in three steps.

Step 1. We claim that $J = \emptyset$. Suppose by contradiction that $J \neq \emptyset$. Fix $j \in J$. For any $\varepsilon > 0$, choose $\varphi_{\varepsilon,j} \in C_0^\infty(\mathbb{R}^N)$ such that

$$\varphi_{\varepsilon,j} = 1 \quad \text{in } B_\varepsilon(x_j), \qquad \varphi_{\varepsilon,j} = 0 \quad \text{in } \mathbb{R}^N \setminus B_{2\varepsilon}(x_j), \qquad |\nabla \varphi_{\varepsilon,j}| \le 2/\varepsilon.$$

Evidently, $\varphi_{\varepsilon,j}u_n \in X^{1,p}(\mathbb{R}^N)$. It follows from $\langle I'_\lambda(u_n), \varphi_{\varepsilon,j}u_n\rangle \to 0$ that

$$\begin{aligned}
&\Big(a + b\|u_n\|^{(\theta-1)p}\Big)\left(\int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\nabla u_n \nabla(\varphi_{\varepsilon,j}u_n)\,dx\right.\\
&\quad\left.+\iint_{\mathbb{R}^{2N}} \frac{|u_n(x)-u_n(y)|^{p-2}(u_n(x)-u_n(y))(\varphi_{\varepsilon,j}(x)u_n(x)-\varphi_{\varepsilon,j}(y)u_n(y))}{|x-y|^{N+ps}}\,dx\,dy\right)\\
&= \iint_{\mathbb{R}^{2N}} \frac{|u_n(y)|^{p^*_\mu}|u_n(x)|^{p^*_\mu-2}u_n(x)u_n(x)\varphi_{\varepsilon,j}(x)}{|x-y|^{\mu}}\,dx\,dy + \lambda\int_{\mathbb{R}^N} f(x)\varphi_{\varepsilon,j}(x)u_n\,dx + o(1).
\end{aligned} \tag{5.12}$$

For the left-hand side of (5.12), applying Hölder's inequality and Lemma 4.3 yields

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\nabla u_n\nabla\varphi_{\varepsilon,j}u_n\,dx\\
&\quad\le \lim_{\varepsilon\to 0}\lim_{n\to\infty}\left(\int_{\mathbb{R}^N}|\nabla u_n|^p\,dx\right)^{\frac{p-1}{p}}\left(\int_{\mathbb{R}^N}|\nabla\varphi_{\varepsilon,j}u_n|^p\,dx\right)^{\frac{1}{p}}\\
&\quad\le C\lim_{\varepsilon\to 0}\lim_{n\to\infty}\left(\int_{\mathbb{R}^N}|\nabla\varphi_{\varepsilon,j}u_n|^p\,dx\right)^{\frac{1}{p}} = 0,
\end{aligned} \tag{5.13}$$

and

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\lim_{n\to\infty}\left|\iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)|^{p-2}(u_n(x)-u_n(y))(\varphi_{\varepsilon,j}(x)-\varphi_{\varepsilon,j}(y))u_n(y)}{|x-y|^{N+ps}}\,dx\,dy\right|\\
&\le C\lim_{\varepsilon\to 0}\lim_{n\to\infty}\left(\iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{p-1}{p}}\left(\iint_{\mathbb{R}^{2N}}\frac{|(\varphi_{\varepsilon,j}(x)-\varphi_{\varepsilon,j}(y))u_n(y)|^p}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{1}{p}}\\
&\le C\lim_{\varepsilon\to 0}\lim_{n\to\infty}\left(\frac{|(\varphi_{\varepsilon,j}(x)-\varphi_{\varepsilon,j}(y))u_n(y)|^p}{|x-y|^{N+ps}}\,dx\,dy\right)^{\frac{1}{p}} = 0.
\end{aligned} \tag{5.14}$$

This together with equations (5.9) leads to

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\lim_{n\to\infty}\Big(a+b\|u_n\|^{(\theta-1)p}\Big)\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}dy\right)\varphi_{\varepsilon,j}(x)\,dx\\
&\quad\ge \lim_{\varepsilon\to 0}\lim_{n\to\infty} a\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}dy\right)\varphi_{\varepsilon,j}(x)\,dx\\
&\qquad+\lim_{\varepsilon\to 0}\lim_{n\to\infty} b\left(\int_{\mathbb{R}^N}\left(|\nabla u_n|^p+\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy\right)\varphi_{\varepsilon,j}(x)\,dx\right)^\theta\\
&\quad= a\xi_j + b\xi_j^\theta.
\end{aligned} \tag{5.15}$$

For the first term on the right-hand side of (5.12), it follows from (5.10) that

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\lim_{n\to\infty}\iint_{\mathbb{R}^{2N}}\frac{|u_n(y)|^{p^*_\mu}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p^*_\mu}\varphi_{\varepsilon,j}\,dx\\
&\quad=\lim_{\varepsilon\to 0}\left(\iint_{\mathbb{R}^{2N}}\frac{|u(y)|^{p^*_\mu}}{|x-y|^\mu}\,dy\,|u(x)|^{p^*_\mu}\varphi_{\varepsilon,j}\,dx+\sum_{j\in J}\nu_j\delta_{x_j}\right)=\nu_j.
\end{aligned} \tag{5.16}$$

Moreover,

$$\lim_{\varepsilon\to 0}\lim_{n\to\infty}\int_{\mathbb{R}^N} f\varphi_{\varepsilon,j}u_n\,dx = \lim_{\varepsilon\to 0}\int_{\mathbb{R}^N} f\varphi_{\varepsilon,j}u\,dx = 0. \tag{5.17}$$

Therefore, by substituting (5.13)–(5.17) into (5.12), we obtain

$$\nu_j \geq a\xi_j + b\xi_j^{\theta}. \tag{5.18}$$

Combining (5.11) with (5.18) implies

$$\nu_j \geq \begin{cases} \left(\dfrac{aS_{H,M}}{1-bS_{H,M}^{\theta}}\right)^{\frac{\theta}{\theta-1}} & \text{if } \theta = \frac{2N-\mu}{N-p},\ a>0,\ 0<b<S_{H,M}^{-\theta}, \\ \left(\dfrac{bS_{H,M}^{\theta}+\sqrt{b^2S_{H,M}^{2\theta}+4aS_{H,M}}}{2}\right)^{\frac{2\theta-1}{\theta-1}} & \text{if } \theta = \frac{3N-\mu-p}{2(N-p)},\ a>0,\ b>0. \end{cases} \tag{5.19}$$

For $R>0$, assume that $\psi_R \in C_0^{\infty}(\mathbb{R}^N)$ satisfies $\psi_R \in [0,1]$, $\psi_R(x)=1$ for $|x-x_j|\leq R$, $\psi_R(x)=0$ for $|x-x_j|>2R$, and $|\nabla\psi_R|\leq \frac{2}{R}$. By (5.9) and (5.10), we have

$$\begin{aligned}
c &= \lim_{n\to\infty}\left(I_\lambda(u_n)-\frac{1}{\theta p}\langle I_\lambda'(u_n),u_n\rangle\right) \\
&= \lim_{R\to\infty}\lim_{n\to\infty}\left(\left(\frac{a}{p}-\frac{a}{\theta p}\right)\left(\int_{\mathbb{R}^N}|\nabla u_n|^p\psi_R\,dx+\iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\psi_R(x)\,dy\,dx\right)\right. \\
&\quad \left.+\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\iint_{\mathbb{R}^{2N}}\frac{|u_n(y)|^{p_\mu^*}|u_n(x)|^{p_\mu^*}\psi_R(x)}{|x-y|^{\mu}}\,dy\,dx-\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N}fu_n\,dx\right) \\
&= \lim_{R\to\infty}\left(\left(\frac{a}{p}-\frac{a}{\theta p}\right)\left(\int_{\mathbb{R}^N}|\nabla u|^p\psi_R\,dx+\iint_{\mathbb{R}^{2N}}\frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\psi_R(x)\,dy\,dx\right)+\left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_j\right. \\
&\quad +\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\iint_{\mathbb{R}^{2N}}\frac{|u(y)|^{p_\mu^*}|u(x)|^{p_\mu^*}\psi_R(x)}{|x-y|^{\mu}}\,dy\,dx \\
&\quad \left.+\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\nu_j-\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N}fu\,dx\right) \\
&\geq \left(\frac{a}{p}-\frac{a}{\theta p}\right)\left(\int_{\mathbb{R}^N}|\nabla u|^p dx+\iint_{\mathbb{R}^{2N}}\frac{|u(x)-u(y)|^p}{|x-y|^{N+ps}}\,dy\,dx\right)+\left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_j \\
&\quad +\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\iint_{\mathbb{R}^{2N}}\frac{|u(y)|^{p_\mu^*}|u(x)|^{p_\mu^*}}{|x-y|^{\mu}}\,dy\,dx+\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\nu_j-\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N}fu\,dx \\
&\geq \left(\frac{a}{p}-\frac{a}{\theta p}\right)S|u|_{p^*}^p+\left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_j+\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\iint_{\mathbb{R}^{2N}}\frac{|u(y)|^{p_\mu^*}|u(x)|^{p_\mu^*}}{|x-y|^{\mu}}\,dy\,dx \\
&\quad +\left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\nu_j-\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N}fu\,dx,
\end{aligned}$$

which implies that

$$c \geq \begin{cases} \left(\dfrac{a}{p}-\dfrac{a}{\theta p}\right)S|u|_{p^*}^p+\left(\dfrac{a}{p}-\dfrac{a}{\theta p}\right)\xi_j-\left(1-\dfrac{1}{\theta p}\right)\lambda\displaystyle\int_{\mathbb{R}^N}fu\,dx, \\ \qquad\qquad \text{if } \theta=\frac{2N-\mu}{N-p},\ a>0,\ b>0, \\ \left(\dfrac{a}{p}-\dfrac{a}{\theta p}\right)S|u|_{p^*}^p+\left(\dfrac{a}{p}-\dfrac{a}{\theta p}\right)\xi_j+\left(\dfrac{1}{\theta p}-\dfrac{1}{2p_\mu^*}\right)\nu_j-\left(1-\dfrac{1}{\theta p}\right)\lambda\displaystyle\int_{\mathbb{R}^N}fu\,dx, \\ \qquad\qquad \text{if } \theta=\frac{3N-\mu-p}{2(N-p)},\ a>0,\ b>0. \end{cases}$$

Then we apply the Hölder inequality, the Sobolev embedding, and Young inequality to derive

$$\begin{aligned}\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N} fu\,dx &= \left(1-\frac{1}{\theta p}\right)\lambda|f|_{(p^*)'}|u|_{p^*}\\ &\le \left(\frac{a}{p}-\frac{a}{\theta p}\right)S|u|_{p^*}^p + \frac{p-1}{p}\left[\left(a-\frac{a}{\theta}\right)S\right]^{-\frac{1}{p-1}}\left(1-\frac{1}{\theta p}\right)^{\frac{p}{p-1}}\lambda^{\frac{p}{p-1}}|f|_{(p^*)'}^{\frac{p}{p-1}}.\end{aligned} \tag{5.20}$$

By (5.20) we obtain

$$c \ge \begin{cases} \left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_j - \frac{p-1}{p}\left[\left(a-\frac{a}{\theta}\right)S\right]^{-\frac{1}{p-1}}\left(1-\frac{1}{\theta p}\right)^{\frac{p}{p-1}}\lambda^{\frac{p}{p-1}}|f|_{(p^*)'}^{\frac{p}{p-1}}, \\ \qquad\qquad \text{if } \theta = \frac{2N-\mu}{N-p},\ a>0,\ b>0, \\ \left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_j + \left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\nu_j - \frac{p-1}{p}\left[\left(a-\frac{a}{\theta}\right)S\right]^{-\frac{1}{p-1}}\left(1-\frac{1}{\theta p}\right)^{\frac{p}{p-1}}\lambda^{\frac{p}{p-1}}|f|_{(p^*)'}^{\frac{p}{p-1}}, \\ \qquad\qquad \text{if } \theta = \frac{3N-\mu-p}{2(N-p)},\ a>0,\ b>0. \end{cases}$$

Combining (5.11) with (5.19), we arrive at $c \ge \Lambda - \Theta(\lambda)$, which contradicts our initial assumption. Thus the claim $J = \emptyset$ holds.

Step 2. We claim $\nu_\infty = 0$. Let $R > 0$. Set

$$\xi_\infty = \lim_{R\to\infty}\limsup_{n\to\infty}\int_{\{x\in\mathbb{R}^N:|x|>R\}}\left(|\nabla u_n|^p + \int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy\right)dx,$$

$$\nu_\infty = \lim_{R\to\infty}\limsup_{n\to\infty}\int_{\{x\in\mathbb{R}^N:|x|>R\}}\int_{\mathbb{R}^N}\frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}\,dx.$$

According to Theorem 4.4, we know that ξ_∞ and ν_∞ are well defined and we have

$$\limsup_{n\to\infty}\int_{\mathbb{R}^N}\left(|\nabla u_n|^p + \int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\,dy\right)dx = \xi(\mathbb{R}^N) + \xi_\infty, \tag{5.21}$$

$$\limsup_{n\to\infty}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}\,dx = \nu(\mathbb{R}^N) + \nu_\infty. \tag{5.22}$$

To rule out the possibility of concentration for mass at infinity, we take a suitable cutoff function $\chi_R \in C^\infty(\mathbb{R}^N)$ satisfying $\chi_R \in [0,1]$, $\chi_R(x) = 0$ for $|x| < R$ and $\chi_R(x) = 1$ for $|x| > 2R$, $|\nabla\chi_R| < \frac{2}{R}$. Following a discussion analogous to that of Theorem 4.4, we derive

$$\xi_\infty = \lim_{R\to\infty}\limsup_{n\to\infty}\int_{\mathbb{R}^N}|\nabla u_n|^p\chi_R(x)\,dx + \int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\chi_R(x)\,dy\,dx, \tag{5.23}$$

and

$$\nu_\infty = \lim_{R\to\infty}\limsup_{n\to\infty}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N}\frac{|u_n(y)\chi_R(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)\chi_R(x)|^{p_\mu^*}\,dx. \tag{5.24}$$

Moreover, we have

$$S_{H,M}\nu_\infty^{\frac{p}{2p_\mu^*}} < \xi_\infty. \tag{5.25}$$

Given that $\|u_n\|^p$ and $\|u_n\|_{HL}^{2p_\mu^*}$ are bounded, up to subsequence, we can assume that $\|u_n\|^p$ and $\|u_n\|_{HL}^{2p_\mu^*}$ are both convergent. Then by (5.21) and (5.22) we obtain

$$\lim_{n\to\infty} \|u_n\|^p = \int_{\mathbb{R}^N} d\xi + \xi_\infty, \tag{5.26}$$

$$\iint_{\mathbb{R}^{2N}} \frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu} dy |u_n(x)|^{p_\mu^*} dx = \int_{\mathbb{R}^N} d\nu + \nu_\infty. \tag{5.27}$$

The fact $\langle I'_\lambda(u_n), \chi_R u_n\rangle \to 0$ as $n \to \infty$ entails that

$$\begin{aligned}
&\left(a + b\|u_n\|^{(\theta-1)p}\right)\left(\int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\nabla u_n \nabla(\chi_R u_n)\, dx\right.\\
&\quad\left. + \iint_{\mathbb{R}^{2N}} \frac{|u_n(x)-u_n(y)|^{p-2}(u_n(x)-u_n(y))(\chi_R(x)u_n(x)-\chi_R(y)u_n(y))}{|x-y|^{N+ps}}\, dx\, dy\right)\\
&= \iint_{\mathbb{R}^{2N}} \frac{|u_n(y)|^{p_\mu^*}|u_n(x)|^{p_\mu^*-2}u_n(x)u_n(x)\chi_R(x)}{|x-y|^\mu}\, dx\, dy + \lambda\int_{\mathbb{R}^N} f(x)\chi_R u_n\, dx + o(1).
\end{aligned} \tag{5.28}$$

By (4.8), (4.9) and the Hölder inequality, we get

$$\lim_{R\to\infty}\lim_{n\to\infty}\int_{\mathbb{R}^N} |\nabla u_n|^{p-2}\nabla u_n \nabla\chi_R u_n\, dx = 0, \tag{5.29}$$

$$\lim_{R\to\infty}\limsup_{n\to\infty}\iint_{\mathbb{R}^{2N}} \frac{|u_n(x)-u_n(y)|^{p-2}(u_n(x)-u_n(y))u_n(y)(\chi_R(x)-\chi_R(y))}{|x-y|^{N+ps}}\, dx\, dy = 0. \tag{5.30}$$

Hence, it follows from $\theta > 1$, (5.23), (5.26) and (5.28)–(5.30) that

$$\begin{aligned}
&\lim_{R\to\infty}\limsup_{n\to\infty}\left(a + b\|u_n\|^{(\theta-1)p}\right)\left(\int_{\mathbb{R}^N}|\nabla u_n|^p\chi_R\, dx + \iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)|^p\chi_R(x)}{|x-y|^{N+ps}}\, dy\, dx\right)\\
&= \left[a + \left(\int_{\mathbb{R}^N} d\xi + \xi_\infty\right)^{\theta-1}\right]\\
&\quad\times\lim_{R\to\infty}\limsup_{n\to\infty}\left(\int_{\{x\in\mathbb{R}^N:|x|>R\}}|\nabla u_n|^p\, dx + \int_{\{x\in\mathbb{R}^N:|x|>R\}}\int_{\mathbb{R}^N}\frac{|u_n(x)-u_n(y)|^p}{|x-y|^{N+ps}}\, dy\, dx\right)\\
&\geq \left(a + b\xi_\infty^{\theta-1}\right)\xi_\infty = a\xi_\infty + b\xi_\infty^\theta.
\end{aligned} \tag{5.31}$$

Besides, it is straightforward to observe that

$$\lim_{R\to\infty}\limsup_{n\to\infty}\int_{\mathbb{R}^N} f(x)\chi_R u_n\, dx = \lim_{R\to\infty}\int_{\mathbb{R}^N} f(x)\chi_R u\, dx = 0. \tag{5.32}$$

Therefore, we combine (5.28)-(5.32) with (5.24) and obtain that

$$a\xi_\infty + b\xi_\infty^\theta \leq \nu_\infty.$$

In conjunction with (5.25), this leads to

$$aS_{H,M}\nu_\infty^{\frac{p}{2p_\mu^*}} + bS_{H,M}^\theta\nu_\infty^{\frac{\theta p}{2p_\mu^*}} \leq \nu_\infty,$$

indicating that $\nu_\infty = 0$ or

$$\nu_\infty \geq \begin{cases} \left(\dfrac{aS_{H,M}}{1-bS_{H,M}^{\theta}}\right)^{\frac{\theta}{\theta-1}} & \text{if } \theta = \frac{2N-\mu}{N-p},\ a>0,\ 0<b<S_{H,M}^{-\theta}, \\ \left(\dfrac{bS_{H,M}^{\theta}+\sqrt{b^2S_{H,M}^{2\theta}+4aS_{H,M}}}{2}\right)^{\frac{2\theta-1}{\theta-1}} & \text{if } \theta = \frac{3N-\mu-p}{2(N-p)},\ a>0,\ b>0. \end{cases} \tag{5.33}$$

Suppose that (5.33) holds, then we have

$$\begin{aligned} c &= \lim_{n\to\infty}\left(I_\lambda(u_n) - \frac{1}{\theta p}\langle I'_\lambda(u_n), u_n\rangle\right) \\ &= \lim_{n\to\infty}\left(\left(\frac{a}{p}-\frac{a}{\theta p}\right)\|u_n\|^p + \left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\iint_{\mathbb{R}^{2N}}\frac{|u_n(y)|^{p_\mu^*}|u_n(x)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,dx\right. \\ &\quad \left. -\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N} f u_n\,dx\right) \\ &= \left(\frac{a}{p}-\frac{a}{\theta p}\right)\int_{\mathbb{R}^N} d\xi + \left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_\infty + \left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\int_{\mathbb{R}^N} d\nu + \left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\nu_\infty \\ &\quad -\left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N} f u\,dx \\ &\geq \left(\frac{a}{p}-\frac{a}{\theta p}\right)\|u\|^p + \left(\frac{a}{p}-\frac{a}{\theta p}\right)\xi_\infty + \left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\iint_{\mathbb{R}^{2N}}\frac{|u(y)|^{p_\mu^*}|u(x)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,dx \\ &\quad + \left(\frac{1}{\theta p}-\frac{1}{2p_\mu^*}\right)\nu_\infty - \left(1-\frac{1}{\theta p}\right)\lambda\int_{\mathbb{R}^N} f u\,dx. \end{aligned}$$

Ultimately, from equations (5.20) and (5.33), we infer that $c \geq \Lambda - \Theta(\lambda)$, leading to a contradiction. Hence, $\nu_\infty = 0$. In view of $J = \emptyset$ and (5.27), we conclude that

$$\lim_{n\to\infty}\iint_{\mathbb{R}^{2N}}\frac{|u_n(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u_n(x)|^{p_\mu^*}\,dx = \iint_{\mathbb{R}^{2N}}\frac{|u(y)|^{p_\mu^*}}{|x-y|^\mu}\,dy\,|u(x)|^{p_\mu^*}\,dx. \tag{5.34}$$

Step 3. We are now in a position to prove that $u_n \to u$ in $X^{1,p}(\mathbb{R}^N)$. Suppose $d := \inf_{n\geq 1}\|u_n\| > 0$. For any $w, v \in X^{1,p}(\mathbb{R}^N)$, we define

$$\begin{aligned} \langle L(w), v\rangle = &\int_{\mathbb{R}^N}|\nabla w_n|^{p-2}\nabla w_n \nabla v\,dx \\ &+ \iint_{\mathbb{R}^{2N}}\frac{|w_n(x)-w_n(y)|^{p-2}(w_n(x)-w_n(y))(v_n(x)-v_n(y))}{|x-y|^{N+ps}}\,dx\,dy. \end{aligned}$$

Clearly, $L(w)$ is a continuous linear functional in $X^{1,p}(\mathbb{R}^N)$. Then by the boundedness of $\{u_n\}_n$ and $u_n \rightharpoonup u$ in $X^{1,p}(\mathbb{R}^N)$, we deduce

$$\lim_{n\to\infty}\left(a+b\|u_n\|^{(\theta-1)p}\right)\langle L(u), u_n-u\rangle = 0,$$

and

$$\lim_{n\to\infty}\left(a+b\|u\|^{(\theta-1)p}\right)\langle L(u), u_n-u\rangle = 0.$$

Therefore, as $n \to \infty$, there holds

$$\begin{aligned}&\lim_{n\to\infty}\left(a+b\|u_n\|^{(\theta-1)p}\right)\langle L(u_n),u_n-u\rangle-\left(a+b\|u\|^{(\theta-1)p}\right)\langle L(u),u_n-u\rangle\\&\quad=\lim_{n\to\infty}\left(a+b\|u_n\|^{(\theta-1)p}\right)\left(\langle L(u_n),u_n-u\rangle-\langle L(u),u_n-u\rangle\right).\end{aligned}$$

It follows from $\langle I'_\lambda(u_n)-I'_\lambda(u),u_n-u\rangle\to 0$ that

$$\begin{aligned}&\left(a+b\|u_n\|^{(\theta-1)p}\right)\langle L(u_n),u_n-u\rangle-\left(a+b\|u\|^{(\theta-1)p}\right)\langle L(u),u_n-u\rangle\\&\quad=\iint_{\mathbb{R}^{2N}}\left(\frac{|u_n(y)|^{p^*_\mu}}{|x-y|^\mu}dy\,|u_n(x)|^{p^*_\mu-2}u_n(x)-\frac{|u(y)|^{p^*_\mu}}{|x-y|^\mu}dy\,|u(x)|^{p^*_\mu-2}u(x)\right)(u_n(x)-u(x))\,dx\\&\qquad+o(1).\end{aligned}$$

Hence, we conclude from (5.34) that

$$\lim_{n\to\infty}\left(a+b\|u_n\|^{(\theta-1)p}\right)\left(\langle L(u_n),u_n-u\rangle-\langle L(u),u_n-u\rangle\right)=0.$$

Since $d:=\inf_{n\geq 1}\|u_n\|>0$ and $b>0$, we have

$$\lim_{n\to\infty}\left(\langle L(u_n),u_n-u\rangle-\langle L(u),u_n-u\rangle\right)=0.$$

Now recall the famous Simon inequalities:

$$|\alpha-\beta|^p\leq\begin{cases}C'_p\left(|\alpha|^{p-2}\alpha-|\beta|^{p-2}\beta\right)\cdot(\alpha-\beta) & \text{if } p\geq 2,\\ C''_p\left[\left(|\alpha|^{p-2}\alpha-|\beta|^{p-2}\beta\right)\cdot(\alpha-\beta)\right]^{\frac{p}{2}}\left(|\alpha|^p+|\beta|^p\right)^{\frac{2-p}{2}} & \text{if } 1<p<2,\end{cases}\tag{5.35}$$

for all $\alpha,\beta\in\mathbb{R}^N$, where C'_p and C''_p are positive constants depending only on p.

If $p\geq 2$, from equation (5.35), we derive that

$$\begin{aligned}&\int_{\mathbb{R}^N}|\nabla(u_n-u)|^p\,dx+\iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)-u(x)+u(y)|^p}{|x-y|^{N+ps}}\,dx\,dy\\&\quad\leq C'_p\left(\langle L(u_n),u_n-u\rangle-\langle L(u),u_n-u\rangle\right)\to 0\end{aligned}$$

as $n\to\infty$. Hence $u_n\to u$ in $X^{1,p}(\mathbb{R}^N)$.

For the case $1<p<2$, let $A=u_n(x)-u_n(y)$, $B=u(x)-u(y)$. Using (5.35) and concavity we have

$$\begin{aligned}&\int_{\mathbb{R}^N}|\nabla(u_n-u)|^p\,dx+\iint_{\mathbb{R}^{2N}}\frac{|u_n(x)-u_n(y)-u(x)+u(y)|^p}{|x-y|^{N+ps}}\,dx\,dy\\&\quad\leq C''_p\int_{\mathbb{R}^N}\left[\left(|\nabla u_n|^{p-2}\nabla u_n-|\nabla u|^{p-2}\nabla u\right)\cdot(\nabla u_n-\nabla u)\right]^{\frac{p}{2}}\left(|\nabla u_n|^p+|\nabla u|^p\right)^{\frac{2-p}{2}}dx\\&\qquad+C''_p\iint\limits_{\mathbb{R}^{2N}}\frac{\left[\left(|A|^{p-2}A-|B|^{p-2}B\right)\cdot(A-B)\right]^{\frac{p}{2}}\left(|A|^p+|B|^p\right)^{\frac{2-p}{2}}}{|x-y|^{N+ps}}\,dx\,dy\\&\quad\leq C\left(\langle L(u_n),u_n-u\rangle-\langle L(u),u_n-u\rangle\right)^{\frac{p}{2}}\to 0\end{aligned}$$

as $n\to\infty$. Hence $u_n\to u$ in $X^{1,p}(\mathbb{R}^N)$. In conclusion, we get $u_n\to u$ strongly in $X^{1,p}(\mathbb{R}^N)$ as $n\to\infty$.

Finally, we consider $\inf_n \|u_n\|_{X^{1,p}(\mathbb{R}^N)} = 0$. Then either 0 is an accumulation point of the sequence $\{u_n\}_n$ and so there exists a subsequence of $\{u_n\}_n$ strongly converging to $u = 0$, or 0 is an isolated point of the sequence $\{u_n\}_n$ and so there exists a subsequence, still denoted by $\{u_n\}_n$, such that $\inf_n \|u_n\| > 0$. In the first case we are done, while in the latter case we can process as above. □

Set $B_\rho(0) := \{u \in X^{1,p}(\mathbb{R}^N) : \|u\| < \rho\}$.

Theorem 5.6. *There exists $\lambda^* > 0$ such that for all $\lambda \in (0, \lambda^*)$, problem (1.1) admits a nonnegative weak solution u_1 in $X^{1,p}(\mathbb{R}^N)$ with $I_\lambda(u_1) < 0$.*

Proof. By Lemma 5.3, there exist $\lambda_0 > 0$ and $\gamma > 0$ such that

$$I_\lambda(u) \geq \gamma > 0 \quad \text{for } \lambda \in (0, \lambda_0) \quad \text{and} \quad u \in X^{1,p}(\mathbb{R}^N) \quad \text{with } \|u\| = \rho.$$

In the complete metric space $\overline{B}_\rho(0) := \{u \in X^{1,p}(\mathbb{R}^N) : \|u\| < \rho\}$, we apply Ekeland's variational principle [21] to prove that there exists a $(PS)_{c_0}$ sequence $\{u_n\}_n \subset B_\rho(0)$ with

$$c_0 = \inf\{I_\lambda(u) : u \in \overline{B}_\rho(0)\}.$$

Next, we aim to show that $-\infty < c_0 < 0$. Choose $\varphi_0 \in X^{1,p}(\mathbb{R}^N)$ such that $\int_{\mathbb{R}^N} f\varphi_0 \, dx > 0$ and fix $\lambda \in (0, \lambda^*)$. Then for any $t > 0$, we have

$$I_\lambda(t\varphi_0) = \frac{at^p}{p}\|\varphi_0\|^p + \frac{bt^{\theta p}}{\theta p}\|\varphi_0\|^{\theta p} - \frac{t^{2p_\mu^*}}{2p_\mu^*}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} \frac{|\varphi_0{}^+(y)|^{p_\mu^*}}{|x-y|^\mu}\, dy\, |\varphi_0{}^+(x)|^{p_\mu^*}\, dx - \lambda t \int_{\mathbb{R}^N} f(x)\varphi_0 \, dx.$$

Then we can deduce that there exists a sufficiently small $t > 0$ such that $\|t\varphi_0\| \leq \rho$ and $I_\lambda(t\varphi_0) < 0$. Hence, according to the definition of c_0, it follows that $c_0 < I_\lambda(t\varphi_0) < 0$ and it's evident that $c_0 > -\infty$.

Selecting $\lambda^* \in (0, \lambda_0]$ such that $0 < \Lambda - \Theta(\lambda)$ for all $\lambda \in (0, \lambda^*)$. From Lemma 5.5 and $c_0 < 0$, we can obtain that there exist a subsequence of $\{u_n\}_n$ and $u_1 \in X^{1,p}(\mathbb{R}^N)$ such that $u_n \to u_1$ strongly in $X^{1,p}(\mathbb{R}^N)$. Therefore, $I'_\lambda(u_1) = 0$ and $I_\lambda(u_1) = c_0 < 0$. Hence we complete the proof of Theorem 1.2. □

Drawing on the ideas introduced by Chabrowski [16], Alves [2] and Goncalves and Alves [28], we are going to explore that equation (1.1) has anther solution. Firstly we know that I_λ satisfies the mountain pass geometry by Lemmas 5.3 and 5.4. Hence applying the mountain pass theorem [3], there exists a $(PS)_c$ sequence $\{v_n\}_n$ with

$$c = \inf_{\gamma \in \Gamma} \max_{t \in [0,1]} I_\lambda(\gamma(t)),$$

$$\Gamma = \{\gamma \in C([0,1], X^{1,p}(\mathbb{R}^N)) : \gamma(0) = 0, \gamma(1) = e\}.$$

Lemma 5.7. *Suppose $a > 0$, $b > 0$, and either $\theta = \frac{3N-\mu-p}{2(N-p)}$ or $a > 0$, $0 < b < S_{H,M}^{-\theta}$, $\theta = \frac{2N-\mu}{N-p}$. Under the assumption (f), there exists $\lambda^{**} \in (0, \lambda^*)$, such that for any $\lambda \in (0, \lambda^{**})$, one has*

$$c \leq \sup_{t \geq 0} I_\lambda(tU) < \Lambda - \Theta(\lambda).$$

Proof. Employing the function U in Lemma 5.4, we consider the funtions

$$g(t) := I_\lambda(tU) = \frac{a\|U\|^p}{p}t^p + \frac{b\|U\|^{\theta p}}{\theta p}t^{\theta p} - \frac{t^{2p^*_\mu}}{2p^*_\mu} - \lambda t\int_{\mathbb{R}^N} fU\,dx$$

and

$$\tilde{g}(t) := \frac{a\|U\|^p}{p}t^p + \frac{b\|U\|^{\theta p}}{\theta p}t^{\theta p} - \frac{t^{2p^*_\mu}}{2p^*_\mu}$$

for all $t \geq 0$. There exists $t_1 > 0$ such that $\tilde{g}'(t_1) = 0$ and $\max_{t\geq 0}\tilde{g}(t) = \tilde{g}(t_1) = \Lambda + h(\varepsilon) > 0$, where t_1 satisfies

$$t_1 = \begin{cases} \left(\dfrac{a\|U\|^p}{1-b\|U\|^{\theta p}}\right)^{\frac{1}{\theta p-p}} & \text{if } \theta = \frac{2N-\mu}{N-p},\ a>0,\ 0<b<S^{-\theta}_{H,M}, \\ \left(\dfrac{b\|U\|^{\theta p}+\sqrt{b^2\|U\|^{2\theta p}+4a\|U\|^p}}{2}\right)^{\frac{1}{\theta p-p}} & \text{if } \theta = \frac{3N-\mu-p}{2(N-p)},\ a>0,\ b>0. \end{cases}$$

When $c = 0$, the proof is similar to Theorem 1.2. When $c > 0$, we can choose $\lambda_1 \in (0, \lambda^*]$ such that $\Lambda - \Theta(\lambda_1) > 0$. It is easy to observe that

$$\lim_{t\to 0^+}\left(\frac{a\|U\|^p}{p}t^p + \frac{b\|U\|^{\theta p}}{\theta p}t^{\theta p}\right) = 0.$$

So there exists $t_2 \in (0, t_1)$ such that for any $\lambda \in (0, \lambda_1)$, we have

$$\max_{0\leq t\leq t_2} g(t) \leq \max_{0\leq t\leq t_2}\left(\frac{a\|U\|^p}{p}t^p + \frac{b\|U\|^{\theta p}}{\theta p}t^{\theta p}\right) \leq \Lambda - \Theta(\lambda_1) < \Lambda - \Theta(\lambda).$$

Choosing $\lambda^{**} \in (0, \lambda_1]$ such that for any $\lambda \in (0, \lambda^{**})$, there holds

$$\lambda t_2\int_{\mathbb{R}^N} fU^+\,dx > \frac{p-1}{p}\left[\left(a-\frac{a}{\theta}\right)S\right]^{-\frac{1}{p-1}}\lambda^{\frac{p}{p-1}}|f|^{\frac{p}{p-1}}_{(p^*)'} + h(\varepsilon).$$

Then, for any $\lambda \in (0, \lambda^{**})$, one can obtain

$$\begin{aligned}\sup_{t\geq t_2} g(t) &\leq \sup_{t\geq t_2}\tilde{g}(t) - \lambda t_2\int_{\mathbb{R}^N} fU^+\,dx \\ &< \tilde{g}(t_1) - \frac{p-1}{p}\left[\left(a-\frac{a}{\theta}\right)S\right]^{-\frac{1}{p-1}}\lambda^{\frac{p}{p-1}}|f|^{\frac{p}{p-1}}_{(p^*)'} - h(\varepsilon) \\ &= \Lambda - \Theta(\lambda).\end{aligned}$$

Therefore, for any $\lambda \in (0, \lambda^{**})$ we have

$$c \leq \sup_{t\geq 0} I_\lambda(tU) = \sup_{t\geq 0} g(t) < \Lambda - \Theta(\lambda).$$

Hence, the proof is complete. □

Theorem 5.8. *There exists $\lambda^{**} \in (0, \lambda^*]$ such that for all $\lambda \in (0, \lambda^{**})$, problem (1.1) has another nonnegative weak solution u_2 in $X^{1,p}(\mathbb{R}^N)$ with $I_\lambda(u_2) > 0$.*

Proof. Using Lemmas 5.5 and 5.7, there exist a subsequence of $\{v_n\}_n$, still denoted by $\{v_n\}_n$, and a function $u_2 \in X^{1,p}(\mathbb{R}^N)$ such that $v_n \to u_2$ strongly in $X^{1,p}(\mathbb{R}^N)$. Therefore,

$$I'_\lambda(u_2) = 0 \quad \text{and} \quad I_\lambda(u_2) = c > 0 = I_\lambda(0),$$

indicating that u_2 is a nontrivial and nonnegative solution of (1.1). □

Proof of Theorem 1.2. Combining the proof of Theorem 5.6 with Theorem 5.8, we can obtain Theorem 1.2. □
